APPROVAL SIGNATURES CERTIFY THAT ALL REQUIREMENTS OF REPORT HAVE BEEN MET INCLUDING THE REPORTING OF NEW TECHNOLOGY/REPORTABLE ITEMS PER SPB'S 92 AND 93. DISCLOSURES ARE MADE ON FORMS 25-207 AND 25-207-1.
NEW TECHNOLOGY: ☐ IS CONTAINED IN THIS REPORT, ☒ IS NOT CONTAINED IN THIS REPORT.

ABSTRACT:

This report outlines the detailed procedures and results of qualification tests performed on two Voltage Excitation Assemblies P/N 1B67324-1 Serial Nos. 01 and 03, manufactured by the McDonnell Douglas Corporation, Santa Monica, California. The two specimens were subjected to pre-environmental, sinusoidal vibration, random vibration, temperature, and post-environmental test according to detailed test procedure drawing 1T30855. The environmental tests were conducted in the Guidance and Controls Laboratory and the Electrical Sub-System Laboratory of the Missile and Space Systems Division. All test results were within specified limits.

TECHNICAL MEMORANDUM NUMBER(S) TM-DSV-4B-EE-6155, REV. A

ENGINEERING RESOLUTIONS AND CONCLUSIONS

Two units, Part No. 1B67324-1, Serial Numbers 01 and 03, were tested under Line Item P-42B. Each of the units showed one marginal out-of-tolerance resistance measurement during pre-environmental test. The out-of-tolerance readings were minor and were not considered significant criteria for disqualification of the item.

The measured resistance of the 28 volt DC input circuit on Serial Number 01 was 5% low, and the measured resistance of the 5 volt DC output circuit on Serial Number 03 was 1/2% low. The current measurements of the same circuits were within tolerance, as were all other electrical measurements. The square wave output calibration procedure originally specified adjustment of amplitude to 5.00 ± .01 volts true rms with frequency remaining within 2000 ± 200 Hz. The frequency of S/N 03 exceeded the maximum frequency limit by 8 Hz. The calibration procedure was revised to specify adjustment of the frequency with the amplitude remaining within the specified tolerance. This revision made the calibration procedure compatible with that specified for the Production Acceptance Test. Calibrated by the revised procedure, the amplitude and frequency of both S/N 01 and S/N 03 remained within tolerance through all subsequent tests.

(USE CONTINUATION SHEET AS NECESSARY)

STATEMENT OF QUALIFICATION

Based on the results of Design Qualification tests presented in the attached report, it is the conclusion of the Douglas Aircraft Company that voltage excitation assembly, Part Number 1B67324-1, is qualified for its installation on Saturn S-IVB.

1.0 INTRODUCTION

This report presents the detailed procedures and results of qualification tests performed on two Voltage Excitation Assemblies P/N 1B67324-1 (S/Ns 01 and 03) manufactured by the McDonnell Douglas Company, Santa Monica, California. The tests were conducted by the Guidance and Controls Laboratory and the Electrical Subsystems Laboratory during the period 26 December 1967 through 15 January 1968.

1.1 Purpose of Test

The purpose of the test was to demonstrate to the National Aeronautics and Space Administration, Marshall Space Flight Center, the ability of the specimens to meet the requirements outlined in test control drawing 1T10611. The testing effort was authorized by S.O. 5769-6304, EWO 29284, line item F-42B. Reference detailed test procedure drawing 1T30855.

1.2 Physical Description

The voltage excitation assembly consists of four encapsulated modules on a common base assembly. The total size is 2.59 x 2.75 x 5.87 inches. The weight of each assembly is approximately six pounds. See addendum pages A-1 and B-1. Three voltage assemblies are located in the forward and aft skirts of the Saturn IV-B vehicle.

1.3 Functional Description

The assembly has six outputs; 5 vdc, -20 vdc, and four 2000 Hz square-wave. The 5 vdc and -20 vdc supply power to various signal conditioning modules and assemblies. The 5 vdc is also used as excitation for all

1.3 Functional Description (Continued)

position potentiometers associated with acceleration, vibration, pressure, and other transducers. The 2000 Hz squarewave outputs drive magnetic amplifiers used for battery heater control, battery, current, voltage and temperature measurements. (The assembly is a redesign of the 5-volt Excitation Module P/N 1A77310.) Reference addendum page A-2 for a schematic diagram.

1.4 Applicable Documents

The following documents were applicable in conducting the environmental tests outlined in this report:

Government Documents

MIL-C-45662A	Calibration System Requirements
NPC-200-2	Quality Program Provisions for Space System Contractors

2.0 REQUIREMENTS

2.1 Test Sequence

The tests shall be performed in the sequence outlined below. The sequence may be changed by mutual agreement between the test conductor and the test director. Each of the environmental tests shall be preceded by a pre-environmental test and followed by a post-environmental test.

TEST	DESCRIPTION
1	Pre-test inspection
2	Circuit resistance test
3	Calibration
4	Pre-environmental tests
5	Vibration, sinusoidal and random
6	High temperature ($+135 \pm 5^{\circ}F$)
7	Post-environmental tests
8	Post-test inspection

2.2 Elapsed Time Between Tests

If the elapsed time between a post-environmental test of a specific environment and the next environmental test is less than 24 hours, the intervening pre-environmental test of the next environment need not be performed, if no significant change in ambient conditions has occurred. However, if there is a 24-hour or longer delay between the performance of a pre-test and its associated environmental test, the pre-test shall be repeated before the environmental test is performed.

2.3 Recording of Test Data

Test preparations and testing shall be by the Group AEC4 test conductor. All test data shall be recorded on test data sheets. Each test data sheet shall be completed and approved by the test conductor prior to

2.3 Recording of Test Data (Continued)

starting the next test. Photographs of the unit under test (UUT), test setups, and testing, shall be taken as required. A log book shall be maintained of all testing, including abnormal conditions.

2.4 Test Equipment Certification

All equipment shall be certified in accordance with MIL-C-45662A and NPC-200-2 which are described in SPB 711.1. Maintain a record of all equipment used, including name of equipment, model number, serial number, and manufacturer.

2.5 Standard Conditions

Unless specified otherwise, test and measurements shall be performed with the UUT stabilized as follows:

Temperature:	68 to 90°F
Relative Humidity:	90% maximum
Pressure:	25 to 32 inches Hg

2.6 Damage or Failure

If the test specimen fails or is damaged in any way, the testing shall be stopped at the time of the incident. There shall be no change or alterations made in the testing configuration during the stopped period. The test conductor shall be notified and in turn shall notify the test director. Testing shall resume upon approval of the test conductor. In the event of a failed or rejected part, ensure that SPB 710.2 Failure and Rejection Report is completed and sufficient photographs taken.

2.7 Temperature Stabilization

Temperature stabilization is defined as the state existing 30 minutes after which further temperature change occurs at a rate no greater than 5°F per hour unless otherwise specified.

3.0 PROCEDURES AND RESULTS

The procedures and results of all tests are described in the following paragraphs and in the order performed. Reference pages A-6 and A-7 for test equipment utilized during the tests.

3.1 Pre-Test Inspection

The specimens were inspected and determined to be in conformance with Douglas Drawing 1367324.

3.2 Circuit Resistance Check

The resistance between the following pins was measured and recorded before connecting any connector to the specimen. A Leeds and Northrup Model 5305 wheatstone bridge was used for measurements in the 0 to 0.5 megohm range. After 50 vdc was applied for 30 seconds, the 5 megohm measurements were made using a General Radio Type 1862-B megohmmeter.

Connector			Requirement
J1:	Between Pins:	G and H	1 ohm maximum
		C and J	25 ohms minimum
		B and J	1 ohm maximum
		J and Unit Case	5 megohms minimum
J2:	Between Pins:	H and L	1 ohm maximum
		J and C	1K (±50) ohms
		J and L	1.5K ohm minimum
		J and Unit Case	5 megohms minimum
		K and B	1K (±50) ohms
		K (-) and L (+)	2K ohms minimum
		M and L	1 ohm maximum
		L and Unit Case	5 megohms minimum
		E and M	5 megohms minimum

3.2 Circuit Resistance Check (Continued)

Connector		Requirement
J3: Between Pins:	F and G	1 ohm maximum
	G and H	5 megohms minimum
	H and K	1 ohm maximum
	K and C	5 megohms minimum
	C and J	1 ohm maximum
	J and B	5 megohms minimum
	B and A	1 ohm maximum
J2 and J3	E and E	10K (±0.5K) ohms

(S/N) 01 resistance between pins G(+) and J(-) of connector J1 was 5.2% below the requirement. See addendum page C-1. S/N 03 resistance between pins J(+) and L(-) of connector J2 was 0.5% below the requirement, see page D-1. All other measurements were within specified limits.

3.3 Circuit Loading

a. A 12.5-ohm (±5%), 4-watt resistor was connected across pins J and L and a 200-ohm (±5%), 5-watt resistor across pins K and L of connector J2, respectively, by switching S2 to position 2. (See page A-3.)

b. A 10-ohm (±5%), 10-watt resistor was connected between each pair of pins listed below by switching S4 to position 2. (See page A-4.)

J3-F and J3-G
J3-H and J3-K
J3-C and J3-J
J3-B and J3-A

3.4 Calibration

Each specimen was connected to the test setup (see pages A-3 and A-4) and were loaded by setting panel switches S2 and S4 to "ON". 28 vdc power was applied to the specimen by closing S1. The +5 vdc output voltage was adjusted by potentiometer R5 (module A3) to +5.000 ± 0.003 vdc. The -20 vdc output voltage was adjusted to -20.000 ± 0.003 vdc by potentiometer R8 (module A4). The DC inputs and outputs were measured by a Cimron 7500A

3.4 Calibration (Continued)

digital voltmeter. The square wave frequency between pins J3-A and J3-B was adjusted to 2000 ± 5 Hz by potentiometer R7 (module A1). The frequency was measured by a Systron-Donner electronic counter. The DC output ripples were measured by a Tektronix Model 549 oscilloscope. The square wave peak-to-peak voltages across each of the output pairs F and G, H and K, C and J, B and A of connector J3 were measured on the oscilloscope; the frequency and balance on the electronic counter.

Measurements for both S/Ns 01 and 03 were within specified limits, reference data pages C-2 and D-2.

3.5 Pre-Environmental Tests

The test specimen was connected to the test setup shown on pages A-3 and A-4 and were loaded by setting panel switches S2 and S4 to "ON". 24 vdc power applied by closing S1 to ON position. The input voltages output voltages, ripple, and frequencies were measured as outlined in paragraph 3.4. The DC load currents were calculated taking the voltage drops across the load resistors with the Cimron 7500A digital voltmeter and dividing by the known load resistances. This was done because the panel meters indicated erroneous currents. Square wave amplitudes were measured by setting S5 to desired output winding position. (These amplitude readings were taken right at the pins and not at the loads.) The square wave frequency and balance were repeated for 28, 32, 24 vdc inputs. After completing the above, the load resistors for the +5 vdc and -20 vdc outputs were disconnected by switching S2 to "OFF" and repeating

3.5 Pre-Environmental Tests (Continued)

the above for each input voltage with the exception that no current measurements were made.

The output requirements were as follows:

Connector	Pins	Voltages
J2	C(+) and M(-)	5.000 (±0.025) vdc
J2	M(+) and B(-)	20.0 (±0.04) vdc
J3	F(+) and G(-)	10 (±1) volts peak-to-peak
J3	H(+) and K(-)	10 (±1) volts peak-to-peak
J3	C(+) and J(-)	10 (±1) volts peak-to-peak
J3	B(+) and A(-)	10 (±1) volts peak-to-peak

All pre-environmental test data for S/Ns 01 and 03 were within specified limits. See pages C-3 through C-10 for S/N 01 and pages D-3 through D-12 for S/N 03. The calibration was repeated for S/N 01 after A-axis sinusoidal vibration due to a change in the test control drawing. All measurements were within specified limits, see page C-11. The photograph on page B-2 shows the test setup during the pre-environmental test.

3.6 Vibration Tests

3.6.1 Vibration test were performed on the C-125 vibration system in the EE Subsystems Laboratory and test specimens hard mounted to a rigid test fixture during tests, see pages B-3 and B-4. The Acoustics and Structural Dynamics section approved the vibration test setups, specified accelerometer locations (see page A-5) and controlled the vibration aspects of the tests. Six vibration accelerometer outputs were to be monitored and data to be recorded on magnetic tape. Due to instrumentation problems accelerometer No. 2 response data was not obtained. S/N 01 random C-axis accelerometer 4 did not record. S/N 03 sine A-axis

3.6 Vibration Tests (Continued)

3.6.1 (Continued)

accelerometer 3 did not record. The input voltage and current, the DC output voltages and currents, and square wave outputs were continuously recorded before, during and after vibration on a consolidated Electrodynamics Model 5-124 oscillograph. The DC output ripple was observed throughout the tests on an oscilloscope. Specimen operation during the vibration tests were performed with 28 vdc applied between pins J1-J(+) and J1-G(-), and all output loads connected.

3.6.2 Sinusoidal Vibration

The following frequency range was scanned logarithmically at a rate of 1.0 octave per minute from low frequency to high frequency and back to low frequency in each of the three mutually perpendicular directions at the listed inout levels:

*Direction A

Hz	Vibration Levels
20 - 36	0.4" D.A. Disp.
36 - 60	27 g's peak
60 - 150	9.5 g's peak
150 - 250	0.008" D.A. Disp.
250 - 2000	25 g's peak

3.6.2 Sinusoidal Vibration (Continued)

*Direction B and C

Hz	Vibration Levels
20 - 36	.22" D.A. Disp.
36 - 60	15 g's peak
60 - 150	5.7 g's peak
150 - 250	.0046" D.A. Disp.
250 - 2000	15 g's peak

*Direction A (Radial) perpendicular to skirt.
Direction B (Thrust) tangential to skirt.
Direction C (Tangential) parallel to skirt.

During A-axis vibration S/Ns 01 and 03 measurements were within specified limits. S/N 01 also underwent an additional pre-environmental test after A-axis vibration. During B-axis sine vibration both specimens met the requirements although they were susceptible to the magnetic field produced by the shaker and responded with an 8 Hz increase in the square wave outputs. S/N 03 input current did increase momentarily (10 ma for 2 seconds) during B-axis sine vibration at 25 Hz upsweep. All measurements during C-axis vibration were within tolerance. Reference pages C-12 through C-50 for S/N 01 data and pages D-13 through D-40 for S/N 03.

3.6.3 Random Vibration

The random vibration had an approximate gaussian amplitude distribution and a peak-to-rms ratio of three. Equalization of the random input was accomplished by using a random vibration level of the actual test level on the bare table. The test specimen was attached to a bracket and

3.6.3 Random Vibration (Continued)

a 10-second loop was recorded. The random input loop was analyzed and then the remaining vibration accomplished. The equalized spectrum was monitored and readjusted during the tests as necessary by using individual meters on each channel of the spectral density equalizer-analyzer. The acceleration spectral density applied to test specimen was within ± db (on a power basis) when measured with a filter having a bandwidth of 50 Hz or less, and was recorded using a spectral density power analyzer in conjunction with an X-Y plotter.

The specimens were subjected to random excitation for 12 minutes per axis. The excitation was applied as one input over the frequency interval from 20 to 2000 Hz as follows:

Direction A

Hz	Vibration Levels
20 - 100	.2 g^2/Hz
100 - 150	+8 db/oct
150 - 700	.6 g^2/Hz
700 - 900	-18 db/oct
900 - 2000	.135 g^2/Hz

Directions B and C

Hz	Vibration Levels
20 - 100	.05 g^2/Hz
100 - 150	+8 db/oct
150 - 700	.15 g^2/Hz
700 - 900	-18 db/oct
900 - 2000	0.034 g^2/Hz

3.6.3 Random Vibration (Continued)

Tests results were within specified limits during all three axes of vibration for both specimens. S/N 01 data is pages C-51 through C-64, S/N 03 data is on pages D-41 through D-55.

3.6.4 Post-Vibration Test

Subsequent to the sinusoidal and random vibration testing, a post-test was conducted on each specimen. The tests were identical to the procedures outlined in paragraph 3.5. All test results were within specified tolerances. Reference pages C-65 through C-72 and D-56 through D-63 for data recorded during these tests.

3.7 High Temperature

3.7.1 The post-vibration test served as the pre-temperature test. The test chamber was stabilized at 135°F for both specimens which were oriented in the A-axis within a box so as to minimize the air flow around it. All inputs and outputs of the specimen, and 9 thermocouples on the specimen were recorded continuously. The DC output ripples were observed every 15 minutes throughout the test on a Tektronix 549 oscilloscope. Reference pages B-5 and B-6 for photographs.

S/N 01 was operated for 1 hour and 40 minutes prior to start of test, before test data was recorded. See addendum pages C-73 through C-125. S/N 03 was not operated until the start of the test. See addendum pages D-64 through D-118. Both specimens met all requirements and specifications during this test.

3.7.2 Post-Temperature Tests

Subsequent to performing the high temperature tests on S/Ns 01 and 03, both specimens were subjected to post-tests identical to the procedures outlined in paragraph 3.5. All measurements were within specified limits. See data pages C-126 through C-141, and D-119 through D-133 for S/Ns 01 and 03 respectively.

3.8 Post-Test Inspection

Upon completion of all testing, the specimens were examined for evidence of physical damage. No damage was noted.

4.0 DISCUSSION

The original calibration procedure required an adjustment of the square wave output voltages by potentiometer R7 (module A1) to 5.00 ± 0.01 vac (true rms) and a frequency of 2000 ± 200 Hz. Serial No. 03 was unable to meet the frequency requirement which necessitated a calibration procedure change and was performed as described in paragraph 3.4.

A 45 and 20 mv peak-to-peak noise level from the test console during the calibration, pre-environmental, and environmental tests obliterated the ripple on the DC outputs. (No significant change in noise level resulted from the test console with the specimen first connected then disconnected.) At no time during environments did the ripple exceed the noise level (100 mv peak-to-peak maximum ripple). See data sheets D-11 and D-12 for typical noise levels.

4.0 DISCUSSION (Continued)

No noise was noted from the test console during the post test. See data sheets C-132 through C-140 and D-127 through D-133. No apparent cause could be found for the momentary increase in current during sine vibration of S/N 03 in the R-axis.

Horz. Sens 100 μs/cm

DATA SHEET

DATE 1/15/68 POST-TEMPERATURE TEST REPORT NO. R-6155
PART NO. 1B67324-1 CHG. LTR. S/N. 03 LINE ITEM P-42B
S.O. 5769-6304 E.W.O. 29284 T.C.D. 1T10611 MODEL NO. DSV-4B
OBSERVER LABORATORY G&C ENGINEER J. Itagaki

32 VDC Input.

LOADED ✓ NOT LOADED HOURS

Function	Connector	Between Pins	Required	Measured
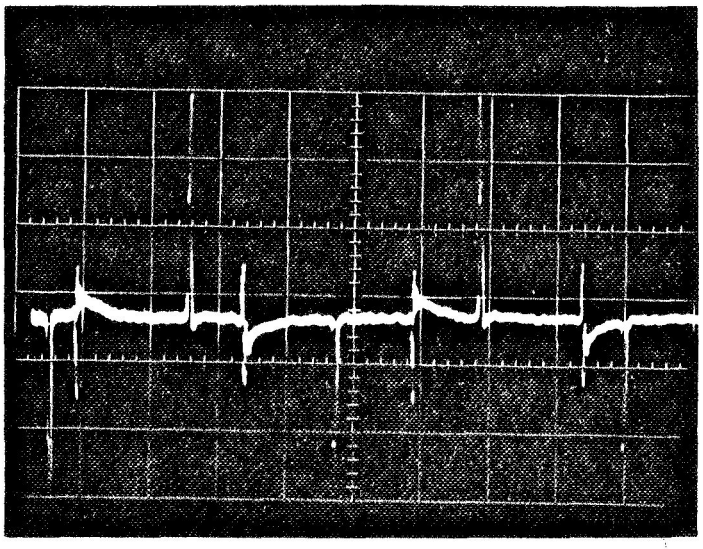
Output Ripple	J2	C(+) and M(-)	0.1 v p-p max	2 mv p-p



Vert. Sens 10 mv/cm
Horz. Sens 100 μs/cm

Function	Connector	Between Pins	Required	Measured
Output Ripple	J2	M(+) and B(-)	0.1 v p-p max	2 mv p-p

Vert. Sens 10 mv/cm
Horz. Sens 100 μs/cm
