FOREWORD

This report is presented by Nortronics-Huntsville, Huntsville, Alabama, as partial fulfillment of Contract NAS8-20082 to the Aero-Astrodynamics Laboratory, George C. Marshall Space Flight Center, in response to the requirements of Appendix F, Schedule Order No. 26. Technical coordination for MSFC and the basic theoretical development of this effort was supplied by Mr. Jesco von Puttkamer of the Technical and Scientific Staff of the Aero-Astrodynamics Laboratory.

SUMMARY

This report documents a computer program designed to calculate the flyback and recovery flight of a lifting booster vehicle after its ascent mission is completed. Upon booster staging, the flyback sequence is initiated, and the vehicle descends, turns, decelerates, cruises, and glides down to landing at the desired base. Range, azimuth, fuel utilization, latitude, and longitude data throughout the whole mission are included. This program is written in FORTRAN II language and is suitable for the SDS 930 or CDC 3200 computer, and could be adapted to larger computers with little difficulty.

Section I
INTRODUCTION

The study of advanced launch vehicles necessitates broad research into many areas of vehicle technology. One of the problems often encountered is the question of economical booster recovery. As a tool in lifting booster recovery studies, this program is designed to calculate the flight path required to recover a vehicle after it has completed its booster mission. Therefore, the program considers the basic aspects of going from staging through maneuvering of the booster into a cruise condition on the correct azimuth to the desired home base, and calculating the cruise and glide-to-landing parameters. Maximum input flexibility has been retained to allow a large number of diverse vehicle concepts to be studied.

The routine is designed to be used in conjunction with boost programs to provide a complete evaluation of recoverable boosters. It can provide assistance in parametric studies and help in the evaulation of many considerations which go into booster design. Some of the technical area evaluations that might be assisted include reentry energy management, cruise fuel requirements, recovery base possibilities, minimum cruise engine sizing, structural loading in entry and turning to base, effect of recovery requirements on overall booster sizing, and many others.

These are several rather unique features in this program. The most important feature is the system of calculating and turning to the cruise back to base azimuth. Other unique features include the energy management option, the vertical load factor option, the method of holding a desired flight angle by roll control, and others. These features are explained in Section III.

The weight data which is included in the appendix is derived primarily from Wright Air Development Center data which was collected and plotted by Northrop for general use in booster weight analysis, and is included here for general interest.

Section II
THEORY

2.1 GROUND RULES

Certain general assumptions have been made in developing the flyback routine. The primary ones are listed below:

- Earth relative motion is used throughout.
- A spherical rotating earth is assumed.
- The vehicle range calculated is ground range.
- No aerodynamic sideslip is considered.
- No winds are considered.
- The ascent flight from which staging data is taken is assumed to be two-dimensional. See note below.
- The flyback routine is three-dimensional.
- The equations developed are modified to facilitate inclusion in the computer routine.

Other specialized assumptions and conditions are explained as they are encountered in this report.

2.2 STARTING DATA

The data required from the ascent flight to start the flyback routine are detailed in Subsection 3.4. In general, the following information is necessary:

- Aerodynamic, propulsion, and weight data for the vehicle.
- Control data for the desired flight.
- Staging conditions -

  Staging weight - W*

  Staging velocity - V*

  Staging range - R*

  Staging flightpath angle - γ*

  Staging altitude - h*

NOTE: *If staging azimuth, latitude, and longitude are known, the launch conditions data are not needed and Subsection 2.3 is unnecessary and should be eliminated as explained in Section III.*

- Launch Conditions -
  - Launch azimuth - Z_L
  - Launch latitude - ψ_L
  - Launch longitude - λ_L

2.3 CALCULATION

It is assumed that the staging position and azimuth are not known. Consequently, this section explains how the staging data are obtained for use in forthcoming calculations. Launch conditions, ascent range, and the assumption of two-dimensional ascent flight, serve as the basis for the computation. Figure 2-1 presents a geometrical representation of the method.

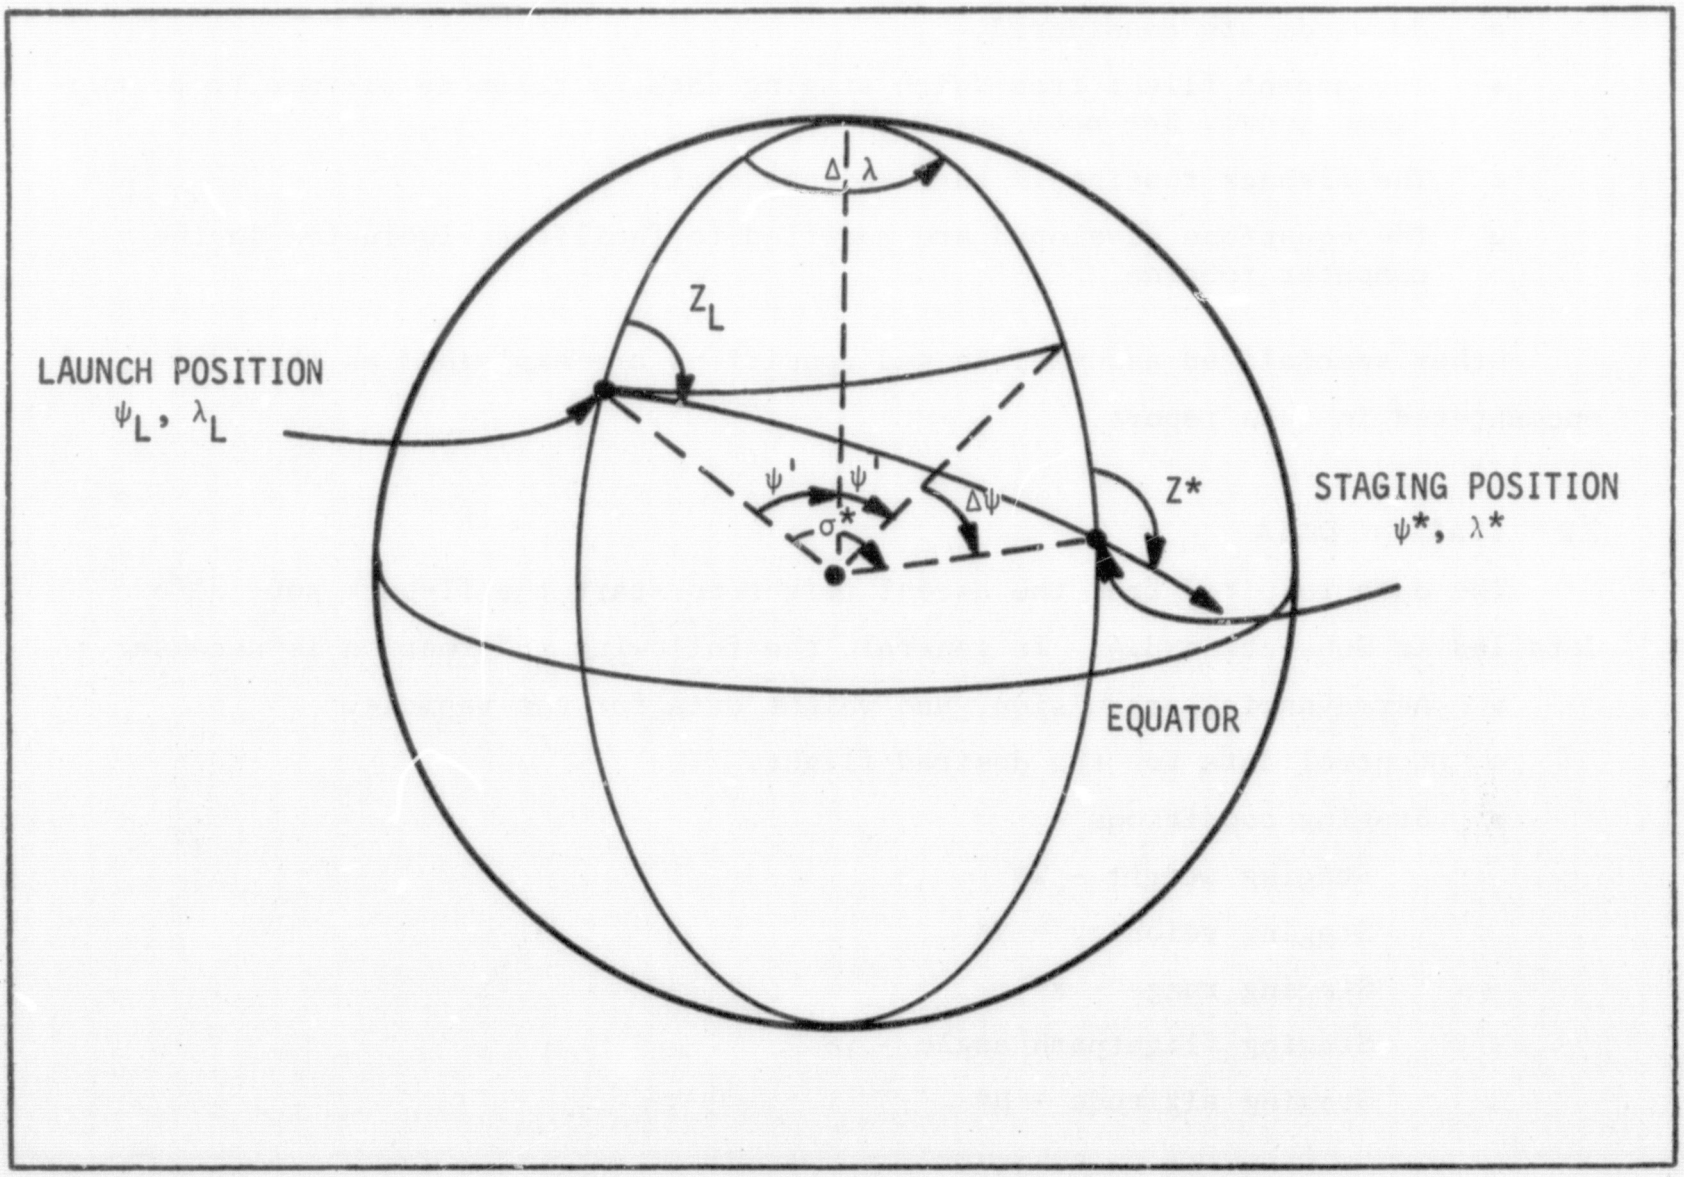

Figure 2-1. GEOMETRY OF STAGING POSITION

The auxiliary latitude, ψ', is latitude measured from the North Pole rather than the normal way from the equator. It is found from

$$\psi' = 90° - \psi_L \tag{1}$$

The range central angle at staging, σ^*, is found from

$$\sigma^* = \frac{57.3\ R^*}{R_e} \tag{2}$$

From the relationships of spherical trigonometry, the change in latitude, $\Delta\psi$, and longitude, $\Delta\lambda$, during ascent may be calculated as follows:

$$\Delta\psi = \cos^{-1}\left[\cos\psi' \cos\sigma^* + \sin\psi' \sin\sigma^* \cos Z_L\right] - \psi' \tag{3}$$

$$\Delta\lambda = \sin^{-1}\left[\frac{\sin Z_L \sin\sigma^*}{\sin(\Delta\psi + \psi')}\right] \tag{4}$$

The supplementary angle to Z^*, β^*, may now be calculated.

$$\beta^* = \sin^{-1}\left[\frac{\sin Z_L \sin\psi'}{\sin(\Delta\psi + \psi')}\right] \tag{5}$$

The staging azimuth therefore can be found by

$$Z^* = 180° - \beta^* \tag{6}$$

The staging latitude is given by

$$\psi^* = \psi_L \pm \Delta\psi \tag{7}$$

where

$\Delta\psi$ is negative when $90° < Z_L < 270°$

$\Delta\psi$ is positive when $270° < Z_L < 360°$

and $0 < Z_L < 90°$

The staging longitude is given by

$$\lambda^* = \lambda_L \pm \Delta\lambda \tag{8}$$

$\Delta\lambda$ is negative for eastern launch in western hemisphere.

$\Delta\lambda$ is positive for western launch in western hemisphere.

$\Delta\lambda$ is positive for eastern launch in eastern hemisphere.

$\Delta\lambda$ is negative for western launch in eastern hemisphere.

2.4 EQUATIONS OF MOTION

The equations of motion are derived relative to three orthogonal axes, the acceleration axes of tangential velocity, azimuth, and altitude. The axes form two planes which intersect on the tangential velocity. These planes are initially parallel and perpendicular to the earth's surface and rotate with the vehicle's flight path angle and azimuth. They do not rotate with the vehicle's roll. This is generally called the wind axis system. Figure 2-2 presents a vectorial representation of the velocities and forces in the wind axis system as used.

The value $\dot{V}$ is found by summing forces along the tangential acceleration axis.

$$m(\dot{V}) = T\cos\alpha - D - mg\sin\gamma + \frac{mV^2\cos^2\gamma\sin\gamma}{r} \tag{9}$$

which reduces to

$$\dot{V} = \frac{T\cos\alpha}{m} - \frac{D}{m} - g\sin\gamma + \frac{V^2\cos^2\gamma\sin\gamma}{r} \tag{10}$$

The equation for the vertical acceleration is

$$mV(\dot{\gamma}) = T\sin\alpha\cos\phi - mg\cos\gamma + L\cos\phi + \frac{mV^2\cos^3\gamma}{r} \tag{11}$$

which may be reduced to

$$\dot{\gamma} = \left(\frac{T\sin\alpha\cos\phi + L\cos\phi}{mV}\right) - \frac{g\cos\gamma}{V} - \frac{V\cos^3\gamma}{r} \tag{12}$$

An explanation of the centripetal force term in the above equations may be in order. The basic formula is

$$CF = \frac{mV_\perp^2}{r} \tag{13}$$

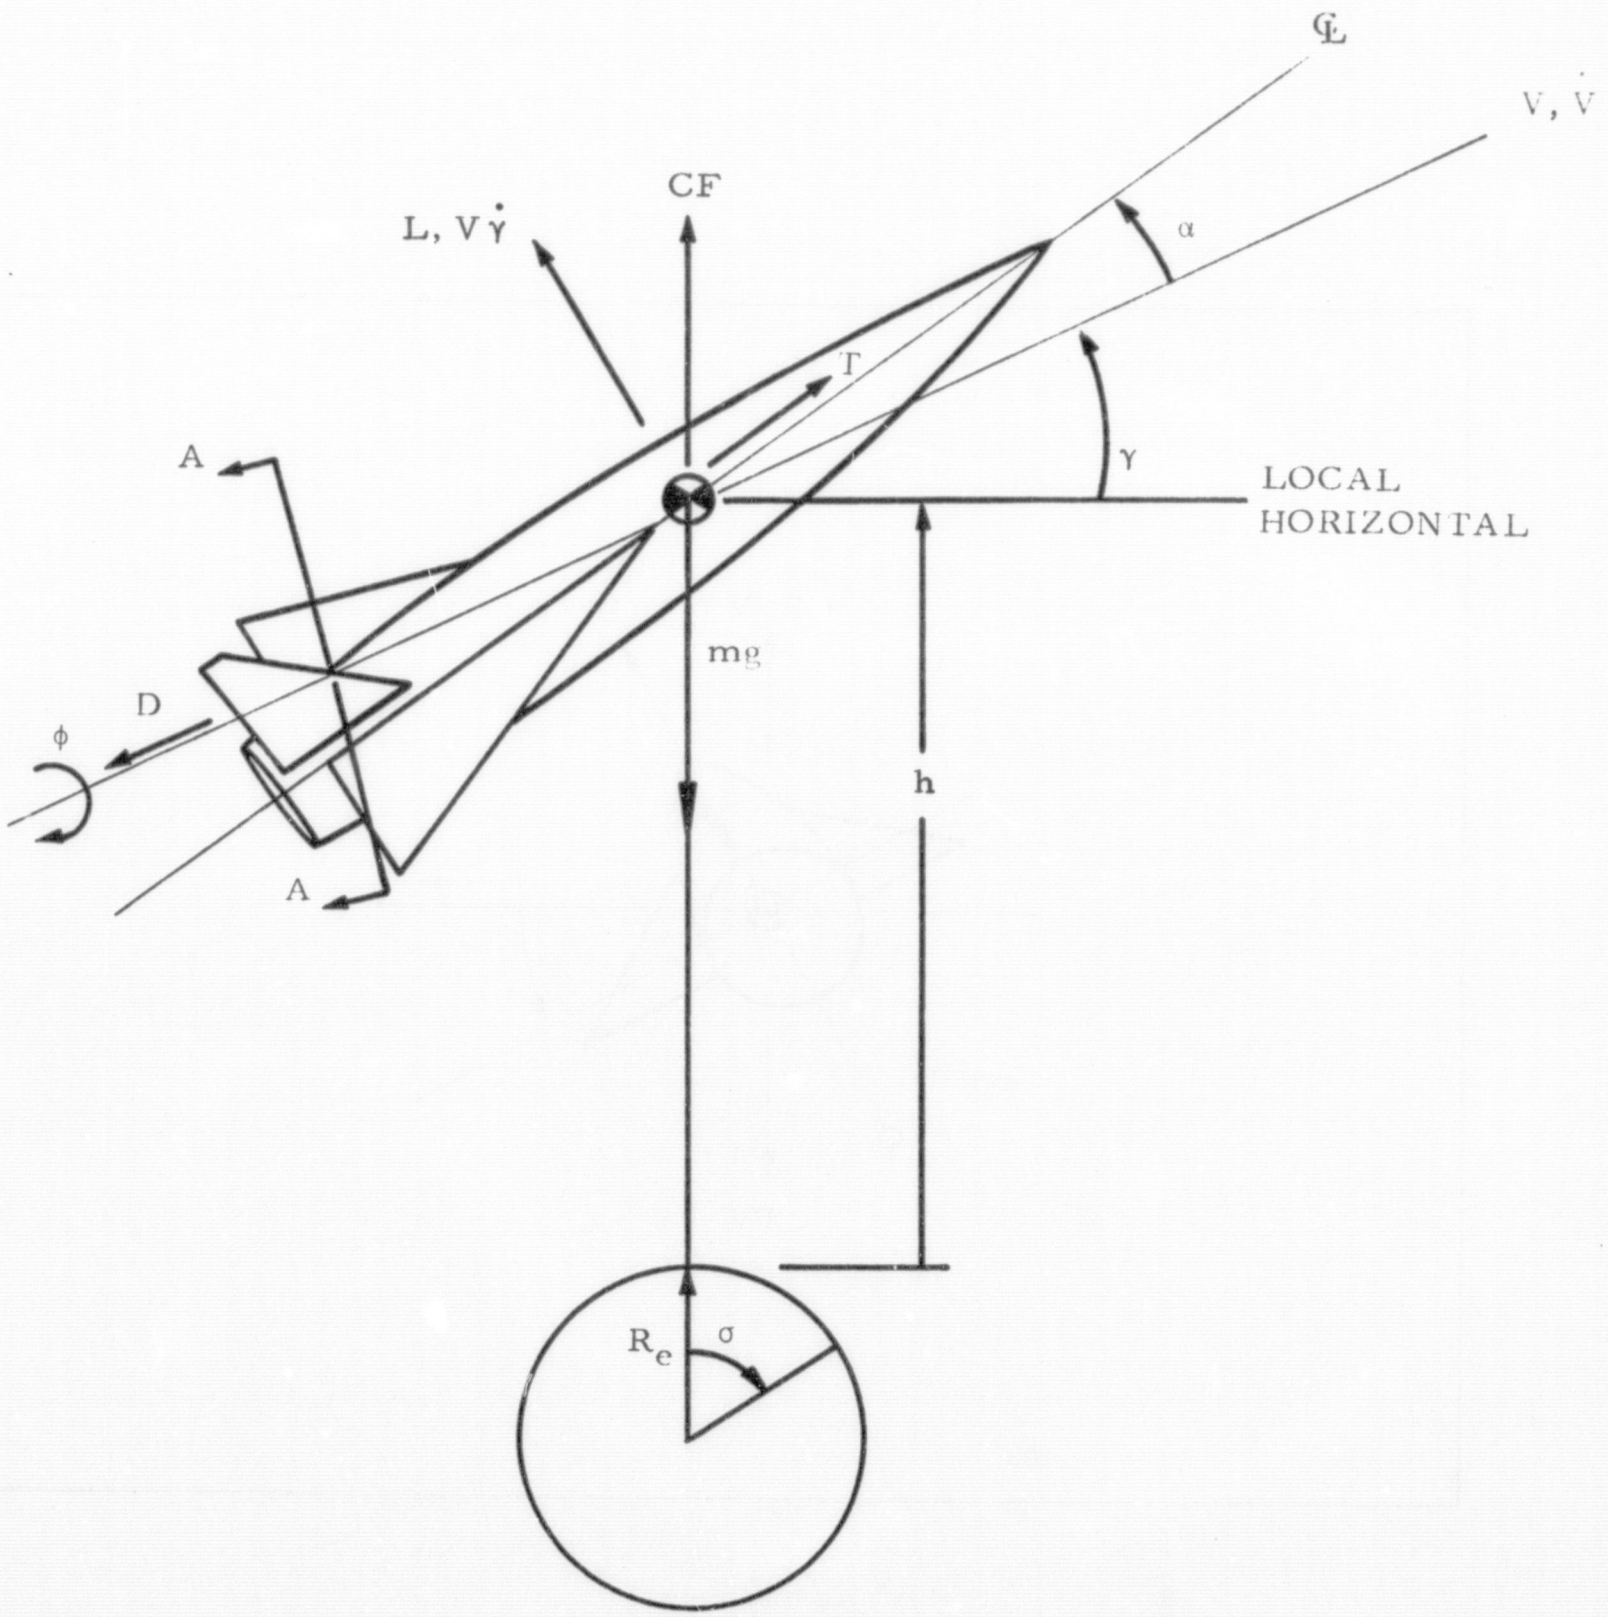

Figure 2-2. WIND AXIS EARTH RELATIVE COORDINATE SYSTEM

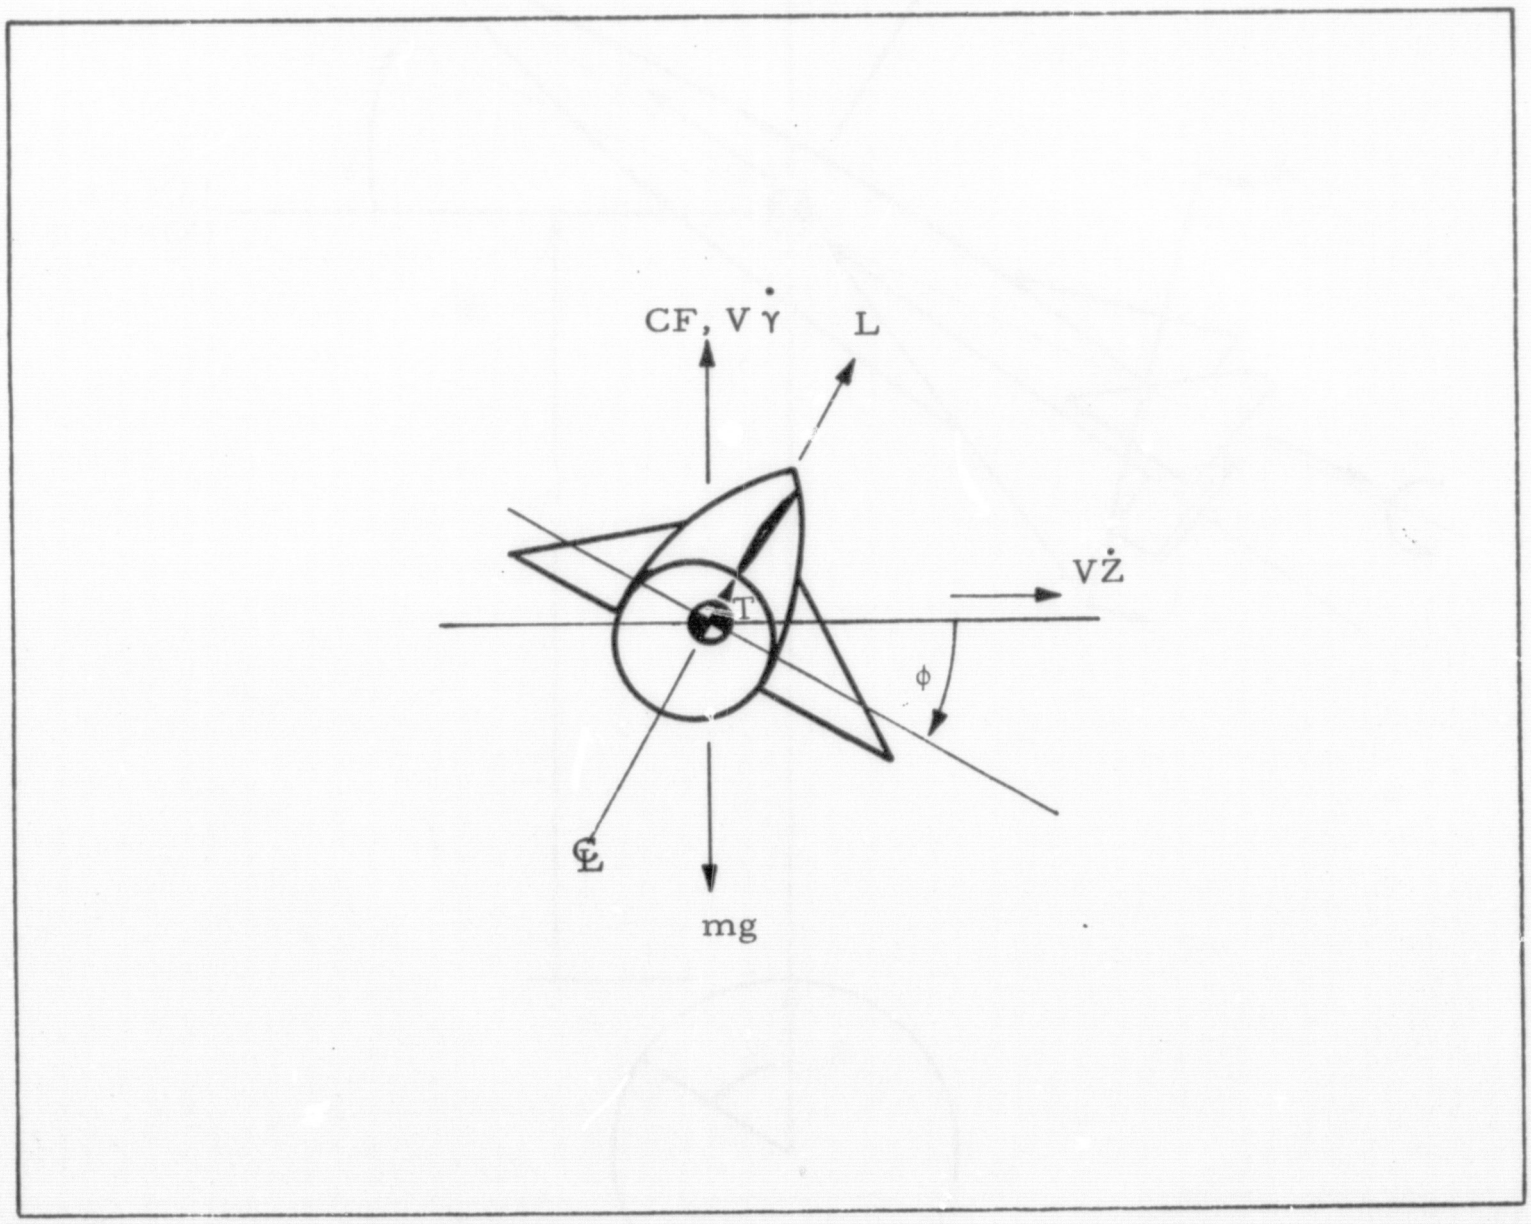

Figure 2-2a. VIEW A-A OF WIND AXIS EARTH RELATIVE COORDINATE SYSTEM

where $V_\perp$ is the velocity perpendicular to the flight path radius about which the vehicle is rotating. Since $V_\perp$ is

$$V_\perp = V \cos \gamma \tag{14}$$

As can be seen from Figure 2-2, the centrifugal force, CF, is

$$CF = \frac{mV^2 \cos^2 \gamma}{r} \tag{15}$$

The equation for the time rate of change of azimuth is

$$mV\ (\dot{Z}) = T \sin \alpha \sin \phi + L \sin \phi \tag{16}$$

which reduces to

$$\dot{Z} = \frac{T \sin \alpha \sin \phi + L \sin \phi}{mV} \tag{17}$$

The above equations use thrust, T, lift, L, drag, D, mass, m, and gravity, g, to find the desired accelerations. The following equations are used to find the above values.

Mach number is used in table look-ups of the aerodynamic parameters. It is found from

$$MN = \frac{V}{SOS} \tag{18}$$

Dynamic pressure is needed to determine aerodynamic forces from aerodynamic coefficients. It is found from

$$q = \frac{\rho V^2}{2} \tag{19}$$

The aerodynamic lift coefficient is found from the equation

$$C_L = k_{23}\left(C_{L_0} + C_{L_\alpha}\ \alpha + C_{L_{\alpha 2}}\ \alpha^2\right) \tag{20}$$

Lift is then found from

$$L = C_L\ q\ S \tag{21}$$

The drag coefficient is determined from

$$C_D = k_{22}\, C_{D_0} + k_1\, k_{24}\, C_L \tan \alpha \tag{22}$$

Then drag is found from

$$D = C_D\, q\, S \tag{23}$$

The vehicle mass is given by

$$m = \frac{W}{g_o} \tag{24}$$

The local gravity is calculated from

$$g = g_o\left(\frac{R_e}{r}\right)^2 \tag{25}$$

where

$$r = R_e + h \tag{26}$$

Other time rates of change that are needed are as follows:

For weight rate of change,

$$\dot{W} = \frac{T}{3600\ SFC} \tag{27}$$

where the 3600 changes the value of $\dot{W}$ from hours to seconds. SFC, as noted in the nomenclature, is a function of hours. For rate of change of altitude,

$$\dot{h} = V \sin \gamma \tag{28}$$

For rate of change of range,

$$\dot{R} = \frac{R_e\, V \cos \gamma}{6076.1\ r} \tag{29}$$

where the 6076.1 changes $\dot{R}$ from ft/sec to nautical miles/sec

After all the necessary rate of change values have been found, it is now possible to sum the values per a change in time. The actual values as developed below are the final values to which this effort is directed. These summation equations are:

For velocity,

$$V_2 = V_1 + \dot{V}\,\Delta t \tag{30}$$

for flight path angle,

$$\gamma_2 = \gamma_1 + \dot{\gamma}\,\Delta t \tag{31}$$

for azimuth,

$$Z_2 = Z_1 + \dot{Z}\Delta t \qquad (32)$$

for weight,

$$W_2 = W_1 + \dot{W}\Delta t \qquad (33)$$

for range,

$$R_2 = R_1 + \dot{R}\Delta t \qquad (34)$$

and finally for altitude.

$$h_2 = h_1 + \dot{h}\Delta t \qquad (35)$$

2.5 ACCELERATION EQUATIONS

The acceleration equations are used to provide constraints under certain control conditions and to provide loading information throughout the routine. Figure 2-3 illustrates the orientation of the acceleration vectors. The load factors are calculated in values of the normal gravity force on the vehicle.

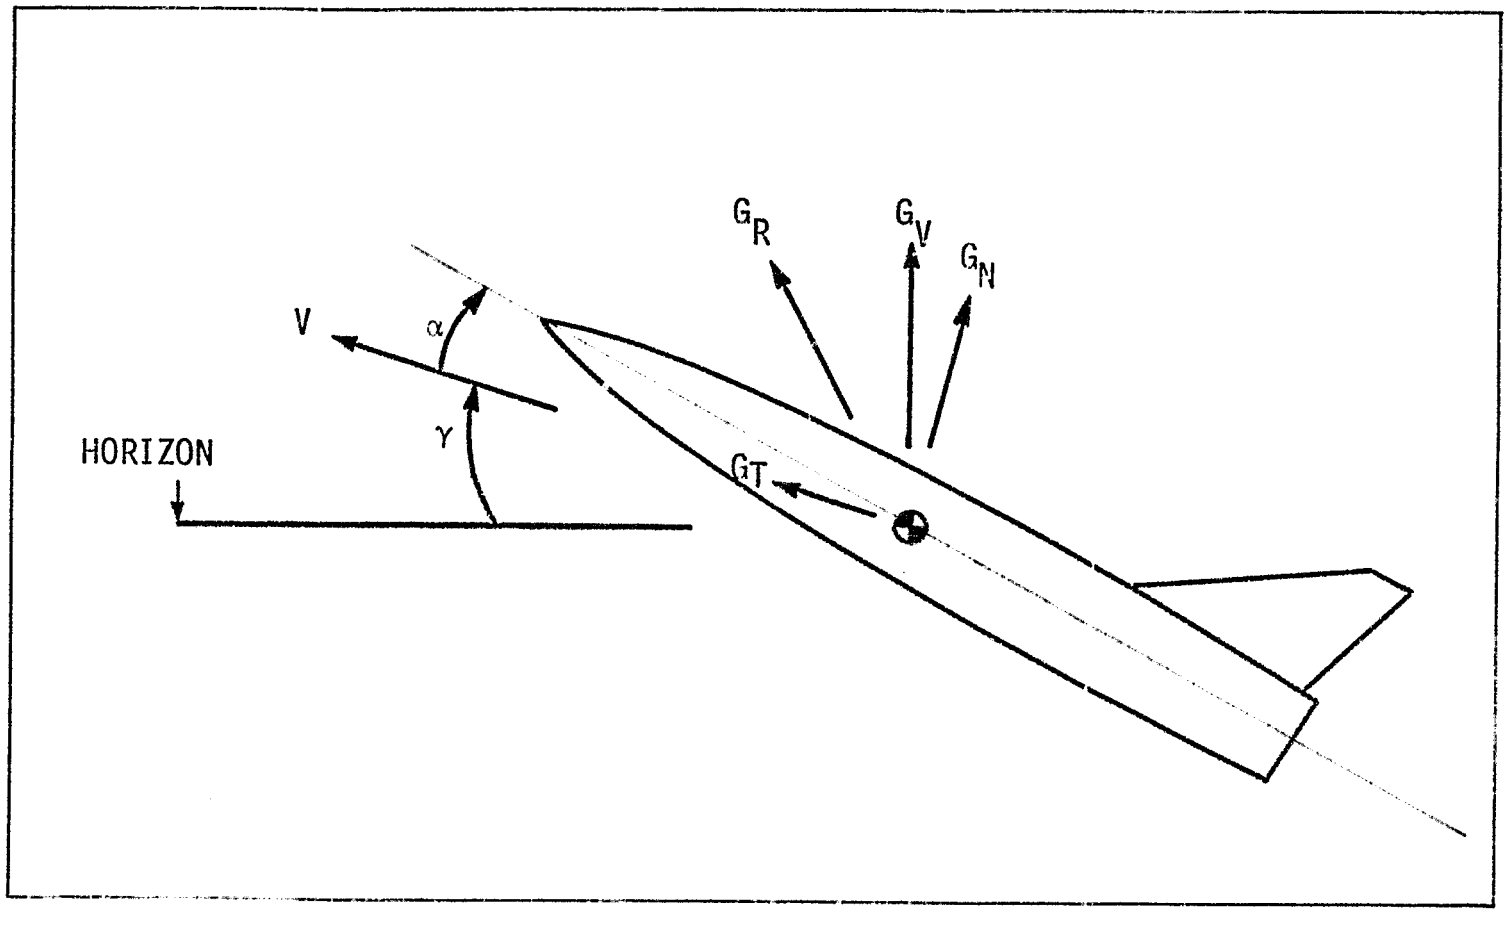

Figure 2-3. ACCELERATION FORCES

The normal load factor is calculated perpendicular to the velocity vector. It is given by

$$G_N = \frac{T}{W} \sin \alpha + \frac{L}{W} \tag{36}$$

The tangential load factor is measured parallel to the velocity vector. It is evaluated from

$$G_T = \frac{T}{W} \cos \alpha - \frac{D}{W} \tag{37}$$

The resultant load factor, G_R, is the vectorial summation of the values of G_N and G_T. G_R is thus the total load on the vehicle, and may be calculated from

$$G_R = \left(G_N^2 + G_T^2 \right)^{1/2} \tag{38}$$

The vertical load factor, G_V, is the load factor on the vehicle acting normal to the local horizontal. It is a special case, used in the calculations presented in Subsection 2.8.3 and is calculated from

$$G_V = G_N \cos \gamma + G_T \sin \gamma \tag{39}$$

2.6 FLYBACK RANGE AND AZIMUTH CALCULATIONS

The routine keeps a running calculation of the flyback range, R_{FB}, and the flyback azimuth, Z_{FB}. Note that this range and azimuth are calculated on a direct great circle distance from the vehicle's actual position to the desired base. The calculations do not take into account the vehicle's actual direction. The fact that the vehicle must turn to the correct azimuth over a period of time is not considered. It should also be noted that the values of Z_{FB} and R_{FB} are constantly changing as the vehicle maneuvers. The main purpose of these calculations is to provide a target azimuth for the turn control. The calculations can also serve the investigator by showing the variation in range and direction of the base, and may then allow consideration of alternate modes of flight, discussed further in later sections. A different home base may also be considered and evaluated by comparison of flyback data using different calculations for more than one base. The geometry on which the calculations are based is given in Figure 2-4.

From the geometrical representation, it follows that

$$\lambda_{FB} = \left|\lambda_H - \lambda\right| \tag{40}$$

$$\psi_H' = \left|90° - \psi_H\right| \tag{41}$$

$$\psi' = \left|90° - \psi\right| \tag{42}$$

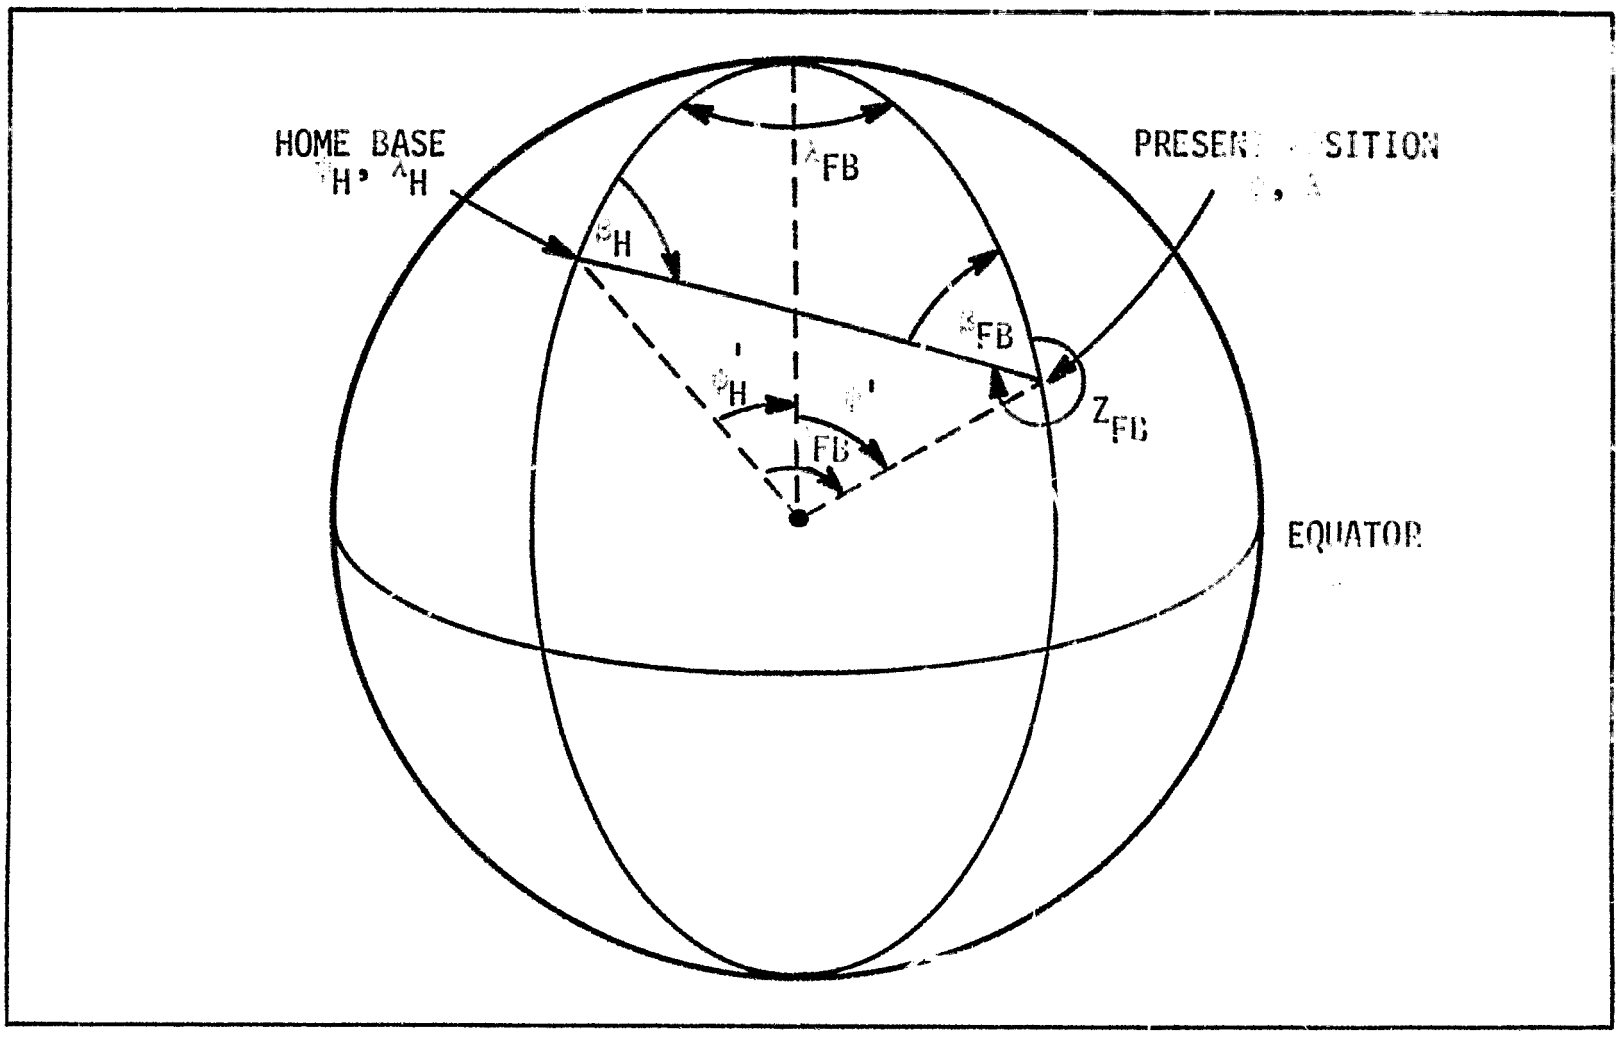

Figure 2-4. GEOMETRY OF FLYBACK CALCULATIONS

The following equations are used to solve for β_{FB} and β_H

$$\tan\left(\frac{\psi_H' - \psi'}{2}\right)\tan\left(\frac{\beta_H + \beta_{FB}}{2}\right) = \cos\left(\frac{\lambda_{FB}}{2}\right)\cos\left(\frac{\psi' - \psi_H'}{2}\right) \tag{43}$$

$$\frac{\beta_H + \beta_{FB}}{2} = \tan^{-1}\left[\frac{\cos\left(\frac{\lambda_{FB}}{2}\right)\cos\left(\frac{\psi' - \psi_H'}{2}\right)}{\tan\left(\frac{\psi_H' - \psi'}{2}\right)}\right] = X \tag{44}$$

$$\tan\left(\frac{\beta_H - \beta_{FB}}{2}\right)\sin\left(\frac{\psi' + \psi_H'}{2}\right) = \cos\left(\frac{\lambda_{FB}}{2}\right)\sin\left(\frac{\psi' - \psi_H'}{2}\right) \tag{45}$$

$$\frac{\beta_H - \beta_{FB}}{2} = \tan^{-1}\left[\frac{\cos\frac{\lambda_{FE}}{2}\sin\frac{\psi' - \psi'_H}{2}}{\sin\frac{\psi' + \psi'_H}{2}}\right] = Y \qquad (46)$$

Then from the above

$$\beta_H + \beta_{FB} = 2X \qquad (47)$$

$$\beta_H - \beta_{FB} = 2Y \qquad (48)$$

Solving for β_{FB}

$$2\beta_{FB} = 2X - 2Y \qquad (49)$$

and

$$\beta_{FB} = X-Y \qquad (50)$$

The flyback range angle, σ_{FB}, can now be computed fro..

$$\frac{\sin\sigma_{FB}}{\sin\lambda_{FB}} = \frac{\sin\psi'_H}{\sin\beta_{FB}} \qquad (51)$$

Solving

$$\sigma_{FB} = \sin^{-1}\left[\frac{\sin\lambda_{FB}\sin\psi'_H}{\sin\beta_{FB}}\right] \qquad (52)$$

Then, from the figure it is obvious that

$$\Sigma_{FB} = 360^\circ - \beta_{FB} \qquad (53)$$

Finally, the flyback range is

$$R_{FB} = R_e\ \sigma_{FB} \qquad (54)$$

2.7 CHANGE IN POSITION

As the routine calculates the flight path, it is necessary to keep a continuous position fix. The instantaneous latitude and longitude are used primarily to determine the flyback range, but they may very well have other uses, such as plotting the complete flight on a suitable map to study range safety problems. Figure 2-5 presents the basic geometry of the calculations. The method employed to calculate the position is presented below.

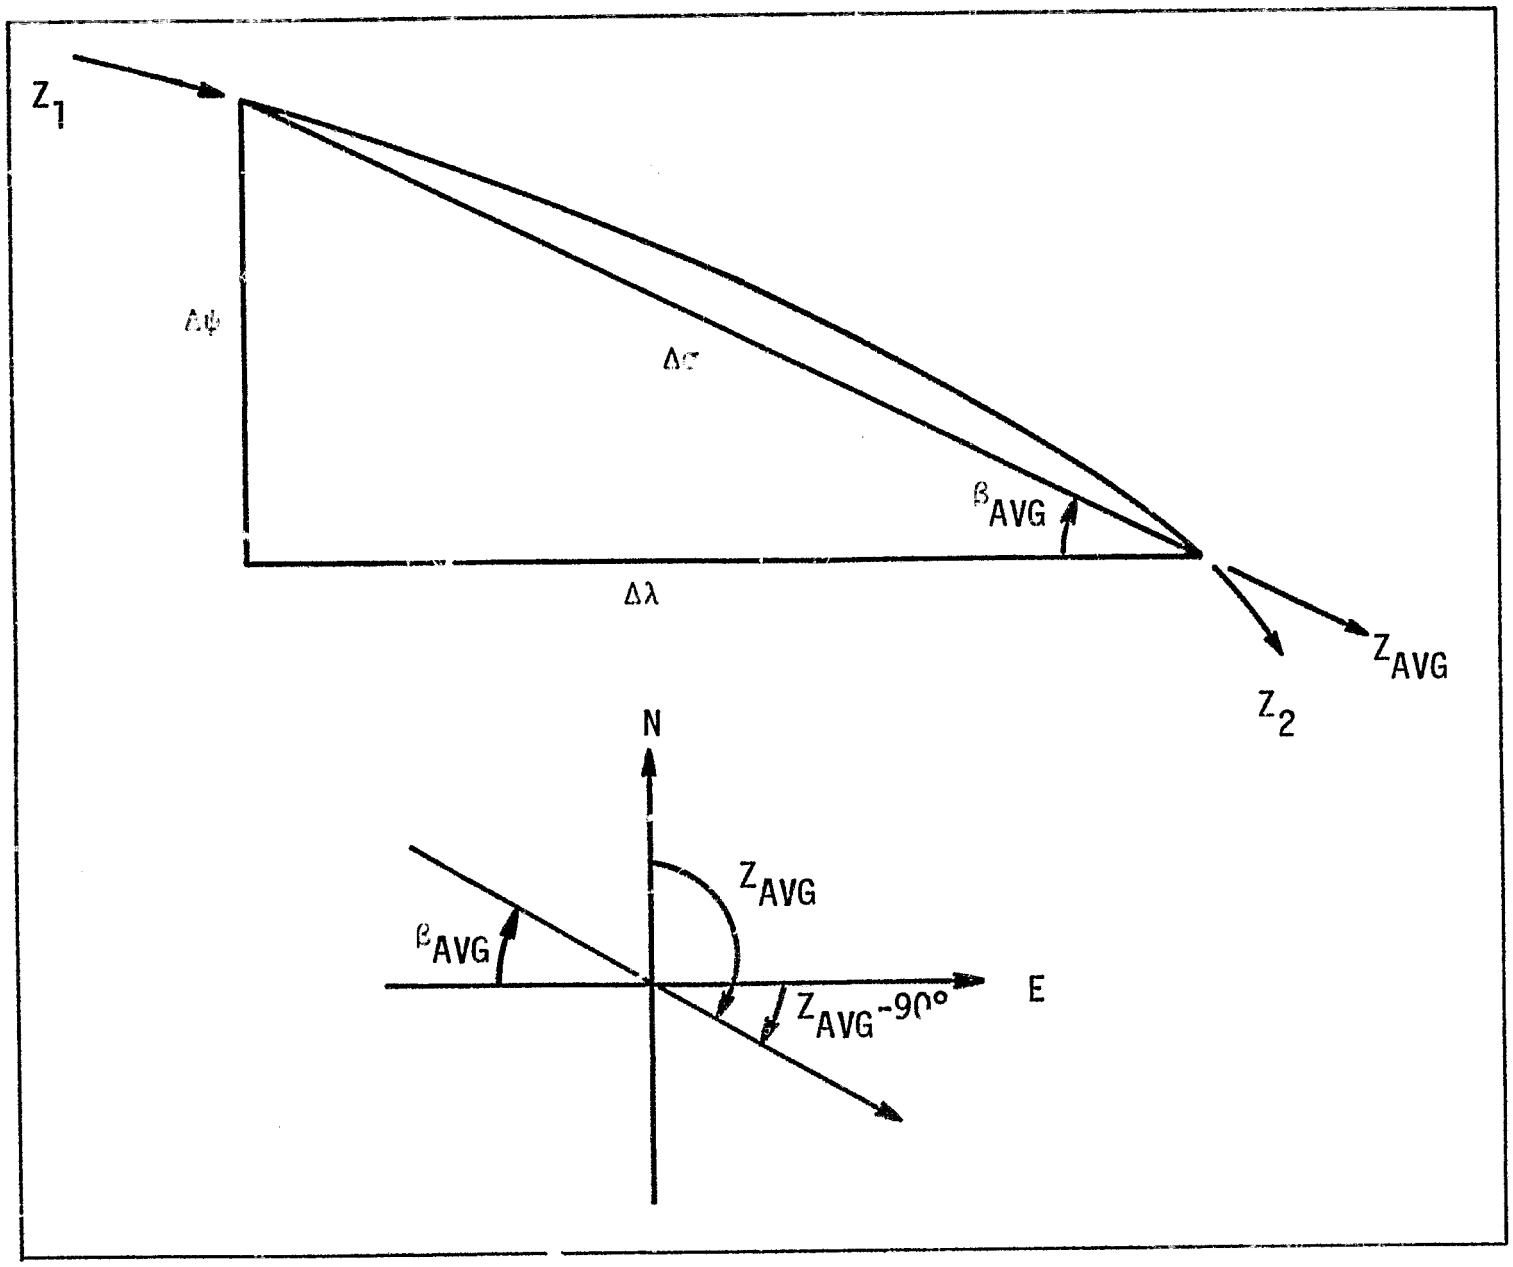

Figure 2-5. GEOMETRY OF POSITION CALCULATION

The average azimuth is

$$Z_{AVG} = \frac{Z_1 + Z_2}{2} \tag{55}$$

The average vertical angle to Z_{AVG}, the β_{AVG}, is found from the following conditions

When $0 < Z_{AVG} < 90°$, $\beta_{AVG} = 90° - Z_{AVG}$

When $90° < Z_{AVG} < 180°$ $\beta_{AVG} = Z_{AVG} - 90°$

When $180° < Z_{AVG} < 270°$ $\beta_{AVG} = 270° - Z_{AVG}$

When $270° < Z_{AVG} < 360°$ $\beta_{AVG} = 360° - Z_{AVG}$

The range angular variation, $\Delta\sigma$, may be calculated from

$$\Delta\sigma = \frac{57.3 \ \Delta R}{R_e} \tag{56}$$

Now using β_{AVG} and $\Delta\sigma$, the change in position may be calculated

$$\Delta\lambda = \Delta\sigma \cos \beta_{AVG} \tag{57}$$

$$\Delta\psi = \Delta\sigma \sin \beta_{AVG} \tag{58}$$

The new longitude is known to be

$$\lambda_2 = \lambda_1 \pm \Delta\lambda \tag{59}$$

where

$\Delta\lambda$ is negative for easterly azimuth in western hemisphere

$\Delta\lambda$ is positive for westerly azimuth in western hemisphere

$\Delta\lambda$ is positive for easterly azimuth in eastern hemisphere

$\Delta\lambda$ is negative for westerly azimuth in eastern hemisphere

The new latitude is

$$\psi_2 = \psi_1 \pm \Delta\psi \tag{60}$$

where

$\Delta\psi$ is negative when $90° < Z_{AVG} < 270°$

$\Delta\psi$ is positive when $270° < Z_{AVG} < 90°$

2.8 ANGLE OF ATTACK CONTROL

The control of the angle-of-attack during the turn and descent to cruise condition in this routine is basic to the efficiency of the flyback flight of

the vehicle. Due to varying vehicles and requirements, no one method may be considered best for all conditions, consequently four options of angle-of-attack control are provided. They are detailed in the following discussions.

2.8.1 Maximum lift or maximum angle-of-attack

A table of angle-of-attack as a function of Mach number is provided. The angle-of-attack may be the maximum allowed or, if desired, it may be the angle-of-attack for maximum lift coefficient as shown by aerodynamic data. This is a simple system and will generally result in the shortest flyback maneuver down to the cruise condition.

2.8.2 Maximum lift-drag ratio

The traditional maximum lift-drag ratio, $(L/D)_{max}$, is generally considered a very efficient flight mode. This mode of determining angle-of-attack, α, is often the most efficient method available. The α for $(L/D)_{max}$ is found from calculation of a table of L/D as a function of ascending α, as below

Search $\alpha \rightarrow L \rightarrow D \rightarrow L/D$

When $(L/D)_{old} > (L/D)_{new}$

In other words, when the table of ascending α finds that L/D is no longer getting larger, then

$$(L/D)_{old} \tilde{=} (L/D)_{max}$$

A convergence scheme finds the correct α for $(L/D)_{max}$ as explained in Section III.

2.8.3 Maximum Vertical Load Factor

The angle-of-attack, α, may be controlled by the maximum vertical load factor, $G_{V_{max}}$. The method for determining $G_{V_{max}}$ follows.

G_V is found from the equation

$$G_V = G_N \cos \gamma + G_T \sin \gamma \tag{61}$$

where

$$G_N = \frac{T}{W} \sin \alpha + \frac{L}{W} \tag{62}$$

and

$$G_T = \frac{T}{W} \cos \alpha - \frac{D}{W} \tag{63}$$

To simplify a very complex problem, it is assumed T = 0. Then G_V is

$$G_V = \frac{L}{W} \cos \gamma - \frac{D}{W} \sin \gamma \tag{64}$$

The terms of the G_V equation are

$$\frac{L}{W} = \frac{C_L \; q \; S}{W} \tag{65}$$

where

$$C_L = k_{23} \left(C_{L_0} + C_{L\alpha} \; \alpha \; + C_{L_{\alpha}2} \; \alpha^2\right) \tag{66}$$

Normally

$$C_{L_{\alpha}2} \simeq 0 \tag{67}$$

and is so assumed here. The term D/W is found from

$$\frac{D}{W} = \frac{C_D \; q \; S}{W} \tag{68}$$

with

$$C_D = k_{22} \; C_{D_0} + k_1 \; k_{24} \left(C_{L_0} + C_{L_{\alpha}} \; \alpha\right) \tan \alpha \tag{69}$$

Letting

$$\mathcal{K} = \frac{q \; S \; k_{23}}{W} \tag{70}$$

Then the G_V equation becomes

$$G_V = C_{L_0} \cos \gamma \, Z + C_{L_\alpha} \alpha \cos \gamma \, Z - \frac{k_{22} \, C_{DO} \sin \gamma \, Z}{k_{23}} \tag{71}$$

$$- k_1 \, k_{24} \, C_{L_0} \tan \alpha \sin \gamma \, Z - k_1 \, k_{24} \, C_{L_\alpha} \alpha \tan \alpha \sin \gamma \, Z$$

Now the equation can be simplified by the following substitutions:

$$A = Z \, C_{L_0} \cos \gamma \tag{72}$$

$$B = Z \, C_{L_\alpha} \cos \gamma \tag{73}$$

$$C = - \frac{Z \, k_{22} \, C_{DO} \sin \gamma}{k_{23}} \tag{74}$$

$$D = - Z \, k_1 \, k_{24} \, C_{L_0} \sin \gamma \tag{75}$$

$$E = - Z \, k_1 \, k_{24} \, C_{L_\alpha} \sin \gamma \tag{76}$$

Now the above grouping results in the equation for G_V becoming

$$G_V = A + B \, \alpha + C + D \tan \alpha + E \, \alpha \tan \alpha \tag{77}$$

Taking the partial differential of G_V with respect to α yields

$$\frac{\partial G_V}{\partial \alpha} = B + D \sec^2 \alpha + E \tan \alpha + E \, \alpha \sec^2 \alpha = 0 \tag{78}$$

Now the partial can be set equal to zero to determine the extremums that exist. Then the maximum is chosen if it exists.

The equation can be further reduced by substituting

$$\tan \alpha = \frac{\sin \alpha}{\cos \alpha} \tag{79}$$

and

$$\sec^2 \alpha = \frac{1}{\cos^2 \alpha} \tag{80}$$

The partial now becomes

$$\frac{E \, \alpha}{\cos^2 \alpha} + \frac{E \sin \alpha}{\cos \alpha} + \frac{D}{\cos^2 \alpha} + B = 0 \tag{81}$$

The equation can now be multiplied by $\cos^2 \alpha$ which yields

$$E\alpha + E \sin\alpha \cos\alpha + D + B \cos^2\alpha = 0 \tag{82}$$

assuming $\alpha \neq 90°$. Then knowing that

$$\frac{\sin 2\alpha}{2} \quad \sin\alpha \cos\alpha \tag{83}$$

The equation further reduces to

$$B \cos^2\alpha + D + \frac{E \sin 2\alpha}{2} + E\alpha = 0 \tag{84}$$

Now since

$$\cos^2\alpha = \frac{1 + \cos 2\alpha}{2} \tag{85}$$

Then

$$\frac{B}{2} + \frac{B}{2} \cos 2\alpha + \frac{E}{2} \sin 2\alpha + E\alpha + D = 0 \tag{86}$$

Let

$$G = B/2$$

$$F = E/2$$

$$\beta = 2\alpha$$

The final form of the equation is then

$$G + G \cos \beta + F \sin \beta + F \beta + D = 0 \tag{87}$$

This equation can now be solved by the Newton-Raphson approximation using the first derivative with respect to β.

For $$f(\beta) = G \cos \beta + F \sin \beta + F\beta + (D + G) = 0.0 \tag{88}$$

$$f'(\beta) = -G \sin\beta + F \cos \beta + F = 0.0 \tag{89}$$

by the N-R formula

$$h_N = -\left[\frac{G \cos \beta + F \sin \beta + F \beta + D + G}{-G \sin \beta + F \cos \beta + F}\right] \tag{90}$$

$$\beta_{new} = \beta_{old} + h_N \tag{91}$$

The calculation of h_N is then repeated until $h_N < .1°$. Experience has shown this is sufficient convergence. Then since

$$\alpha = \beta/2 \tag{92}$$

the value of α for $G_{V_{max}}$ is solved.

2.8.4 Energy Management

All systems of angle-of-attack control are, in a sense, controlling the vehicle's energy. This energy management system approaches the problem directly in that the angle-of-attack is chosen so that the kinetic and potential energy is dissipated at a predetermined controlled rate. The vehicle will then arrive at the cruise condition necessary to insure required flightpath angle, velocity and altitude. Since experience has shown that is often impossible to curve smoothly into the cruise condition, thrust is included for use as necessary. Since the use of thrust changes the vehicle mass, mass must then be considered a variable with time. It is assumed that $\gamma \neq 0$ during the flight. The following derivation also assumes V and γ, the velocity and flightpath angle (when not subscripted) are average values through the integration period. The classic equation for energy is

$$E = mgh + 0.5\ mV^2 \tag{93}$$

The change in energy with time is

$$\frac{dE}{dt} = mg\ \frac{dh}{dt} + gh\ \frac{dm}{dt} + mV\ \frac{dV}{dt} + 0.5\ \frac{dm}{dt}\ \frac{V^2}{2} \tag{94}$$

The change in altitude with time is

$$\frac{dh}{dt} = V\ \sin\gamma \tag{95}$$

The change of mass with time is

$$\frac{dm}{dt} = \frac{\dot{W}}{g} \tag{96}$$

The change in velocity with time is

$$\frac{dV}{dt} = \frac{mg\ \sin\gamma\ + k_{21}T\text{-}D}{m} \tag{97}$$

Substituting the time rate of change values into the energy derivative equation yields

$$\frac{dE}{dt} = mg\ V\ \sin\gamma + \frac{gh\dot{W}}{g} + mV\left(\frac{mg\ \sin\gamma + k_{21}\ T\text{-}D}{m}\right) + \frac{\dot{W}\ V^2}{2g} \tag{98}$$

Collecting terms

$$\frac{dE}{dt} = 2\ mg\ V\ \sin\gamma + h\dot{W} + k_{21}TV - DV + \frac{\dot{W}\ V^2}{2g} \tag{99}$$

The rate of change of energy with time is not, however, the purpose. The purpose here is to control the change of energy during the change of altitude.

Therefore, to find dE/dh the following substitution is made.

$$\frac{dE}{dh} = \frac{dE}{dt}\,\frac{dt}{dh} \tag{100}$$

$$\frac{dt}{dh} = \frac{1}{V \sin \gamma} \tag{101}$$

$$\frac{dE}{dh} = \frac{\frac{dE}{dt}}{V \sin \gamma} \tag{102}$$

Substituting,

$$\frac{dE}{dh} = 2\,mg + \frac{h\dot{W}}{V \sin \gamma} + \frac{k_{21} TV}{V \sin \gamma} - \frac{DV}{V \sin \gamma} + \frac{\dot{W} V^2}{2g\, V \sin \gamma} \tag{103}$$

Multiplying through by sin γ

$$\frac{dE}{dh} \sin\gamma = 2\,mg \sin \gamma + \frac{h\dot{W}}{V} + k_{21}\, T - D + \frac{\dot{W}V}{2g} \tag{104}$$

To solve for γ, the equation becomes

$$\left(\frac{dE}{dh} - 2\,mg\right) \sin\gamma = \frac{h\dot{W}}{V} + k_{21}\, T - D + \frac{\dot{W}V}{2g} \tag{105}$$

$$\gamma = \sin^{-1}\left[\frac{\frac{h\dot{W}}{V} + k_{21}\, T - D + \frac{\dot{W} V}{2g}}{\frac{dE}{dh} - 2\,mg}\right] \tag{106}$$

The above equation may be solved for γ.

The values used for α and γ are now compared with the values of the integration. If they are not within tolerance, α is raised to raise γ or vise-versa and the whole system followed until all tolerances are met. If thrust is used, the thrust variable, k_{21}, may be adjusted to provide the necessary thrust to satisfy the equations.

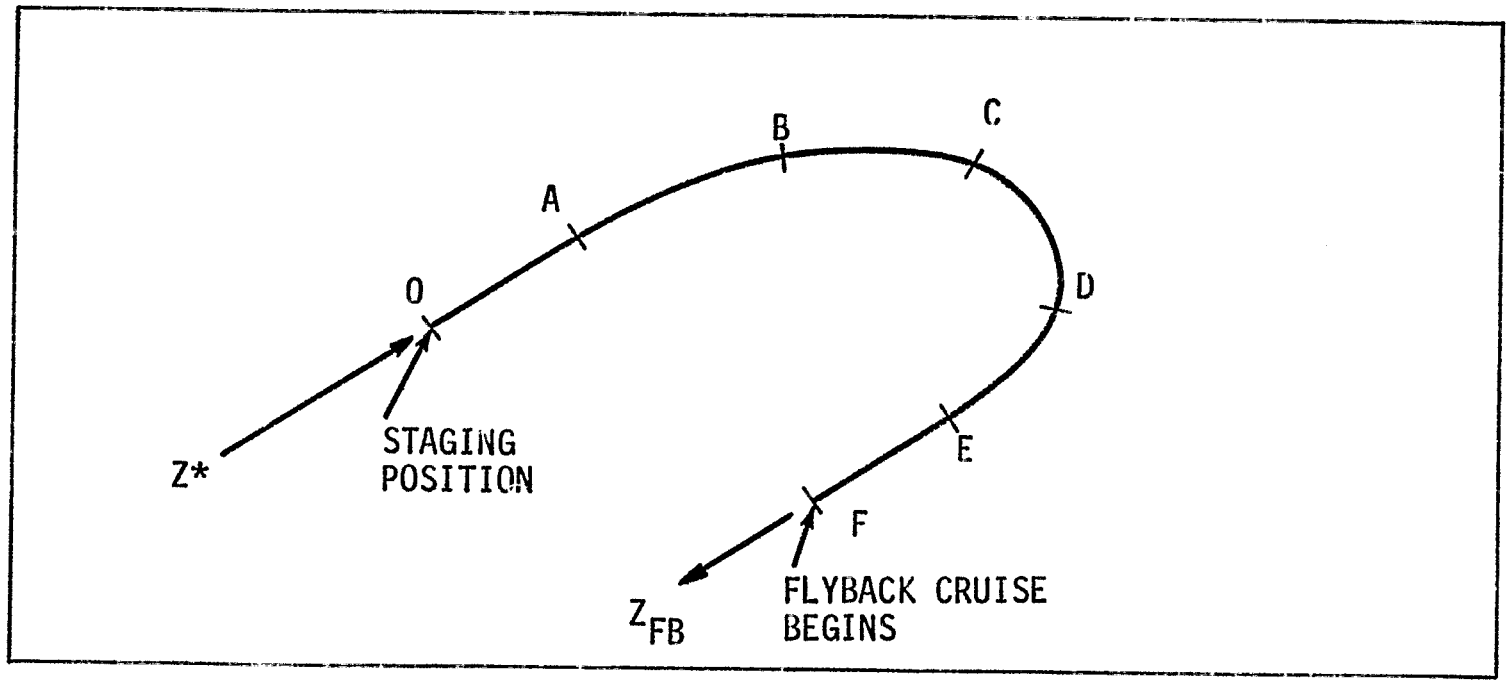

Figure 2-6. ROLL CONTROL CONDITIONS

2.9 ROLL CONTROL

The previous angle-of-attack controls serve to bring the vehicle to the desired cruise altitude and velocity. The roll control is used to bring the vehicle to the desired azimuth. The vehicle, upon staging, may be headed far from the direction of the desired landing base. Consequently, it is necessary to properly direct the vehicle back to the base. This is done through the following sequence of roll controls. Figure 2-6 illustrates the sequence of roll control conditions.

2.9.1 Condition O - A

A given roll angle, ϕ_o, is held until

$$\gamma \leq \gamma_A \tag{107}$$

where γ_A is a given value. ϕ_o is generally 180 degrees. The purpose here is to get the vehicle headed down and well within the aerodynamic control range.

2.9.2 Condition A - B

$\dot{\phi}_A$ is provided and held until

$$\phi = \phi_B \tag{108}$$

where ϕ_B is the given roll angle for the next condition. ϕ is varied by

$$\phi_2 = \phi_1 - \dot{\phi}_A \Delta t \tag{109}$$

2.9.3 Condition B - C

The previously mentioned ϕ_B is held until

$$\gamma \leq \gamma_C \tag{110}$$

where γ_C is the given desired flight path angle for the next condition.

2.9.4 Condition C - D

Basically, condition C - D desires to hold γ_C by varying ϕ until the altitude, h, reaches flyback altitude, h_{FB}. However, two factors tend to alter the ideal. First, the commanded flight path angle, γ_C, may not be possible for the vehicle to follow. Second, the γ_C must be modified so that the vehicle curves smoothly into h_{FB}. Modifications have to be made to account for these conditions.

The condition is controlled by a variation of the basic γ equation. First, two substitutions are made as follows:

$$\gamma = \gamma_C \tag{111}$$

$$\dot{\gamma} = \dot{\gamma}_C \tag{112}$$

Therefore,

$$\dot{\gamma}_C = \left(\frac{T \sin \alpha \cos \phi + L \cos \phi}{m V}\right) - \frac{g \cos \gamma_C}{V} + \frac{V \cos^3 \gamma_C}{r} \tag{113}$$

Solving for ϕ,

$$\cos \phi \left(\frac{T \sin \alpha + L}{mV}\right) = \dot{\gamma}_C + \frac{g \cos \gamma_C}{V} - \frac{V \cos^3 \gamma_C}{r} \tag{114}$$

or

$$\cos \phi = \frac{m V \dot{\gamma}_C + mg \cos \gamma_C - \dfrac{m V^2 \cos^3 \gamma_C}{r}}{T \sin \alpha + L} \tag{115}$$

and

$$\phi = \cos^{-1}\left[\frac{mV\dot{\gamma}_C + mg\cos\gamma_C - \frac{mV^2\cos^3\gamma_C}{r}}{T\sin\alpha + L}\right] \tag{116}$$

Initially, $\dot{\gamma}_C = 0$ and equation 116 is solved for the angle of roll which will maintain the desired γ_C with the given angle-of-attack from the applicable alpha control. However, if the term computed as

$$|\cos\phi| > 1 \quad \text{then } \phi = 0 \text{ by command.} \tag{117}$$

Then, γ_C is allowed to vary when it cannot be held. When

$$|\cos\phi| \leq 1 \tag{118}$$

the first equation again applies. The γ that the vehicle has reached becomes γ_C. This way a wrong γ_C assumption is automatically corrected by the routine.

When the vehicle approaches within a given distance of h_{FB}, Δh_{FB}, a scheme to smoothly curve the flight path to zero at h_{FB} is initiated. Figure 2-7 presents the geometry.

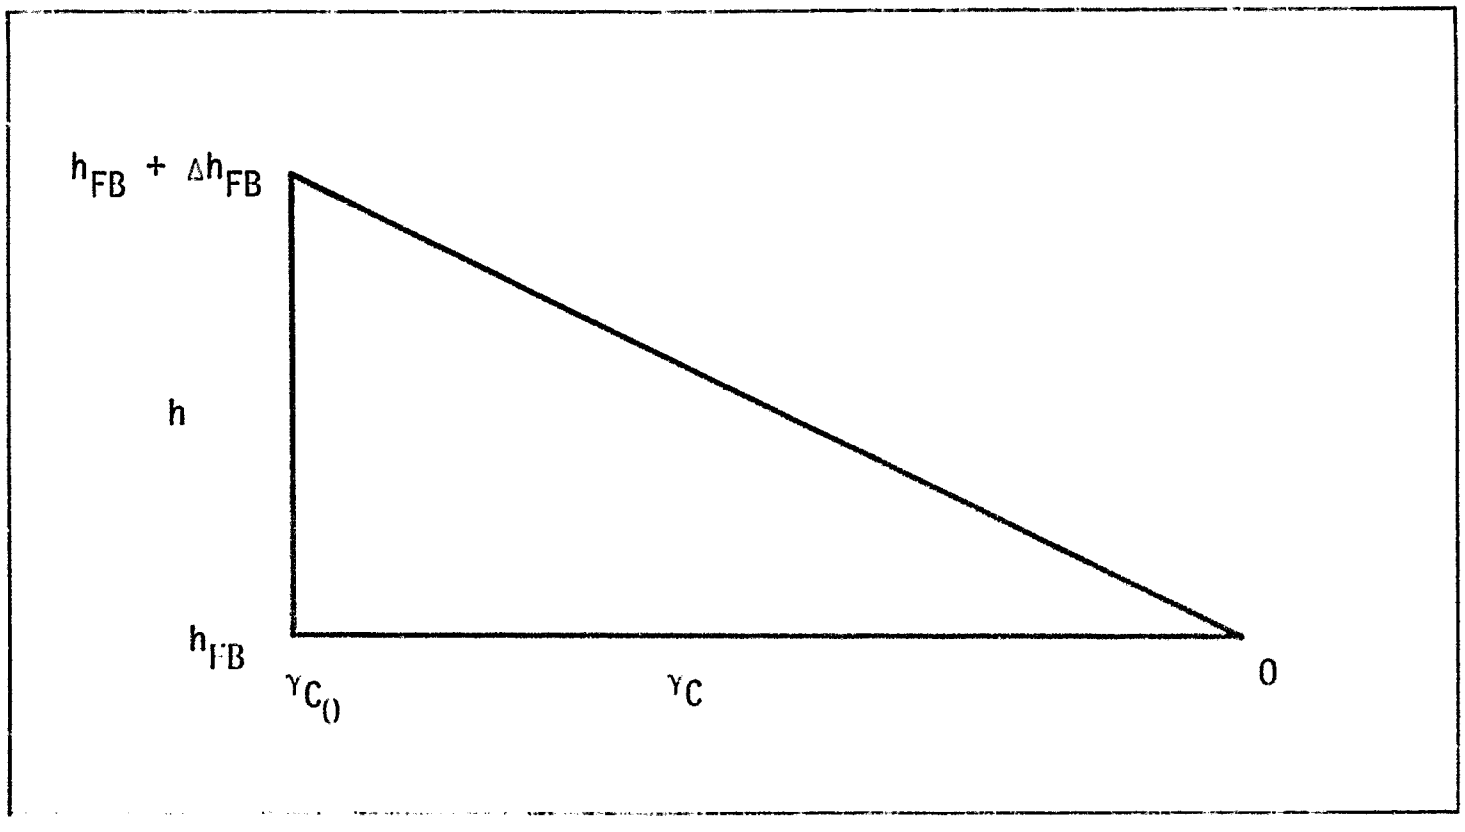

Figure 2-7. GEOMETRY OF FLYBACK ALTITUDE INTERCEPT

$$\gamma_{C0} = \gamma_C \tag{119}$$

where
$$h_{FB} + \Delta h_{FB} = h \tag{120}$$

γ_{C1} is the γ at the start of the time step and γ_{C2} becomes

$$\gamma_{C2} = \frac{\gamma_{C0}}{\Delta h_{FB}} (h - h_{FB}) \tag{121}$$

with $\dot{\gamma}_C$ being

$$\dot{\gamma}_C = \frac{\gamma_{C2} - \gamma_{C1}}{\Delta t} \tag{122}$$

This forces γ_C to smoothly curve to zero when

$$h_{FB} = h \tag{123}$$

thus bringing the vehicle to the flight path angle for cruise.

2.9.5 Condition D - E

This condition brings the vehicle from its turning state to the flyback azimuth, Z_{FB}. Point D is reached when

$$\Delta Z = \Delta Z_R = Z_{FB} - Z \tag{124}$$

ΔZ_R is a given value. From this point Z_R, the required rate of change of azimuth, is controlled by the scheme developed below. Figure 2-8 illustrates the method of Z_{FB} intercept.

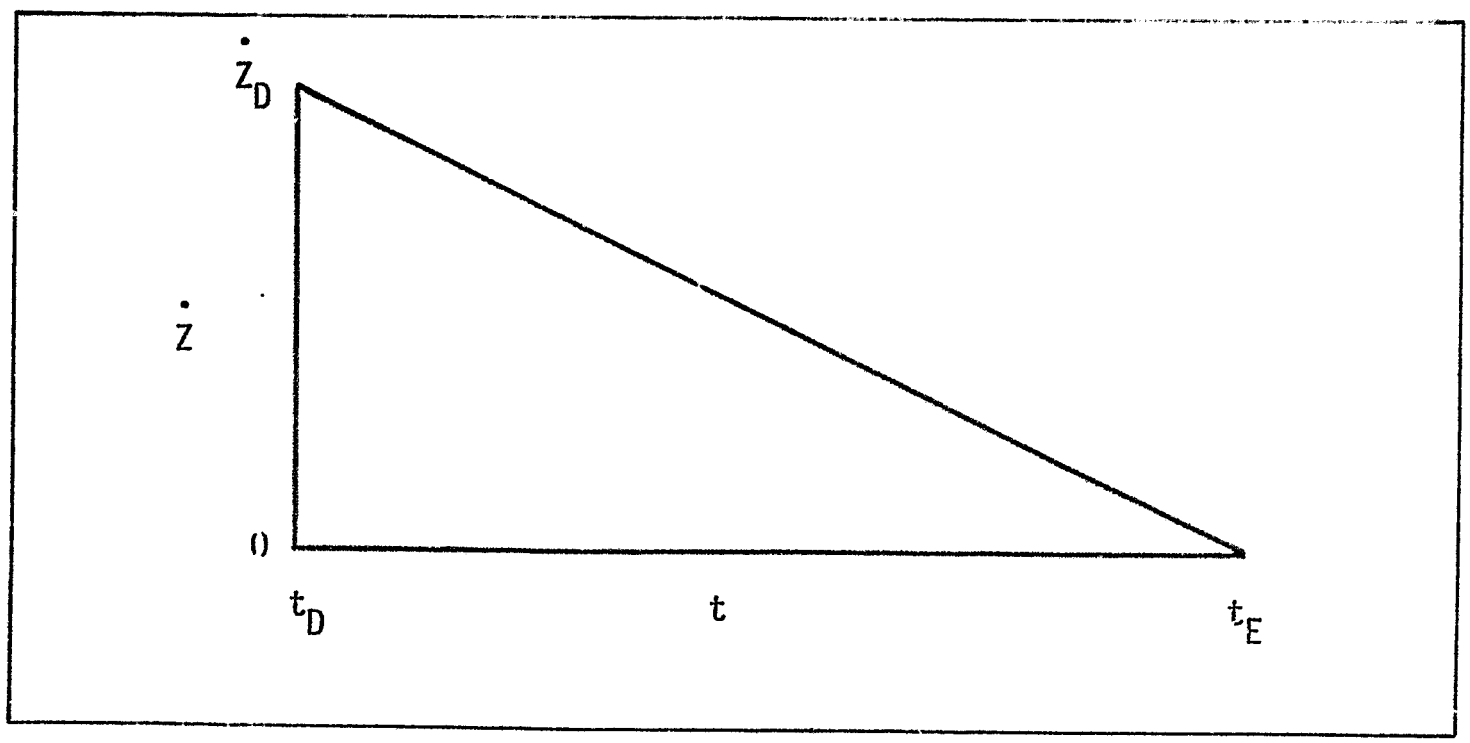

Figure 2-8. GEOMETRY OF FLYBACK AZIMUTH INTERCEPT

Z_R must go from its initial value at Point D to zero at Point E. Also ΔZ must equal zero at Point E. To do so,

$$\Delta Z_R = \int_{t_D}^{t_E} Z_R \tag{125}$$

Therefore the area of the triangle is

$$\Delta Z_R = \frac{\dot{Z}_R \; t_{D-E}}{2} \tag{126}$$

and

$$t_{D-E} = \frac{2 \; \Delta Z_R}{\dot{Z}_R} \tag{127}$$

$\dot{Z}_R$ is then computed from Points D to E from

$$\dot{Z}_R = \dot{Z}_D - \frac{\dot{Z}_D}{t_{D-E}} \left(t - t_D\right) \tag{128}$$

or eliminating t_{D-E},

$$\dot{Z}_R = \dot{Z}_D - \frac{\dot{Z}_D^{\,2}}{2\Delta Z} \; (t - t_D) \tag{129}$$

The roll angle, ϕ, is used to control Z by

$$\text{If } \dot{Z} < \dot{Z}_R, \quad \phi_{OLD} = 1.05 \quad \phi_{NEW}$$

$$\text{If } \dot{Z} > \dot{Z}_R, \quad \phi_{OLD} = 0.95 \quad \phi_{NEW}$$

until $\dot{Z}$ is correct. Point E is reached when

$$Z \geq Z_{FB} \tag{130}$$

Then, by command

$$\phi = 0 \tag{131}$$

and the flight is continued.

2.9.6 Condition E - F

The purpose of condition E - F is to hold the flyback Mach number or altitude after the turn is completed, when necessary. When the correct values of both M and h are attained, this condition is finished. When

$$M \leq M_{FB} \tag{132}$$

The value is held by

$$M = M_{FB} \pm \Delta M_{FB} \tag{133}$$

where ΔM_{FB} is the tolerance allowed on M_{FB}. The engines are assumed started and the throttle variable, k_{20}, is varied to hold M_{FB} as follows:

When $M < M_{FB}$, $k_{20\ NEW} = 1.05\ k_{20\ OLD}$

When $M > M_{FB}$, $k_{20\ NEW} = 0.95\ k_{20\ OLD}$

Standard convergence procedure is used.

Normally M_{FB} will be reached during the descent. However, if

$$h \leq h_{FB} \text{ before } M = M_{FB}, \tag{134}$$

the angle-of-attack may be used to hold the flyback altitude. The altitude should be held to

$$h = h_{FB} \pm \Delta h_{FB} \tag{135}$$

where Δh_{FB} is the allowed tolerance.

When $h > h_{FB}$, $\alpha_{NEW} = 0.95\ \alpha_{OLD}$

When $h < h_{FB}$, $\alpha_{NEW} = 1.05\ \alpha_{OLD}$

and the value of α found by convergence.

NOTE: Conditions C - D, D - E, and E - F are not necessarily separate operations. On many vehicles they will overlap. Consequently, each condition runs to its conclusion independently of the others.

2.10 CRUISE CONTROL

When all conditions above have been met, and

$$\begin{aligned} Z &= Z_{FB} \\ h &= h_{FB} \\ M &= M_{FB} \\ V &= V_{FB} \end{aligned} \tag{136}$$

which are the cruise conditions, the vehicle is ready for cruise to base. As shown, the flyback range, R_{FB}, is continuously calculated. Knowing that and assuming that

$$W = W_{FB} \tag{137}$$

when the cruise conditions are met, SFC and S are input values, and ρ is known; then the weight at the end of cruise, W_H, can be calculated by the following modification of the classic Breguet equation.

$$W_{II} = \left[1 - \frac{R_{FB}}{\frac{7200}{SFC}\left[\frac{\sqrt{C_L}}{C_D}\right]_{MAX}\left[\frac{2\,W_{FB}}{\rho\,S}\right]^{\frac{1}{2}}}\right]^2 W_{FB} \tag{138}$$

$\left[\frac{\sqrt{C_L}}{C_D}\right]_{MAX}$ is calculated from the following:

First the table of α vs $\frac{\sqrt{C_L}}{C_D}$ is determined, i.e.,

$$\alpha \left| C_L \right| \; C_D \left| \sqrt{C_L} \right| \; \frac{\sqrt{C_L}}{C_D}$$

when

$$\left(\frac{\sqrt{C_L}}{C_D}\right)_{OLD} > \left(\frac{\sqrt{C_L}}{C_D}\right)_{NEW} \tag{139}$$

the last two points are used to converge on $\left(\frac{\sqrt{C_L}}{C_D}\right)_{MAX}$.

The time taken during flyback cruise is calculated by

$$t_{FB} = \frac{R_{FB}}{V_{FB}} \tag{140}$$

where

$$V_{FB} = M_{FB}\ (SOS) \tag{141}$$

2.11 GLIDE TO LANDING

The calculation of glide to landing is actually made before the cruise, so that the flyback range is modified to provide the correct value. However, it is included here for continuity, as the routine actually prints the glide conditions, subscripted $_{FG}$, after the cruise data.

Glide Option 1

This glide calculation assumes

$$W_{FG} = W_{EM} = W(EMPTY) \tag{142}$$

$$\rho_{FG} = \rho \text{ at } 0.5\ h_{FB} \tag{143}$$

$$V_{FG} = V_{FB} \tag{144}$$

$$q\ S = \tfrac{1}{2}\ \rho_{FG}\ V_{FG}^2\ S \tag{145}$$

The following equations must be satisfied for a stabilized glide condition, where the forces are summed perpendicular and parallel to the velocity vector. See Figure 2-9.

$$W_{FG} \cos \gamma = q\ S\ C_L \tag{146}$$

$$W_{FG} \sin \gamma = q\ S\ C_D \tag{147}$$

Solving for the flight path angle,

$$\gamma = \cos^{-1}\left[\frac{q\ S\ k_{23}\ C_{L\alpha}\alpha}{W_{FG}}\right] \tag{148}$$

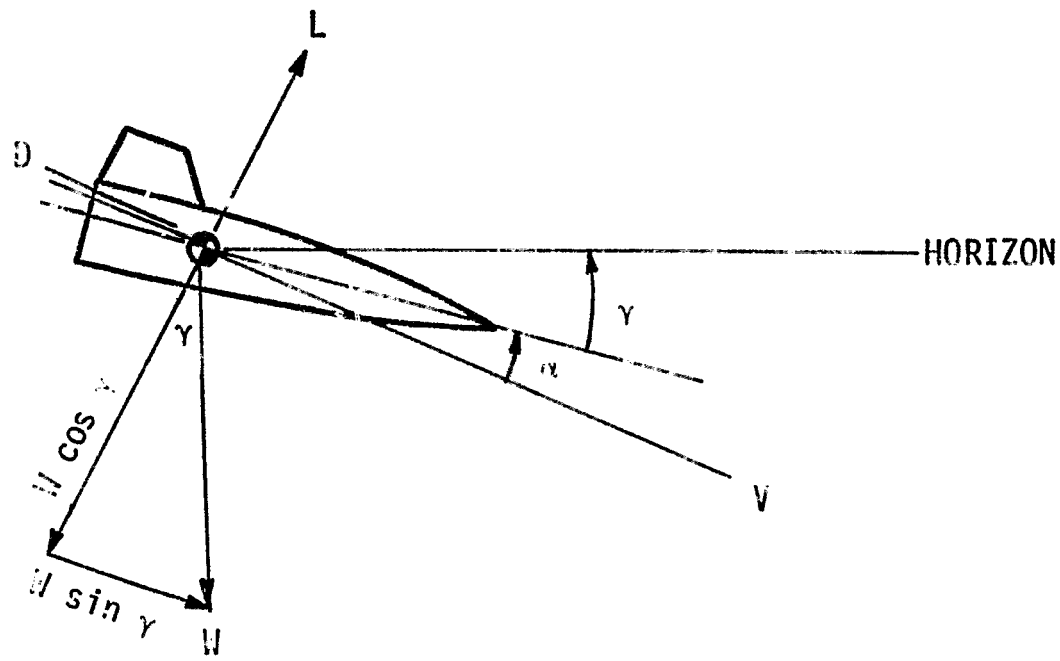
$$\gamma = \sin^{-1}\left[\frac{q\ S(k_{22}\ C_{DO} + k_1\ k_{24}\ C_{L\alpha}\ \alpha \tan \alpha)}{W_{FG}}\right] \tag{149}$$

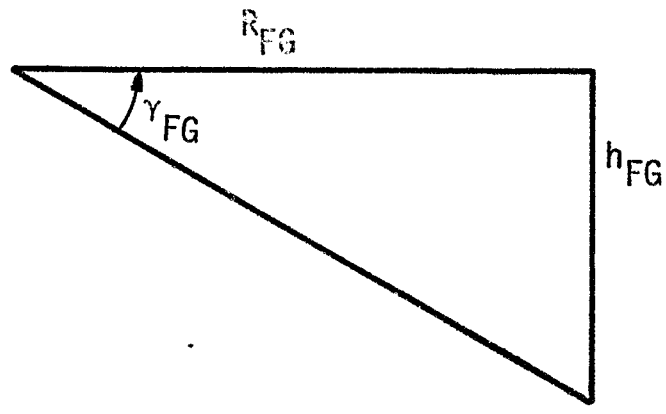
Then the two equations for γ may be solved for α by substituting

$$\cos \gamma = D\alpha \tag{150}$$

and

$$\sin \gamma = E + F\ \alpha\ \tan \alpha \tag{151}$$





OPTION 2

Figure 2-9. GLIDE CONDITIONS

Since

$$1 - \sin^2\gamma = \cos^2\gamma \tag{152}$$

then

$$1 - \sin^2\gamma = D^2\alpha^2 \tag{153}$$

$$\sin^2\gamma = 1 - D^2\alpha^2 \tag{154}$$

and

$$\sin^2\gamma = E^2 + 2EF\,\alpha\tan\alpha + F^2\alpha^2\tan^2\alpha \tag{155}$$

Substituting further

$$1 - D^2\alpha^2 = E^2 + 2EF\,\alpha\tan\alpha + F^2\alpha^2\tan^2\alpha \tag{156}$$

$$F^2\alpha^2\tan^2\alpha + 2EF\,\alpha\tan\alpha + D^2\alpha^2 + (E^2 - 1) = 0 \tag{157}$$

Making the following substitutions,

$$F^2 = X$$

$$2EF = Y$$

$$D^2 = Z$$

$$E^2 - 1 = W$$

then

$$X\alpha^2\tan^2\alpha + Y\,\alpha\tan\alpha + Z\alpha^2 + W = 0 \tag{158}$$

A series expansion of tan α yields

$$\tan\alpha = \alpha + \frac{\alpha^3}{3} + \frac{2\alpha^5}{15} + \cdots \tag{159}$$

Then the first term in the equation becomes

$$X\alpha^2\left(\alpha + \frac{\alpha^3}{3} + \frac{2\alpha^5}{15}\right)^2 = X\alpha^2\left(\alpha^2 + \frac{2\alpha^4}{3} + \cdots\right) \tag{160}$$

$$= X\alpha^4 + \frac{2X\alpha^6}{3} + \cdots$$

All remaining terms in the equation have been found to be insignificant. Therefore, the complete equation may be written in the form

$$X\alpha^4 + \frac{2X\alpha^6}{3} + Y\alpha\left(\alpha + \frac{\alpha^3}{3} + \frac{2\alpha^5}{15}\right) + Z\alpha^2 + W = 0 \tag{161}$$

$$X\alpha^4 + \frac{2X\alpha^6}{3} + Y\alpha^2 + \frac{Y\alpha^4}{3} + \frac{2Y\alpha^6}{15} + Z\alpha^2 + W = 0 \tag{162}$$

or

$$(Z + Y)\alpha^2 + (X + \frac{Y}{3})\alpha^4 + 2(\frac{X}{3} + \frac{Y}{15})\alpha^6 = - W \tag{163}$$

Let

$$a_1 = Z + Y$$

$$a_2 = X + \frac{Y}{3}$$

$$a_3 = 2\left[\frac{X}{3} + \frac{Y}{15}\right]$$

$$-W = V$$

$$\beta = \alpha^2$$

Substituting in the equation yields

$$a_1\,\beta + a_2\,\beta^2 + a_3\,\beta^3 = V \tag{164}$$

The equations for reversion of a series may now be applied, i.e.,

$$A_1 = \frac{1}{a_1}$$

$$A_2 = -a_2/a_1^3 \tag{165}$$

$$A_3 = \frac{1}{a_1^5}(a_2^2 - a_1\,a_3)$$

Then the following may be written:

$$\beta = A_1\,V + A_2\,V^2 + A_3\,V^3 \tag{166}$$

Finally, after solving for β,

$$\alpha_{FG} = \sqrt{\beta} \tag{167}$$

The glide flight path angle, γ_{FG}, may now be obtained from

$$\gamma_{FG} = \cos^{-1} [\, q_{FG}\ S\ k_{23}\ C_L\ \alpha_{FG}\ ] \tag{168}$$

The glide range is given by

$$R_{FG} = \frac{h_{FG}}{\tan \gamma_{FG}} \tag{169}$$

This modifies the flyback range by the quantity

$$R_{FB\ NEW} = R_{FB\ OLD} - R_{FG} \tag{170}$$

Then the time in glide is given by (approximately)

$$t_{FG} = \frac{R_{FG}}{V_{FG} \cos \gamma_{FG}} \tag{171}$$

Glide Option 2

The second glide option uses the maximum lift-drag ratio of the vehicle. $(C_L/C_D)_{max}$ is found by calculating C_L/C_D as a function of α, thus:

$$\alpha \rightarrow C_L \rightarrow C_D \rightarrow \frac{C_L}{C_D}$$

When

$$\left(\frac{C_L}{C_D}\right)_{old} > \left(\frac{C_L}{C_D}\right)_{new} \tag{172}$$

then

$$\left(\frac{C_L}{C_D}\right)_{old} \simeq \left(\frac{L}{D}\right)_{max} = \left(\frac{C_L}{C_D}\right)_{max} \tag{173}$$

As developed previously,

$$q\ S\ C_L = W \cos \gamma_{FG} \tag{174}$$

$$q\ S\ C_D = W \sin \gamma_{FG} \tag{175}$$

Dividing the upper equation by the lower,

$$\frac{C_L}{C_D} = \frac{\cos \gamma_{FG}}{\sin \gamma_{FG}} = \frac{1}{\tan \gamma_{FG}} \tag{176}$$

As shown in Figure 2-9

$$\tan \gamma_{FG} = \frac{h_{FG}}{R_{FG}} \tag{177}$$

Assuming

$$\left(\frac{C_L}{C_D}\right)_{max} = \frac{1}{\tan \gamma_{FG}} \tag{178}$$

And substituting,

$$\left(\frac{C_L}{C_D}\right)_{max} = \frac{R_{FG}}{h_{FG}} \tag{179}$$

or

$$R_{FG} = \left(\frac{C_L}{C_D}\right)_{max} h_{FG} \tag{180}$$

2.12 CONSTRAINTS

Throughout the whole flyback computation, there are two constraints designed to prevent the vehicle from violating either the equations herein or its structural integrity.

First, the angle-of-attack must be controlled. If, at any time, the α control violates the following conditions, α is automatically set as follows

If $\alpha > \alpha_{MAX}$, then set $\alpha = \alpha_{MAX}$

If $\alpha < 0.0$, then set $\alpha = 0.0$

The other constraint is on maximum resultant load factor, or $G_{R_{MAX}}$. When

$$G_R > G_{R_{MAX}} \tag{181}$$

where $G_{R_{MAX}}$ is a given value, α is reduced by

$$\alpha_{NEW} = 0.95\ \alpha_{OLD} \tag{182}$$

the time step is then recalculated, and $G_{R_{MAX}}$ is automatically rechecked.

The α is reduced until

$$G_R \overset{<}{=} G_{R_{MAX}} \tag{183}$$

Figure 2-10, Example Test Vehicle, illustrates the vehicle used in the example run of Section VI.

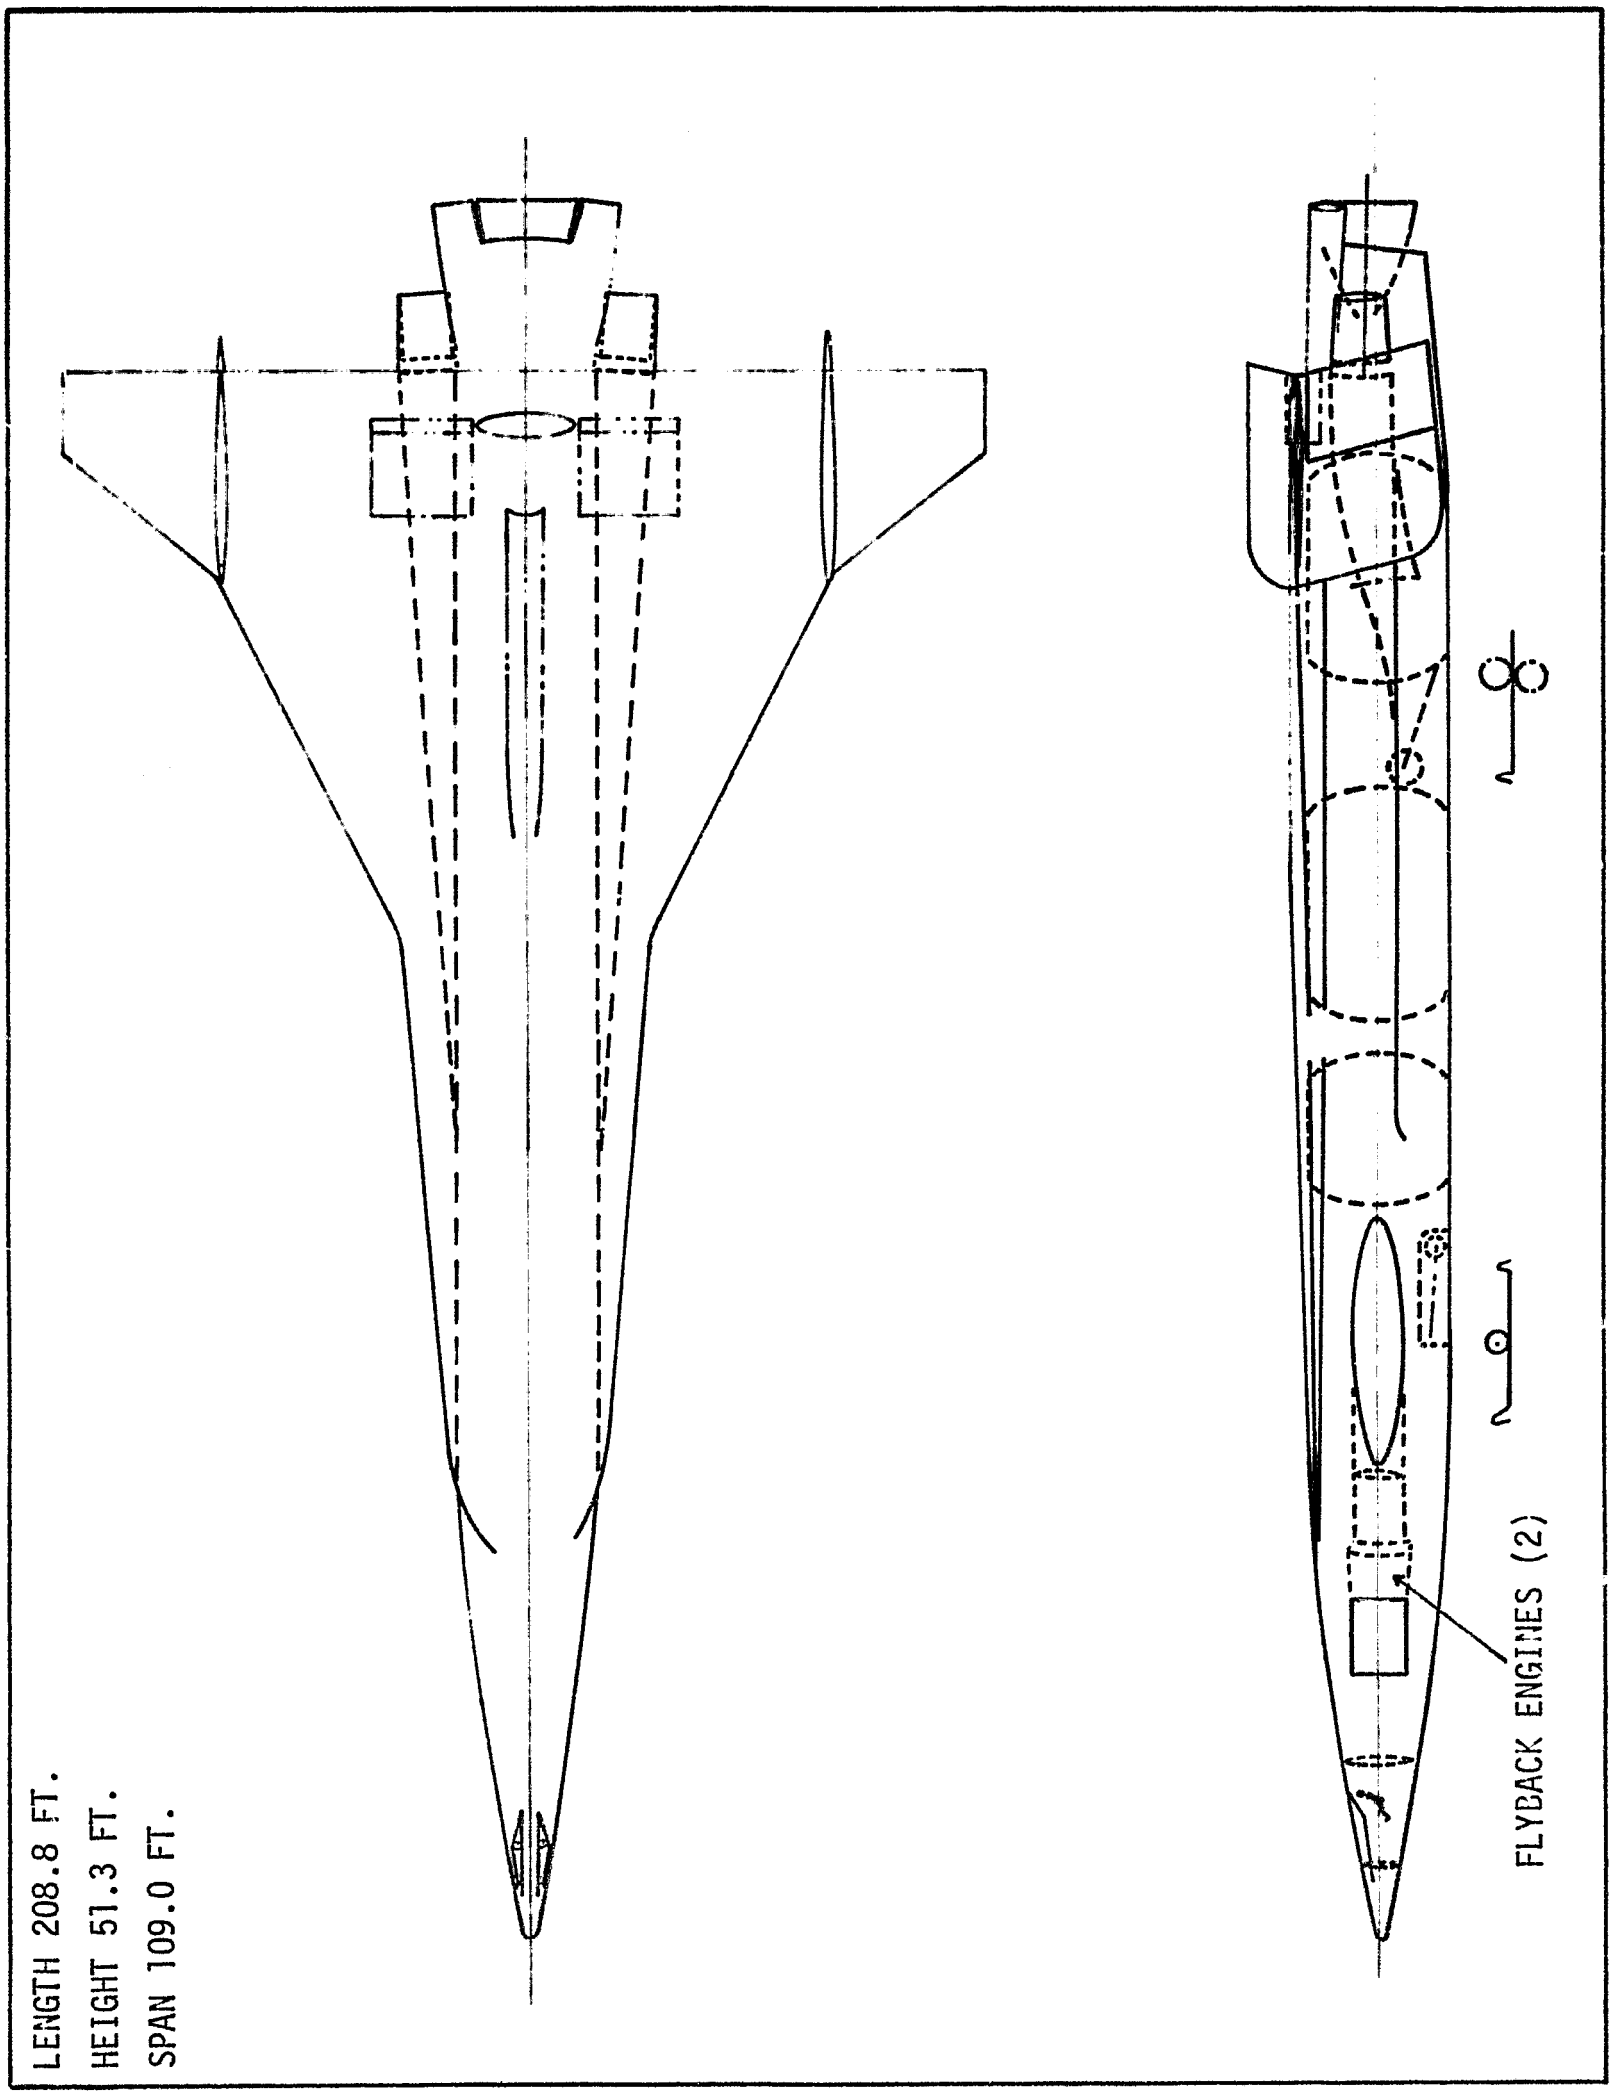


Figure 2-10. EXAMPLE TEST VEHICLE

Section III
IMPLEMENTATION

The computer program to implement the flyback theory has been written in Fortran II - IV for the CDC 3200 computer. This program has been written as a main directional program with 13 subroutines and functions to make the general structure of the program easy to follow and to avoid duplicate programming. The following description of the main program and the subroutines attempts to explain what the program is doing and includes some of the details on programming techniques used. This description is related back to the Theory section as seems appropriate.

3.1 MAIN PROGRAM

A. Input and printout of data as explained in Subsection 3.4.

B. Conversion of data for internal use, i.e., all degree values are converted to radians. Internal variables are given initial values.

C. The staging position is then calculated, as explained in Subsection 2.3. For the change in longitude, standard launch conditions are assumed.
i.e., $\Delta\lambda$ is negative if $Z < 180°$
$\Delta\lambda$ is positive if $Z > 180°$.

If staging azimuth, latitude, and longitude are known, these should be input as ZL, XLAT, and XLON respectively. Cards A80 through A95 in the main routine of Section V should be removed from the program.

D. Bank control (Subsection 2.9) is used as the main body outline. Each bank condition has a corresponding KASE number within the program, i.e., condition 0-A is KASE 1, etc. Each condition is checked for method of flight control - Alt, Mach, or Alpha. An indicator ICK is used to denote which is in control. ICK = + 1 = Mach, ICK = - 1

= Alt, ICK = 0 = Alpha. Subroutine CONTRL is then called to establish the control values (Subsection 3.2). The integration parameters from the previous second are retrieved from subroutine SET. These values are then integrated in RUNGEK and final information including aerodynamic, navigational, and acceleration equations are calculated for the new time step using subroutines DRG, RESULT, ACCEL. Condition end conditions are then tested, if satisfied, the next condition is entered. If not, printout of the results is given from subroutine OUTPUT at specified time intervals.

The PHI control of GAMC in condition C-D (Subsection 2.9.4) was actually programmed in subroutine DRG where the needed value of PHI can be continuously calculated during the integration (DRG, No. B, Subsection 3.3). The GAMC flight path smoothing described has been incorporated in subroutine CONTRL (Subsection 3.2).

In condition D-E (Subsection 2.9.5), PHI is used to bring DELZ to 0.0 (DELZ is the difference between Z and Z_R). Subroutine CONVERG is used to control PHI but the value of PHI is held between 0.0 and 90.0°. PHI is always set to 0.0 at the end of this condition.

Condition E-F (Subsection 2.9.6) is just for continuation of flight to the required ALT and XMACH values. As the controls on ALT and XMACH become effective at whatever point the required values are reached, this condition may actually be included in the earlier conditions; as a result, its control is handled in subroutine CONTRL through the indicator ICK as mentioned previously.

At the conclusion of condition D-E or in condition E-F, the cruise conditions will be met, then the glide and Breguet will be calculated. However, if PHI $\neq$ 0.0 at the time cruise conditions are met, the message PHI IS NOT ZERO will be printed and calculations stopped.

E. The glide condition is calculated first to obtain information needed in the Breguet. Two glide options are included. The method chosen is determined by the input indicator IGLD. Glide option one (IGLD=1) is programmed at the present time as a simple convergence scheme rather than the reversion series explained in Subsection 2.11. The expressions for sin and cos of Gam from Subsection 2.11 are evaluated with varying values of ALPH from 0.0 in steps of 1° until the values for GAM obtained are approximately equal. Testing for convergence is accomplished by checking for a change in sign of the difference between the values calculated for the sin and cos expressions. If the value of either the sin or cos term exceeds 1.0, the error message TERM EXCEEDED 1.0 is printed and calculations are terminated. Such a value would mean that a solution cannot be found for the conditions given. The information calculated for the glide is stored for printout after the Breguet.

Glide option two (IGLD=2) uses a simple convergence scheme to find the ALPH value to give the maximum (CL/CD) term, as for IALP=2 in Subsection 3.2. RFG and GFG are then calculated and RB modified. When printing the glide results, no TIM, VEL, or XMACH values are printed for this option.

F. The program section for calculating the Breguet equation (Subsection 2.10) is entered with the information from the end of the Flyback plus the range, RB, calculated in the GLIDE. To calculate WHT the maximum value of sqrt (CL)/CD, TERM, must be found. To find the ALPH for this, ALPH is varied from .25° in .5° increments until

$$TERM_{old} < TERM_{new}$$

$ALPH_{old}$ ...hen stepped in .1° increments to the actual crossover point. The TERM is not evaluated at ALPH = 0.0 because CD would be 0.0 and the TERM would be undefined. This method assumes the plot of sqrt(CL)/CD vs ALPH will be a smooth curve continuously rising to one peak.

At the end of these calculations

TIM = TIM at end of flyback + TB
RANGE = RANGE at end of flyback + RB
WHT = WHT from Breguet equation
ALPH = ALPH for maximum value of the sqrt (CL)/CD
VEL and ALT = values at end of flyback

After this information is printed, corresponding GLIDE information previously calculated is printed.

At this point, the message CALCULATIONS FINISHED will be printed and an attempt made to read a new set of data.

3.2 SUBROUTINE CONTRL

Subroutine CONTRL is the control routine used by all roll conditions.

Its primary purpose is to set the value of ALPH at each integration interval, but also GAMC is controlled during condition D-E and when ALT

hits DHFB, THR is used to control MACH. These control methods are explained throughout Section II, but have been grouped as one unit so the computer can handle the hierachy.

The control of ALT and XMACH is explained in Subsection 2.9.6. The primary indicator for ALTB-XMB control, ICK, is set within the main program. The values are

-1 ALTB reached
0 Neither ALTB nor XMB reached
+1 XMB reached
+2 Both ALTB and XMB reached

This is checked in CONTRL with LOC to determine when a change in the ALTB-XMB status has occurred. These are checked during all conditions. The values of LOC are:

0 Neither ALTB nor XMB has yet been reached
-1 Program has been operating under ALT control
+1 Program has been operating under MACH control

When both have been reached, LOC is no longer checked as there will be no further change in this control status.

When ALT first falls within ATOL feet of ALTB, routine CONVERG is used to determine the ALPH value to maintain this tolerance on ALT. A test integration is made from subroutine CONTRL with each trial ALPH until the condition is satisfied or ALPH falls outside its maximum and minimum range.

For XMB control when XMACH falls within the tolerance XTOL of XMB, the thrust parameter CK20 is varied to alter THR to hold XMACH on XMB. Subroutine CONVERG is used to converge on a CK20 that will hold DM = XMACH-XMB near 0.0. Here also trial integrations are necessary for each CK20 value tested to determine when the solution has been found. No maximum limit has been set on CK20 but 0.0 is the minimum value.

When ICK = 2, both of the above conditions must be satisfied at each integration interval.

If neither condition has been reached or if XMB only has been reached, GAMC control is then checked. A gradual increase is made in GAMC from DHFB to ALTB as explained in Subsection 2.9.9. IH is used as the indicator where

IH = 0 increasing GAMC not yet begun

IH = 1 now decreasing GAMC.

GAMC is increased by the equation given in Subsection 2.9.4 until GAMC = .5°. This value is held until ALT = ALTB at which time GAMC is set to 0.0 in the ALT control section. Continuously decreasing the last .5° GAMC was found to unnecessarily prolong the time needed to reach ALTB.

From condition D-E until the end of the flyback, provided ALTB has not been reached, ALPH is used to hold GAM on GAMC $\pm$ GCTL regardless of whether GAMC is constant or changing. Routine CONVERG is used to hold DGAM = GAM - GAMC near 0.0. If ALPH cannot hold this value, i.e., if ALPH goes outside the maximum - minimum range, GAMC is set equal to the present value of GAM and ALPH is set to either the maximum or minimum, depending on the direction in which it is out of range. Here again trial integrations must be made for each ALPH test value.

If neither ALTB nor condition D-E have been reached, then ALPH is controlled by the input method using the indicator IALP. These methods of ALPH control are explained in Subsection 2.8.

For IALP = 1, the maximum angle-of-attack is taken from the input table of MACH-Aerodynamic coefficients, and maximum ALPH values as described in the input. This value, called ATRN, is calculated in subroutine DRG but is only used as maximum ALPH unless called for here.

IALP = 2 is the maximum LIFT/DRAG method. A simple convergence routine is used beginning with ALPH = .5° and incrementing in .5° steps until the maximum value for LIFT/DRAG is found. Subroutine DRG is reevaluated for each test ALPH. The correct value has been found when

$$\text{LIFT/DRAG}_{new} < \text{LIFT/DRAG}_{old}$$

The $ALPH_{old}$ value is then incremented in .1° steps to find a more exact value for ALPH.

IALP = 3 is the maximum vertical load factor method of control. The Newton-Raphson method is used to calculate the desired ALPH value as explained in Subsection 2.8.3. In most cases, maximum ALPH cuts off the convergence. In this case, BETG, i.e., 2* ALPH, is set to 25.° to begin the next convergence. The tolerance on BETG is an increment value, DEL, of $\pm$ .1°.

IALP = 4 is the Energy Management solution. The expression for the arc sin of GAM given in Subsection 2.8.4 is solved for the GAM needed, GAMT. Routine CONVERG is used to find the ALPH value required to keep DT = GAMT-GAM within the specified tolerance, i.e., GAM must be equal to GAMT $\pm$ .01°. A test integration must be made for each ALPH value tried.

After APLH has been set by one of these methods, GR must be checked to see that GRMX has not been exceeded, as stated in Subsection 2.12. If GR is greater than GRMX, then ALPH must be changed, using CONVERG, to

bring DG = GR - GRMX near 0.0. However, ALPH must still be kept within the maximum limit set by the ATRN value from the table and above the minimum value of 0.0.

The following tabulation of the heirachy of these ALPH control methods may help clarify their use.

- ALPH must not exceed ATRN and must not be less than 0.0.
- GR must not exceed GRMX.
- ALT must be held on ALTB.
- From conditions D-E on, GAM must be held on GAMC.
- ALPH will be controlled by whatever method is specified by the indicator IALP.

3.3 ADDITIONAL SUBROUTINES

The following subprograms, in addition to subroutine CONTRL, are used in this program:

A. Subroutine CONVERG is the standard convergence routine used throughout the program, especially in subroutine CONTRL. The call parameters are (IND3, IEND, F, ALPH, ALPH2, ALPH1, DELD, DELD2, DELD1, KASE, QTMAX) where

- IND3 is the internal indicator to establish at what point in the convergence the call is being made. The indicator is set to 0.0 on the first call to the routine for any particular convergence. The indicator should be reset to 0.0 at the completion of each integration step (with final results). The routine handles the value other than that.

- IEND indicates an error. The initial value should be 0.0. A value of 1.0 is generated whenever a value of ALPH of less than 0.0 is calculated. ALPH is set to 0.0 and a normal return from the routine is made. IEND is also set to 0.0 when the routine is not converging on a new ALPH value, i.e., when ALPH = ALPH1 or whenever ALPH = ALPH2 at the end of the routine. Which test is made determined by IND3. For this condition, an error message is printed but calculations continue.

- ALPH is input as the current value and returned as the new value to be tried. (ALPH does not have to be ALPH in the program, the routine is also used for PHI convergence).

- ALPH2 and ALPH1 are the stored values from earlier steps in the convergence. They must be provided for storage as the routine may be used for more than one convergence per integration step.

- DELD is the parameter used to determine the value of ALPH. It should correspond to the ALPH input at any particular step.

- DELD2 and DELD1 are values from an earlier step, corresponding to the ALPH2 and ALPH1 values.

- Kase is not used by the Flyback program.

- QTMAX is twice the value about which convergence is to be made. Most cases will be to converge on a value of ALPH to give a DELD value of 0.0, therefore, this value will usually be 0.0.

B. DRG is called at each step of the integration from RUNGEK and again at the conclusion of the integration. There are no call parameters for this routine as all needed information is transmitted through COMMON. This routine calculates the integration related parameters - the ALPH coefficients are looked up, the maximum ALPH value is calculated, DRAG, XLIFT, and QATM are calculated. In addition, for condition C-D, the expression for cos(PHI) (Subsection 2.9.4) is evaluated. For ALPH = 0.0 this equation is invalid and is not evaluated. If this expression has a value greater than 1.0,a GAMC greater than can be held is being asked for. As a result,PHI is set to 0.0 and GAMC is assigned the value of GAM at that moment. No error message is generated. The initial value for DOTC is 0.0. However,when GAMC is charged in CONTRL, DOTC is calculated for the change in GAMC.

C. OUTPUT is the routine used for output of all essential information at the end of each print interval, which may or may not correspond to the integration interval. For output purposes only, if PHI > 90°, the value for XLIFT is printed as a negative value. Subroutine OUT is used as the form for all printout from this routine.

D. OUT is a short routine for printout of any real numbers with four alphameric characters for identification. The call parameters are (I, A, I2, A2, I3, A3, I5, A4, I5, A5) where the I's represent 4 character Hollerith statements for identification of the following real numbers, A's. These are printed in an E12.5 format. If a different format is desired on all output , only this final format in subroutine OUT need be changed.

E. ACCEL is called at the end of each integration for the calculation of the acceleration equations as described in Subsection 2.5. All needed information is carried in COMMON.

F. RESULT is called at the end of each integration interval for the calculation of the navigation equations, including the change in latitude and longitude in the turn. Flyback range and azimuth are also calculated.

The change in position (Subsection 2.7) is computed first. Here the DLON sign option is programmed as DLON negative if Z < 180.0; DLON positive if Z > 180.0°

RB and ZB are then calculated as described in Subsection 2.6. ZB is not calculated during the final condition, E-F. Also at the end of this routine, the atmospheric data is obtained from routine ATMOSP and the mach number is calculated.

G. RUNGEK is the RUNGE-KUTTA integration routine. This is not a generalized routine, but one written specifically for this program. All information needed is carried through COMMON. One call to this routine by the main program completes one integration step. The integration

step indicator is NRK. This indicator is carried in COMMON for use in the supplemental routine, DOTS, where it is incremented. The initial value is set in RUNGEK. The integration interval DELT is input. A value of 1.0 has been used for most of the test work, and is suggested for use by the user. This routine integrates with TIM for GAM, ALT, VEL, RANGE, Z, and WHT. Function DELTA and subroutine DOTS are used exclusively by this routine.

H. DELTA is a short function for averaging the individual step values for the integrated variables in RUNGEK.

I. DOTS calculates the dot equations being integrated. These equations are given in Subsection 2.4. The arrays VK, GL, ZJ, AM, RN correspond to the components of VEL, GAM, Z, ALT and RANGE, respectively.

J. Subroutine SET is a program storage routine. The call parameter I is used to indicate whether information is to be stored or retrieved. I = information to be reset, 0 = information to be stored. All other values needed are carried in COMMON. This routine is used to store the values for the integrated variables at the end of a second; so if a second needs to be reevaluated, the data for the start point will still be available. This only stores the information from the previous completed integration stop. This is used when several different values of ALPH, or PHI must be tested before a new integration step is satisfactory. The variables in this routine with an N suffix are available only through this routine and must not be put in COMMON.

K. Subroutine ATMOSP is an atmospheric data routine. This routine was taken from the report "Advanced Launch Vehicle Computer Programs for Vertical Takeoff Trajectories, Horizontal Takeoff Trajectories, and Horizontal Takeoff Trajectories with Sonic Boom Calculation" (TR-293-6-110). The call parameters are (H, ANS) where H is the ALT value and ANS is the atmospheric data to be returned - speed of sound, gravitational attraction, and atmospheric density. When the altitude factor exceeds

the maximum value for which data is available, the maximum altitude value is used. No diagnostic is generated.

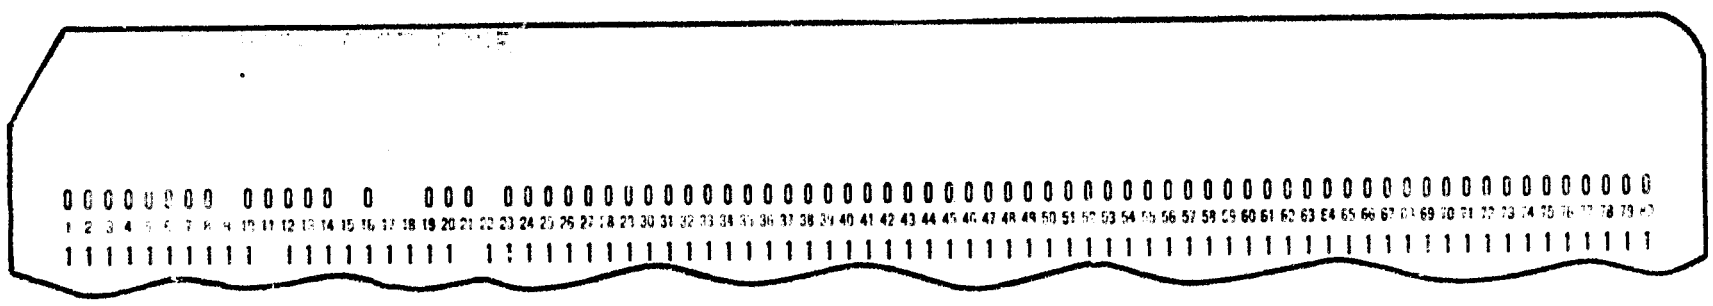
L. Function Y3 is a linear interpolation equation where Y3 is the unknown variable dependent on X3. A value for Y3 is calculated from two sets of points Y2, X2, and Y1, X1.

3.4 INPUT

Input of all data to the program is at the beginning of the main section of the program. The following explanation and illustrations should enable the user to set up a complete set of data. The illustrations below were used by all sample cases in Section VI. All input data is printed out unless otherwise noted.

CARD 1 HEADING

Any information desired as the heading on the first page of output may be put on this card. The format is 20A4.



CARD 2 INTEGERS

The format of this card is (3I2). The first two columns of this card should contain NTAB1, the number of data points to be included in the XMACH-ALPH coefficients table. This value is not printed.

Column 4 of this card should contain an integer, 1 through 4, to indicate the method of Alph control, IALP.

IALP = 1 Table input value
IALP = 2 Maximum lift/drag
IALP = 3 GV equation control
IALP = 4 Energy Management

Column 6 of this card should contain IGLD to indicate the glide option, as explained in Subsection 2.11.

IGLD = 1 glide ALPH determined by GAM equations

IGLD = 2 glide ALPH determined by maximum (CL/CD)

CARDS 3 through NTAB1 + 2. TABLE DATA

The table data is read in one complete set of data per card, i.e.,

XMACHT(1)	CLØTAB(1)	CL1TAB(1)	CL2TAB(1)	CDØTAB(1)	ATR(1)
. .	. .	. .	. .	. .	. .
XMACHT(NTAB1)	CLØTAB(NTAB1)	CL1TAB(NTAB1)	CL2TAB(NTAB1)	CDØTAB(NTAB1)	ATR(NTAB1)

The maximum number of point sets in this table is 16.

XMACHT is Mach number values

CLØTAB corresponds to CLØ

CL1TAB corresponds to CL1

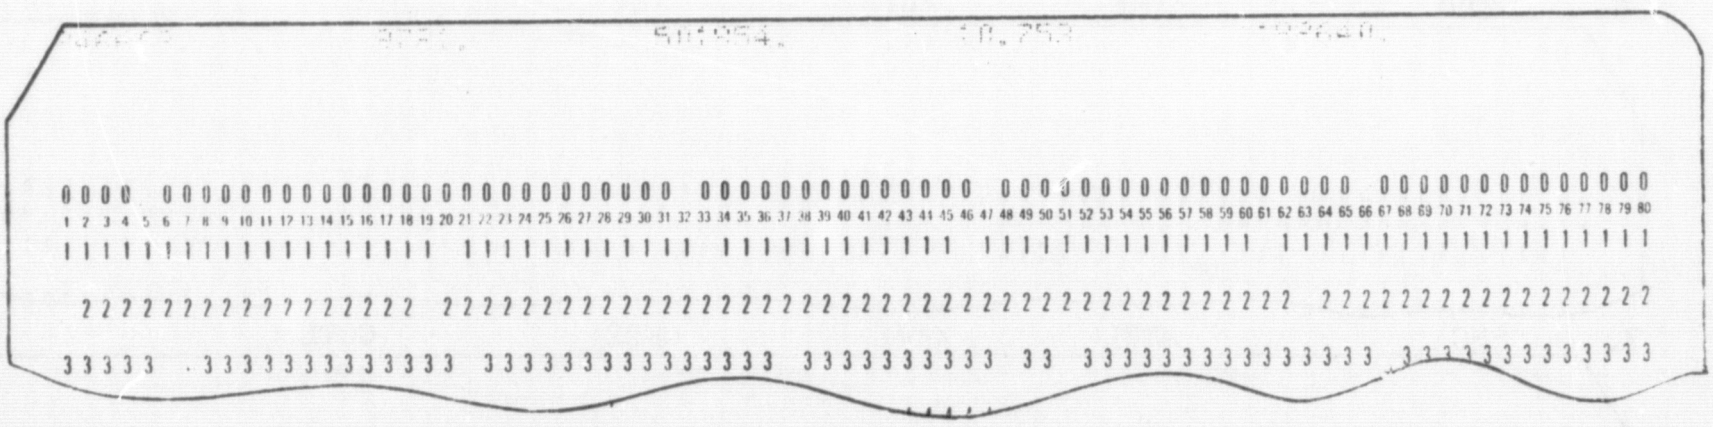
CL2TAB corresponds to CL2

CDØTAB corresponds to CDØ in the program.

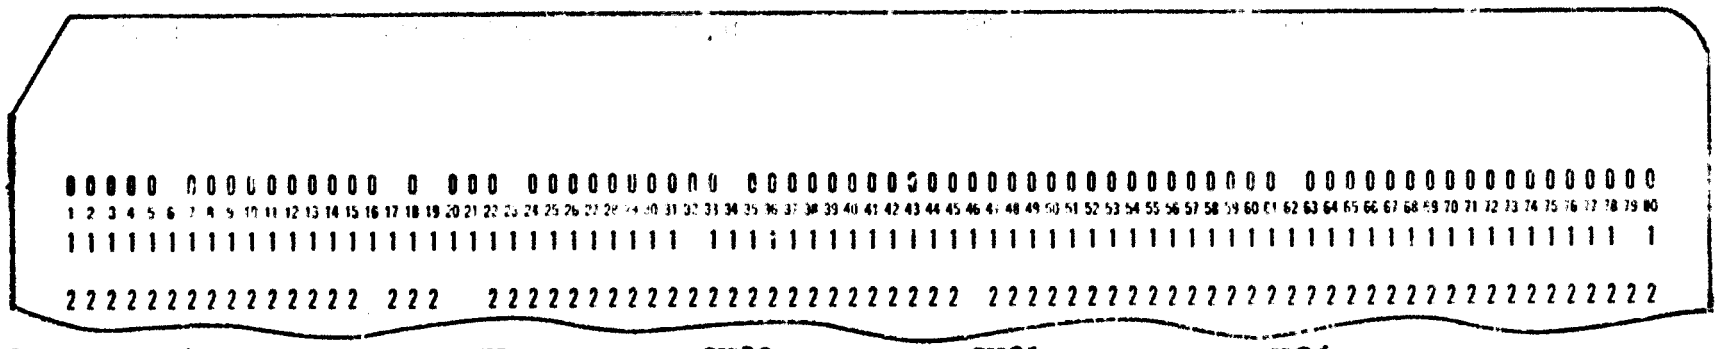
ATR values are the ALPH values to be used for control method IALP = 1 or for maximum ALPH values.

ALL REMAINING CARDS contain single point data input, 5 values per card, until all needed information has been input (format 5E15.5). Definitions of these values can be found in the Nomenclature Section. The last five columns of each card are used and may be used for numbering. The alphabetic O's are slashed in the names over the sample cards for clarity. These cards are:

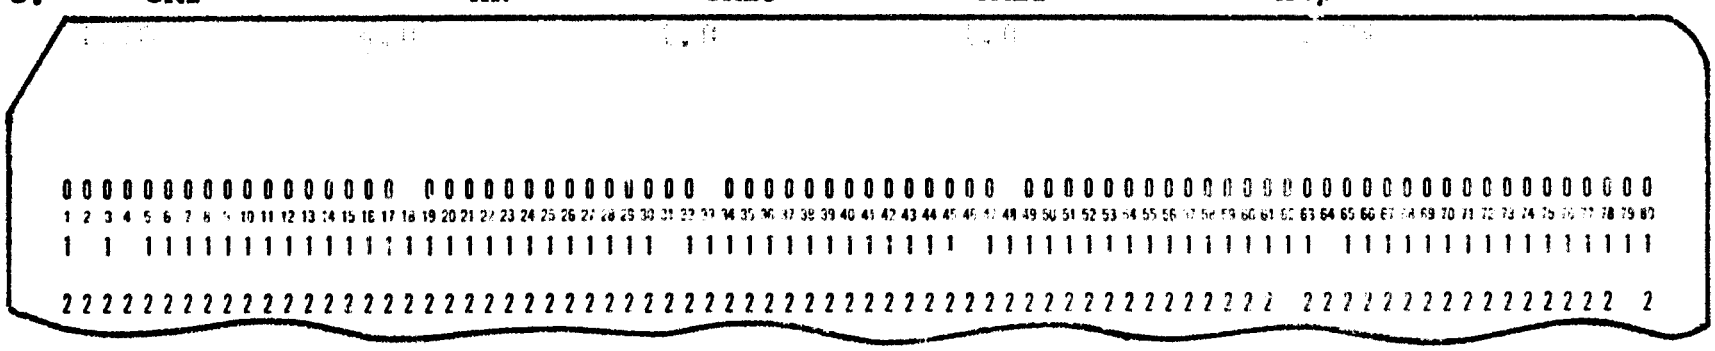
1. WHT VEL RANGE GAM ALT



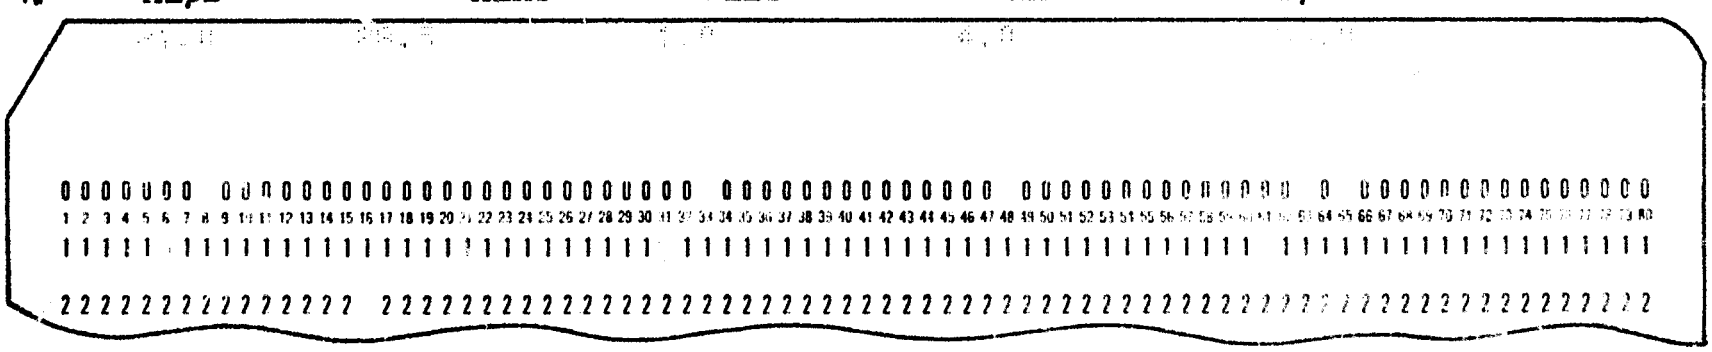
2. ZL RE XLØN XLAT AREA



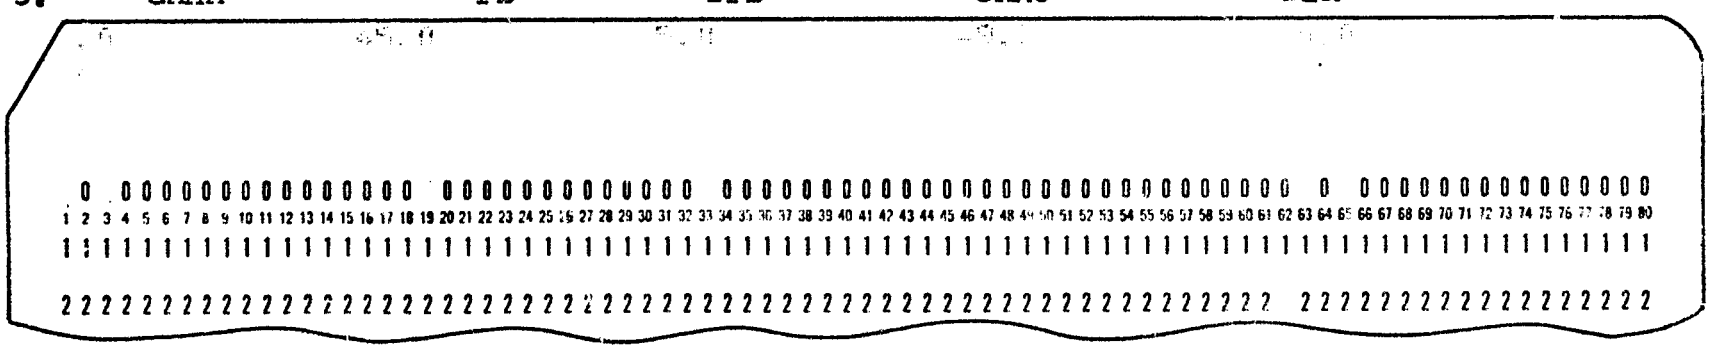
3. CK1 XN CK20 CK21 XGØ



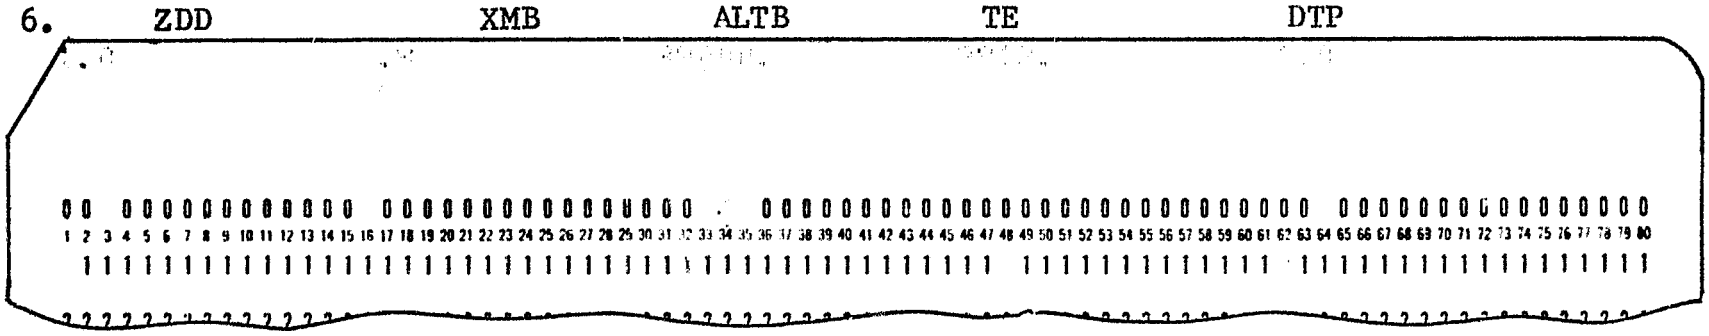
4. XLØB XLAB DELT GRMX PØA



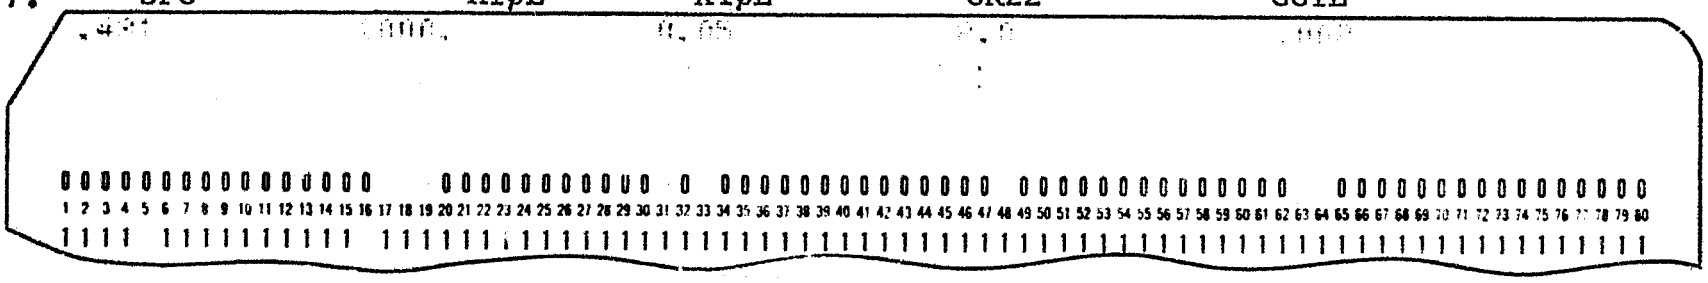
5. GAMA PB DPB GAMC DZR



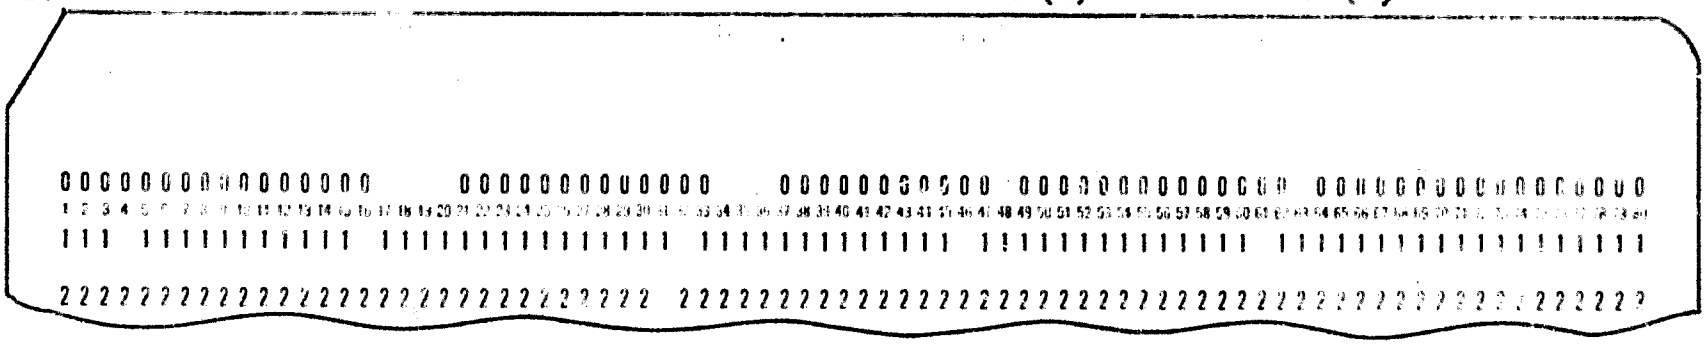
6. ZDD XMB ALTB TE DTP



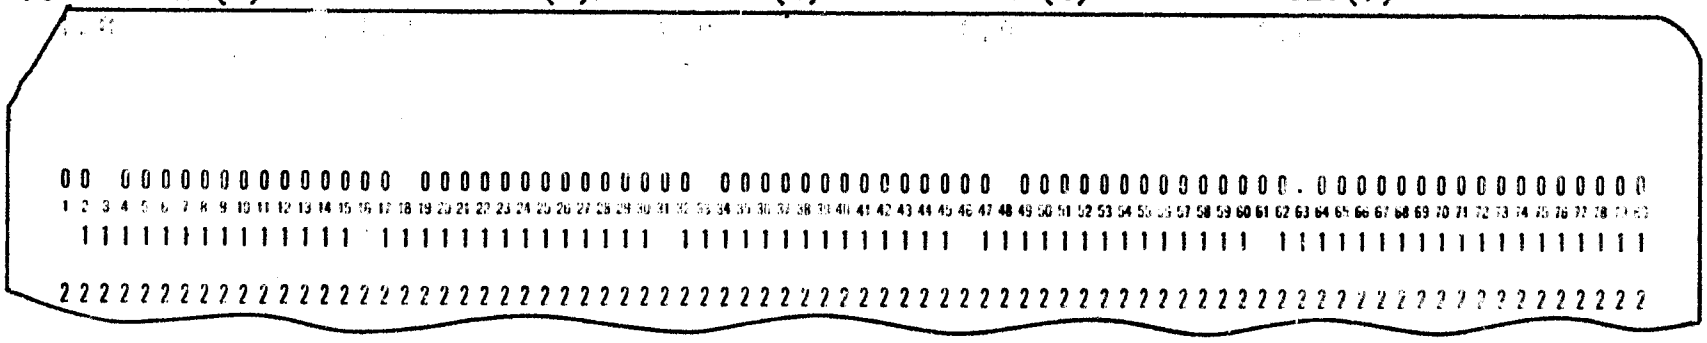
7. SFC ATØL XTØL CK22 GCTL



8. ZTRL DHFB WEMP C23(1) C23(2)

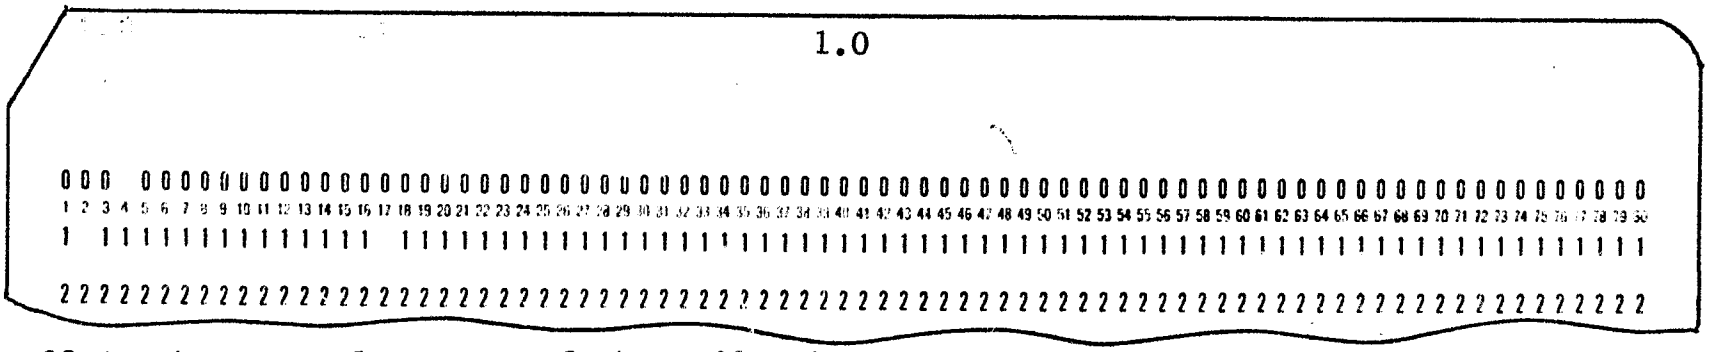


9. C23(3) C23(4) C23(5) C23(6) C23(7)



10. C23(8) DEDH CK24

1.0



C23 is the array for input of the CK23 values.

As many sets of data as desired may be stacked, limited only by your run time. No extra cards should be placed between data sets. When the last set is read, an I/Ø error will be given by the computer.

3.5 USE OF THE PROGRAM

This program, at present, requires a CDC 3200 computer with 32K storage, standard Fortran compiler, reader, and printer. However, the programming is sufficiently general that conversion to a larger machine should not cause any problems. In most cases, logical ifs have been avoided and the FORTRAN II form of input/output has been used.

To compile the program and execute a sample set of data, the following deck set up should be used on the CDC 3200:

7/9 Sequence, 001, etc. (The information here varies from installation to installation.)
7/9 JOB,,,,ND
7/9 FORTRAN, L, X.

Use 7/9 FORTRAN, L, X, P. if a binary deck is desired as output on cards.
Program Main (begins in column 7)
Main program

BLANK
SUBROUTINE 1

BLANK
SUBROUTINE 2
etc., until all subroutines are included
FINIS (begins in column 10)
7/9 LOAD, 56
7/9 RUN, 10 were 10 is the maximum run time (use whatever is needed)
DATA sets, as many as desired
7/8 7/8
7/8 7/8

Compilation time is short, however, run time depends on the data set. An estimate is 10 to 20 minutes, based on test runs.
NOTE: The 7/8 and 7/9 denote multiple punches in column 1.

WEIGHT DATA

The following Tables A-1 through A-3 and Figures A-1 through A-15 present a weight breakdown and structural comparison for different types of bomber, cargo, and fighter aircraft. This data was compiled for use in advance launch studies.

Table A-1. BOMBER AIRCRAFT

	WING WEIGHT POUNDS	TAIL WEIGHT POUNDS	FUSELAGE WEIGHT POUNDS	LANDING GEAR WT. POUNDS	SURFACE CONTROL WT. POUNDS	NACELLE WEIGHT POUNDS	PROPULSION WEIGHT POUNDS	ENGINE WEIGHT POUNDS	FUEL SYSTEM WEIGHT POUNDS	INST. & NAVIG. EQUIP. WT. POUNDS
