8.1 SCHEDULES

8.1.1 SUMMARY PROJECT SCHEDULE

Introduction: The Storable Tug Project schedule was developed to identify the principal project phases and to establish schedule estimates for all hardware and soft ware elements in accordance with the Space Tug Work Breakdown Structure.

The Tug Project Schedule depicts major program milestones and presents project activities at level 5 of the WBS. This schedule establishes the planning baseline for development of the Storable Tug System through design, development, manufacturing, ground test, flight test and operations. It integrates all supporting schedules into an overall project level plan and establishes the sequence and interdependency of activities and events required for the development of an operational Space Tug System.

Groundrules and Assumptions: Following are the ground rules and assumptions used for development of the Storable Tug Project Schedule:

- o ATP is October 1975 at the earliest for Options 1 and 3. ATP for Option 2 to be determined by the contractor.
- o Schedule planning is designed to minimize peak annual funding during DDT&E.
- o Main Stage DDT&E requirements consist of the following major test articles:
  - A structural test article (STA) for dynamic, static and fatigue tests.
  - A main propulsion test vehicle (PTV). Following the completion of live propellant testing the PTV will be refurbished and delivered as an operational flight vehicle.
  - One shipset of Avionics hardware for the Integrated Avionics Test (IAT).
  - A flight test vehicle (MS-1).
- o Operational fleet sizes for each project option are based on a study of traffic capture models.
- o Production rate of vehicles is based on avoiding duplication of major structural assembly tooling and minimizing gaps in manufacturing flow.

- Initial operational capability (IOC) is achieved after completion of one test flight (FOF). IOC dates are as follows:

  Option 1 - December 1979
  Option 2 - December 1983
  Option 3 - December 1979 - initial, December 1983 - evolved.

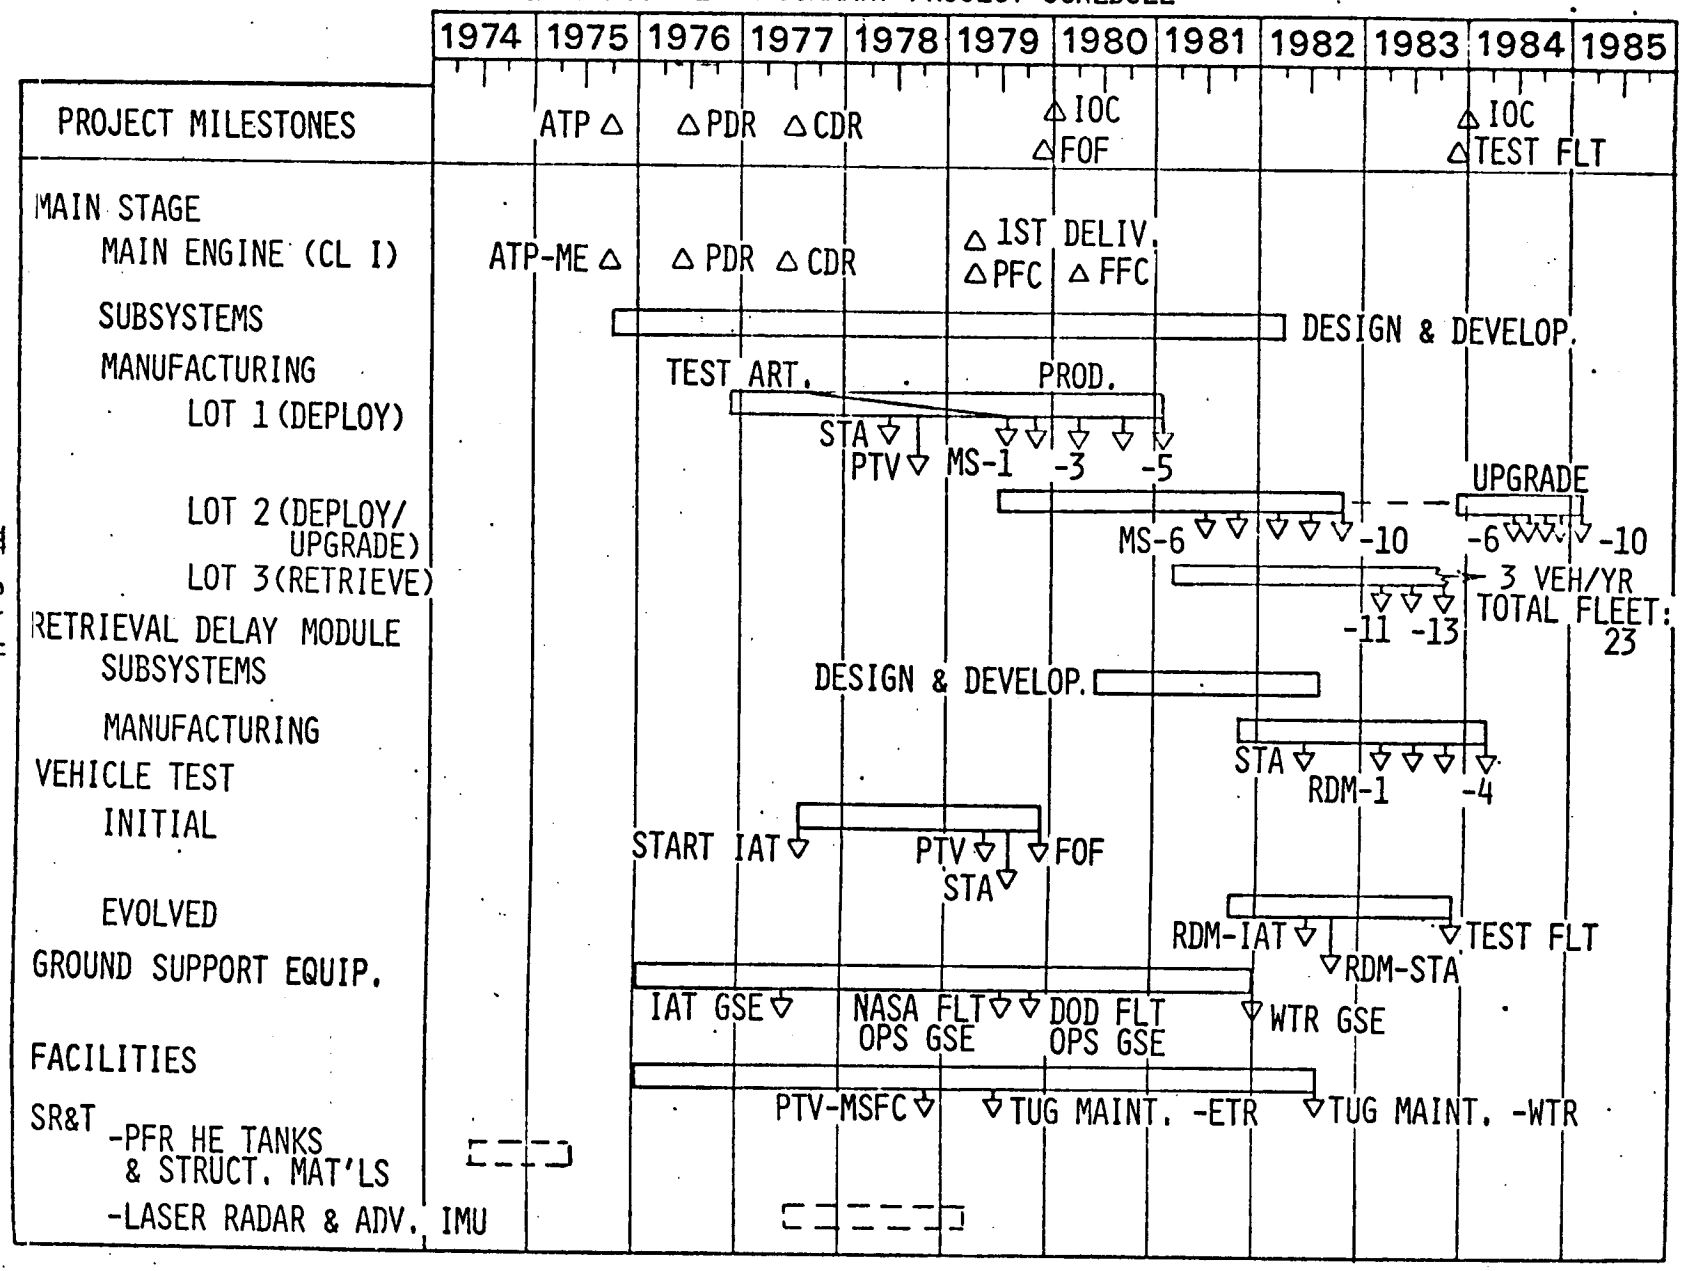
- Maximum number of flights in 1980 is 3, based on the Shuttle traffic model.

Approach: Based on the above groundrules and assumptions a preliminary project milestone schedule was developed to form a baseline for all detail scheduling. Detailed subsystem design and development schedules, manufacturing and factory checkout flows, vehicle test, GSE, facilities, and SR&T Schedules were then developed in conjunction with personnel representing the cognizant management and technical disciplines. These detailed schedules were then summarized and integrated into the Tug Project Schedule through the process of establishing a logical and achievable relationship between the engineering design and development process, procurement of subcontract equipment, hardware fabrication and assembly process and the vehicle test program that minimizes risks and ensures the fulfillment of program objectives. Finally, the major project milestones and activities presented in the Tug Project Schedule were condensed into the Summary Project Schedule.

SUMMARY SCHEDULE - 310-3A/310RE-3A

The primary elements of the 310-3A/310RE-3A Project Schedule include Main Stage, Retrieval Delay Module, Vehicle Test, GSE, Facilities and dependent SR&T. Authorization to Proceed (ATP) occurs on October 1, 1975 with IOC of the initial configuration targeted for December 31, 1979. The Class I main engine ATP occurs at the same time as the main stage with Final Flight Certification occuring 4 months after First Orbital Flight (FOF). Main stage vehicle tests are essentially as described for 110A-1 except that phased retrieval requires additional Integrated Avionics testing and a flight test to demonstrate retrieval capability. First flight of the evolved configuration is targeted for December 1, 1983. Development of the Retrieval Delay Module (RDM) starts on June 1, 1980 with related vehicle tests starting at the same time as main stage evolved vehicle tests. Another feature of the schedule is the 3 Lot buy of production main stages. This production approach was deemed necessary to avoid a manufacturing gap between initial production to meet deploy only operations and production of evolved vehicles. Lot 1 Tugs have deploy only system capability, Lot 2 Tugs begin with deploy capability and are then upgraded to retrieval capability and Lot 3 Tugs will include retrieval capability. Lot 1 includes 5 production vehicles, Lot 2 includes 5 and and Lot 3 includes 13 for a total fleet of 23 vehicles. GSE and Facilities are scheduled essentially as described for 110A-1.

310-3A/310RE-3A SUMMARY PROJECT SCHEDULE



8.1.2 DEVELOPMENT SCHEDULES

8.1.3 PRODUCTION SCHEDULES

The detailed Project Schedule depicts the total development and production phases for the Main Stage and the Auxiliary Stage(s). The detailed Project Schedule is based on a constraint logic that considers overall program objectives and the detailed interaction of constraints on significant program activities. It provides reasonable margins for development problems and minimizes program front-loading.

The detailed Subsystem Schedules provide an order of magnitude increase in detail from the Project Schedule and depict the subsystem activities in both inhouse and subcontractor areas. Subsystem schedule information is presented at WBS level 6 for Structures, Thermal Control and Orbiter Interface, and at WBS level 7 for Propulsion and Avionics subsystems.

8.1.4 OPERATIONS SCHEDULE

Scheduled and planned for concept 310-3A/310RE-3A, option 3 are 37 launches per year with 10 days between launches. Ground servicing as shown on the programmatics/cost operations schedule from land to launch is 10 Tug work days and 9 Tug/orbiter work days.

8.1.5 FACILITIES SCHEDULE

Included in the storable space tug facilities schedule for concept 310-3A/310RE-3A are the various tasks to be completed against major program milestones. The fundamental grouping of these tasks are manufacturing, test, maintenance and refurb-ETR, ETR launch, maintenance and refurb-WTR and WTR launch. Under this Tug concept facilities maintenance extends into 1991, with most of design/construction/activation ending by 1982 in support of WTR launch requirements.

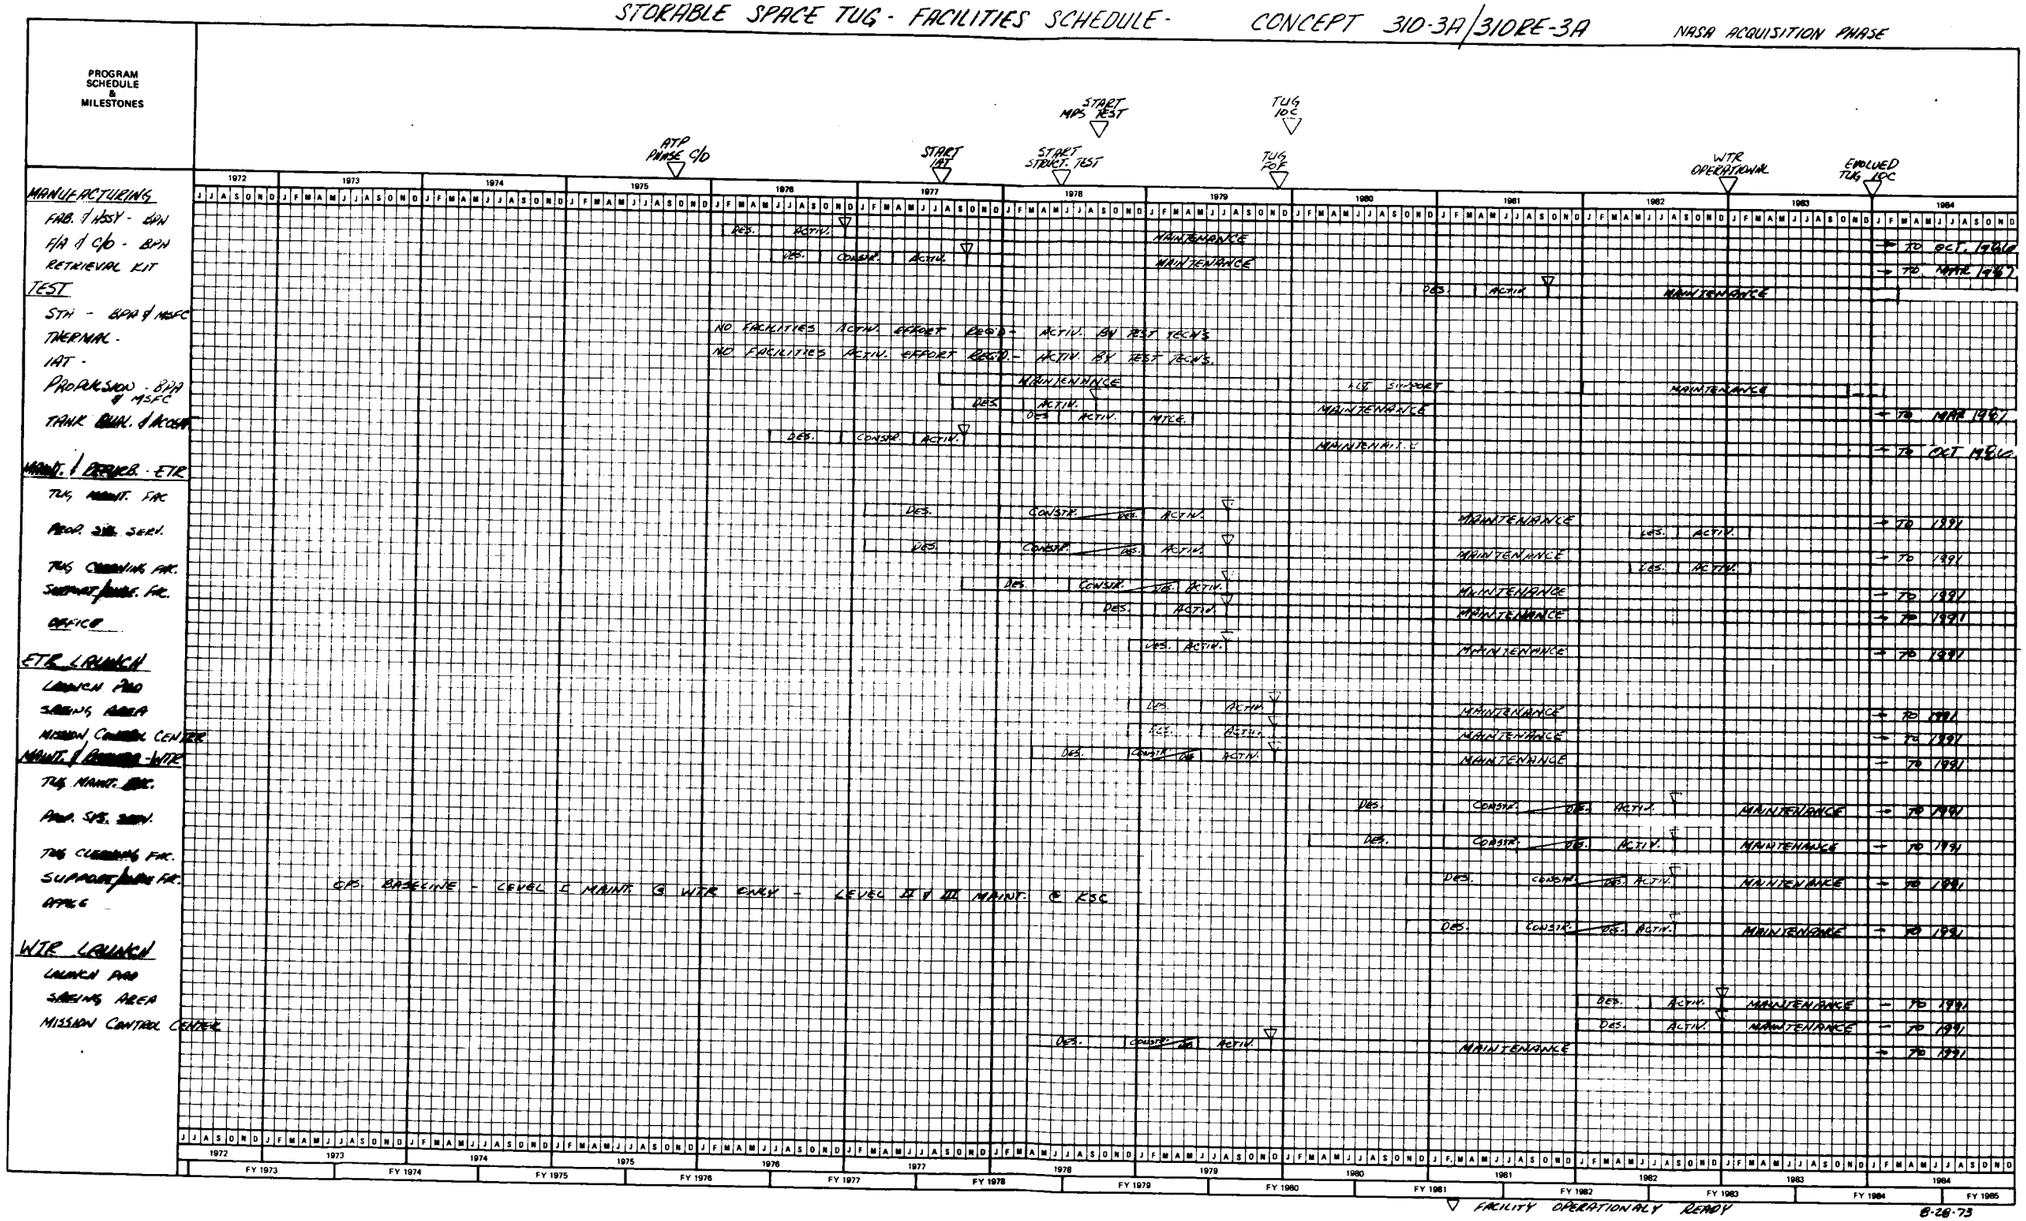
NASA ACQUISITION PHASE



8.1.6 EVALUATION OF MAJOR SCHEDULE DRIVERS

310-3A/310RE-3A

The critical path for this option involves the Class I main engine development, preliminary flight certification (PFR) and delivery of the first flight engine for the Main Stage (MS-1). The main engine ATP being constrained by the October 1975 groundrule (defined in Section 8.1.1), would not allow us the option of advancing the main engine development as exercised under 410AD-2. As a result, the first flight test engine will be delivered 5 months later than required for our Main Stage flight vehicle flow resulting in out-of-station installation and the addition of Cold Flow II checkout.

The Main Stage production is presented in 3 lots based on a compromise between the traffic model requirements and the desireability of having a continuous manufacturing flow. Lot 1 consists of 4 vehicles which will satisfy the mission requirements for the initial phase of operations (1980-1983). Lot 2 consists of 5 vehicles manufactured for the initial (deploy only) capability and will subsequently be upgraded as the evolved (retrieval) hardware becomes available.

Lot 3 consists of 13 vehicles manufactured to the evolved configuration, with Main Stage production ending in February 1987.

Development of the Retrieval Delay Module starts in 1980 for the November 1983 test flight with the evolved Main Stage.

8.1.7 IMPACT OF OPTION SENSITIVITIES

8.1.8 DOD VS NASA SCHEDULES

Phasing of the DOD acquisition process as defined in AFSCP800-4 differs from the NASA acquisition approach as indicated below:

DOD	NASA
Conceptual Phase	Phase A
Validation Phase	Phase B
Full Scale Development Phase)	
Production Phase)	Phase C/D
Deployment Phase)	

310-3A/310RE-3A

The rationale for initial differencies between the DOD and NASA schedules is similar to the 110A-1 discussed above. Three vehicles are required for Initial Tug flight test and for payload missions during the 1980-1983 period. Production contract award is scheduled 3 months after the completion of test flight no. 3. Flight test of the Evolved Tug is accomplished with vehicles upgraded from the initial configuration. Production Go-Ahead will follow the flight test as in the initial configuration. The availability of production vehicles is accelerated a few months by utilizing early funding for long lead items.

8.2 VEHICLE TEST PROGRAM (310-3A/310RE-3A)

8.2.0 Test Summary

The approach used to developing the Vehicle Test Program for the 310-3A/310RE-3A configuration is basically the same as described in Part I, paragraph 8.2.1. The addition of a Retrieval Delay Module, MS retrieval electronics and level IIB autonomy to the Tug program for the 310RE-3A configuration will also be verified in both the ground and flight test programs.

Table 8.2-1 summarizes the design verification approach in terms of test verification requirements and method of requirement satisfaction. Figure 8.2-1 presents a summary schedule of the total vehicle test program.

8.2.1 Ground Test Articles - Type and Description

8.2.1.1 Propulsion Test Vehicle (PTV)

The PTV for the 310-3A/310RE-3A is the same as described in Part I, paragraph 8.2.1.1.

8.2.1.2 Structural Test Articles (STA)

The structural test article (STA) for this configuration consists of two major assemblies which are tested, as described in PartII, para. 8.2.1.2.

- o Main Stage (IOC 12/79)
- o Retrieval Delay Module (IOC 12/83)

8.2.1.2.1 Main Stage Structural Test Article

The description of the main stage STA is the same as that described in Part II,paragraph 8.2.1.2.1.

8.2.1.2.2 Retrieval Delay Module (RDM)

The (RDM) is approximately 3 feet long by 12 feet in diameter. The RDM-STA has mass simulated equipment for dynamic test purposes and will require approximately 50 strain gages and 20 dynamic sensors.

310-3A/310RE-3A VEHICLE TEST

EVOLVED RETRIEVAL PLUS RET. DELAY ADDS $10.0LM TO VEHICLE TEST

- o TEST PROGRAM OBJECTIVES:
  - DESIGN VERIFICATION
  - SITE/GSE VALIDATION
  - SYSTEM VERIFICATION
- o GROUND TEST PROGRAM (HARDWARE/OPS = $25.31M)
  - PROP: 1 MS ART. VERIFIES COLD FLOW SYSTEM OPS - REFURBISH TO OPS
  - STRUCT: 2 ART. (1 MS & 1 RDM) VERIFY DYN, STATIC, FATIGUE, SEP - KSC SITE VALIDATION
  - AVIONICS: 2 LABS VERIFY HARDWARE/SOFTWARE FOR INITIAL AND EVOLVED CONFIGURATION
  - MOCKUPS: 2 SOFT & 2 HARD MS & RDM MOCKUPS SUPPORT DESIGN DEVELOPMENT & MAINTENANCE DEMONSTRATION
- o FLIGHT TEST PROGRAM (HARDWARE/OPS = $16.82M)
  - 1 MS & 1 RDM VEHICLE
  - 8 FLIGHTS (1 DEDICATED, 7 OPS)
- o TOTAL VEHICLE TEST = $42.13M

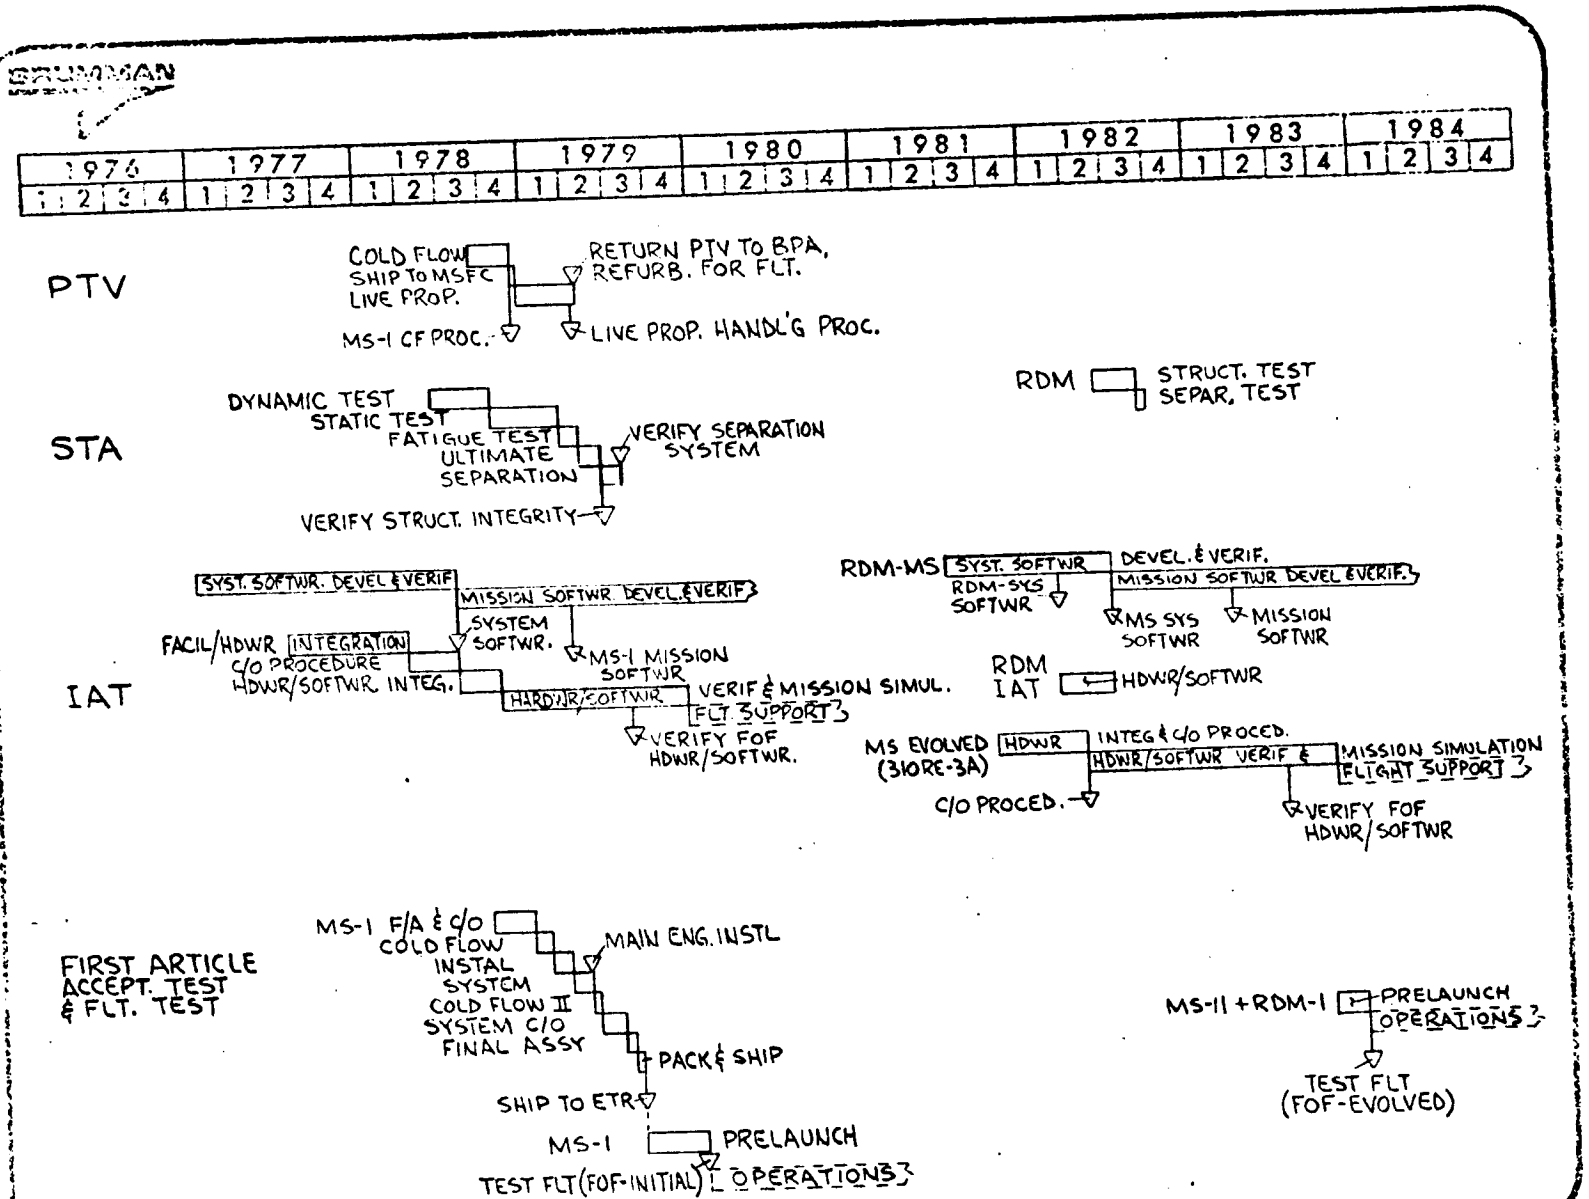

FIG. 8.2-1 310-3A/310RE-3A VEHICLE TEST SCHEDULE

8.2.1.3 Integrated Avionics Testing

8.2.1.3.1 Main Stage (MS) Integrated Avionics Hardware & Software Test Facilities

Integrated avionics hardware and software testing for the 310-3A basic vehicle will be accomplished using an IAT & ASDL facility as described in Part I, paragraph 8.2.1.3.1. As the retrieval capability and autonomy level IIB is incorporated into the MS avionics, the IAT facility and the ASDL will be modified to reflect these changes. The IAT and ASDL will be used for hardware and software verification of the retrieval capability including mission simulations.

8.2.1.3.2 Retrieval Delay Module (RDM)

Integrated avionics hardware testing for the Retrieval Delay Module will be accomplished in the IAT and ASDL facilities developed for the main stage.

A breadboard of the RDM wiring, RDM avionics hardware, and the RDM avionics GSE will be integrated and tested in the same facility as the main stage IAT to permit common usage of facility test equipment.

A software model of the RDM mission and dynamics will be integrated into the MS ASDL for Main Stage RDM mission software development and mission support.

8.2.1.4 Mockups

In addition to the mockups described in Part I, paragraph 8.2.1.4 mockups of the RDM will be required for this configuration.

8.2.2 Flight Test Articles

8.2.2.1 Main Stage (MS)

The main stage (MS) flight test article for the 310-3A configuration will be the same as described in Part I, paragraph 8.2.2.1.

The main stage flight test article for the 310RE-3A configuration will be the first production - configured vehicle with retrieval capability. A DFI system will be installed.

8.2.2.2 Retrieval Delay Module

The Retrieval Delay Module (RDM) will be the first production configured RDM with a DFI system added. Since the RDM operational mode requires the MS to have retrieval capability it will be tested in late 1983 with the FOF of the 310RE-3A MS.

8.2.3 Ground Test Program

This section describes the major elements of the vehicle ground test program. The test programs described in the following paragraphs include the Propulsion Test Vehicle (PTV), Structural Test Article (STA), Integrated Avionics Testing including software development, and mockups required in support of program requirements.

8.2.3.1 Propulsion Test Vehicle (PTV) Program

The Main Propulsion System and Auxiliary Propulsion System Test program for the 310-3A configuration is the same as described in part I, paragraph 8.2.3.1. There is no significant change in the APS test program because of the additional APS thrusters for the 310RE-3A configuration.

The manloading and schedule for the PTV test program as shown in Figure 8.2-2.

8.2.3.2 Structural Test Article (STA) Program

8.2.3.2.1 Main Stage (MS)

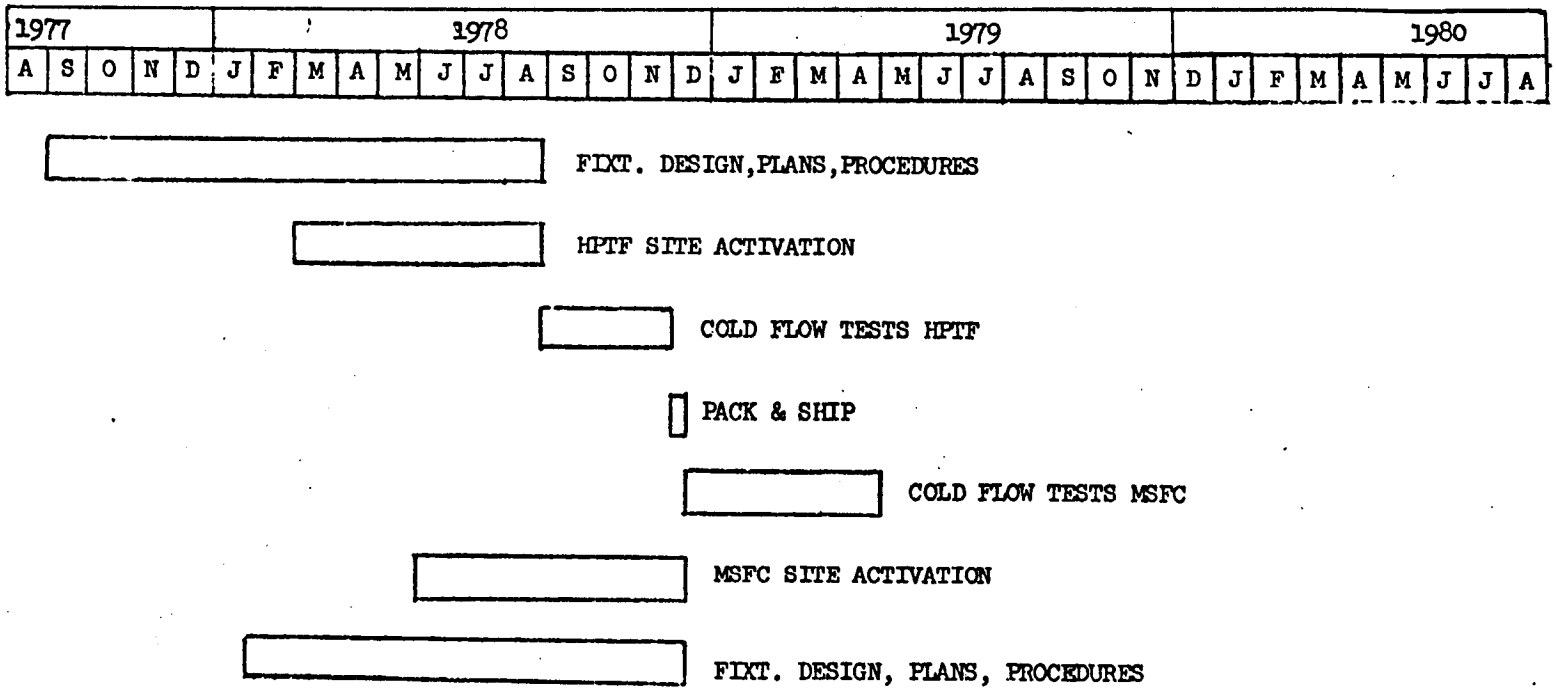
The MS structural test program for the 310-3A/310RE-3A configuration is as described in Part II, paragraph 8.2.3.2.1.

The manloading and test schedule for the 310-3A/310RE-3A configuration is the same as shown in Part I, figure 8.2-3 with the start and end dates shifted three months later.

8.2.3.2.2 Retrieval Delay Module Structural Test Article Program

The structural test program for the retrieval delay module (RDM) is reduced from that of the kick stages in that vibration mode survey is not required. Due to its small size, mass and structural simplicity the static tests provide adequate verification of the dynamic analysis. In other respects the test philosophy is the same as described in part I, paragraph 8.2.3.2.1

Due to the reduced scope of the RDM test program as compared to kick stages, a new schedule and manloading is presented in Figure 8.2-3.

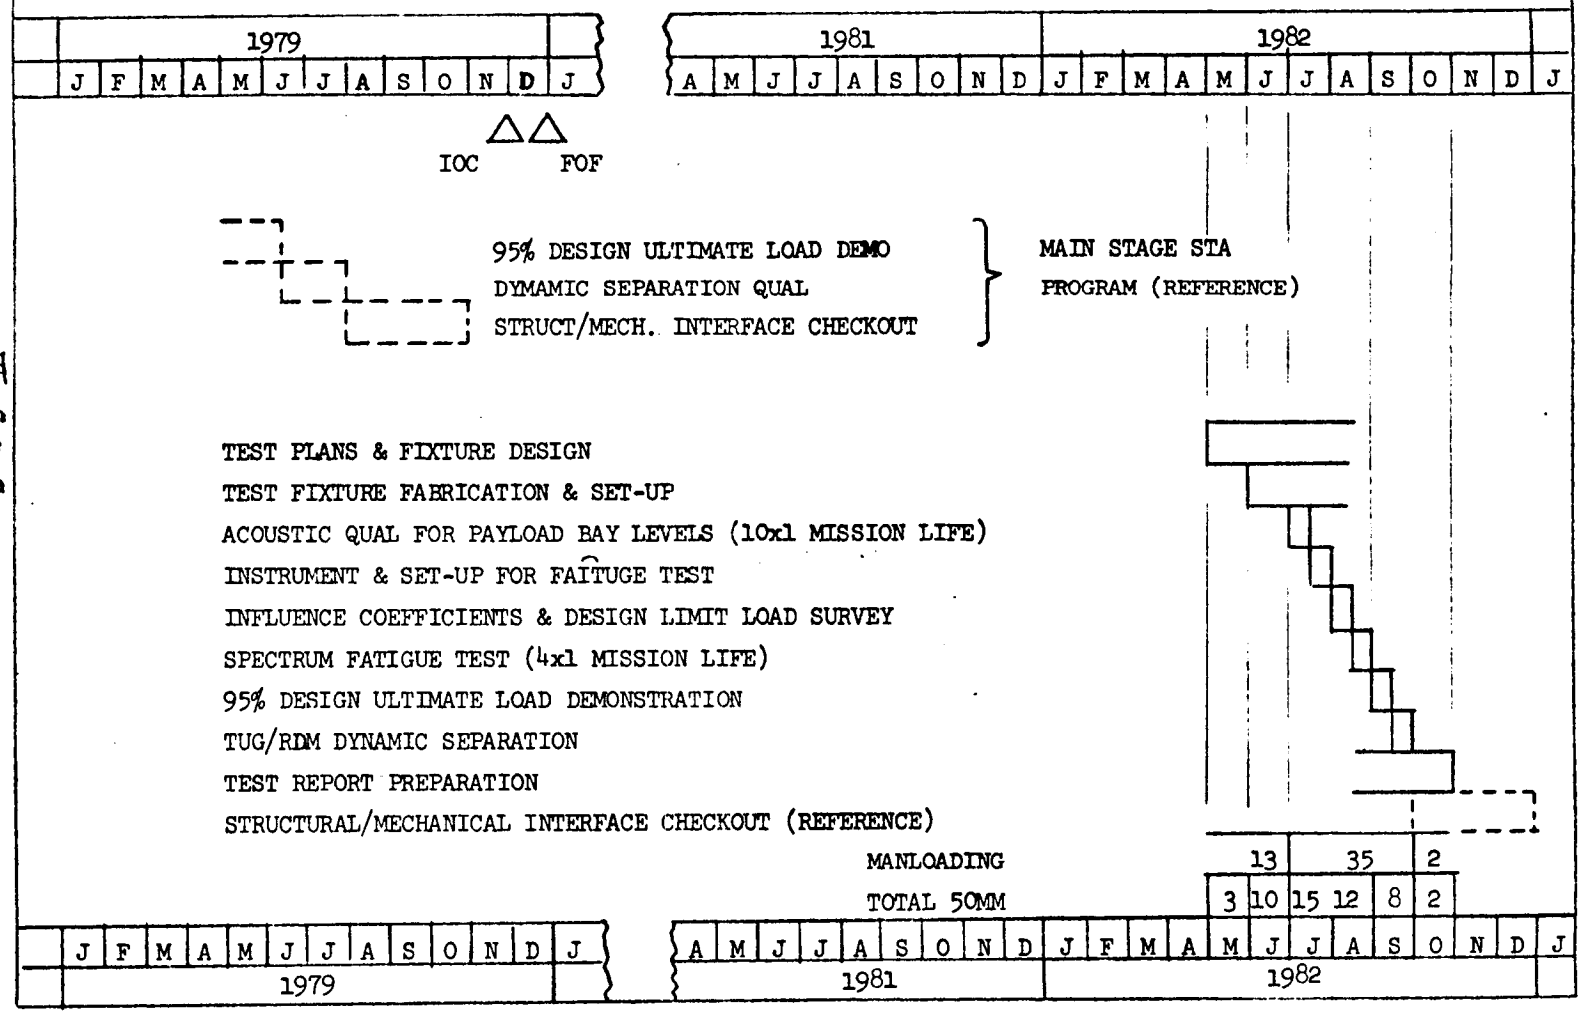


MANPOWER 1 1 2 2 3 6 7 10 16 15 18 24 35 41 44 40 33 29 28 15 7 TOTAL 377 MM

Figure 8.2-2 310-3A/310RE PTV TEST SCHEDULE & MANPOWER

FIGURE 8.2-3 RDM STA PROGRAM (310RE-3A)

SCHEDULE AND MANLOADING



8.2.3.3 Integrated Avionics Test Program

8.2.3.3.1 Main Stage (MS) Avionics Hardware and Software Integrated Avionics

The integrated avionics test philosophy and test program for the 310-3A/310RE-3A configuration is basically the same as described in Part 1, paragraph 8.2.3.3.1. All hardware, software, test procedure, and GSE will be verified using an IAT facility and/or ASDL prior to entry into the flight vehicle flow. The evolution of level IIB autonomy and retrieval capability will be incorporated and verified in the IAT facility and ASDL prior to incorporation the flight vehicle. At the completion of system hardware/software verification, mission simulation will be performed for the evolved MS in the IAT facility.

The test phases for the 310-3A/310RE-3A manpower and schedule are shown in Figure 8.2-4.

In addition to the IAT for the 310-3A/310RE-3A configuration an integrated fuel cell/reactant tank systems test will be performed at the fuel cell subcontractor to verify system energy capacity.

8.2.3.3.2 Retrieval Delay Module (RDM)

The RDM avionics test philosophy is the same as for the main stage. A RDM breadboard will be integrated and GSE, test procedures and functional operation verified. Main stage software for RDM mission will be developed in the ASDL and verified in the main stage IAT.

A RDM antenna pattern test will be performed since the RDM will contain a complete communications system.

The schedule of RDM avionics testing is shown in Figure 8.2-4.

8.2.3.4 Mockups

Mockups will be used throughout the MS and RDM development stage as described in Part I, paragraph 8.2.3.4. In addition the STA will be used for launch operations checkout as described for the 110A configuration.

8.2.4 Flight Test Program

8.2.4.1 Flight Vehicle Test and Checkout

The philosophy and objectives of the Flight Vehicle Test and checkout program are the same as described in Part I, paragraph 8.2.4.1.

The factory testing of the first 310-3A contains the same basic tests as described in Part I, paragraph 8.2.4.1 except that fuel cell tests are required and late engine delivery

FIGURE 8.2-4

necessitates performing portions of the MPS fluid tests after subsystem build-up.

The facility and equipment requirements are basically the same as described in Part I, except that fuel cell GSE is required in the HPTF for this vehicle.

Test schedules and manpower requirements are presented for the basic 310-3A vehicle in Figures 8.2-5 and 8.2-6, and for the retrieval delay module in Figures 8.2-7 and 8.2-8.

8.2.4.2 Flight Test

The main stage (MS) flight test program for the 310-3A configuration is the same as described in Part I, paragraph 8.2.4

There will be a total of eight flights for the 310-3A/310RE configuration from which flight test data will be obtained. Five data flights are planned for the initial configuration and three for the evolved configuration. A DFI system will be installed on the MS and/or RDM during the flight test program

The first orbital flight (FOF) will be a dedicated flight test deploying a dummy payload.

Flight Test data will be obtained during the following operational flights

(3) Single payload deploy
(1) Multi payload deploy
(1) Retrieval demonstration
(1) Round Trip
(1) Retrieval delay

The retrieval demonstration uses the RDM as a target vehicle. The Shuttle will deploy the RDM and its performance will be evaluated while it is free flying in the vicinity of the Shuttle. When the Tug returns to the vicinity of the Orbiter it will demonstrate the retrieval capability by retrieving the deployed RDM.

The flight test schedule and test costs for this configuration are shown in Figure 8.2-9.

8.2.5 Impact of a Two Year IOC Delay

A two year delay of IOC for the 310-3A/310RE-3A configuration with an identical delay in the ATP of the program,will not impact the Vehicle Test Program other than merely starting the program two years later.

  - TEST OPS: $2.94 M
  - LAUNCH OPS: $1.45 M
  - FLIGHT OPS: $1.80 M
- CONSUMABLES (FOF ONLY): $62 K

FIGURE 8.2-9 FLIGHT TEST PROGRAM SCHEDULE (310-3A/310RE-3A)

8.2.6.1 Key Elements

The analyses of the key elements of the test program for the basic 310-3A configuration are the same as described in Part I, paragraph 8.2.6.1. Specifically the test program key elements and the new issues arising out of the evolved 310RE-3A configuration are as follows:

- No System Level Hot Firing Tests

  The analysis is the same as described in Part I.

- Dynamic Static and Fatigue Tests performed on a single STA

  The analysis is the same as described in Part I.

- Use of a single STA program to cover both the basic and evolved configurations.

  The STA will be configured to include the structure hard points for the retrieval avionics and mechanical interfaces. The test program will include the projected mass simulation for the evolved hardware during dynamic tests and the projected loading for static and fatigue tests. By enveloping the basic and evolved designs in a single STA program both designs will be verified minimizing test program costs.

- Integrated Avionics Testing is accomplished in two separate yet complementary facilities

  The basic analysis is the same as described in Part 1. In addition the IAT and ASDL facilities for this configuration will be used for verification and mission simulations for the incorporation of rendezvous radar, retrieval electronics and level IIb autonomy during transition from the 310-3A to 310RE-3A configurations.

- One dedicated Flight test minimizes risk of losing Tug/Payload

  The Main Stage (MS) flight test program for the 310-3A configuration will be the same as described in Part I, paragraph 8.2.6.1 providing only a single dedicated test flight The Retrieval Delay Module (RDM) and MS retrieval capability will be demonstrated as part of a deploy only operational mission and will not require a separate dedicated flight test program. Since the basic Tug functional operation will have been fully developed by the time the RDM and retrieval capability is ready to be tested, and the test will be conducted within shuttle retrieval range, this approach offers the advantage of minimum risk at minimum test cost.

8.2.6.2 SR&T Assumptions

The basic assumption for the 310-3A/310RE-3A SR&T requirements are described in Part I, paragraph 8.2.6.2. SR&T requirements, test programs affected and a brief description of the interaction with the test programs affected is summarized in Table 8.2-2.

8.2.6.3 Reusability Demonstration

Reusability demonstrations for the 310-3A/310RE-3A are the same as described in Part I, paragraph 8.2.6.3.

8.2.6.4 Life Verification Tests

The life verification test requirements for the 310-3A/310RE-3A are the same as described in Part I paragraph 8.2.6.3

TECHNOLOGY REQUIREMENTS	TEST PROG. AFFECTED	REMARKS
Main engine life and high performance	o GFE eng. devel. prog. o Flight test prog.	Early life verif. of eng. components and area ratio nozzle performance assures phase C/D engine development. PTV is not affected since eng. is not required. FOF could tolerate slightly reduced eng. performance.
PFR helium tank		Early verif. of low weight PFR tank assures maximum tug performance.
Materials compatibility Data	o Tank qual o STA prog. o PTV prog.	Early verif. of material compatibility with MMH and N_2O_4 assures on-time development of main stage tankage including tank qual. STA and PTV testing.
Fracture Mechanics data	o Tank qual. o STA prog.	Early fracture mechanics data allows on-time development of structural subsystem including tankage quals and STA testing.
Heat Pipes	o Flight test prog.	Early verif. of heat pipe design approach allows on-time developments of Thermal Control Subsystem thereby maximizing Tug performance.
Advanced IMU	o Integrated avionics o Flight Vehicle Factory checkout o STA	Early devel of Advanced IMU will assure on time devel of software and integration procedures in the IAT LAB for FLT VEH buildup and test and accurate simulation for STA prog.
Graphite Composite	o STA Prog.	Early Devel of graphite composite honeycomb face sheets assures that STA program progresses as planned.
Laser Radar	o Integrated Avionics o Flight Vehicle factory checkout o STA	Early devel of light weight low power Laser Radar will assure on time development of software and integration procedures in the IAT LAB for FLT VEH buildup & test and accurate simulation for STA program.

310-3A/310RE-3A GROUND TESTS

Vehicle Test Program

The vehicle test program for 310-3A/310RE-3A was developed in a similar manner to that described for 110A-1.

Structural Test Article (STA)

The MS structural test program for the 310A-3A/310RE-3A configuration is identical to 110A-1. The differences for this configuration are the deletion of the kickstage, phased addition of the RDM, and added avionic retrieval hardware and mechanical interfaces. The 310-3A STA will be configured to include the evolved 310RE-3A hardware interfaces and the test program will envelope both configurations. The RDM STA will be tested similarily to the mainstage in 1982.

Propulsion Test Vehicle (PTV)

The PTV test program for this configuration is identical to the PTV test program for the 110A-1 configuration.

GRUMMAN

310-3A/310RE-3A GROUND TESTS (CONTINUED)

Integrated Avionics Tests

The MS Integrated Avionics Test program for the 310-3A configuration is the same as for 110A-1.

The IAT and ASDL will be initially configured for the basic mission hardware and software including autonomy level IIIA. As the retrieval capability and Autonomy level II B is evolved, the IAT hardware and ASDL software will be updated and evolved system verification and mission simulation performed.

The RDM bread board will be integrated and functionally tested in the main stage IAT facility to take advantage of the existing facility simulation and GSE capabilities.

Mockups

The Main stage mockups for this configuration are the same as for 110A. In addition a mockup of the RDM will be required for this configuration. The evolved system hardware will also be installed and evaluated using the M.S. mockups.

GRUMMAN

310-3A/310RE-3A FLIGHT TESTS

Eight flights are included in the flight test program for configuration 310-3A/310RE-3A. The MS Flight test program for the 310-3A configuration is the same as for 110A-1. The major difference is the evolution of the RDM and MS retrieval capability.

The RDM and MS retrieval capability will be demonstrated as part of a normal deploy only operational flight. During this flight an RDM will be deployed from the shuttle. When the tug returns from its deployment mission it will demonstrate retrieval capability by retrieving the RDM. RDM performance will be evaluated while it is free flying in the vicinity of the shuttle. Subsequent operational flights will serve to demonstrate all Tug mission modes.

8.3 Facilities Plan - Option 3A - Concept 310-3A/310 RE-3A

8.3.1 Manufacturing Facility

Same as concept 110A-1 except 25,400 sq. ft. of floor space is required for fabrication and assembly of the TUG.

8.3.2 Test Facilities

Same as concept 110A-1.

8.3.3 Operations Facilities

Same as concept 110A-1 except TUG Maintenance Facility at ETR will have 4 horizontal stations in a 12,000 sq. ft. addition to the Shuttle OMS Facility. The Kickstage SRM Processing Facility is not required.

8.3.4 Impact of 2 Year IOC Delay

Same as concept 110A-1 except expenditure of $3.7 million of facility DDT & E costs can be delayed for 2 years.

STORABLE SPACE TUG

III-8.3-2

8.4 Vehicle Manufacturing

This section establishes the manufacturing requirements for 310A-3A/310RE-3A spacecraft including the assembly sequence, tooling, schedule, manufacturing test, special processes and facilities.

The 310A-3A spacecraft consists of a main stage and a Retrieval Delay Module (RDM), which is phased-in for the evolved configuration (310RE-3A). The main stage is essentially the same as the 410AD-2 configuration. The RDM is a short (27") element added between the payload and the main stage which contains docking provisions and GN&C, communications, data management, APS and EPS equipment.

8.4.1 Plan/Flow/Time

The manufacturing sequence is identical to configuration 410AD-2 discussed in Part II section 8.4.1. The manufacturing flow and master schedule are shown in figures 8.4-1 and 8.4-2 respectively.

8.4.2 Tooling Requirements (including GSE)

See Part II section 8.4.2

8.4.3 Facility Requirements

See Part II section 8.4.3

8.4.4 Special Requirements

See Part II section 8.4.4

8.4.5 Summary Analysis/Philosophy

See Part II section 8.4.5

8.4.6 GSE Requirements

See Part I section 8.4.7

8.5 310-3A/310RE-3A SPECIAL PROGRAMMATICS

This chart summarizes the salient features defined for implementing and managing Program 310-3A/310RE-3A.

The main factors derived from our analysis of 110A-1 include: defining the initial/evolved flight build up based on Shuttle/Tug launch constraint and ground crew launch capability; implementing a 3 lot main stage production run with deploy capability, deploy capability up graded to retrieval, and retrieval capability vehicles to avoid initial/evolved production gaps; refurbishing the propulsion test article for operational use; and defining a fall back position for every identified risk.

Specific areas for government participation include: establishing Tug/Shuttle interface requirements before Orbiter design freeze; providing payload interface design requirements and mission model data; initiating required activities for supporting Research and Technology; providing GFE systems and components (eg: main engines, and DOD secure comm); supporting propulsion system testing and development; supporting integrated avionics hardware testing and related software development; providing required facilities; performing vehicle flight operations and ground operations; and providing logistic support.

310-3A/310RE-3A SPECIAL PROGRAMMATICS

- o PROGRAM IMPLEMENTATION AND MANAGEMENT
  - INITIAL/EVOLVED FLIGHT BUILD-UP SET BY SHUTTLE/TUG LAUNCH CONSTRAINT AND GROUND CREW LAUNCH CAPABILITY
  - 3 LOT PRODUCTION (DEPLOY, DEPLOY-UPGRADE, AND RETRIEVE) TO AVOID MFG GAP
  - PROPULSION ARTICLE REFURBISHED FOR FLIGHT
  - FALL BACK POSITION SHOWN FOR EVERY IDENTIFIED RISK

- o AREAS FOR GOVERNMENT PARTICIPATION
  - FIRM TUG/SHUTTLE INTERFACES BEFORE ORBITER PDR
  - PROVIDE PAYLOAD INTERFACE DESIGN REQUIREMENTS AND MISSION MODEL DATA
  - INITIATE REQUIRED SR&T
  - SUPPORT SYSTEM TEST - AVIONIC HARDWARE/SOFTWARE, PROPULSION
  - PROVIDE GFE SYSTEMS AND COMPONENTS, FACILITIES, LOGISTIC SUPPORT
  - PERFORM VEHICLE GROUND AND FLIGHT OPERATIONS

GRUMMAN

8.6 COST DATA

Included in this section are the cost data for an evolved tug configuration 310-3A--310RE-3A. Cost data are provided for the initial program 310-3A and the combined total evolved program.

- Initial Program 310-3A
  - o Storable Space Tug System Project Expected Cost-Spares Cost (INT & OPS)-First Unit Cost (Data Forms A, 2 and 3, subparagraph No's 8.6.1, 8.6.2 and 8.6.3) (Computer P/O)
  - o Storable Space Tug Funding Schedules-DDT & E, Production and Operations (Data Form C, subparagraph 8.6.4, 8.6.5, 8.6.6 and 8.6.7.)
  - o First Unit Production Cost per WBS (including Avionics to level 7) Main Stage and Auxiliary Stage(s), (subparagraph 8.6.8)
  - o Form B (Technical Characteristics subparagraph 8.6.11)
- Combined Evolved Program 310-3A/310RE-3A
  - o Same as initial program plus:
    - o Average Cost/Flight (subparagraph 8.6.9)
    - o Storable Space Tug System Project Cost Estimate data by SOW-DDT & E, Production and Operations (Data Form T (SOW'S) subparagraph 8.6.10)

CONCEPT 310/310RE-3A

COSTED FLIGHT BUILD-UP

TABLE 4.3.3.2-8

III-8.7-7

310-3A/310RE-3B FLIGHT OPERATIONS BUILDUP

The methodology used to establish the 310-3A/310RE-3A flight buildup is keyed to achieving all flights defined by the 100% payload capture analysis after the second year of initial operations and the first year of evolved operations. The primary factors considered include: NASA defined Shuttle/Tug launch constraints, initial ETR ground crew launch capabilities, and flight mode buildup.

Shuttle/Tug launch constraints affect the first year of operations and allow only 3 flights. During the second year of operations the allowable Shuttle/Tug launches exceed the payload capture traffic model.

Initial ground crew launch capability is derived in the same manner as that described for 110A-1. We approached the evolved flight build up in a similar fashion. The ground crew capability for 1984 was based on the learning effect of adding additional personnel to accommodate the increase flight rate between 1983 and 1985.

As in the prior options, we recommend that initial/evolved flight crew experience be developed by starting with the simplest flight mode and then progressively introducing the more complex flight modes required initially for 1982 and subsequently for 1985.

Our recommended flight buildup for 310-3A/310RE-3A, including 3 flights in 1980, 12 flights in 1981, and 27 flights in 1984 encompasses 355 total flights through 1990 or 35 less than 100% payload capture traffic.

PROGRAM SENSITIVITY TO IOC SHIFT - 310-3A/310RE-3A

The schedule shift and stretch programmatic options can also be used for implementing program concept 310-3A/310RE-3A under a 2 year delay.

In this program IOC delay results in 68 undeployed payloads and 52 unretrieved payloads. Similar conclusions can be drawn on production impact as in the two prior options.

In addition, development impact conclusions considering type of contractor support available to NASA/DOD for defining Tug/Shuttle systems and interfaces, vehicle test, facilities and SR&T are also similar to the results of 110A-1. However, in the stretch program the IOC delay allows a more relaxed schedule for Class I main engine development to avoid the critical path. Assuming that the initial period of schedule stretch is devoted to systems engineering studies we estimate that cost of stretch-out will be $8M. Peak funding occurs in 1980 and is $66M for the schedule stretch option.

8.9 Risk Assessment

In making an assessment of the risk associated with each configuration in each capability option we have considered the type of technology items associated with each vehicle and the impact that it would have on the program if, for one reason or another, the item would be unavailable and an alternative solution would be required. The impact is defined, usually, in terms of added weight, lost performance and total program cost increase; in some cases the impact can be decreased weight or reduced cost.

It is assumed that all of the weight increases and all of the cost increases will occur simultaneously without benefit of any offsetting decreases in either weight or cost. For example in configuration 110A-1 we have assumed that the 44 lb. weight impact of abandoning spun aluminum tanks in favor of welded aluminum tanks is combined with a $10.0 million cost increase as a result of abandoning aluminum tanks in favor of titanium tanks due to materials compatibility or fracture mechanic issues.

Taking the summation of all the weight increases, these are converted to costs by using the $75K/lb. figure derived when we were first selecting subsystem options for incorporation with 110A-1. The $75K/lb. number represents the last step (actually the slope of the line) in our subsystems synthesis process which provides a curve of Δ weight versus Δ total program costs as we added lighter and more costly subsystems options to achieve a behicle with 3500 lb. deploy capability. In this manner we arrived at a estimate of the costs expected if we had to recover the weight growth.

In similar fashion we then summed all of the potential cost increases, ignori any offsetting cost decreases, and added these to the dollars representing the weig increases. The 110A-1 has no projected performance loss since it uses the OME 7.5K engine; the assumption is that the basic OME will have been developed to meet its weight, performance and reusability goals for the Shuttle Orbiter. In the case of configurations which use the Class I engine, for example 410AD-2, we have assumed that a 3 second Isp performance loss is possible. To convert this performance loss to costs we use the payload sensitivity factor to loss in Isp (97 lbs/sec), divide this by the payload sensitivity to inert weight and then multiply by $111/lb. to convert it to costs.

Taking all of the costs and adding them together we get a total low cost risk value of $15.3M for 110A-1 which ranges to a high value of 94.3M for 320A-3A/320AE-3A.

8.10 RISK ASSESSMENT (continued)

Where no suitable alternative exists (for example the Class I engine, or the laser radar, or the Space Storable SRM) we have identified that item as both a cost and a schedule risk without attempting to quantify the risk. In general, we are relying on the successful completion of the proposed SR&T programs to reduce or eliminate the risk of schedule slippage.

Taking configuration 110A as an example:

110A-1: This is an extremely low risk program with only two items representing a technical risk, the spun-form aluminum tanks and the prestressed filament reinforced (PFR) helium tanks. Both of these items are low risk and both have suitable, low risk alternatives available.

The incorporation of separate tanks (rather than the nested tanks used in the other configurations) further reduces the risk associated with this configuration. Level III (rather than Level IIB) autonomy also reduces the risk since there is no reliance on the 621B Navigation Satellite program. The OME 7.5K engine is the lowest risk engine program available, so its use on 110A-1 further reduces risk. The use of scaled-up LM batteries rather than fuel cells with their associated cryogenic storage tanks and valves is again the lowest risk approach available for providing electrical power. The all-aluminum structure is the lowest cost/lowest risk approach available. The short mission duration (34 hours) eliminates the need for multi-layer insulation (MLI) on most of the external surfaces there minimizing the risk of damage to the MLI during vehicle ground operations.

Since the 110A-1 does not have to communicate with payloads it has the the lowest risk communications equipment, a dedicated frequency station, to develop. Although our current approach includes making the communications equipment compatible with the NASA Tracking and Data Relay Satellite System (TDRSS) an option which can further reduce risk, is to eliminate the requirement for this equipment to meet the spread spectrum and CCIR interference requirements associated with TDRSS. The modifications of an existing IMU (the Carousel VB) and an existing computer (the CDC 469) are again the lowest risk approach identified in the GN&C and DMS areas.

Although the use of an apogee kick stage (AKS) to deploy heavier payloads reduces the sensitivity of the configuration to inert weight growth or I_{sp} loss, it does add complication to flight operations, increasing risk. Elimination of the AKS can further reduce the risk of this configuration.

310-3A/310 RE-3A RISK ASSESSMENT

TECHNOLOGY ITEM IMPACT	
• CLASS I ENG	-3 SEC ISP
• PFR TANK	+48 LB
• ADVANCED IMU	+30 LB
• GRAPHITE COMPOSITE	+38 LB
• LASER RADAR	COST/SCHED
• MATERIALS COMPATIBILITY	+13 LB
• FRACTURE MECHANICS	+13 LB
• HEAT PIPES	SCHED

VEHICLE SENSITIVITY (DEPLOY)	PLAIN
$\frac{\partial P/L}{\partial W \text{ FIXED}}$ (LB/LB)	-3.66
$\frac{\partial P/L}{\partial ISP}$ (LB/SEC)	96

- TECHNICAL RISK
  - POTENTIAL WT IMPACT: +129 LB } ≈ 760 LB OF PAYLOAD
  - POTENTIAL ISP LOSS: -3 SEC }
  - OPEN WEIGHT REDUCTION OPTION: ADV. FUEL CELL
- SCHEDULE RISK
  - PROPOSED SR&T PROGRAMS COMPLETED PRIOR TO ATP PROTECT AGAINST SCHEDULE SLIP
  - AVAILABILITY OF 621 B SATELLITES & MAIN ENGINE
- COST RISK
  - POTENTIAL Δ COST $25.9M

MODERATE RISK PROGRAM

310-3A/310RE-3A RISK ASSESSMENT

The technology items and their potential impact are shown on the opposite chart. If the PFR helium tank does not meet its goals, a 6Al4V titanium tank adds 48 lbs. to the vehicle. If the advanced IMU (Micron) is unavailable, a Carousel VB IMU plus a rate gyro unit adds 30 lbs. If the graphite composite shell fails to meet its objectives an aluminum honeycomb shell adds 30 lbs. The laser radar is an item for which no attractive alternative exists, hence it represents both a cost and schedule risk. If materials compatibility or fracture mechanics data indicate the need to change propellant tank materials from titanium to either aluminum or stainless steel the added weight would: be + 13 lbs. or +3 lbs. respectively. If the heat pipes are replaced by incorporating high heat rejection items on the active loop, there are no weight changes. To recover the weight impact on payload capability due to these possible weight increases, the advanced fuel cell is an open option.

The Class I engine is a new design based on current technology with the exception of the uncertainity in engine life and in the predicted performance with the high expansion ratio nozzles used. It is estimated that this engine can miss its performance goals by -3 seconds Isp.

Although the proposed SR&T programs protect against schedule slippage by virtue of being completed at ATP, the availability of both the main engine and the 621B Navigation Satellites remain schedule risk items.

Converting the potential Isp loss and weight increases to a total program cost at a $111K/lb value and adding the potential cost increase items, yields a total cost risk of $25.9M for 310-3A/310RE-3A.

RISK ASSESSMENT 310-3A/310RE-3A

BASELINE	ALTERNATIVE	WEIGHT, LBS	TOTAL PROGRAM COST, $M
CLASS I ENGINE	NO ALTERNATIVE	-	COST/SCHED RISK
LASER RADAR	RF RADAR PLUS REMOTE TV DOCKING (ALSO A TECHNOLOGY ISSUE) HENCE NO ALTERNATIVE	-	COST/SCHED RISK
PFR HELIUM TANK	6 AL 4V TITANIUM TANK	+48	+2.80

HEAT PIPES	USE ACTIVE LOOP/BYPASS	NONE	NONE

SUMMING HIGHER WEIGHTS & COSTS ONLY ---------- 129 LBS ---------- $3.74M

CONVERT WEIGHT TO $ at $111K/LB ---------- (129 X 111K) ---------- 14.30

CONVERT - 3 ISP TO $ ---------- $\left(\frac{3 \times 96}{3.66} \times 111K\right)$ ---------- 7.85

TOTAL COST RISK ---------- $25.89M

Section 8.10 Supporting Research and Technology

This section includes a summary matrix chart which identifies all of the SR & T items and where they are applied to each configuration in each capability option.

Following the summary matrix there are individual tables for each configuration which summarize the technology items for that particular configuration and give a very brief synopsis of the type of SR & T program proposed and the estimated funding and schedule requirements. The text following each table is the facing page text prepared for the main presentation.

Following the tables for each configuration, an additional form is filled out for each technology item providing status information, justification for the proposed SR & T program, objectives, technical approach, and a more detailed schedule showing when the proposed program must be completed in order to support the particular configuration.

In dealing with the subject of SR & T we have identified two distinct groups - one where technology is needed and the other where there is no doubt that the technology is available and it is a straightforward engineering task to accumulate data that will preclude making a "false start" where several alternates are under study; we have called the latter group "desired data".

The storable Tug will benefit from the fact that the APOLLO LM program has used similar materials, propellants, equipments and procedures; the Shuttle Orbiter will expand on this data base for the Tug. The low number of identified SR & T items and the modest sums projected are based on the assumption that several existing or planned efforts related to the Shuttle will continue to provide data. These include the planned propellant and materials compatibility testing in support of the Shuttle Orbital Maneuvering Subsystem, its engines, tanks and components both at NASA/WSTF and at the Shuttle contractor's facilities. In addition, we have identified the Air Force funded efforts to develop the advanced Micron IMU for aircraft programs, as an effort which we would build-on rather than to start from scratch.

We have not attempted to detail the SR & T programs required on the Class I engine (with or without the two position nozzle) except to point out the uncertainty associated with the anticipated engine life and the predicted performance of very high expansion ratios within the mixture ratio of interest. The engine contractor will provide the proposed SR & T efforts required on the engine and we will provide comments on same at NASA's request.

The overall "message" which we hope will become obvious to the reader is that there are no real "show-stoppers" among the SR & T items identified.

TECHNOLOGY REQUIREMENTS AND DESIRED DATA - 310-3A/310RE-3A

The upper part of the facing chart contains the supporting research and technology (SR&T) items required for 310-3A/310RE-3A; the lower part of the chart contains what we have termed as "desired data". The distinction between the two is that the "desired data" items do not require technology but are considered straightforward engineering development tasks to produce design data prior to Tug program go-ahead (ATP); this will preclude impacting Tug schedules should the data indicate the desirability of an alternative approach, (vis., aluminum or stainless steel tanks rather than titanium).

Excluding the SR&T on the Class I engine, the total SR&T funds requested for 310-3A/310RE-3A is $1,290 K to be expended over an 18 month period culminating at Tug ATP or prior to go-ahead on the evolved Tug. The advanced (Micron) IMU is the long lead item (18 months), again excluding the Class I engine.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Avionics (GN&C)
(Discipline)

TITLE Low Weight/Power, (Rendezvous and Docking) Laser Radar

WBS No. 320-03-03-02

STATUS ITT-Gilfillan has been under NASA Contracts since 1964 to design, develop, build, and test various spaceborne laser radar systems. The third generation system will be delivered in late November 1973.

JUSTIFICATION The application of the above developed technology to meet specific space tug rendezvous and docking requirements is desired.

In addition in order to improve the payload capability of the storable tug, low weight Avionics equipments (specifically, low weight/low power laser radar) are required.

OBJECTIVES To design, develop, fabricate, and test a low weight, low power, rendezvous and docking laser radar.

III-8.10-5

TECHNICAL APPROACH Using Tug requirements, design for light weight, low power by using new components, lighter mirror drives and improved optics

TITLE Prestressed Filament Reinforced (PFR) Tanks

WBS No. 320-03-04-02

STATUS Structural Composites Industries, Inc. (SCI) and Arde-Portland, Inc. are under contract to LeRC to demonstrate the feasibility of the PFR tanks. This program will result in the construction of a 24 in. diam. Ardeform PFR tank of the type assumed by our study. If successful the basic technology will be proven.

JUSTIFICATION
A PFR ambient helium storage tank is comparable with the weight of a SHe tank and its associated heat exchanger. It provides a simple and less operationally complex system compared to the SHe tank. The PFR tank also provides a leak-before-burst design which results in increased Tug safety.

OBJECTIVES
Design, fabricate, and test 3 to 6 PFR tanks to demonstrate that current manufacturing and quality control techniques are adequate to produce a reliable, low weight tank suitable for containing gaseous helium (or hydrogen and oxygen in the case of fuel cell reactant tanks). The program will resemble a pre-qualification test program which will demonstrate the ability of the PFR tank to undergo the dynamic loading, compatibility, environmental exposure and etc. tests required for acceptance as a flight item.

III-9.10-1

TECHNICAL APPROACH

Fabricate 3 to 6 tanks and subject them to a pre-qualification test program to demonstrate the maturity of the design.

MANPOWER 2 man years

TITLE SPACE TUG HEAT PIPES WBS No. 320-04-02

STATUS

Heat pipes (HP) are currently being used in both ground and space application. The variable conductance heat pipe (VCHP) principle is particularly attractive for Tug application but requires further development.

JUSTIFICATION

The fuel cell and certain high power density avionics units carried on the Space Tug require active cooling. Trade studies which have examined pumped loop radiators, sublimators and various heat pipes have indicated the obvious merits of the variable conductance heat pipe. A VCHP radiator could interface with the pumped loop heat transport system of the fuel cell, eliminating the cost and complexity of a selective stagnation radiator with its associated unreliable automatic bypass valves. A VCHP header, a heat transport device, could provide for high power density avionics heat transport without recourse to the active loop.

61-01-8-III

OBJECTIVES

Emphasis will be placed on experimentally obtaining the large turn down ratios which appear theoretically achievable and in developing predictive techniques.

TECHNICAL APPROACH

Design, fabricate and test a VCHP radiator and VCHP header and experimentally determine performance with emphasis on turn down ratio and shut off heat flux levels.

8.11 SPECIAL COST SENSITIVITIES

REFERENCE:

Due to the size and development of the Special Cost Sensitivities Analysis reference is made herein to Part I, concept 110A-1, paragraph 8.11 of Volume 8.

8.12 DOD ACQUISITION APPROACH

310-3A/310RE-3A

The rationale for phasing from the Full Scale Development Phase to the Production Phase for the initial 310-3A configuration is as described in Part I, Paragraph 8.12.2. Production go-ahead for the evolved 310RE configuration is based upon completion of the First Orbital Flight (FOF) which is planned to demonstrate retrieval during an operational deploy only mission. Upon the Tugs return to the vicinity of the Shuttle a retrieval demonstration will be conducted using a shuttle deployed Retrieval Delay Module (RDM) as the target vehicle. This flight, together with the previous years of deploy only operations, will provide the assurance to allow for production go-ahead.

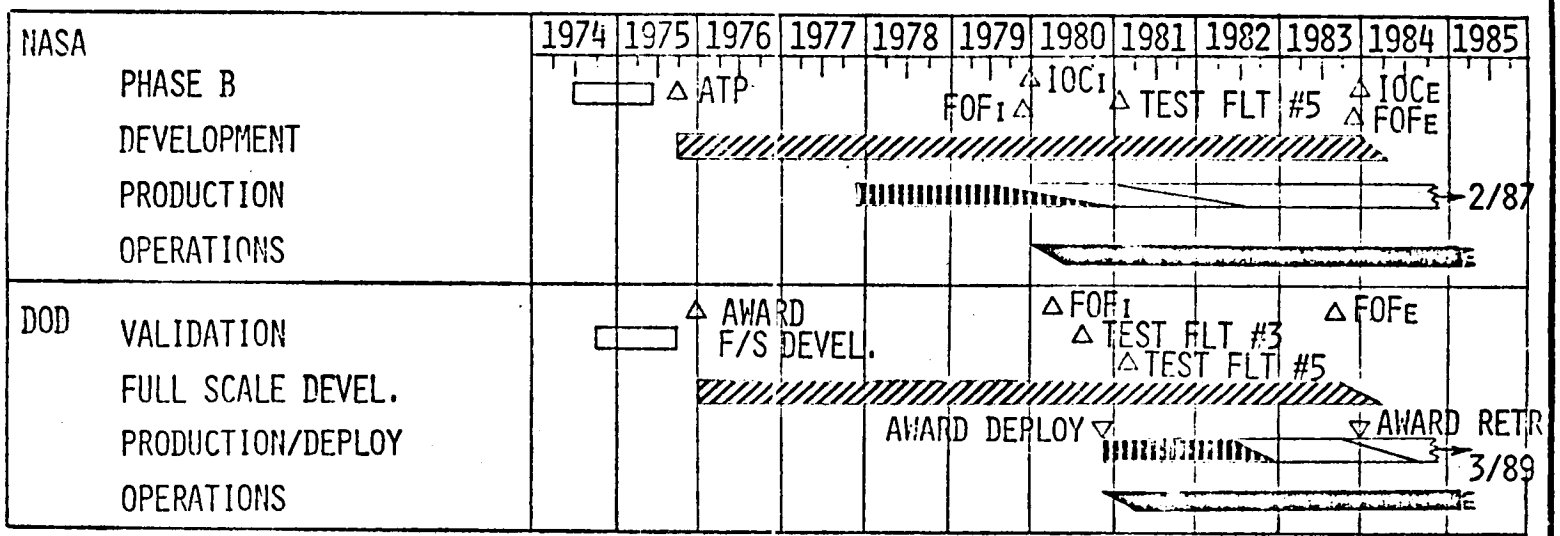
DOD ACQUISITION APPROACH (AFSCP 800-3) 310-3A/310RE-3A

Implementing program concept 310-3A/310RE-3A in accordance with DOD full funding requirements (AFSCP 800-3) results in a longer development activity plus a delay in the start of production and operations.

In this program the initial Full Scale Development Phase as in 110A-1, also lasts 63 months (1 year longer than the NASA equivalent DDT&E Phase) and includes all test flights. The evolved development activity is similarly defined and ends at the 84 IOC milestone.

The initial production award is keyed to the third test flight as in Option 1 and evolved production is keyed to the first evolved test flight. Initial payload deploy operations are performed with the three flight test vehicles. Similarly, initial payload retrieval operations are performed with two upgraded deploy/retrieval test vehicles. Through the initial/evolved program the operational fleet will be supplemented with production vehicles as they become available. We recommend that production article procurement follow a 2 lot deploy buy (4/3 vehicles per lot), a 2 block vehicle upgrade (2 vehicles for evolved flight test and 3 vehicles for operations), plus a 4 lot retrieve buy (3/3/3 and 4 vehicles per lot).

DOD ACQUISITION APPROACH (AFSCP 800-3) 310A/310RE-3A



FULL SCALE DEVELOPMENT

- o EXTEND TO INCLUDE 5 INITIAL & 3 EVOLVED TEST FLIGHTS
- o USE FLIGHT TEST VEHICLES FOR INITIAL PAYLOAD OPERATIONS
- o ADD 2ND & 3RD DEPLOY VEHICLES FOR INITIAL OPERATIONS

PRODUCTION/DEPLOYMENT

- o PROVIDE 7 ADDITIONAL DEPLOY VEHICLES (4/3 - 2 LOT BUY)
- o UPGRADE 2 DEPLOY VEHICLES FOR EVOLVE FLIGHT TEST
- o PROVIDE 13 ADDITIONAL RETRIEVE VEHICLES (3/3/3/4-4 LOT BUY) AND UPGRADE 3 DEPLOY VEHICLES

OPERATIONS

- o DELETE 7 TEST FLIGHTS - 348 TOTAL FLIGHTS
- o TOTAL FLEET - 23 MAIN STAGES AND 4 RDM

GRUMMAN

DOD ACQUISITION FUNDING 310-3A/310RE-3A

DOD funding is shown in the accompanying chart. A total of 23 vehicles is costed. Three Tugs are included in DDT&E. Seven are produced of the initial 310 configuration of which six are upgraded to the evolved 310RE configuration. Thirteen 310RE Tugs are produced in addition to the above vehicles. In comparison with the NASA 310-3A/310RE-3A program, costs have been adjusted for transfer of the cost of two Tugs to DDT&E plus transfers of early Operations Costs during initial testing, and costs associated with extension of Engineering and ground test operations. For reduction of changes, $4M was deleted for changes avoided by delaying production as compared with the "NASA" schedule.

Total program funding is $871M and peak annual funding is $106M. This compares with $858M and $85M on the NASA program.

8.1.1 SUMMARY PROJECT SCHEDULE

Introduction: The Storable Tug Project schedule was developed to identify the principal project phases and to establish schedule estimates for all hardware and soft ware elements in accordance with the Space Tug Work Breakdown Structure.

The Tug Project Schedule depicts major program milestones and presents project activities at level 5 of the WBS. This schedule establishes the planning baseline for development of the Storable Tug System through design, development, manufacturing, ground test, flight test and operations. It integrates all supporting schedules into an overall project level plan and establishes the sequence and interdependency of activities and events required for the development of an operational Space Tug System.

Groundrules and Assumptions: Following are the ground rules and assumptions used for development of the Storable Tug Project Schedule:

- o ATP is October 1975 at the earliest for Options 1 and 3. ATP for Option 2 to be determined by the contractor.
- o Schedule planning is designed to minimize peak annual funding during DDT&E.
- o Main Stage DDT&E requirements consist of the following major test articles:
  - A structural test article (STA) for dynamic, static and fatigue tests.
  - A main propulsion test vehicle (PTV). Following the completion of live propellant testing the PTV will be refurbished and delivered as an operational flight vehicle.
  - One shipset of Avionics hardware for the Integrated Avionics Test (IAT).
  - A flight test vehicle (MS-1).
- o Operational fleet sizes for each project option are based on a study of traffic capture models.
- o Production rate of vehicles is based on avoiding duplication of major structural assembly tooling and minimizing gaps in manufacturing flow.

- Initial operational capability (IOC) is achieved after completion of one test flight (FOF). IOC dates are as follows:

  Option 1 - December 1979
  Option 2 - December 1983
  Option 3 - December 1979 - initial, December 1983 - evolved.

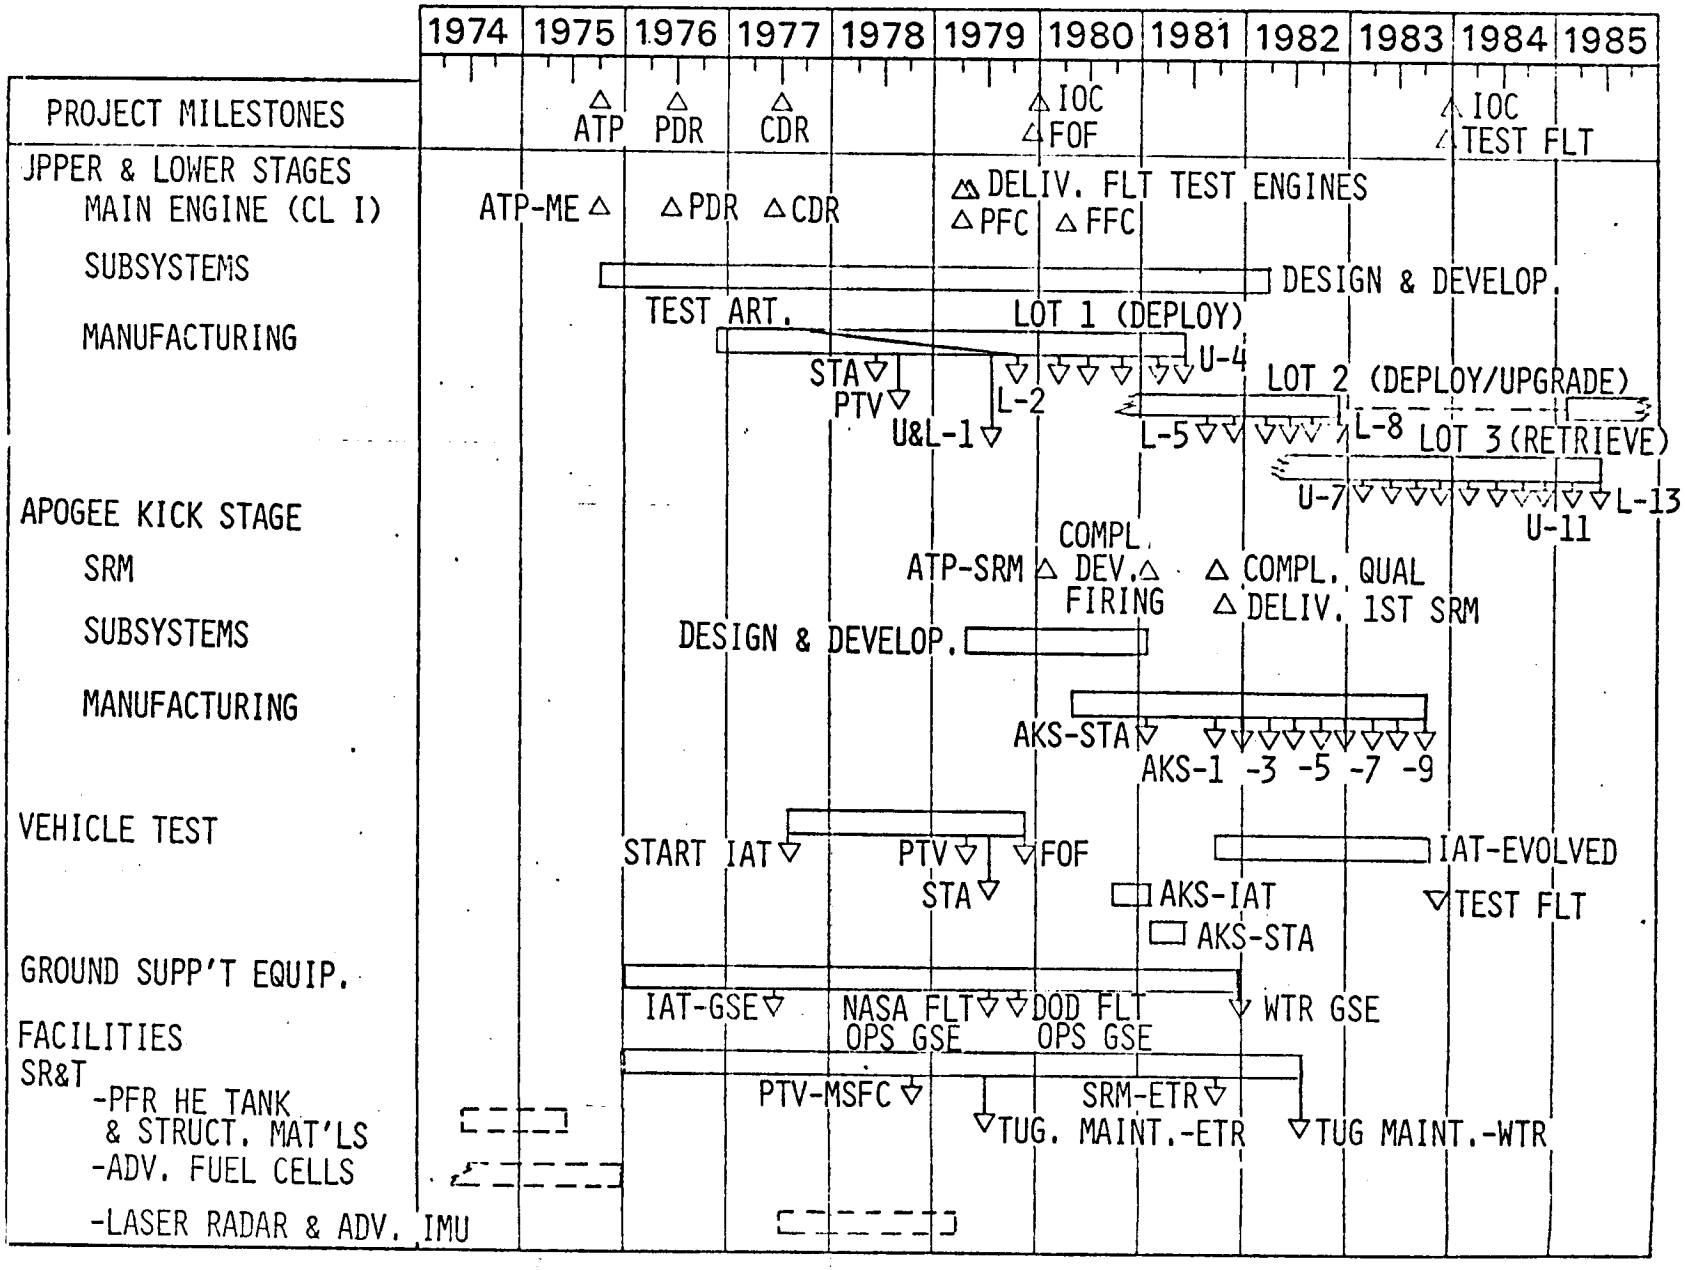
- Maximum number of flights in 1980 is 3, based on the Shuttle traffic model.

Approach: Based on the above groundrules and assumptions a preliminary project milestone schedule was developed to form a baseline for all detail scheduling. Detailed subsystem design and development schedules, manufacturing and factory checkout flows, vehicle test, GSE, facilities, and SR&T Schedules were then developed in conjunction with personnel representing the cognizant management and technical disciplines. These detailed schedules were then summarized and integrated into the Tug Project Schedule through the process of establishing a logical and achievable relationship between the engineering design and development process, procurement of subcontract equipment, hardware fabrication and assembly process and the vehicle test program that minimizes risks and ensures the fulfillment of program objectives. Finally, the major project milestones and activities presented in the Tug Project Schedule were condensed into the Summary Project Schedule.

SUMMARY SCHEDULE - 320A-3A/320AE-3A

The primary elements of the 320A-3A/320AE-3A Project Schedule include Upper and Lower Main Stages, Apogee Kick Stage, Vehicle Test, GSE, Facilities and dependent SR&T. Authorization to Proceed (ATP) occurs on October 1, 1975, with IOC of the initial configuration targeted for December 31, 1979. The Class I main engine milestones are the same as for 310-3A/310RE-3A except that quantities of engines are doubled since this is a two stage vehicle. Main Stage vehicle tests are essentially the same as for 110A-1 except for additional Integrated Avionics testing to demonstrate retrieval capability. First flight of the evolved configuration is targeted for December 1, 1983. Upper and Lower Stage manufacturing begins December 1, 1976 with production of the major ground test articles and continues through production of 11 upper and 13 lower stages to support fleet operations. These are manufactured in 3 Lots similar to 310-3A/310RE-3A for the purpose of avoiding a manufacturing gap between deploy only vehicles and evolved vehicles. As with 110A-1, development of the Apogee Kick Stage starts in May 1979 ($3\frac{1}{2}$ years after main stage ATP) and continues through the same vehicle tests to an operational test flight during the second year of operations. Nine kick stages will be manufactured to support fleet operations. GSE and Facilities are scheduled essentially the same as for 110A-1.

320A-3A/320AE-3A SUMMARY PROJECT SCHEDULE



8.1.2 DEVELOPMENT SCHEDULES

8.1.3 PRODUCTION SCHEDULES

The detailed Project Schedule depicts the total development and production phases for the Main Stage and the Auxiliary Stage(s). The detailed Project Schedule is based on a constraint logic that considers overall program objectives and the detailed interaction of constraints on significant program activities. It provides reasonable margins for development problems and minimizes program front-loading.

The detailed Subsystem Schedules provide an order of magnitude increase in detail from the Project Schedule and depict the subsystem activities in both inhouse and subcontractor areas. Subsystem schedule information is presented at WBS level 6 for Structures, Thermal Control and Orbiter Interface, and at WBS level 7 for Propulsion and Avionics subsystems.

8.1.4 OPERATIONS SCHEDULE

Scheduled and planned for concept 320A-3A/320AE-3A, option 3 are 30 launches per year with 12 days between launches. Ground servicing as shown on the programmatics/cost operations schedule from land to launch is 10 tug work days and 9 tug/orbiter work days.

8.1.5 FACILITIES SCHEDULE

Included in the storable space tug facilities schedule for concept 320A-3A/320AE-3A are the various tasks to be completed against major program milestones. The fundamental grouping of these tasks are manufacturing, test, maintenance and refurb-ETR, ETR launch, maintenance and refurb-WTR and WTR launch. Under this tug concept facilities maintenance extends into 1991, with most of design/construction/activation ending by 1982in support of WTR launch requirements.

8.1.6 EVALUATION OF MAJOR SCHEDULE DRIVERS (cont'd)

320A-3A/320AE-3A

The avionics subsystem appears on the critical path for the Two Stage Tug option resulting from the introduction of an Advanced Fuel Cell. The purchase order for the Advanced Fuel Cell would have to be issued shortly after ATP to allow for the long development time (minimum of 34 months). In addition, a two year period of SR&T effort would have to precede the P.O., thus placing the start of SR&T in early 1974.

Also on the critical path (as in option 310-3A/310RE-3A) is the main engine for reasons discussed above.

Production of the Two Stage Tug is scheduled in 3 lots of upper and lower stages, manufactured alternately, and providing a continuous manufacturing flow at 3 month centers. Total fleet consists of 11 upper and 13 lower stages.

Development of the Apogee Kick Stage is delayed until 1979 to meet a late 1981 first flight requirement.

8.2 Vehicle Test Program (320A-3A/320AE-3A)

8.2.0 Our approach to development of the 320A-3A/320AE-3A Vehicle Test Program is essentially as described in Part I, Paragraph 8.2.0. The mission flight modes for this option include both single stage and two stage operations. The main stages are essentially identical and are connected when in the two stage mode by an interstage structure. As such, the various test articles in the Vehicle Test Program include only one stage with interfaces being simulated as required. Table 8.2-1 summarizes the design verification approach in terms of major test verification requirements and method of requirement satisfaction. Figure 8.2-1 presents a summary schedule of the total 320A-3A/320AE-3A Vehicle Test Program.

8.2.1 Ground Test Articles - Type and Description

8.2.1.1 Propulsion Test Vehicle (PTV)

Since the two main stages are identical in terms of Structure and propulsion subsystems, the PTV for this program consists of one stage only as described in Part I, Paragraph 8.2.1.1

8.2.1.2 Structural Test Article (STA)

Although the 320A-3A configuration has twin stages the STA will consist of only one of these stages since they are structurally identical. Both the orbiter/stage adapter and the interstage adapter will be included in the main stage STA, forming an assembly 24 feet long by 15 feet wide. Other details of the STA are the same as described in Part II, Paragraph 8.2.1.2.

The Apogee Kick Stage (AKS) STA is as described in Part I, Paragraph 8.2.1.2.2.

8.2.1.3 Integrated Avionics Testing

8.2.1.3.1 Main Stage (MS) Avionics Hardware and Software

The integrated avionics hardware and software testing for the 320A-3A/320AE-3A is the same as described in Part I, Paragraph 8.2.1.3.1. The second stage hardware and software interfaces will be simulated for the IAT program. IAT facility computers, dummy loads and controlled signal simulators will be used to simulate the second stage avionics where concurrent functional operation is required for mission simulation

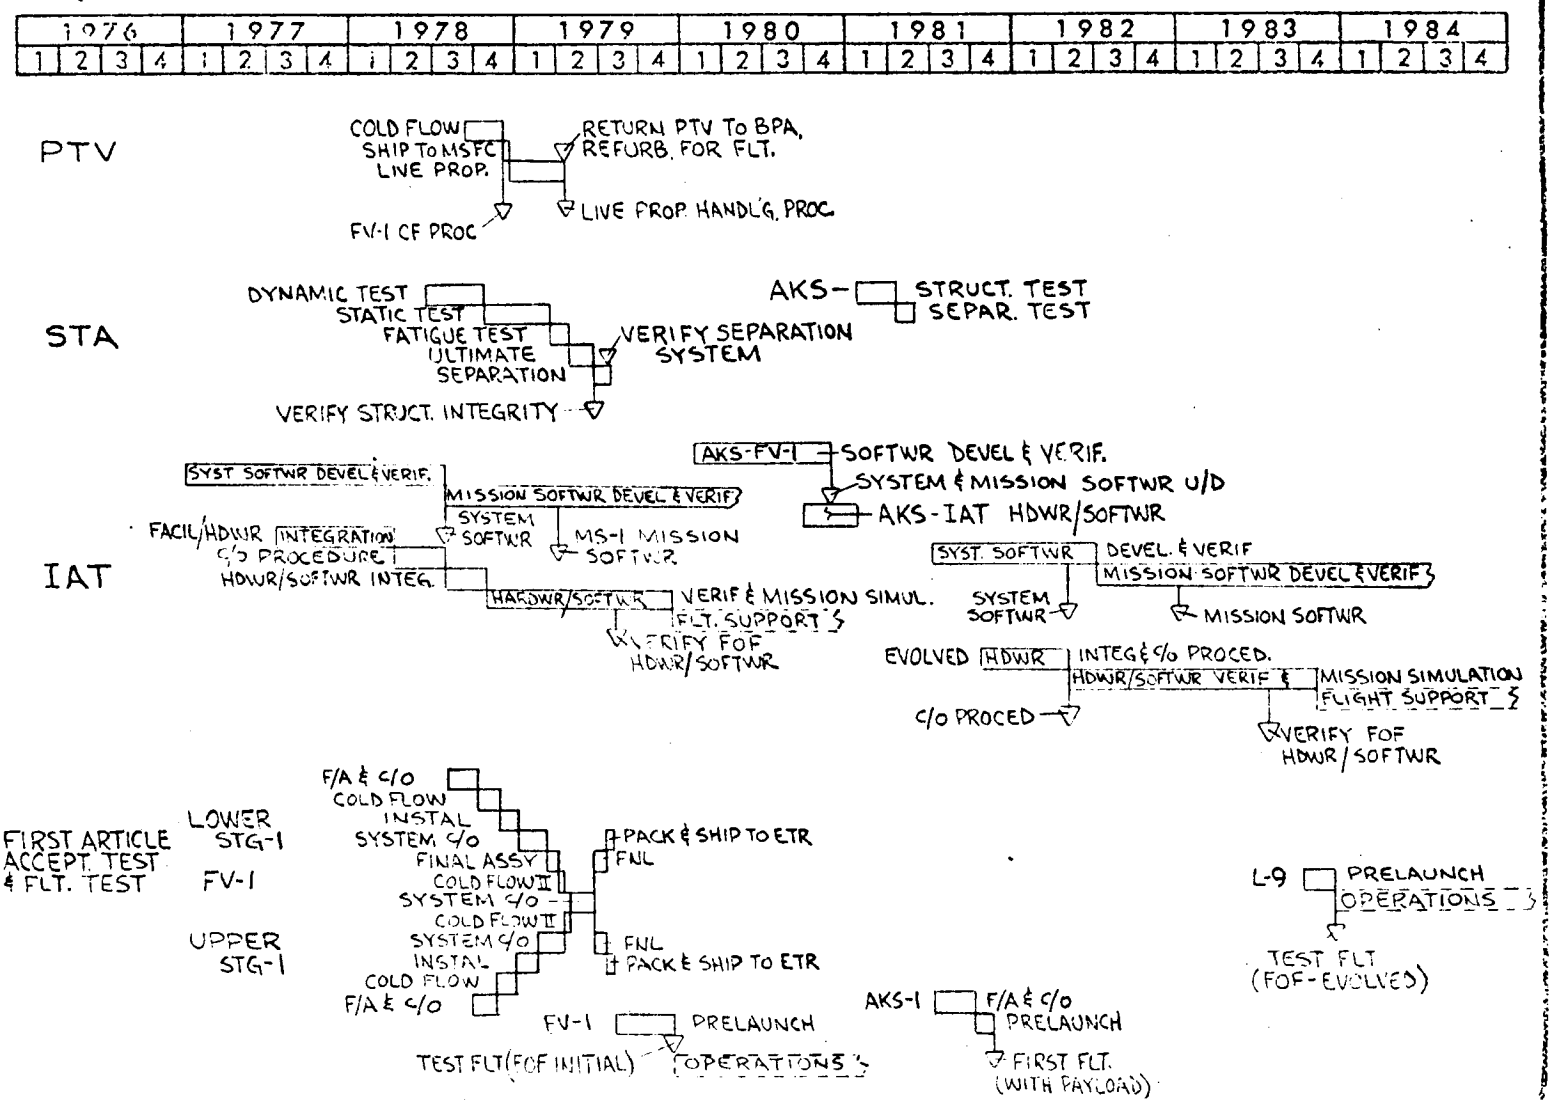

FIG. 8.2-1 320A-3A/320AE-3A VEHICLE TEST SCHEDULE

8.2.1.3.2 Apogee Kick Stage (AKS)

A breadboard of the Apogee Kick Stage will be integrated in the IAT facility and tested as described in Part I, Paragraph 8.2.1.3.2

8.2.1.4 Mockups

Mockups will be provided for all elements of this configuration as described in Part I, Paragraph 8.2.1.4.

8.2.2 Flight Test Article - Description

Since the flight test program for this configuration will include a single stage Tug flight test without payload, only the lower stage will be provided as described in Part I, Paragraph 8.2.2.1. The AKS flight test article is as described in Part I, Paragraph 8.2.2.2.

8.2.3 Ground Test Program

This section describes the major elements of the vehicle ground test program. The test programs described in the following paragraphs include the Propulsion Test Vehicle (PTV), Structural Test Article (STA), Integrated Avionics Testing including software development, and mockups required in support of program requirements.

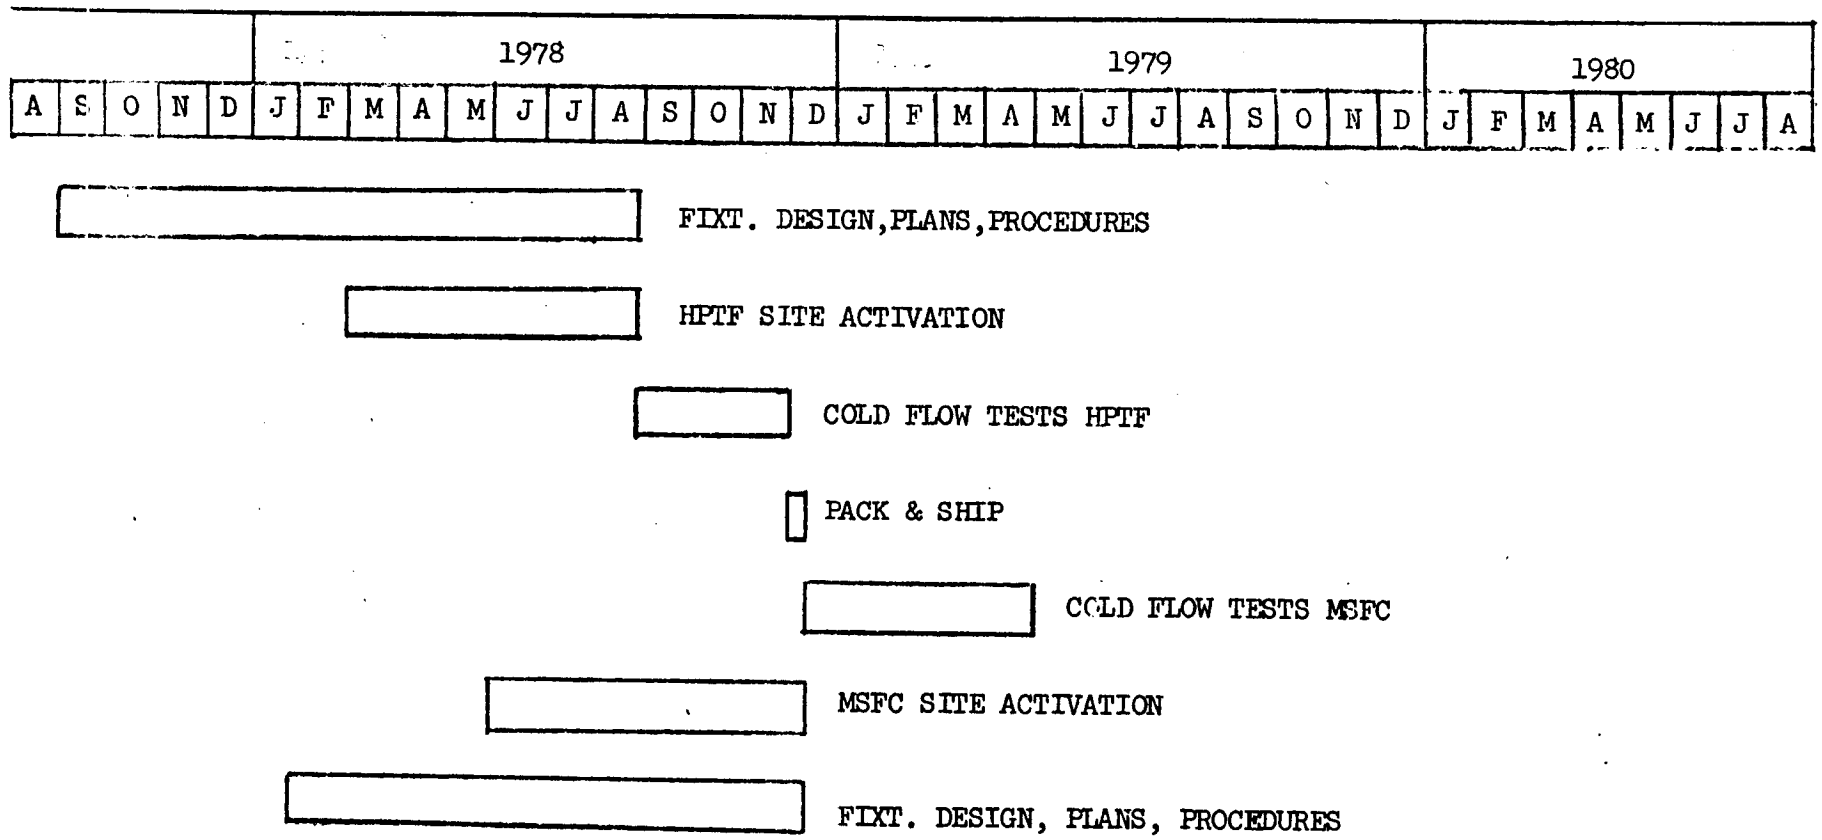
8.2.3.1 Propuslion Test Vehicle Program

The single article Propulsion Test Program is as described in Part I, Paragraph 8.2.3.1. The test schedule and manloading is shown in Figure 8.2-2. AKS SRM development and qualification will be accomplished at the engine contractors facilities as described in Part I, Paragraph 8.2.3.1

8.2.3.2 Structural Test Article (STA) Program

8.2.3.2.1 Main Stage

Since only one of the main stages will be tested the test program is essentially as described in Part II, Paragraph 8.2.3.2.1. The test schedule and manloading are the same as that shown in Part I, Figure 8.2-3 except the test program starts in June 1978.



MANPOWER 1 1 2 2 3 5 7 10 16 15 18 24 35 41 44 40 33 29 28 15 7 TOTAL 377 MM

Figure 8.2-2 320A-3A/320AE-3A PTV TEST SCHEDULE & MANPOWER

8.2.3.2.2 Apogee Kick Stage (AKS)

The AKS STA program is as described in Part I, Paragraph 8.2.3.2.2. The test schedule and manpower is as shown in Part I, Figure 8.2-4.

8.2.3.3 Integrated Avionics Test Program

8.2.3.3.1 Main Stage (MS) Avionics Hardware and Software

The integrated avionics test philosophy and test program for the 320A-3A/320AE-3A is essentially the same as described in Part I, Paragraph 8.2.3.3.1. The second stage avionics for this configuration is similar to the first stage and from a hardware viewpoint will be simulated for IAT. The ASDL will be used for development of software for both stages and the same set of MS avionics hardware will be used in the IAT for mission simulation for each stage. The evolution of this configuration to include retrieval capability will be incorporated into the IAT and ASDL facilities. System Hardware/Software verification and mission simulation will be performed for the evolved configuration in the IAT facility.

The test schedule and manloading are shown in figure 8.2-3. Test logic and constraints are the same as those described for configuration 110A.

8.2.3.3.2 Apogee Kick Stage (AKS)

A breadboard of the Apogee Kick Stage will be integrated into the IAT facility and tested as described for configuration 110A.

The schedule for the AKS avionics is also shown in figure 8.2-3.

8.2.3.4 Mockups

The 320A-3A/320AE-3A mockup program is essentially as described in Part I, Paragraph

8.2.4 Flight Test Program

This section describes the flight test program for the 320A-3A/320AE-3A configuration. In addition, the section also includes a description of the vehicle level factory and launch site test and checkout approach. In order to maintain continuity the section begins with the checkout and test approach and follows with the discussion of the flight test program.

8.2.4.1 Flight Vehicle Checkout and Test

The philosophy and objectives of the flight vehicle ground test program are the same as those described in Part I, Paragraph 8.2.4.1

The Factory Testing of the first 320A-3A contains the same tests as the 110A-1, except that two stages are staggered through fluid and subsystem checkout avoiding the need for two sets of checkout equipment. The final plugs out system check is performed on the two stages together to demonstrate the ability of the electrically isolated stages to mate (structure to structure electrical continuity) without adverse effect on system operation. Subsequent stages will be tested as independent vehicles with the same basic flow as the 110A-1 main stage.

The pre launch testing initially includes a single stage only and is as that described in Part III, Paragraph 8.2.4.1.

The facilities and equipment requirements are the same as those described in Part I, Paragraph 8.2.4.1.4 except for the addition of fuel cell related GSE.

The factory Test Schedule and Manpower Requirements are shown in Figure 8.2-4 while the prelaunch schedule and manpower is the same as described in Part III, Figure 8.2-6.

The AKS schedules and manpower requirements for first vehicle factory flow and prelaunch are the same as those described in Part I, Figures 8.2-9 and 8.2-10 respectively.

8.2.4.2 Flight Test

Since the first year of 320A-3A operations includes single stage deploy only flights, First Orbital Flight (FOF) will be a dedicated flight test using only one main stage essentially as described in Part I, Paragraph 8.2.4.2.

There will be a total of nine additional operational flights for the 320A-3A/320AE-3A configuration from which flight test data will be obtained. Six data flights are planned for the initial configuration and three for the evolved.

FIGURE 8.2-4

Introduction of single stage retrieval will be accomplished during an operational deploy only flight in 1983. A telescoping test fixture deployed from the Shuttle will serve as the retrieval target. Two stage round trip operations will be demonstrated during a normal operational flight in 1984. Flight test data will be acquired during the first two years of 320AE-3A operations via the installed DFI system. Flight test data will be obtained, as a minimum, on the following operationa flights:

(3) Single payload deploy - single stage
(1) Multi payload deploy - single stage
(1) Single payload deploy - single stage with AKS
(1) Single payload deploy - two stage
(1) Retrieval demonstration - single stage
(1) Round trip - single stage
(1) Retrieve/round trip - two stage

The flight test schedule and test program costs are shown in Figure 8.2-5.

8.2.5 Analysis of the Test Program

8.2.5.1 Key Elements

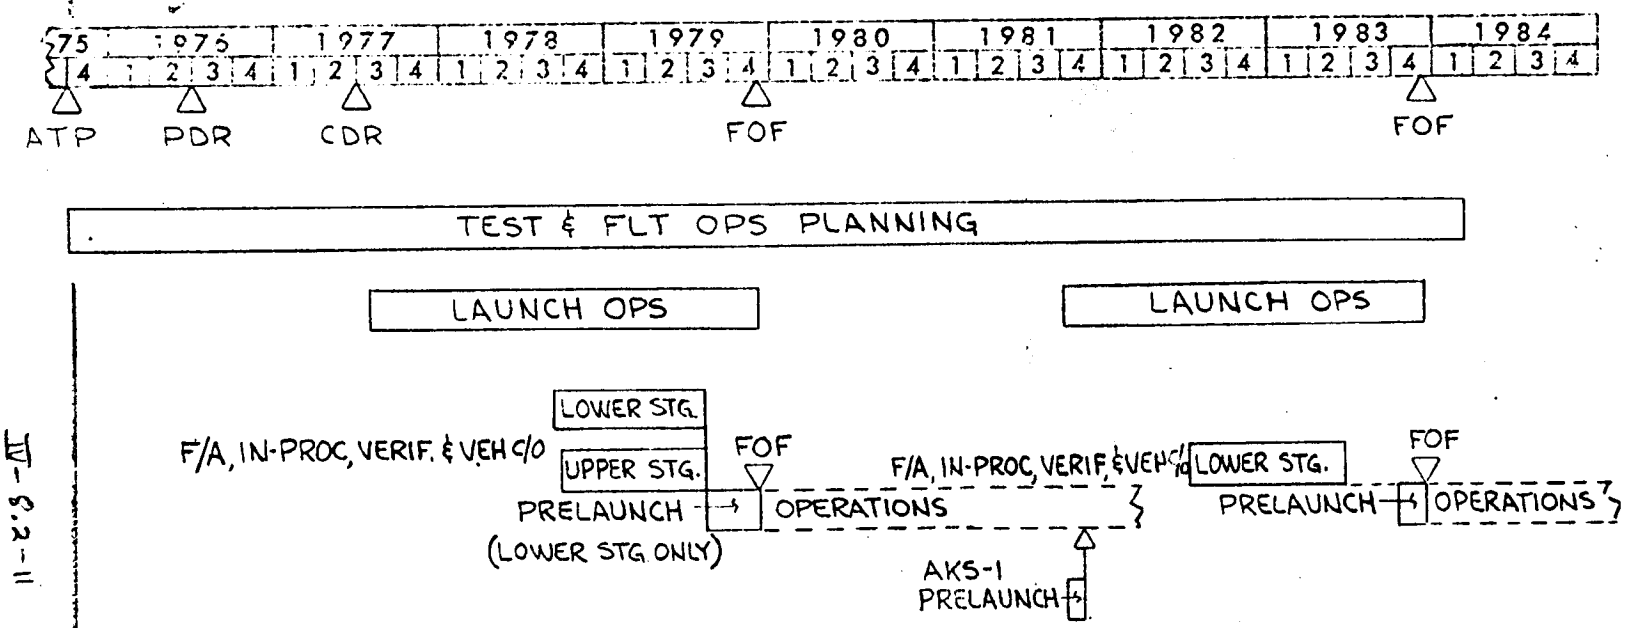
The analysis of the key elements of the test program for the 320A-3A configuration is basically as described in Part I, Paragraph 8.2.6.1. The following summary highlights only those new issues arising from the two stage operational mode and the evolved 320AE-3A configuration.

- No System Level Hot Firing Tests:
  As described in Part I

- Dynamic Static and Fatigue Tests performed on a single STA:
  As described in Part I

- Use of a Single STA program to cover both the Basic and Evolved Configuration:
  As described in Part III

- Integrated Avionics Testing Accomplished in two separate yet Complimentary Facilities:
  Essentially as described in Part III except that the evolved configuration will contain Level III a autonomy through all program phases



FLIGHT TEST PROGRAM COST

- FLIGHT TEST HARDWARE: 1 MAIN STAGE + DFI
- FLIGHT TEST MANPOWER (FOF ONLY)
  - TEST OPS: $3.74 M
  - LAUNCH OPS: $1.84 M
  - FLIGHT OPS: $2.36 M
- CONSUMABLES (FOF ONLY): $31 K

FIGURE 8.2-5 - FLIGHT TEST PROGRAM SCHEDULE (320A-3A/320AE-3A)

- One Dedicated Flight Test Minimizes Risk of Losing Tug/Payload:
  The main stage flight test program for the 320A-3A configuration is essentially as described in Part I, Paragraph 8.2.6. Demonstration of retrieval will be accomplished as part of a single stage 320AE-3A deploy only mission and will not require a separate dedicated flight test. The retrieval target could involve an extension boom mounted to the Orbiter of the variety used to deploy solar panels

- No System Level Thermal Vacuum Test
  As described in Part I.

8.2.5.2 SR&T Assumptions

The basic assumption for the 320A-3A/320AE-3A SR&T requirements are described in Part I, Paragraph 8.2.6.2. SR&T requirements, test programs affected and a brief description of the interaction with the test programs affected is summarized in Table 8.2-2.

8.2.5.3 Reusability Demonstration

Reusability demonstrations are as described in Part I, Paragraph 8.2.6.3.

8.2.5.4 Life Verification Tests

Life verification tests are as described in Part I, Paragraph 8.2.6.4

TECHNOLOGY REQUIREMENTS	TEST PROG. AFFECTED	REMARKS
Main engine life and high performance	o GFE eng. devel. prog. o Flight test prog.	Early life verif. of eng. components and area ratio nozzle performance assures phase C/D engine development. PTV is not affected since eng. is not required. FOF could tolerate slightly reduced eng. performance.
PFR helium tank		Early verif. of low weight PFR tank assures maximum tug performance.
Materials compatibility Data	o Tank qual o STA prog. o PTV prog.	Early verif. of material compatibility with MMH and N_2O_4 assures on-time development of main stage tankage including tank qual. STA and PTV testing.
Fracture Mechanics data	o Tank qual. o STA prog.	Early fracture mechanics data allows on-time development of structural subsystem including tankage quals and STA testing.
Heat Pipes	o Flight test prog.	Early verif. of heat pipe design approach allows on-time developments of Thermal Control Subsystem thereby maximizing Tug performance.
Advanced IMU	o Integrated avionics o Flight Vehicle Factory checkout o STA	Early devel of Advanced IMU will assure on time devel of software and integration procedures in the IAT LAB for FLT VEH buildup and test and accurate simulation for STA prog.
Graphite Composite	o STA Prog.	Early Devel of graphite composite honeycomb face sheets assures that STA program progresses as planned.
Laser Radar	o Integrated Avionics o Flight Vehicle factory checkout o STA	Early devel of light weight low power Laser Radar will assure on time development of software and integration procedures in the IAT LAB for FLT VEH buildup & test and accurate simulation for STA program.

Table 8.2-2 SR&T Assumptions
(Page 1 of 2)

TECHNOLOGY REQUIREMENTS	TEST PROG. AFFECTED	REMARKS
2-Position Main Engine Nozzle	o GFE eng. Devel. prog. o Flight test	Early assurance of 2-position feasibility assure eng. develop and viability of 2 stage configuration. Delay in devel could severely curtail initial ops.
Advanced Fuel Cell	o Fuel Cell Qual o Integrated Fuel Cell/ Feed sys. test	Early devel. of light weight high power fuel cell assure on-time completion of fuel cell qual and integrated tests.

SUMMARY

320A-3A/320AE-3A - GROUND TESTS

Vehicle Test Program

The vehicle test program for 320A-3A/320AE-3A was developed in a similar manner to that described for 110A-1

Structural Test Article (STA)

Since the two 320A Main Stages are basically structurally identical only one MS STA will be tested. The STA program for this configuration is essentially the same as that described for the 110A STA. The 320A STA will be configured to include the evolved 320AE-3A avionic retrieval hardware and mechanical interfaces, and testing will envelope both configurations.

Propulsion Test Vehicle (PTV)

The PTV and AKS propulsion test programs for this configuration are the same as those described for the 110A configuration. The two-position nozzle will be developed and qualified along with the engine at the engine contractors facility.

320A-3A/320AE-3A GROUND TEST (Cont'd)

Integrated Avionics Test

The 320A MS and AKS integrated avionics test program is the same as described for the 110A configuration. The second stage will be simulated for the IAT software verification and mission simulations. The retrieval capability will be incorporated in the IAT facility and ASDL software as it is developed. IAT testing for the evolved system will include hardware and software verifications and mission simulations.

Mockups

The mockups required for the 320A MS and AKS are the same as the mockups described for the 110A configuration and includes all stages. Installation of the evolved configuration hardware will be verified using the MS mockup.

320A-3A / 320AE-3A FLIGHT TESTS

320A-3A/320AE-3A FLIGHT TESTS

10 flights are included in the 320A-3A/320AE-3A Flight Test Program. Since the first year of operations for 320A-3A includes single stage deploy only flights, FOF will be a dedicated flight test using only one main stage in a manner similar to that described for 110A-1. Single stage multi deploy, single stage with AKS and two stage deploy missions will be introduced incrementally during the second year of operations to demonstrate a build-up in Tug flight modes and operations. Flight test data will be acquired via the DFI during these payload deploy operational missions. Introduction of single stage retrieval (320AE-3A) will be accomplished during an operational deploy only flight in 1983 using as a retrieval target a telescoping test fixture deployed from the Shuttle. Two stage round trip operations will be demonstrated during a normal operational flight in 1984. Flight test data will also be acquired during the first two years of 320AE-3A operations via the installed DFI system.

8.3 Facilities Plan - Option 3A - Concept 320A-3A/320 ARE-3A

8.3.1 Manufacturing Facilities

Same as concept 110A-1 except 39,900 sq. ft. of floor space is required for fabrication and assembly of the TUG.

8.3.2 Test Facilities

Same as concept 110A-1.

8.3.3 Operations Facilities

Same as concept 110A-1 except TUG Maintenance Facility at ETR will have 6 horizontal stations in a 18,000 sq. ft. addition to the Shuttle OMS Facility. TUG Maintenance Facility at WTR will have 4 horizontal stations in a 12,000 sq. ft. addition to the Shuttle OMS Facility.

STORABLE SPACE TUG

8.4 Vehicle Manufacturing

This section establishes the requirements for the 320A-1/320AE-1 spacecraft including the assembly sequence, tooling, schedule, manufacturing test, special processes and facilities.

The spacecraft is a two stage vehicle with apogee kick stage. Each stage of the spacecraft is interchangeable and can be used as the first or second stage of the stack by replacing adapter fittings. Manufacture of the stages is the same as the single stage vehicle with the basic diameter reduced from 10 feet to roughly 8 feet. A special adapter to the orbiter is required and so is an interstage structure. Each spacecraft has nested titanium propellant tanks and a composite honeycomb outer shell. The orbiter adapter and interstage construction use aluminum sheetmetal substructure and a composite honeycomb outer shell.

8.4.1 Plan/Flow/Time

The assembly breakdown of the two stage Tug is shown in figure 8.4-1. The manufacturing sequence is the same as the single stage vehicle discussed in Part II Section 8.4. A major problem with the two stage vehicle is that two sets of weld assembly tooling and additional assembly/checkout stations are required to meet early schedule committments. The typical manufacturing flow and master schedule are shown in Figure 8.4-2 and 8.4-3 respectively.

8.4.2 Tooling Requirements (including GSE)

Tooling requirements are the same as discussed in Part II Section 8.4.2 however an additional set of weld fixtures and another final assembly fixture are required.

8.4.3 Facility Requirements

The two stage vehicle requires additional floor space in structural and final assembly areas as shown in Fig. 8.4-4. Supporting areas in Plant 2 and 3 and cold flow (HPTF) will be the same as discussed in Part I section 8.4.3.

8.4.4 Special Requirements

See Part II Section 8.4.4

8.4.5 Summary Analysis/Philosophy

See Part II section 8.4.5

8.4.6 GSE Requirements

See Part I section 8.4.7

8.5 320A-3/320AE-3A SPECIAL PROGRAMMATICS

The salient features defined for implementing and managing Program 320A-3A/320AE-3A include: defining the initial/evolved flight build up based on Shuttle/Tug launch constraint and ground crew launch capability; implementing 3 lot production (deploy, deploy-upgrade and retrieve); developing common upper stage and lower stage subsystems; using lower stage to perform single stage payload deploys; refurbishing the propulsion test article for operational use; and defining a fall back position for every identified risk.

Specific areas for government participation include: establishing Tug/Shuttle interface requirements before Orbiter design freeze; providing payload interface design requirements and mission model data; initiating required activities for supporting Research and Technology; providing GFE systems and components (eg: main engines, and DOD secure comm); supporting propulsion system testing and development and supporting as integrated avionics hardware testing and related software development; providing required facilities; performing vehicle ground operations, and logistic support operations.

320A-3A/320AE-3A SPECIAL PROGRAMMATICS

- o PROGRAM IMPLEMENTATION AND MANAGEMENT
  - INITIAL/EVOLVED FLIGHT BUILD-UP SET BY SHUTTLE/TUG LAUNCH CONSTRAINTS AND GROUND CREW LAUNCH CAPABILITY
  - 3 LOT PRODUCTION (DEPLOY, DEPLOY-UPGRADE, AND RETRIEVE) TO AVOID MFG GAP
  - COMMON UPPER/LOWER SUBSYSTEMS
  - LOWER STAGE USED AS SINGLE STAGE
  - PROPULSION ARTICLE REFURBED FOR FLIGHT
  - FALL BACK POSITION SHOWN FOR EVERY IDENTIFIED RISK

- o AREAS FOR GOVERNMENT PARTICIPATION
  - FIRM TUG/SHUTTLE INTERFACES BEFORE ORBITER PDR
  - PROVIDE PAYLOAD INTERFACE DESIGN REQUIREMENTS AND MISSION MODEL DATA
  - INITIATE REQUIRED SR&T
  - SUPPORT SYSTEM TEST - AVIONIC HARDWARE/SOFTWARE, PROPULSION
  - PROVIDE GFE SYSTEMS AND COMPONENTS, FACILITIES, LOGISTIC SUPPORT
  - PERFORM VEHICLE GROUND AND FLIGHT OPERATIONS

GRUMMAN

8.6 COST DATA

Included in this section are the cost data for an evolved tug configuration 320A-3A/320AE-3A. Cost data are provided for the initial program 320A-3A and the combined total evolved program.

- Initial Program 320A-3A
  - Storable Space Tug System Project Expected Cost-Spares Cost (INT & OPS)-First Unit Cost (Data Forms A1, 2 and 3, subparagraph no's 8.6.1, 8.6.2 and 8.6.3) (Computer P/O)
  - Storable Space Tug Funding Schedules-DDT & E, Production and Operations (Data Form C, subparagraph 8.6.4, 8.6.5, 8.6.6 and 8.6.7)
  - First Unit Production Cost per WBS (including Avionics to level 7) Main Stage and Auxiliary Stage(s), (subparagraph 8.6.8)
  - Form B (Technical Characteristics subparagraph 8.6.11)
- Combined Evolved Program 320A-3A/320AE-3A
  - Same as initial program plus:
    - Average Cost/Flight (subparagraph 8.6.9)
    - Storable Space Tug System Project Cost Estimate data by SOW-DDT & E, Production and Operations (Data Form T (SOW'S) subparagraph 8.6.10)

320A-3A/320AE-3A FLIGHT OPERATIONS BUILDUP

The 320A-3A/320AE-3A flight buildup is defined with the same methodology used in 310-3A/310RE-3A, ie considering: NASA defined Shuttle/Tug launch constraints, initial and evolved ETR ground crew launch capabilities, and flight mode buildup.

However, in this program a slightly larger ground crew had to be used to accommodate multiple stages during the buildup from 3 flights in 1980 to 18 flights in 1982. During the evolved period the same crew size was increased to handle the higher flight rate needed for 1986.

During the flight buildup period we recommend that initial/evolved flight crew experience be developed by starting with the simplest flight mode and then progressively introducing the more complex flight modes required for 1982 and beyond.

Our recommended flight buildup for 320A-3A/320AE-3A, including 3 flights in 1980, 15 flights in 1981, and 30 flights in 1984, encompasses 301 total flights through 1990 or 24 less than 100% payload capture traffic.

8.9 Risk Assessment

In making an assessment of the risk associated with each configuration in each capability option we have considered the type of technology items associated with each vehicle and the impact that it would have on the program if, for one reason or another, the item would be unavailable and an alternative solution would be required. The impact is defined, usually, in terms of added weight, lost performance and total program cost increase; in some cases the impact can be decreased weight or reduced cost.

It is assumed that all of the weight increases and all of the cost increases will occur simultaneously without benefit of any offsetting decreases in either weight or cost. For example in configuration 110A-1 we have assumed that the +4 lb. weight impact of abandoning spun aluminum tanks in favor of welded aluminum tanks is combined with a $10.0 million cost increase as a result of abandoning aluminum tanks in favor of titanium tanks due to materials compatibility or fracture mechanics issues.

Taking the summation of all the weight increases, these are converted to costs by using the $75K/lb. figure derived when we were first selecting subsystem options for incorporation with 110A-1. The $75K/lb. number represents the last step (actually the slope of the line) in our subsystems synthesis process which provides a curve of Δ weight versus Δ total program costs as we added lighter and more costly subsystems options to achieve a behicle with 3500 lb. deploy capability. In this manner we arrived at a estimate of the costs expected if we had to recover the weight growth.

In similar fashion we then summed all of the potential cost increases, ignoring any offsetting cost decreases, and added these to the dollars representing the weight increases. The 110A-1 has no projected performance loss since it uses the OME 7.5K engine; the assumption is that the basic OME will have been developed to meet its weight, performance and reusability goals for the Shuttle Orbiter. In the case of configurations which use the Class I engine, for example 410AD-2, we have assumed that a 3 second Isp performance loss is possible. To convert this performance loss to costs we use the payload sensitivity factor to loss in Isp (97 lbs/sec), divide this by the payload sensitivity to inert weight and then multiply by $111/lb. to convert it to costs.

Taking all of the costs and adding them together we get a total low cost risk value of $15.3M for 110A-1 which ranges to a high value of 94.3M for 320A-3A/ 320AE-3A.

320A-3A/320AE-3A RISK ASSESSMENT

- COST RISK
  - POTENTIAL Δ COST $94.3 M

HIGH RISK PROGRAM

RISK ASSESSMENT 320A-3A/320AE-3A

The following items and their potential impact are shown on the opposite chart. The Class I engine is a new design based on current technology with the exception of the uncertainty in engine life and in the predicted performance with the high expansion, 2-position nozzle used. The 2-position, radiation cooled nozzle is itself a technology issue which complicates and increases the risk associated with the development of this engine. It is estimated engine performance can be low by 3 seconds Isp and engine nozzle/actuation system weight can increase by 10 lbs.

All existing weight reduction options have been incorporated into this vehicle; if any or all of these options fail to meet their goals there are no lighter weight alternatives available; the only recourse is to incorporate the Class II engine at a $72M cost increase, and to initiate a super weight reduction program (SWIP) down to the piece-part by piece-part level.

Although the proposed SR & T programs protect against schedule slippage by virtue of being completed at ATP, the availability of both the main engine and the advanced fuel cell remain schedule risk items.

Converting the potential weight increases to a total program cost at a $125K/lb value and adding to that the potential cost increase items, yields a total cost risk of $94.3M for 320A-3A/320AE-3A.

RISK ASSESSMENT 320-3A/320AE-3A

TOTAL COST RISK ----------		$94.34M

Section 8.10 Supporting Research and Technology

This section includes a summary matrix chart which identifies all of the SR & T items and where they are applied to each configuration in each capability option.

Following the summary matrix there are individual tables for each configuration which summarize the technology items for that particular configuration and give a very brief synopsis of the type of SR & T program proposed and the estimated funding and schedule requirements. The text following each table is the facing page text prepared for the main presentation.

Following the tables for each configuration, an additional form is filled out for each technology item providing status information, justification for the proposed SR & T program, objectives, technical approach, and a more detailed schedule showing when the proposed program must be completed in order to support the particular configuration.

In dealing with the subject of SR & T we have identified two distinct groups - one where technology is needed and the other where there is no doubt that the technology is available and it is a straightforward engineering task to accumulate data that will preclude making a "false start" where several alternates are under study; we have called the latter group "desired data".

The storable Tug will benefit from the fact that the APOLLO LM program has used similar materials, propellants, equipments and procedures; the Shuttle Orbiter will expand on this data base for the Tug. The low number of identified SR & T items and the modest sums projected are based on the assumption that several existing or planned efforts related to the Shuttle will continue to provide data. These include the planned propellant and materials compatibility testing in support of the Shuttle Orbital Maneuvering Subsystem, its engines, tanks and components both at NASA/WSTF and at the Shuttle contractor's facilities. In addition, we have identified the Air Force funded efforts to develop the advanced Micron IMU for aircraft programs, as an effort which we would build-on rather than to start from scratch.

We have not attempted to detail the SR & T programs required on the Class I engine (with or without the two position nozzle) except to point out the uncertainty associated with the anticipated engine life and the predicted performance of very high expansion ratios within the mixture ratio of interest. The engine contractor will provide the proposed SR & T efforts required on the engine and we will provide comments on same at NASA's request.

The overall "message" which we hope will become obvious to the reader is that there are no real "show-stoppers" among the SR & T items identified.

TECHNOLOGY REQUIREMENTS AND DESIRED DATA - 320-3A/320AE-3A

The upper part of the facing chart contains the supporting research and technology (SR&T) items required for 320-3A/320AE-3A; the lower part of the chart contains what we have termed as "desired data". The distinction between the two is that the "desired data" items do not require technology but are considered straightforward engineering development tasks to produce design data prior to Tug program go-ahead (ATP); this will preclude impacting Tug schedules should the data indicate the desirability of an alternative approach, (vis., aluminum or stainless propellant tanks rather than titanium.

Excluding the SR&T on the Class I engine with its two-position nozzle, the total SR&T funds requested for 320-3A/320AE-3A is $3,290 K to be expended over a 24 month period culminating at Tug ATP or prior to go-ahead on the evolved Tug. The advanced fuel cell is the long lead item (24 months) followed by the advanced (Micron) IMU (18 months). The unusually large sum for the advanced fuel cell ($2,000 K) is the result of compressing the SR&T program to support advanced fuel cell availability prior to Tug ATP.

The SR&T for the Class I engine with a two-position nozzle will be provided by the engine contractor.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Avionics (CN&C)
(Discipline)

TITLE Low Weight/Power, (Rendezvous and Docking) Laser Radar WBS No. 320-03-03-02

STATUS ITT-Gilfillan has been under NASA Contracts since 1964 to design, develop, build, and test various spaceborne laser radar systems. The third generation system will be delivered in late November 1973.

JUSTIFICATION The application of the above developed technology to meet specific space tug rendezvous and docking requirements is desired.

In addition in order to improve the payload capability of the storable tug, low weight Avionics equipments (specifically, low weight/low power laser radar) are required.

OBJECTIVES To design, develop, fabricate, and test a low weight, low power, rendezvous and docking laser radar.

5-01.8-II

TECHNICAL APPROACH Using Tug requirements, design for light weight, low power by using new components, lighter mirror drives and improved optics

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Main Propulsion (Discipline)

TITLE Prestressed Filament Reinforced (PFR) Tanks WBS No. 320-03-04-02

STATUS Structural Composites Industries, Inc. (SCI) and Arde-Portland, Inc. are under contract to LeRC to demonstrate the feasibility of the PFR tanks. This program will result in the construction of a 24 in. diam. Ardeform PFR tank of the type assumed by our study. If successful the basic technology will be proven.

JUSTIFICATION

A PFR ambient helium storage tank is comparable with the weight of a SHe tank and its associated heat exchanger. It provides a simple and less operationally complex system compared to the SHe tank. The PFR tank also provides a leak-before-burst design which results in increased Tug safety.

OBJECTIVES

Design, fabricate, and test 3 to 6 PFR tanks to demonstrate that current manufacturing and quality control techniques are adequate to produce a reliable, low weight tank suitable for containing gaseous helium (or hydrogen and oxygen in the case of fuel cell reactant tanks). The program will resemble a pre-qualification test program which will demonstrate the ability of the PFR tank to undergo the dynamic loading, compatibility, environmental exposure and etc. tests required for acceptance as a flight item.

TECHNICAL APPROACH

Fabricate 3 to 6 tanks and subject them to a pre-qualification test program to demonstrate the maturity of the design.

MANPOWER 2 man years FUNDING $125,000

TITLE ADVANCED FUEL CELLS - WBS No. 320-03-03-05

STATUS NASA-Lewis & AF-Aero Propulsion Lab are supporting advanced fuel cell technology and an aircraft high power fuel cell program, respectively. Total funding for fiscal '72 thru '74 by these agencies ~ $1.5 million. The supporting program that is recommended is in addition to the on-going contracts.

JUSTIFICATION

Significant improvement is required in the development of long life, high energy density cells resulting in a substantial weight advantage plus improved, simpler maintainability requirements.

OBJECTIVES

To develop a low weight high performance fuel cell with a wide range of power output without voltage degradation, eliminating membrane hot spots. In addition, develop advanced heat & water removal concepts to eliminate components.

II-8-10-9

TECHNICAL APPROACH Increase current density, resulting in decreased electrode area. Replace water separator with jet pump. Replace coolant pump with oxygen driven diaphram pump. Test highly stable long life materials and passive water removal concept.

TITLE Advanced (Low Weight) Inertial Measurement Unit for Space Application

STATUS Advanced Lightweight Unit being developed under Air Force Contract. Primarily for aircraft application.

JUSTIFICATION To improve payload capability of a storable tug, low weight Astrionics Equipments are required.

OBJECTIVES To develop the advanced IMU to the point where it can be used in a space application.

IV-8.10-11

TECHNICAL APPROACH
1. Develop software mechanizations for redundancy management.
2. Develop software and procedures for calibration of gyros on the launch pad.
3. Test the software with the hardware in the lab.

TITLE GRAPHITE/EPOXY HONEYCOMB WBS No. 320-03-01-03

STATUS Graphite/Epoxy honeycomb is well within Grumman's capability; however, the use of .0025" single ply to achieve a buildup to 0.012 face sheets requires further development.

JUSTIFICATION This design provides the lightest weight shell structure.

OBJECTIVES To establish, by test, design allowables for honeycomb structural components using metallic honeycomb core with graphite/epoxy face sheets utilizing 2.5 mil ply thickness to achieve a total face sheet thickness of 12 Mil.

TECHNICAL APPROACH Std. Test specimens will be fabricated using various combinations of ply directions to validate design allowables obtained from classic lamination theory.

TITLE Material Compatibility WBS No. 320-03-01-01-02

STATUS Material compatibility of Ti-6AL-4V STA and 2219-T37 Aluminum alloy in the presence of MMH at temperatures up to 150°F is required. Compatibility of N_2O_4 with 2219-T87 is also required.

JUSTIFICATION Compatibility of propellants with tankage material must be assessed to obtain the reuse life of the tanks under cyclic loads.

OBJECTIVES The objective of the program is to obtain the static and fatigue properties of the tankage parent and weldment materials under cyclic exposure to propellants and load.

TECHNICAL APPROACH Static and fatigue properties of candidate materials specimens will be obtained prior to and after exposure to the propellants. Tests will be performed at R.T. and 150°F.

TITLE Fracture Mechanics Test Data

STATUS Fracture mechanics test data for thin gage (.020 to .040) for Titanium 6AL-4V STA and 2219-T87 aluminum alloy exposed to N_2O_4 and MMH at temperatures up to 200°F is not available.

JUSTIFICATION Fracture mechanics data for thin gage tank material are required to assess the fracture mode and life cycle of the tug propellant tanks.

OBJECTIVES The objectives of the program are to obtain K_{ic}, K_{th} and flaw growth data for parent and weldment materials in the induced thermal environment up to 200°F. Data to be obtained prior to and after exposure to the candidate propellants. In addition to fracture mechanics data, NDE techniques are to be employed on the test specimens to assess flaw detection capability.

TECHNICAL APPROACH Standard fracture elemental specimens are to be employed. Tests are to be employed. Tests are to be conducted at room temperature and at 150 and 200°F. Surface flaws of various sizes are to be used and NDE techniques are to be employed to document size where practical.

TITLE SPACE TUG HEAT PIPES

WBS No. 320-04-02

STATUS

Heat pipes (HP) are currently being used in both ground and space application. The variable conductance heat pipe (VCHP) principle is particularly attractive for Tug application but requires further development.

JUSTIFICATION

The fuel cell and certain high power density avionics units carried on the Space Tug require active cooling. Trade studies which have examined pumped loop radiators, sublimators and various heat pipes have indicated the obvious merits of the variable conductance heat pipe. A VCHP radiator could interface with the pumped loop heat transport system of the fuel cell, eliminating the cost and complexity of a selective stagnation radiator with its associated unreliable automatic bypass valves. A VCHP header, a heat transport device, could provide for high power density avionics heat transport without recourse to the active loop.

OBJECTIVES

Emphasis will be placed on experimentally obtaining the large turn down ratios which appear theoretically achievable and in developing predictive techniques.

TECHNICAL APPROACH

Design, fabricate and test a VCHP radiator and VCHP header and experimentally determine performance with emphasis on turn down ratio and shut off heat flux levels.

8.1.1 SUMMARY PROJECT SCHEDULE

Introduction: The Storable Tug Project schedule was developed to identify the principal project phases and to establish schedule estimates for all hardware and soft ware elements in accordance with the Space Tug Work Breakdown Structure.

The Tug Project Schedule depicts major program milestones and presents project activities at level 5 of the WBS. This schedule establishes the planning baseline for development of the Storable Tug System through design, development, manufacturing, ground test, flight test and operations. It integrates all supporting schedules into an overall project level plan and establishes the sequence and interdependency of activities and events required for the development of an operational Space Tug System.

Groundrules and Assumptions: Following are the ground rules and assumptions used for development of the Storable Tug Project Schedule:

- o ATP is October 1975 at the earliest for Options 1 and 3. ATP for Option 2 to be determined by the contractor.
- o Schedule planning is designed to minimize peak annual funding during DDT&E.
- o Main Stage DDT&E requirements consist of the following major test articles:
  - A structural test article (STA) for dynamic, static and fatigue tests.
  - A main propulsion test vehicle (PTV). Following the completion of live propellant testing the PTV will be refurbished and delivered as an operational flight vehicle.
  - One shipset of Avionics hardware for the Integrated Avionics Test (IAT).
  - A flight test vehicle (MS-1).
- o Operational fleet sizes for each project option are based on a study of traffic capture models.
- o Production rate of vehicles is based on avoiding duplication of major structural assembly tooling and minimizing gaps in manufacturing flow.

- Initial operational capability (IOC) is achieved after completion of one test flight (FOF). IOC dates are as follows:

  Option 1 - December 1979
  Option 2 - December 1983
  Option 3 - December 1979 - initial, December 1983 - evolved.

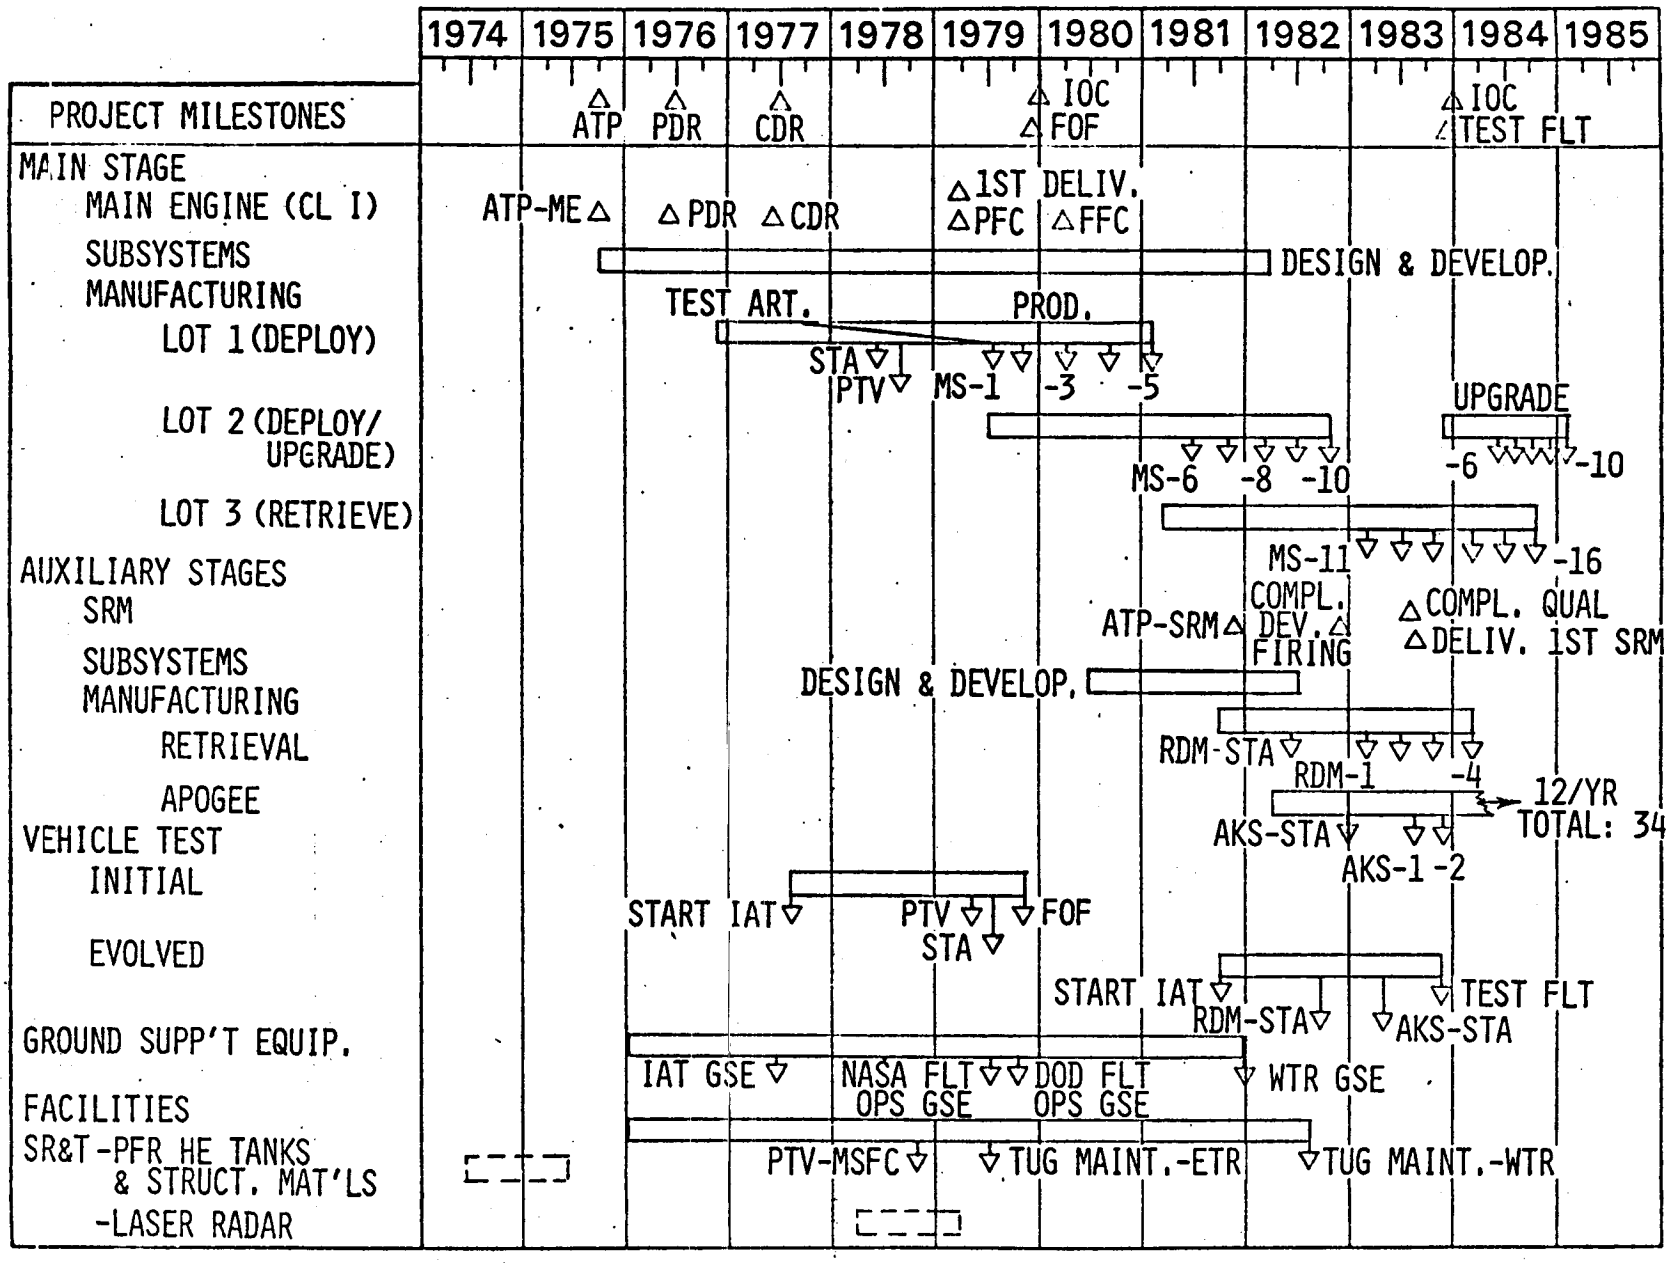
- Maximum number of flights in 1980 is 3, based on the Shuttle traffic model.

Approach: Based on the above groundrules and assumptions a preliminary project milestone schedule was developed to form a baseline for all detail scheduling. Detailed subsystem design and development schedules, manufacturing and factory checkout flows, vehicle test, GSE, facilities, and SR&T Schedules were then developed in conjunction with personnel representing the cognizant management and technical disciplines. These detailed schedules were then summarized and integrated into the Tug Project Schedule through the process of establishing a logical and achievable relationship between the engineering design and development process, procurement of subcontract equipment, hardware fabrication and assembly process and the vehicle test program that minimizes risks and ensures the fulfillment of program objectives. Finally, the major project milestones and activities presented in the Tug Project Schedule were condensed into the Summary Project Schedule.

SUMMARY SCHEDULE - 310-3B/310ARE-3B

The primary elements of the 310-3B/310ARE-3B Project Schedule are as described for 310-3A/310RE-3A except for addition of an Apogee Kick Stage. Authorization to Proceed (ATP) occurs on October 1, 1975 with IOC of the initial configuration target for December 31, 1979. The Class I main engine milestones are the same as for 310-3A/310RE-3A with Final Flight Certification occuring 4 months after First Orbital Flight (FOF). Vehicle tests are essentially the same as for 310-3A/310RE-3A except for the addition of structural testing of the Apogee Kick Stage (AKS-STA). First flight of the evolved vehicle is targeted for December 1, 1983. Main Stage Manufacturing begins December 1, 1976 with production of the major ground test articles and continues through production of 16 vehicles to support fleet operations. These are manufactured in 3 Lots for the purpose of avoiding manufacturing gaps. Development of the Apogee Kick Stage and the Retrieval Delay Module begins in June 1980, with related vehicle tests starting at the same time as main stage evolved vehicle tests. 34 Apogee Kick Stages and 4 Retrieval Delay Modules will be manufactured to support fleet operations. GSE and Facilities are scheduled essentially the same as for 110A-1.

310-3B/310ARE-3B SUMMARY PROJECT SCHEDULE



8.1.2 DEVELOPMENT SCHEDULES

8.1.3 PRODUCTION SCHEDULES

The detailed Project Schedule depicts the total development and production phases for the Main Stage and the Auxiliary Stage(s). The detailed Project Schedule is based on a constraint logic that considers overall program objectives and the detailed interaction of constraints on significant program activities. It provides reasonable margins for development problems and minimizes program front-loading.

The detailed Subsystem Schedules provide an order of magnitude increase in detail from the Project Schedule and depict the subsystem activities in both inhouse and subcontractor areas. Subsystem schedule information is presented at WBS level 6 for Structures, Thermal Control and Orbiter Interface, and at WBS level 7 for Propulsion and Avionics subsystems.

8.1.4 OPERATIONS SCHEDULE

Scheduled and planned for concept 310-3B/310ARE-3B, option 3 are 37 launches per year with 10 days between launches. Ground servicing as shown on the programmatics/cost operations schedule from land to launch is 10 Tug work days and 9 Tug/orbiter work days.

8.1.5 FACILITIES SCHEDULE

Included in the storable space tug facilities schedule for concept 310-3B/310ARE-3B are the various tasks to be completed against major program milestones. The fundamental grouping of these tasks are manufacturing, test, maintenance and refurb-ETR, ETR launch, maintenance and refurb-WTR and WTR launch. Under this Tug concept facilities maintenance extends into 1991, with most of design/construction/activation ending by 1982 in support of WTR launch requirements.

8.1.6 EVALUATION OF MAJOR SCHEDULE DRIVERS (cont'd)

310-3B/310ARE-3B

The project schedule for this option is identical to the 310-3A/310RE-3A schedule except for the following areas: Lot 3 of the Main Stage production consists of 6 vehicles, with MS production ending in January 1985.

In addition to the Retrieval Delay Module an Apogee Kick Stage is developed and ready for deployment by the end of 1983.

8.2 VEHICLE TEST PROGRAMS (310-3B/310ARE-3B)

8.2.0 Test Summary

The approach used to develope the Vehicle Test Program for the 310-3B/310ARE-3B configuration is basically the same as described in Part I, Paragraph 8.1.2. The addition of an Apogee Kick Stage, Retrieval Delay Module, MS Retrieval Electronics and Level IIb autonomy to the Tug program for the 310ARE-3B configuration will also be verified in both the ground and flight test programs.

Table 8.2 -1 summarizes the test verification approach in terms of major verification requirements and method of requirement satisfaction. Figure 8.2-1 presents a summary schedule of the total Vehicle Test Program.

8.2.1 Ground Test Articles - Type and Description

8.2.1.1 Propulsion Test Vehicle (PTV)

The PTV for the 310-3B/310ARE-3B configuration is the same as described in Part I, Paragraph 8.2.1.1.

8.2.1.2 Structural Test Articles (STA)

The structural test article (STA) for this configuration consists of three major assemblies which are tested, as described in Part II, Paragraph 8.2.1.2.

- Main Stage STA(IOC 12/79)
- Apogee Kick Stage (IOC 1984)
- Retrieval Delay Module (IOC 12/83)

The description of the main stage STA is the same as that described in Part II, Paragraph 8.2.1.2.1

There are two auxiliary stages developed for this configuration. The Apogee kick stage STA is the same as described in Part II, Paragraph 8.2.1.2.2. The Retrieval Delay Module STA is the same as described in Part III, Paragraph 8.2.1.2.2.

8.2.1.3 Integrated Avionics Test Facilities

Integrated avionics hardware and software testing for the 310-3B basic vehicle will be accomplished using an IAT and ASDL facility as described in Part I, Paragraph 8.2.1.3.1. As the retrieval capability and level IIB autonomy is incorporated into the MS avionics, the IAT facility and/or ASDL will be updated to reflect these changes.

TABLE 8-2-1

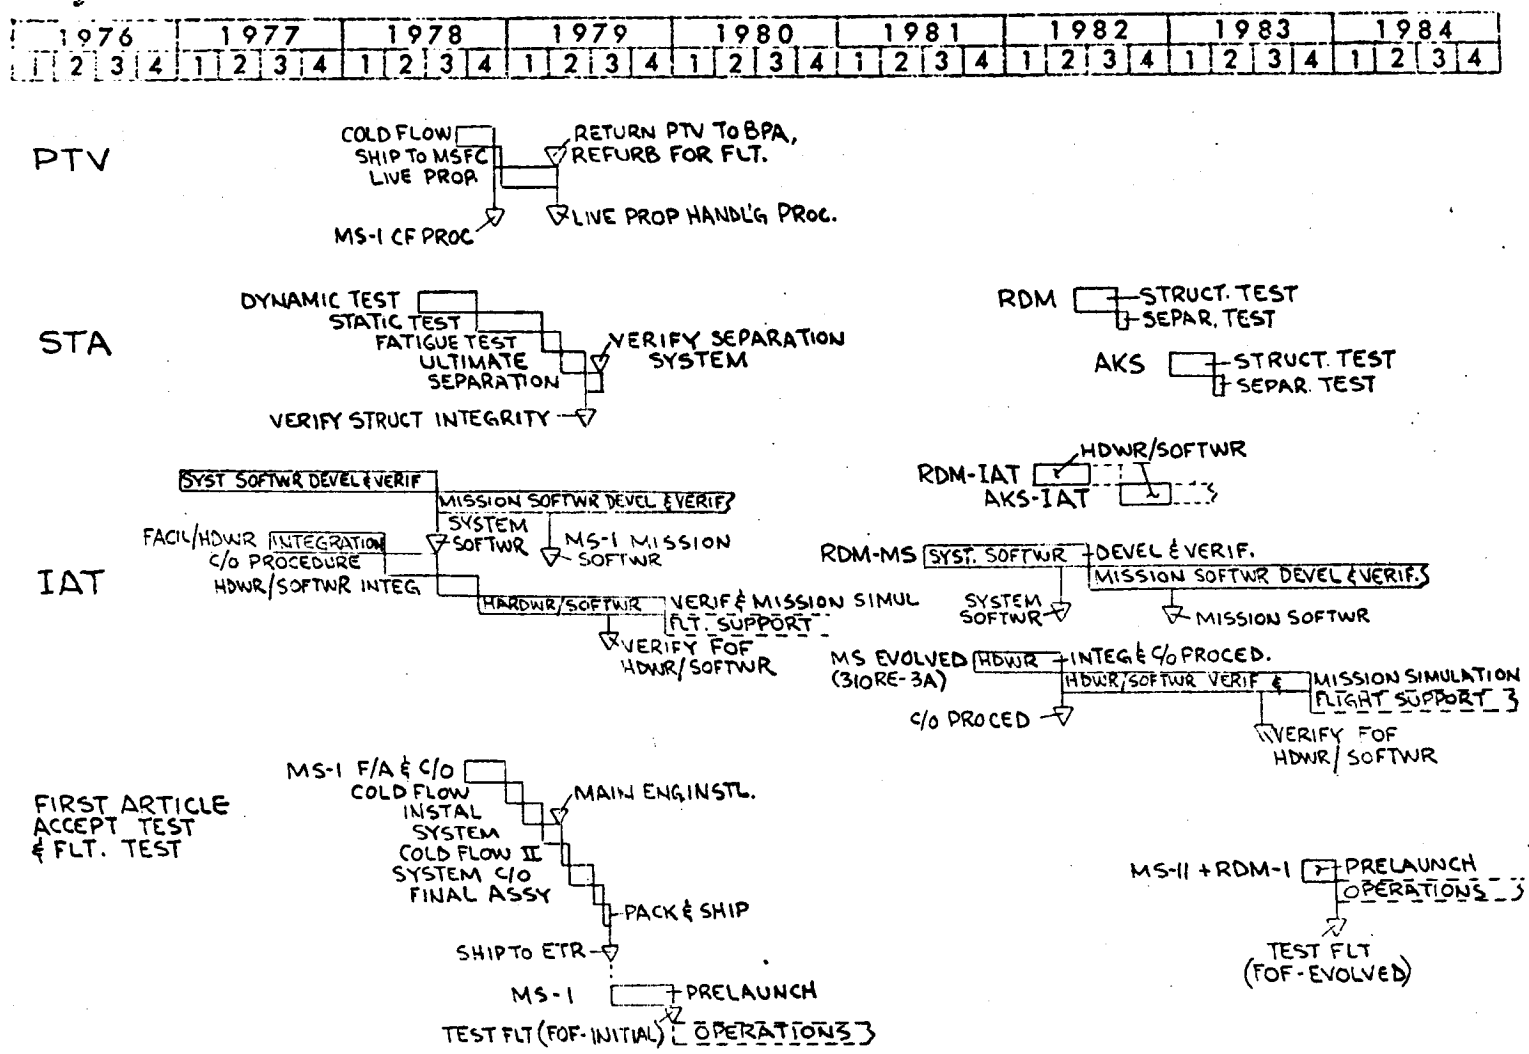

FIG. 8.2-1 310-3B/310ARE-3B VEHICLE TEST SCHEDULE

A breadboard of the Retrieval Delay Module will be integrated in the IAT facility and tested as described in Part III, Paragraph 8.2.1.3.2.

A breadboard of the Apogee Kick Stage will be integrated in the IAT facility and tested as described in Part I, Paragraph 8.2.1.3.2.

8.2.1.4 Mockups

The mockups for this configuration are the same as described in Parts I and III, Paragraph 8.2.1.4.

8.2.2 Flight Test Articles

The Main Stage (MS) Flight Test Article and the Apogee Kick Stage (AKS) Flight Test Articles are as described in Part I, Paragraphs 8.2.2.1 and 8.2.2.2, with the AKS not flight tested until late 1983.

The MS Flight Test Article for the 310ARE-3B configuration is the first flight - configured vehicle with retrieval capability and includes a DFI system.

The Retrieval Delay Module Flight Test Article is the same as described in Part III, Paragraph 8.2.2.2.

8.2.3 Ground Test Program

This section describes the major elements of the vehicle ground test program. The test programs described in the following paragraphs include the Propulsion Test Vehicle (PTV), Structural Test Article (STA), Integrated Avionics Testing including software development, and mockups required in support of program requirements.

8.2.3.1 Propulsion Test Vehicle (PTV) Program

The Main Propulsion System and Auxiliary Propulsion System test program for the 310-3B configuration is the same as described in Part I, Paragraph 8.2.3.1.

8.2.3.2 Structural Test Article (STA) Program

The MS Structural Test Program for the 310-3B/310ARE-3B configuration is as described in Part II, Paragraph 8.2.3.2.1.

The manloading and test schedule for the 310-3B/310ARE-3B configuration is the same as shown in Part I, Figure 8.2-3 with the start and end dates shifted three months later.

The Apogee Kick Stage structural test program is the same as described in Part I, Paragraph 8.2.3.2.2 except that it starts in January of 1983. The Retrieval Delay Module structural test program is the same as described in Part III, Paragraph 8.2.3.2.2.

8.2.3.3 Integrated Avionics Test Program

The integrated avionics test philosophy and test program for the 310-3B/310ARE-3B configuration is basically the same as described in Part I, Paragraph 8.2.3.3.1. In addition to those tests defined in Part I, the evolution of the Retrieval Capability and Level IIB autonomy will be incorporated and verified in the IAT facility and ASDL prior to incorporation in the flight vehicle. At the completion of system hardware/software verification, mission simulation will be performed for the evolved MS in the IAT facility.

Fuel Cell - Reactant tank systems test will also be conducted the same as those described in Part III, Paragraph 8.2.3.3.1.

The RDM test program for the 310-3B/310ARE-3B is the same as described in Part III, Paragraph 8.2.1.3.2.

The AKS test program for the 310-3B/310ARE-3B is the same as described in Part I, Paragraph 8.2.1.3.2.

The test program, for the 310-3B/310ARE-3B configuration and schedule are shown in Figure 8.2 -2.

8.2.3.4 Mockups

The mockups will be used throughout the MS, RDM and AKS development stage as described in Part I, Paragraph 8.2.3.4. In addition the STA will be used for launch operations check-out as described for the 110A configuration.

8.2.4. Flight Test Program

8.2.4.1 Flight Vehicle Test and Checkout

The 310-3B configuration mainstage vehicle factory and pre-launch test and checkout requirements, schedule and manpower is the same as described in Part III, Paragraph 8.2.4.1.

The AKS factory and pre-launch (IOC TBD) flow is the same as shown in Part I, Figure 8.2-9 and the RDM factory and pre-launch flow is the same as described in Part III, Figure 8.2-9.

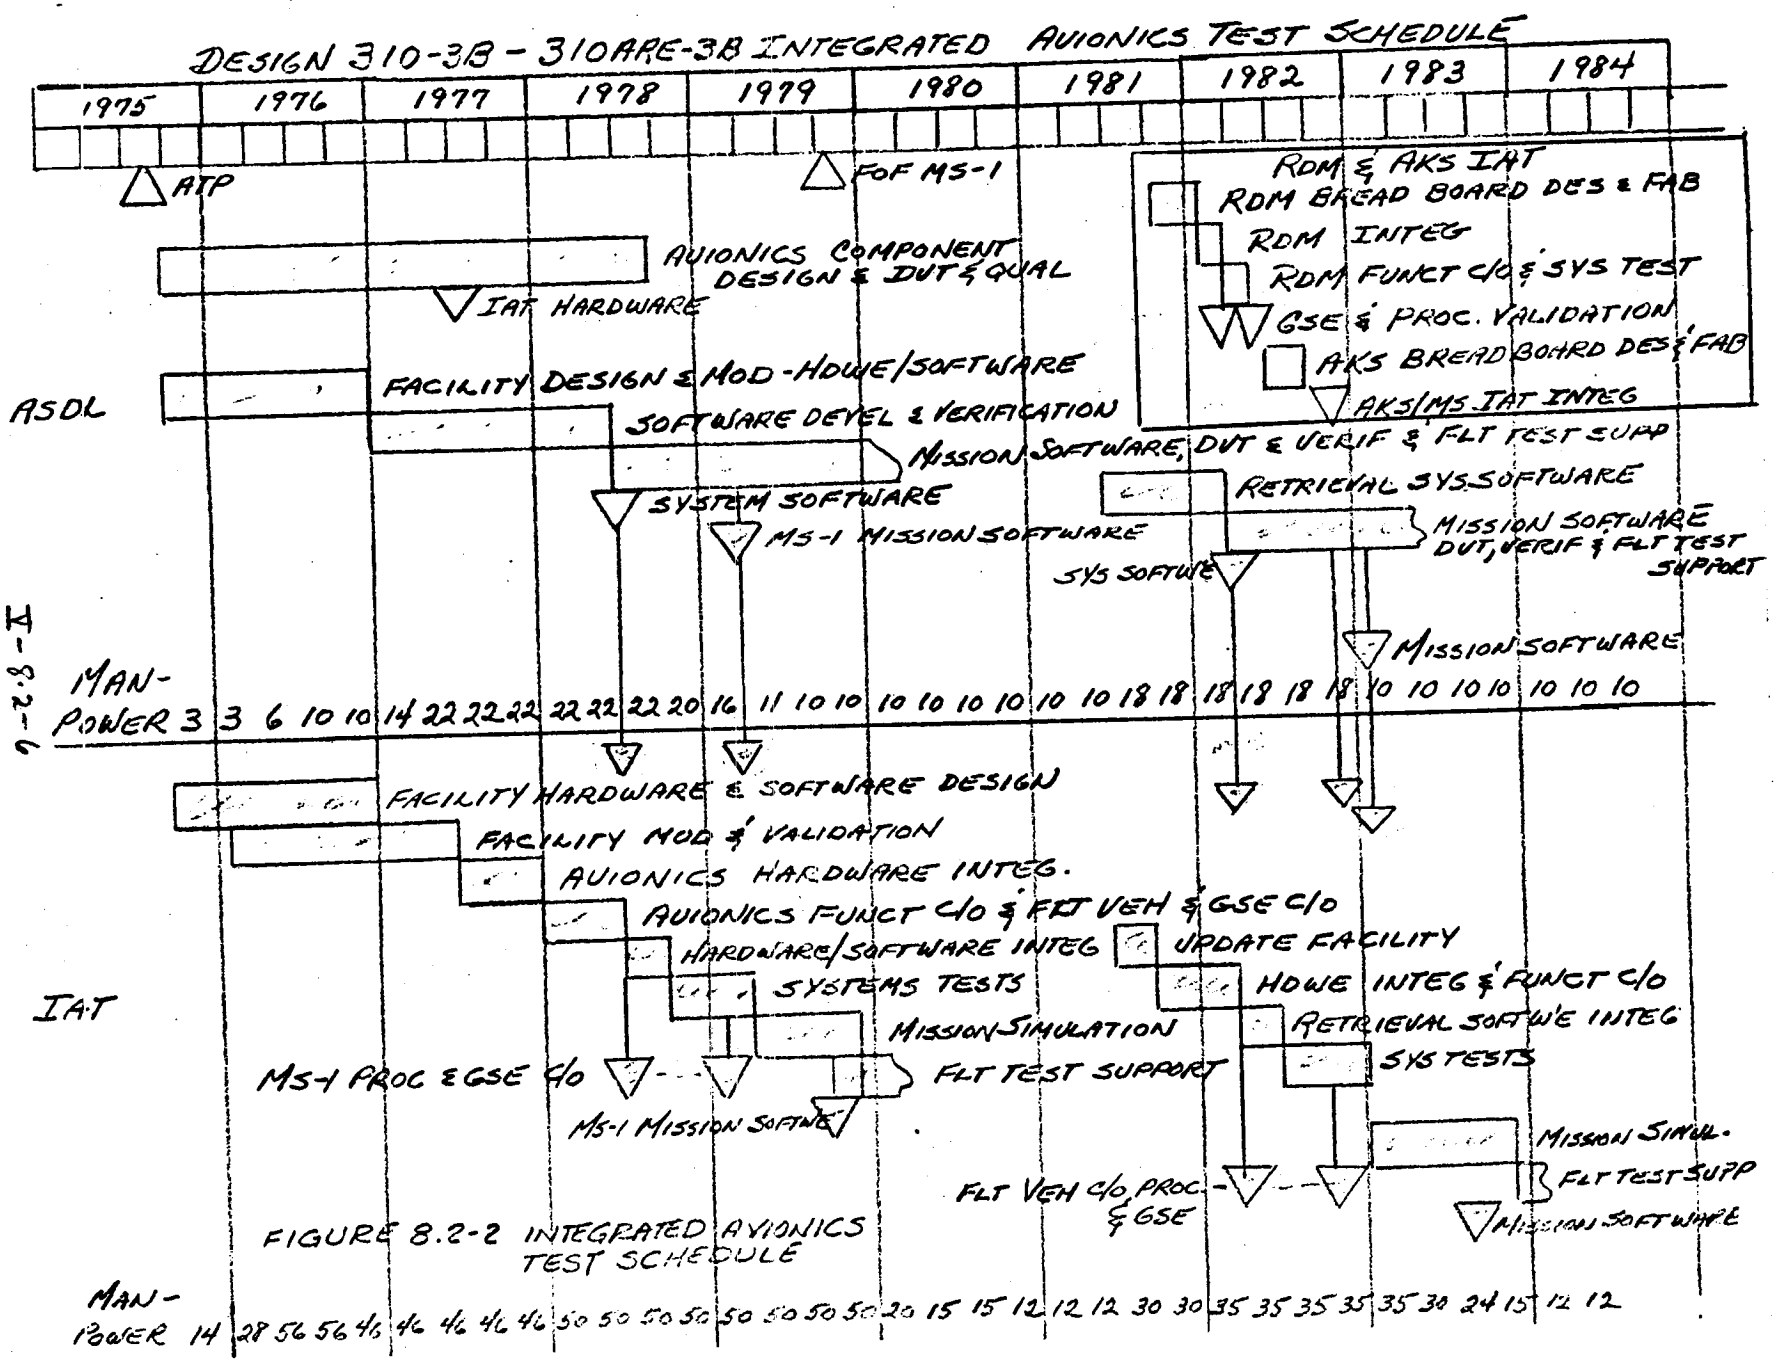

FIGURE 8.2-2 INTEGRATED AVIONICS TEST SCHEDULE

8.2.4.2 Flight Test

In addition to the eight flights described for the 310-3A/310RE3A configuration in Part III, Paragraph 8.2.3.2, one additional deploy only data flight with an AKS will be required for this configuration. The flight test schedule and test costs for this configuration are shown in Figure 8.2-3.

8.2.5 Analysis of the Test Program

8.2.5.1 Key Elements

The key elements of the 310-3B/310ARE-3b configuration, Vehicle Test Program, are the same as described in Part III, Paragraph 8.2.6.1.

8.2.5.2 SR&T Assumptions

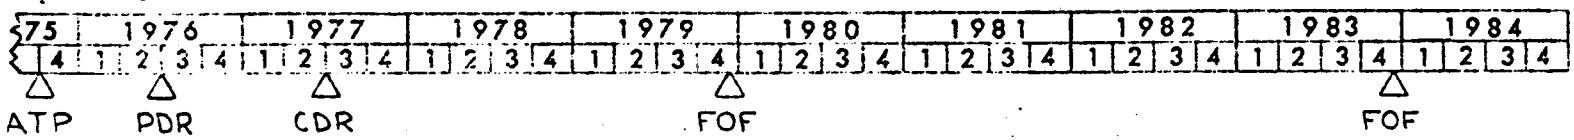
The basic assumptions for the 310-3B/310ARE-3B SR&T requirements are described in Part I, Paragraph 8.2.6.2. SR&T requirements, test programs affected and a brief description of the interaction with the test programs affected is summarized in Table 8.2-2.

8.2.5.3 Reusability Demonstration

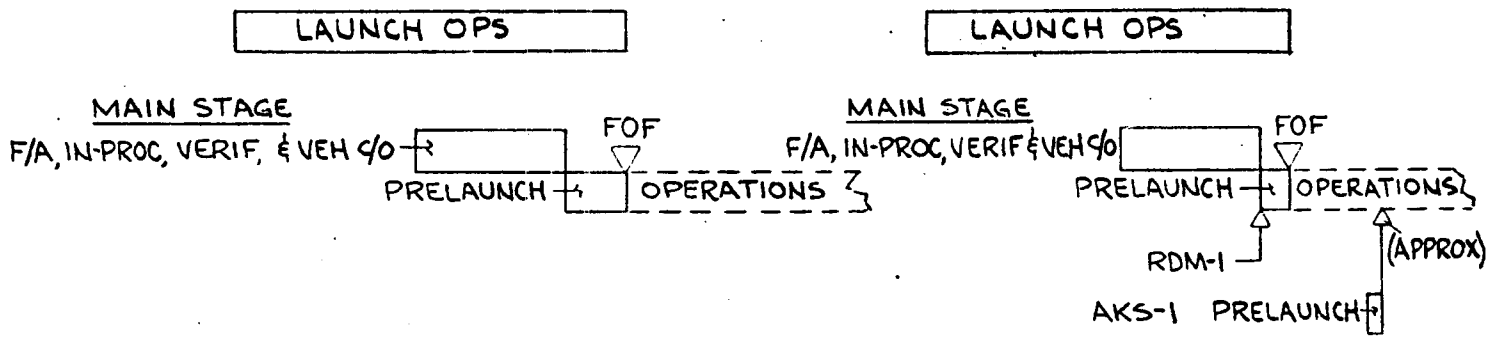
Reusability demonstrations for the 310-3B/310ARE-3B configuration are the same as described in Part I, Paragraph 8.2.6.3.

8.2.5.4 Life Verification Tests

The life verification test requirements for the 310-3B/310ARE-3B configuration are the same as described in Part I, Paragraph 8.2.6.4.



TEST & FLT OPS PLANNING



FLIGHT TEST PROGRAM COST

- FLIGHT TEST HARDWARE: 1 MAIN STAGE + DFI
  1 RDM + DFI
- FLIGHT TEST MANPOWER (FOF ONLY)
  - TEST OPS: $2.94 M
  - LAUNCH OPS: $1.51 M
  - FLIGHT OPS: $2.28 M
- CONSUMABLES (FOF ONLY): $62 K

FLIGHT TEST PROGRAM SCHEDULE (310-3B/310ARE-3B)

FIG. 8.2-3

TECHNOLOGY REQUIREMENTS	TEST PROG. AFFECTED	REMARKS
Main engine life and high performance	o GFE eng. devel. prog. o Flight test prog.	Early life verif. of eng. components and area ratio nozzle performance assures phase C/D engine development. PTV is not affected since eng. is not required. FOF could tolerate slightly reduced eng. performance.
PFR helium tank		Early verif. of low weight PFR tank assures maximum tug performance.
Materials compatibility Data	o Tank Qual o STA prog. o PTV prog.	Early verif. of material compatibility with MMH and N_2O_4 assures on-time development of main stage tankage including tank qual. STA and PTV testing.
Fracture Mechanics data	o Tank qual. o STA prog.	Early fracture mechanics data allows on-time development of structural subsystem including tankage quals and STA testing.
Heat Pipes	o Flight test prog.	Early verif. of heat pipe design approach allows on-time developments of Thermal Control Subsystem thereby maximizing Tug performance.
Laser Radar	o Integrated Avionics o Flight Vehicle factory checkout o STA	Early devel. of light weight low power Laser Radar will assure on time development of software and integration procedures in the IAT LAB for FLT VEH buildup & test and accurate simulation for STA program.

GRUMMAN

310-3B/310ARE-3B GROUND TESTS

VEHICLE TEST PROGRAM

The vehicle test program for 310-3B/310ARE-3B was developed in a similar manner to that described for 110A-1.

STRUCTURAL TEST ARTICLES (STA)

The structural test programs for the 310-3B/310ARE-3B are identical to those described for the MS 110A and the RDM for the 310RE configuration. The AKS STA for this configuration will be tested as described for the 110A STA test program, however, the test will be accomplished in 1983. The 310-3B STA will be configured to include the evolved 310ARE-3B avionic retrieval hardware and mechanical interfaces, and the test loads will envelope both configurations.

PROPULSION TEST VEHICLE (PTV)

The PTV and AKS PTV and AKS propulsion test programs for this configuration are the same as those described for configuration 110A.

310-3B/310ARE-3B GROUND TEST (cont'd)

TEST	TEST ART.	OBJECTIVES	APPROACH

EVALUATE EQUIPMENT ACCESSABILITY AND MAINTAINABILITY. EVALUATE SHUTTLE & PAYLOAD INTERFACE AND LINES RUN PRIOR TO FAR OR FINAL HARDWARE.	o COMPONENT INSTALLATION o ESTABLISH LINE LENGTHS FOR FINAL HARDWARE FAB. o DEMONSTRATE MAINTAINABILITY - ASSESSMENT & DEMO OF EQUIP CLEARANCES, LINES CLEARANCES - CONNECTOR & MOUNTING ACCESSABILITY DEMO o SHUTTLE & PAYLOAD INTERFACE ASSESSMENT.

GROUND TEST COST - INITIAL = $18.76M
INITIAL + EVOLVED = $26.53M

310-3B/310ARE-3B GROUND TESTS (cont'd)

INTEGRATED AVIONICS TESTS

The MS and Integrated Avionics Test program for the 310-3B configuration is the same as for 110A-1. The IAT and ASDL will initially be configured for the basic mission hardware and software including autonomy level IIIA.

As the retrieval capability and Autonomy Level IIB is evolved, the IAT hardware and ASDL software will be updated and evolved system verification and mission simulations performed.

The RDM and AKS breadboards will be integrated and functionally tested in the main stage IAT facility to take advantage of the existing facility simulation and GSE capabilities.

MOCKUPS

The MS and AKS mockups for this configuration will be the same as those described for configuration 110A. In addition mockups of the RDM will be required for this configuration. Installation of the evolved configuration hardware will also be evaluated using the MS mockups.

310-3B/310ARE-3B FLIGHT TESTS

TEST	OBJECTIVES	APPROACH
o MAIN STAGE (310-3B) - 1ST PROD UNIT INCLUDING DFI o MAIN STAGE (310ARE-3B) - 1ST PROD UNIT INCLUDING DFI o RDM - 1ST PROD. UNIT INCLUDING DFI o AKS - 1ST PROD. FLIGHT TEST COST - INITIAL = $13.39M
- INITIAL + EVOLVED = $19.83M

TOTAL VEHICLE TEST = $46.36M

310-3B-310ARE-3B FLIGHT TESTS

Nine flights are included in the 310-3B/310ARE-3B flight test program.

The MS flight test program for the 310-3B configuration will be the same as described for 110A. The AKS flight test program is also the same as described for 110A-1 with FOF of the AKS occuring in 1984.

The RDM and MS retrieval capability will be flight verified as described for configuration 310RE-3A.

8.3 Facilities Plan - Option 3B - Concept 310A-3B/310 ARE-3B

8.3.1 Manufacturing Facilities

Same as concept 110A-1 except 29,700 sq. ft. of floor space is required for fabrication and assembly of the TUG.

8.3.2 Test Facilities

Same as concept 110A-1 except 1AT will require 1300 sq. ft. of floor space at JSC.

8.3.3 Operations Facilities

Same as concept 110A-1 except TUG Maintenance Facility at ETR will have 4 horizontal stations in a 12,000 sq. ft. addition to the Shuttle OMS Facility.

8.4 Vehicle Manufacturing

This section establishes the requirements for the 310-3B/310ARE-3B spacecraft including the assembly sequence, tooling, schedule, manufacturing test, special processes and facilities.

The 310-3B spacecraft is a single stage vehicle with a kick stage (AKS) and a retrieval module (RDM) added for the evolved configuration 310ARE/3B. The spacecraft is essentially the same as the 410 and 310 vehicles described in Parts II and III.

8.4.1 Plan/Flow/Time

The manufacturing sequence is identical to configuration 410AD-2 discussed in Part II section 8.4.1. The manufacturing flow and master schedule are shown in figures 8.4-1 and 8.4-2 respectively.

8.4.2 Tooling Requirements (including GSE)

See Part II section 8.4.2.

8.4.3 Facility Requirements

See Part II section 8.4.3.

8.4.4 Special Requirements

See Part II section 8.4.4.

8.4.5 Summary Analysis/Philosophy

See Part II section 8.4.5

8.4.6 GSE Requirements

See Part I section 8.4.7

8.5 310-3B/310ARE-3B SPECIAL PROGRAMMATICS

Program 310-3B/310ARE-3B has features similar to those defined for implementing and managing Program 310-3A/310RE-3A.

These features include: defining the initial/evolved flight build up based on Shuttle/Tug launch constraint and ground crew launch capability; implementing 3 lot production (deploy, deploy-upgrade, and retrieve); refurbishing the propulsion test article for operational use; and defining a fall back position for every identified risk.

Specific areas for government participation in 310-313/310ARE-3B include: establishing Tug/Shuttle interface requirements before Orbiter design freeze; providing payload interface design requirements and mission model data; initiating required activities for supporting Research and Technology; providing GFE systems and components (eg: main engines, and DOD secure comm); supporting propulsion system testing and development and supporting integrated avionics hardware testing and related software development; providing required facilities; and performing vehicle ground operations, flight operations, and logistic support operations.

310-3B/310ARE-3B SPECIAL PROGRAMMATICS

- o PROGRAM IMPLEMENTATION AND MANAGEMENT
  - INITIAL/EVOLVED FLIGHT BUILD UP SET BY SHUTTLE/TUG LAUNCH CONSTRAINT AND GROUND CREW LAUNCH CAPABILITY
  - 3 LOT PRODUCTION (DEPLOY, DEPLOY-UPGRADE, AND RETRIEVE) TO AVOID MFG GAP
  - PROPULSION ARTICLE REFURBED FOR FLIGHT
  - FALL BACK POSITION SHOWN FOR EVERY IDENTIFIED RISK

- o AREAS FOR GOVERNMENT PARTICIPATION
  - FIRM TUG/SHUTTLE INTERFACES BEFORE ORBITER PDR
  - PROVIDE TUG/PAYLOAD INTERFACE DESIGN REQUIREMENTS AND MISSION MODEL DATA
  - INITIATE REQUIRED SR&T
  - SUPPORT SYSTEM TEST - AVIONIC HARDWARE/SOFTWARE PROPULSION
  - PROVIDE GFE SYSTEMS AND COMPONENTS, FACILITIES, LOGISTIC SUPPORT
  - PERFORM VEHICLE GROUND AND FLIGHT OPERATIONS

GRUMMAN

8.6 COST DATA

Included in this section are the cost data for an evolved tug configuration 310-3B/310ARE-3B. Cost data are provided for the initial program 310-3B and the combined total evolved program.

- Initial Program 310-3B
  - Storable Space Tug System Project Expected Cost-Spares Cost (INT & OPS)-First Unit Cost (Data Forms A1, 2 and 3, subparagraph No's 8.6.1, 8.6.2 and 8.6.3) (Computer P/O)
  - Storable Space Tug Funding Schedules -DDT & E, Production and Operations (Data Form C, Subparagraph 8.6.4, 8.6.5, 8.6.6 and 8.6.7)
  - Form B (Technical Characteristics subparagraph 8.6.11)
- Combined Evolved Program 310-3B/310ARE-3B
  - Same as initial program plus:
    - Average Cost/Flight (subparagraph 8.6.9)
    - Storable Space Tug System Project Cost Estimate data by SOW-DDT & E, Production and Operations (Data Form T (SOW'S) subparagraph 8.6.10)

TABLE 4.3.4.2-9

310-3B/310ARE-3B FLIGHT OPERATIONS BUILDUP

The same methodology was used to establish the 310-3B/310ARE-3B flight buildup as in the two prior phased programs.

Our recommended flight buildup for 310-3B/310ARE-3B, including 3 flights in 1980, 12 flights in 1981, and 39 flights in 1984, encompasses 365 total flights through 1990 or 29 less than 100% payload capture traffic.

8.9 Risk Assessment

In making an assessment of the risk associated with each configuration in each capability option we have considered the type of technology items associated with each vehicle and the impact that it would have on the program if, for one reason or another, the item would be unavailable and an alternative solution would be required. The impact is defined, usually, in terms of added weight, lost performance and total program cost increase; in some cases the impact can be decreased weight or reduced cost.

It is assumed that all of the weight increases and all of the cost increases will occur simultaneously without benefit of any offsetting decreases in either weight or cost. For example in configuration 110A-1 we have assumed that the +4 lb. weight impact of abandoning spun aluminum tanks in favor of welded aluminum tanks is combined with a $10.0 million cost increase as a result of abandoning aluminum tanks in favor of titanium tanks due to materials compatibility or fracture mechanics issues.

Taking the summation of all the weight increases, these are converted to costs by using the $75K/lb. figure derived when we were first selecting subsystem options for incorporation with 110A-1. The $75K/lb. number represents the last step (actually the slope of the line) in our subsystems synthesis process which provides a curve of Δ weight versus Δ total program costs as we added lighter and more costly subsystems options to achieve a behicle with 3500 lb. deploy capability. In this manner we arrived at a estimate of the costs expected if we had to recover the weight growth.

In similar fashion we then summed all of the potential cost increases, ignoring any offsetting cost decreases, and added these to the dollars representing the weight increases. The 110A-1 has no projected performance loss since it uses the OME 7.5K engine; the assumption is that the basic OME will have been developed to meet its weight, performance and reusability goals for the Shuttle Orbiter. In the case of configurations which use the Class I engine, for example 410AD-2, we have assumed that a 3 second Isp performance loss is possible. To convert this performance loss to costs we use the payload sensitivity factor to loss in Isp (97 lbs/sec), divide this by the payload sensitivity to inert weight and then multiply by $111/lb. to convert it to costs.

Taking all of the costs and adding them together we get a total low cost risk value of $15.3M for 110A-1 which ranges to a high value of 94.3M for 320A-3A/320AE-3A.

Where no suitable alternative exists (for example the Class I engine, or the laser radar, or the Space Storable SRM) we have identified that item as both a cost and a schedule risk without attempting to quantify the risk. In general, we are relying on the successful completion of the proposed SR&T programs to reduce or eliminate the risk of schedule slippage.

Taking configuration 110A as an example:

110A-1: This is an extremely low risk program with only two items representing a technical risk, the spun-form aluminum tanks and the prestressed filament reinforced (PFR) helium tanks. Both of these items are low risk and both have suitable, low risk alternatives available.

The incorporation of separate tanks (rather than the nested tanks used in the other configurations) further reduces the risk associated with this configuration. Level III (rather than Level IIB) autonomy also reduces the risk since there is no reliance on the 621B Navigation Satellite program. The OME 7.5K engine is the lowest risk engine program available, so its use on 110A-1 further reduces risk. The use of scaled-up LM batteries rather than fuel cells with their associated cryogenic storage tanks and valves is again the lowest risk approach available for providing electrical power. The all-aluminum structure is the lowest cost/lowest risk approach available. The short mission duration (34 hours) eliminates the need for multi-layer insulation (MLI) on most of the external surfaces there minimizing the risk of damage to the MLI during vehicle ground operations.

Since the 110A-1 does not have to communicate with payloads it has the the lowest risk communications equipment, a dedicated frequency station, to develop. Although our current approach includes making the communications equipment compatible with the NASA Tracking and Data Relay Satellite System (TDRSS) an option which can further reduce risk, is to eliminate the requirement for this equipment to meet the spread spectrum and CCIR interference requirements associated with TDRSS. The modifications of an existing IMU (the Carousel VB) and an existing computer (the CDC 469) are again the lowest risk approach identified in the GN&C and DMS areas.

Although the use of an apogee kick stage (AKS) to deploy heavier payloads reduces the sensitivity of the configuration to inert weight growth or I_{sp} loss, it does add complication to flight operations, increasing risk. Elimination of the AKS can further reduce the risk of this configuration.

310-3B/310ARE-3B RISK ASSESSMENT

TECHNOLOGY ITEM IMPACT	
• CLASS I ENG	-3 SEC ISP
• PFR TANK	+48 LB
• ADV IMU	+30 LB
• GRAPHITE COMPOSITE	+38 LB
• LASER RADAR	COST/SCHED
• MATERIALS COMPATIBILITY • FRACTURE MECHANICS	+13 LB
• HEAT PIPES	SCHED

$\frac{\partial P/L}{\partial ISP}$ (LB/SEC)	96	93

II-8.9-2

TECHNICAL RISK
- POTENTIAL WT IMPACT: +129 LB } ≈ 622 LB OF PAYLOAD (W AKS)
- POTENTIAL ISP LOSS: -3 SEC }
- OPEN WEIGHT REDUCTION OPTION: ADV FUEL CELL

SCHEDULE RISK
- PROPOSED SR&T PROGRAMS (COMPLETED PRIOR TO ATP) PROTECT AGAINST SCHEDULE SLIP
- AVAILABILITY OF 621 B SATELLITES & MAIN ENGINE

• COST RISK
- POTENTIAL Δ COST $23.1 M

MODERATE RISK PROGRAM

310-3B/310ARE-3B RISK ASSESSMENT

The technology items and their potential impact are shown on the opposite page. If the prestressed filament reinforced (PFR) helium tank fails to meet its goals, a 6Al4V titanium tank adds 48 lbs to the vehicle. If the advanced (Micron) IMU is unavailable, a Carousel VB IMU plus a rate gyro unit adds 30 lbs. If the graphite composite shell fails to meet its objectives, an aluminum honeycomb shell adds 38 lbs. The laser radar is an item which has no alternative, hence it represents both a schedule and cost risk. If materials compatibility or fracture mechanics data indicate the need to change propellant tank material from titanium to either aluminum or stainless steel, the added weight would be +13 lbs or +3 lbs respectively. If the heat pipes are replaced by incorporating high heat rejection items on the active loop, there are no weight changes. To recover the weight impact on payload capability due to these possible weight increases, the advanced fuel cell is an open option.

The Class I engine is a new design based on current technology with the exception of the uncertainty in engine life and in the predicted performance with the high expansion ratio nozzles used. It is estimated this engine can miss its performance goals by -3 seconds Isp.

Although the proposed SR&T programs protect against schedule slippage by virtue of being completed at ATP, the availability of both the main engine and the 621B Navigation Satellites remain schedule risk items.

Converting the potential Isp loss and weight increases to a total program cost at a $111/lb value and adding to the potential cost increase items, yields a total cost risk of $23.1M for 310-3B/310ARE-3B.

RISK ASSESSMENT 310-3B/310ARE-3B

BASELINE	ALTERNATIVE	WEIGHT LBS	TOTAL PROGRAM COSTS, $M
CLASS I ENGINE	NO ALTERNATIVE	-	COST/SCHED RISK
LASER RADAR	RF RADAR PLUS REMOTE TV DOCKING (ALSO A TECHNOLOGY ISSUE), HENCE NO ALTERNATIVE	-	COST/SCHED RISK

HEAT PIPES	USE ACTIVE LOOP/BYPASS	NONE	NONE

SUMMING HIGHER WEIGHTS & COSTS ONLY	129 LBS	$1.65M
CONVERT WEIGHT TO $ at $111K/LB	(129 X 111 K)	14.30
CONVERT - 3 SEC ISP TO $	$\frac{(3 \times 96}{3.66} \times 111$ K)	7.85
TOTAL COST RISK		$ 23.80M

Section 8.10 Supporting Research and Technology

This section includes a summary matrix chart which identifies all of the SR & T items and where they are applied to each configuration in each capability option.

Following the summary matrix there are individual tables for each configuration which summarize the technology items for that particular configuration and give a very brief synopsis of the type of SR & T program proposed and the estimated funding and schedule requirements. The text following each table is the facing page text prepared for the main presentation.

Following the tables for each configuration, an additional form is filled out for each technology item providing status information, justification for the proposed SR & T program, objectives, technical approach, and a more detailed schedule showing when the proposed program must be completed in order to support the particular configuration.

In dealing with the subject of SR & T we have identified two distinct groups - one where technology is needed and the other where there is no doubt that the technology is available and it is a straightforward engineering task to accumulate data that will preclude making a "false start" where several alternates are under study; we have called the latter group "desired data".

The storable Tug will benefit from the fact that the APOLLO LM program has used similar materials, propellants, equipments and procedures; the Shuttle Orbiter will expand on this data base for the Tug. The low number of identified SR & T items and the modest sums projected are based on the assumption that several existing or planned efforts related to the Shuttle will continue to provide data. These include the planned propellant and materials compatibility testing in support of the Shuttle Orbital Maneuvering Subsystem, its engines, tanks and components both at NASA/WSTF and at the Shuttle contractor's facilities. In addition, we have identified the Air Force funded efforts to develop the advanced Micron IMU for aircraft programs, as an effort which we would build-on rather than to start from scratch.

We have not attempted to detail the SR & T programs required on the Class I engine (with or without the two position nozzle) except to point out the uncertainty associated with the anticipated engine life and the predicted performance of very high expansion ratios within the mixture ratio of interest. The engine contractor will provide the proposed SR & T efforts required on the engine and we will provide comments on same at NASA's request.

The overall "message" which we hope will become obvious to the reader is that there are no real "show-stoppers" among the SR & T items identified.

TECHNOLOGY REQUIREMENTS AND DESIRED DATA - 310-3B/310ARE-3B

The upper part of the facing chart contains the supporting research and technology (SR&T) items required for 310-3B/310ARE-3B; the lower part of the chart contains what we have termed as "desired data". The distinction between the two is that the "desired data" items do not require technology but are considered straightforward engineering development tasks to produce design data prior to Tug program go-ahead (ATP); this will preclude impacting Tug schedules should the data indicate the desirability of an alternate approach, (vis., aluminum or stainless steel propellant tanks rather than titanium).

Excluding the SR&T on the Class I engine the total SR&T funds requested for 310-3B/310ARE-3B is $1290K to be expended over an 18 month period cluminating at Tug ATP or prior to go-ahead on the evolved Tug. The advanced (Micron) IMU is the long lead item (18 months), again excluding the Class I engine.

TITLE Low Weight/Power, (Rendezvous and Docking) Laser Radar

WBS No. 320-03-03-02

STATUS ITT-Gilfillan has been under NASA Contracts since 1964 to design, develop, build, and test various spaceborne laser radar systems. The third generation system will be delivered in late November 1973.

JUSTIFICATION The application of the above developed technology to meet specific space tug rendezvous and docking requirements is desired.

In addition in order to improve the payload capability of the storable tug, low weight Avionics equipments (specifically, low weight/low power laser radar) are required.

OBJECTIVES To design, develop, fabricate, and test a low weight, low power, rendezvous and docking laser radar.

V-8.4-4

TECHNICAL APPROACH Using Tug requirements, design for light weight, low power by using new components, lighter mirror drives and improved optics

TITLE Prestressed Filament Reinforced (PFR) Tanks

WBS No. 320-03-04-02

STATUS Structural Composites Industries, Inc. (SCI) and Arde-Portland, Inc. are under contract to LeRC to demonstrate the feasibility of the PFR tanks. This program will result in the construction of a 24 in. diam. Ardeform PFR tank of the type assumed by our study. If successful the basic technology will be proven.

JUSTIFICATION

A PFR ambient helium storage tank is comparable with the weight of a SHe tank and its associated heat exchanger. It provides a simple and less operationally complex system compared to the SHe tank. The PFR tank also provides a leak-before-burst design which results in increased Tug safety.

OBJECTIVES

Design, fabricate, and test 3 to 6 PFR tanks to demonstrate that current manufacturing and quality control techniques are adequate to produce a reliable, low weight tank suitable for containing gaseous helium (or hydrogen and oxygen in the case of fuel cell reactant tanks). The program will resemble a pre-qualification test program which will demonstrate the ability of the PFR tank to undergo the dynamic loading, compatibility, environmental exposure and etc. tests required for acceptance as a flight item.

TECHNICAL APPROACH

Fabricate 3 to 6 tanks and subject them to a pre-qualification test program to demonstrate the maturity of the design.

TITLE Fracture Mechanics Test Data

STATUS Fracture mechanics test data for thin gage (.020 to .040) for Titanium 6AL-4V STA and 2219-T87 aluminum alloy exposed to N_2O_4 and MMH at temperatures up to 200°F is not available.

JUSTIFICATION Fracture mechanics data for thin gage tank material are required to assess the fracture mode and life cycle of the tug propellant tanks.

OBJECTIVES The objectives of the program are to obtain K_{ic}, K_{th} and flaw growth data for parent and weldment materials in the induced thermal environment up to 200°F. Data to be obtained prior to and after exposure to the candidate propellants. In addition to fracture mechanics data, NDE techniques are to be employed on the test specimens to assess flaw detection capability.

V-8.9-19

TECHNICAL APPROACH Standard fracture elemental specimens are to be employed. Tests are to be employed. Tests are to be conducted at room temperature and at 150 and 200°F. Surface flaws of various sizes are to be used and NDE techniques are to be employed to document size where practical.

TITLE SPACE TUG HEAT PIPES

WBS No. 320-04-02

STATUS

Heat pipes (HP) are currently being used in both ground and space application. The variable conductance heat pipe (VCHP) principle is particularly attractive for Tug application but requires further development.

JUSTIFICATION

The fuel cell and certain high power density avionics units carried on the Space Tug require active cooling. Trade studies which have examined pumped loop radiators, sublimators and various heat pipes have indicated the obvious merits of the variable conductance heat pipe. A VCHP radiator could interface with the pumped loop heat transport system of the fuel cell, eliminating the cost and complexity of a selective stagnation radiator with its associated unreliable automatic bypass valves. A VCHP header, a heat transport device, could provide for high power density avionics heat transport without recourse to the active loop.

V-89-21

OBJECTIVES

Emphasis will be placed on experimentally obtaining the large turn down ratios which appear theoretically achievable and in developing predictive techniques.

TECHNICAL APPROACH

Design, fabricate and test a VCHP radiator and VCHP header and experimentally determine performance with emphasis on turn down ratio and shut off heat flux levels.

8.1 SCHEDULES

8.1.1 SUMMARY PROJECT SCHEDULE

Introduction: The Storable Tug Project schedule was developed to identify the principal project phases and to establish schedule estimates for all hardware and soft ware elements in accordance with the Space Tug Work Breakdown Structure.

The Tug Project Schedule depicts major program milestones and presents project activities at level 5 of the WBS. This schedule establishes the planning baseline for development of the Storable Tug System through design, development, manufacturing, ground test, flight test and operations. It integrates all supporting schedules into an overall project level plan and establishes the sequence and interdependency of activities and events required for the development of an operational Space Tug System.

Groundrules and Assumptions: Following are the ground rules and assumptions used for development of the Storable Tug Project Schedule:

- o ATP is October 1975 at the earliest for Options 1 and 3. ATP for Option 2 to be determined by the contractor.
- o Schedule planning is designed to minimize peak annual funding during DDT&E.
- o Main Stage DDT&E requirements consist of the following major test articles:
  - A structural test article (STA) for dynamic, static and fatigue tests.
  - A main propulsion test vehicle (PTV). Following the completion of live propellant testing the PTV will be refurbished and delivered as an operational flight vehicle.
  - One shipset of Avionics hardware for the Integrated Avionics Test (IAT).
  - A flight test vehicle (MS-1).
- o Operational fleet sizes for each project option are based on a study of traffic capture models.
- o Production rate of vehicles is based on avoiding duplication of major structural assembly tooling and minimizing gaps in manufacturing flow.

- Initial operational capability (IOC) is achieved after completion of one test flight (FOF). IOC dates are as follows:

  Option 1 - December 1979
  Option 2 - December 1983
  Option 3 - December 1979 - initial, December 1983 - evolved.

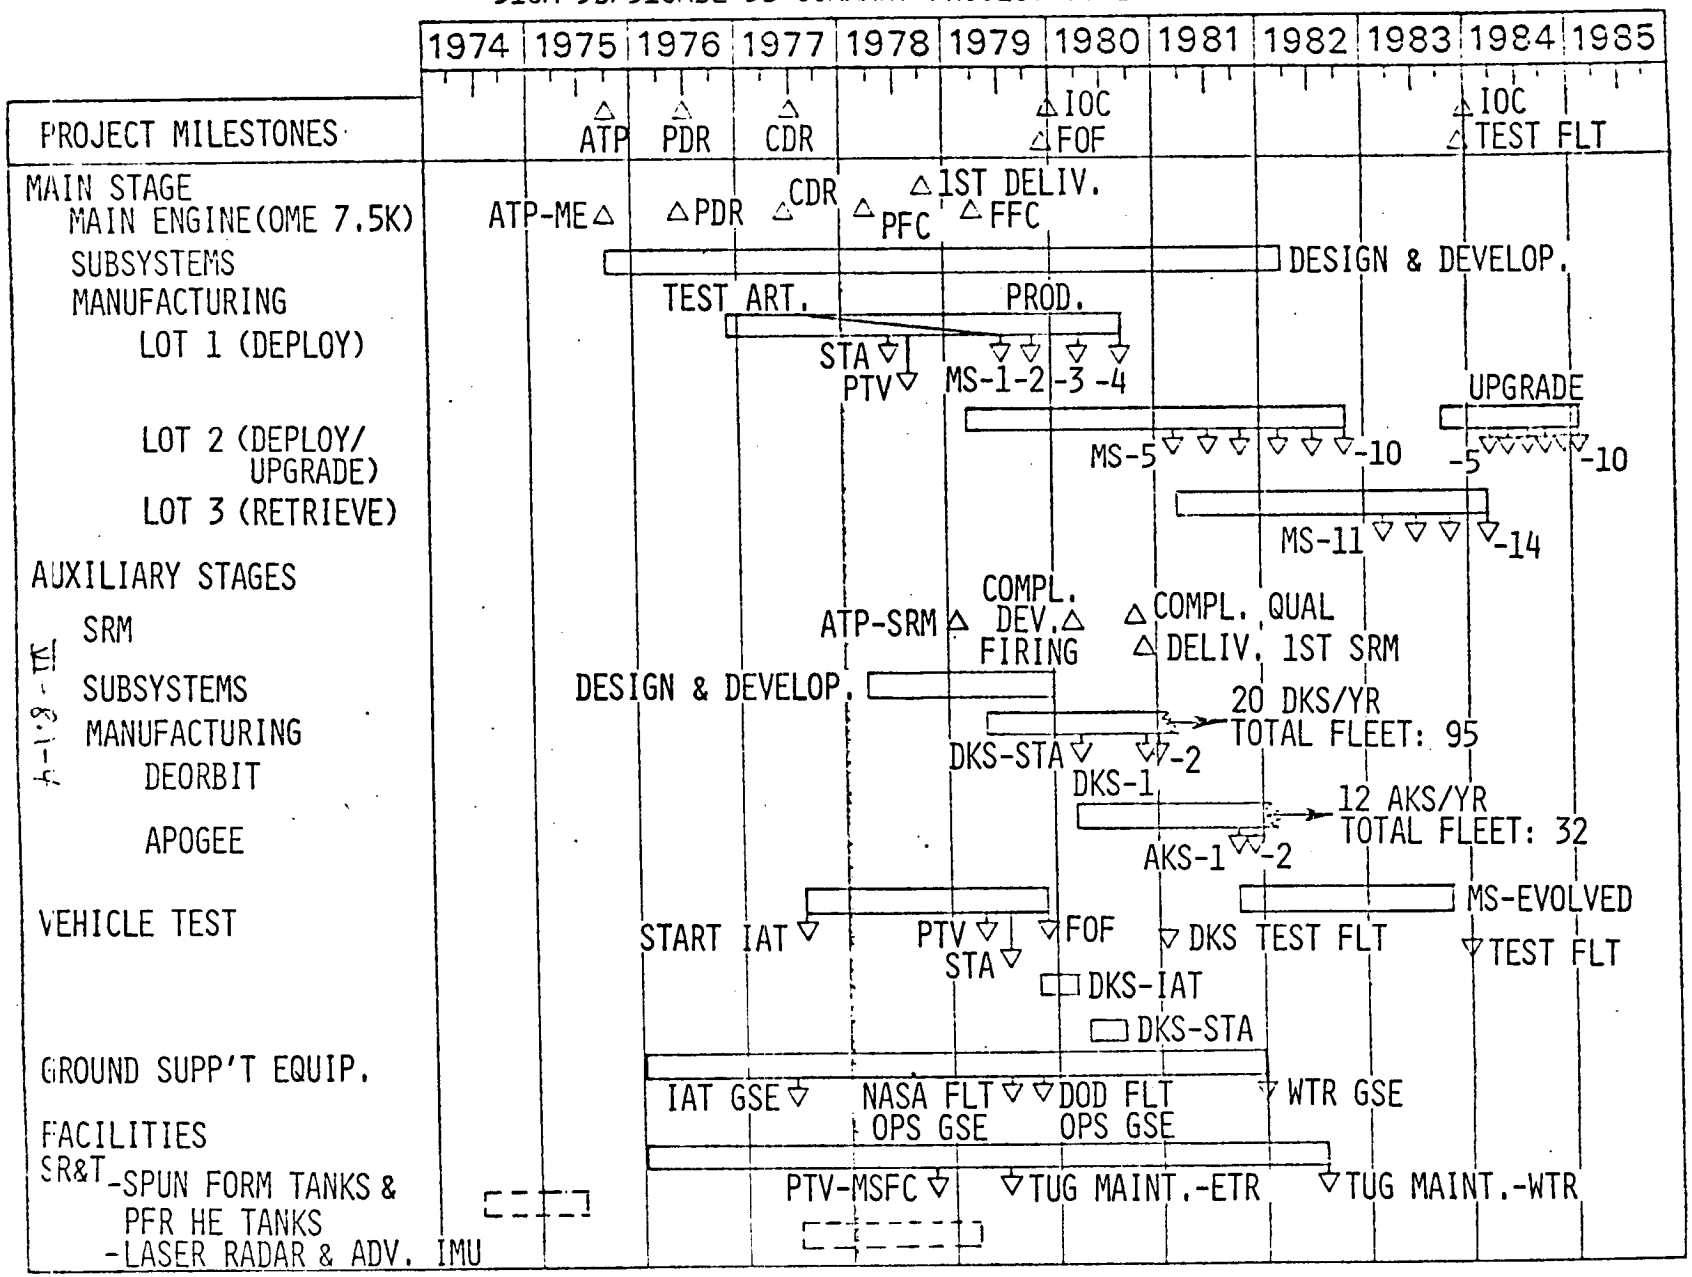
- Maximum number of flights in 1980 is 3, based on the Shuttle traffic model.

Approach: Based on the above groundrules and assumptions a preliminary project milestone schedule was developed to form a baseline for all detail scheduling. Detailed subsystem design and development schedules, manufacturing and factory checkout flows, vehicle test, GSE, facilities, and SR&T Schedules were then developed in conjunction with personnel representing the cognizant management and technical disciplines. These detailed schedules were then summarized and integrated into the Tug Project Schedule through the process of establishing a logical and achievable relationship between the engineering design and development process, procurement of subcontract equipment, hardware fabrication and assembly process and the vehicle test program that minimizes risks and ensures the fulfillment of program objectives. Finally, the major project milestones and activities presented in the Tug Project Schedule were condensed into the Summary Project Schedule.

SUMMARY SCHEDULE 510A-3B/510ADE-3B

The primary elements of the 510A-3B/510ADE-3B Project Schedule are as described for 310-3A/310RE-3A except for addition of an Apogee Kick Stage an substitution of a Deorbit Kick Stage for the Retrieval Delay Module. Authorization to Proceed (ATP) occurs on October 1,1975 with IOC of the initial configuration targeted for December 31, 1979. The OME main engine milestones are the same as for 110A-1 with Final Flight Certification occuring 8 months before First Orbital Flight (FOF). Main Stage vehicle tests are essentially the same as for 310-3A/310RE-3A. First flight of the evolved vehicle is targeted for December 1, 1983. Main Stage manufacturing begins December 1, 1976 with production of the major ground test articles and continues through production of 14 vehicles to support fleet operations. They are manufactured in 3 lots for the purpose of avoiding manufacturing gaps between deploy only vehicles and evolved vehicles. Development of the Apogee and Deorbit Kick Stages begins in March 1978, to permit deployment of the DKS with payloads in 1981, approximately 3 years prior to the evolved vehicle IOC. The Apogee Kick Stage is scheduled for deployment in November 1981. 95 Deorbit Kick Stages and 32 Apogee Kick Stages will be manufactured to support fleet operations. GSE and Facilities are scheduled essentially the same as for 110A-1.

510A-3B/510ADE-3B SUMMARY PROJECT SCHEDULE



8.1.2 DEVELOPMENT SCHEDULES

8.1.3 PRODUCTION SCHEDULES

The detailed Project Schedule depicts the total development and production phases for the Main Stage and the Auxiliary Stage(s). The detailed Project Schedule is based on a constraint logic that considers overall program objectives and the detailed interaction of constraints on significant program activities. It provides reasonable margins for development problems and minimizes program front-loading.

The detailed Subsystem Schedules provide an order of magnitude increase in detail from the Project Schedule and depict the subsystem activities in both inhouse and subcontractor areas. Subsystem schedule information is presented at WBS level 6 for Structures, Thermal Control and Orbiter Interface, and at WBS level 7 for Propulsion and Avionics subsystems.

8.1.4 OPERATIONS SCHEDULE

Scheduled and planned for concept 510A-3B/510ADE-3B, option 3 are 30 launches per year with 12 days between launches. Ground servicing as shown on the programmatics/cost operations schedule from land to launch is 10 tug work days and 9 tug/orbiter work days.

8.1.5 FACILITIES SCHEDULE

Included in the storable space tug facilities schedule for concept 510A-3B/510ADE-3B are the various tasks to be completed against major program milestones. The fundamental grouping of these tasks are manufacturing, test, maintenance and refurb-ETR, ETR launch, maintenance and refurb-WTR and WTR launch. Under this tug concept facilities maintenance extends into 1991, with most of design/construction/activation ending by 1982 in support of WTR launch requirements.

8.1.6 EVALUATION OF MAJOR SCHEDULE DRIVERS (cont'd)

510A-3B/510DE-3B

The critical path for the option may be traced through the following tasks:

- o Structural design, including the integral nested tank design.
- o Spun form tank fabrication and assembly.
- o Main Stage structural assembly
- o Flight test vehicle (MS-1) final assembly, equipment installation and checkout.
- o Ship to ETR.
- o Prelaunch activity for FOF in December 1983.

Development of the Deorbit Kick Stage is advanced to 1978 allowing deployment of the DKS with payloads in 1981. Approximately 3 years prior to the evolved Tug IOC.

The Apogee Kick Stage is subsequently manufactured for deployment in November 1981. Production of the Main Stage consists of 3 lots as in other evolved programs. Total fleet size is 14 Main Stage Vehicles.

8.2 VEHICLE TEST PROGRAM (510A-3B/510ADE-3B)

8.2.0 Test Summary

The approach used to develop the Vehicle Test Program for the 510A-3B/510ADE-3B configuration is basically the same as described in Part I, paragraph 8.2.1. The addition of a Retrieval Delay Module, Deorbit Kick Stage, MS retrieval electronics and level IIb autonomy to the Tug Program for the 510A-3B/510ADE-3B configuration will also be verified in both the ground and flight test programs.

Table 8.2-1 summarizes the test verification approach in terms of major verification requirements and method of requirement satisfaction. Figure 8.2-1 presents a summary schedule of the total Vehicle test program.

8.2.1 Ground Test Articles - Type and Description

8.2.1.1 Propulsion Test Vehicle (PTV)

The PTV for the 510A-3B/510ADE-3B configuration is the same as described in Part I, paragraph 8.2.1.1

8.2.1.2 Structural Test Articles (STA)

The Structural Test Articles for this configuration are the same as described in Part II, paragraph 8.2.1.2

8.2.1.3 Integrated Avionics Testing

The integrated avionics hardware and software testing for the 510A-3B/510A-3B main stage will be accomplished using an IAT and ASDL facility as described in Part III, paragraph 8.2.1.3. , and the AKS/DKS as described in Part II.

8.2.1.4 Mock-ups

Mock-ups will be provided for both the main stage and the kick stages as described in Part I, paragraph 8.2.1.4. The early Deorbit kick stage mock-ups will be modified to serve as the later Apogee Kick State mock-ups.

8.2.2 Flight Test Articles

The main stage and Apogee kick stage flight test articles are the same as described in Part I, paragraphs 8.2.2.1 and 8.2.2.2

The Deorbit Kick stage flight test article will be the same as described in Part II, paragraph 8.2.2

TABLE 8.2-1

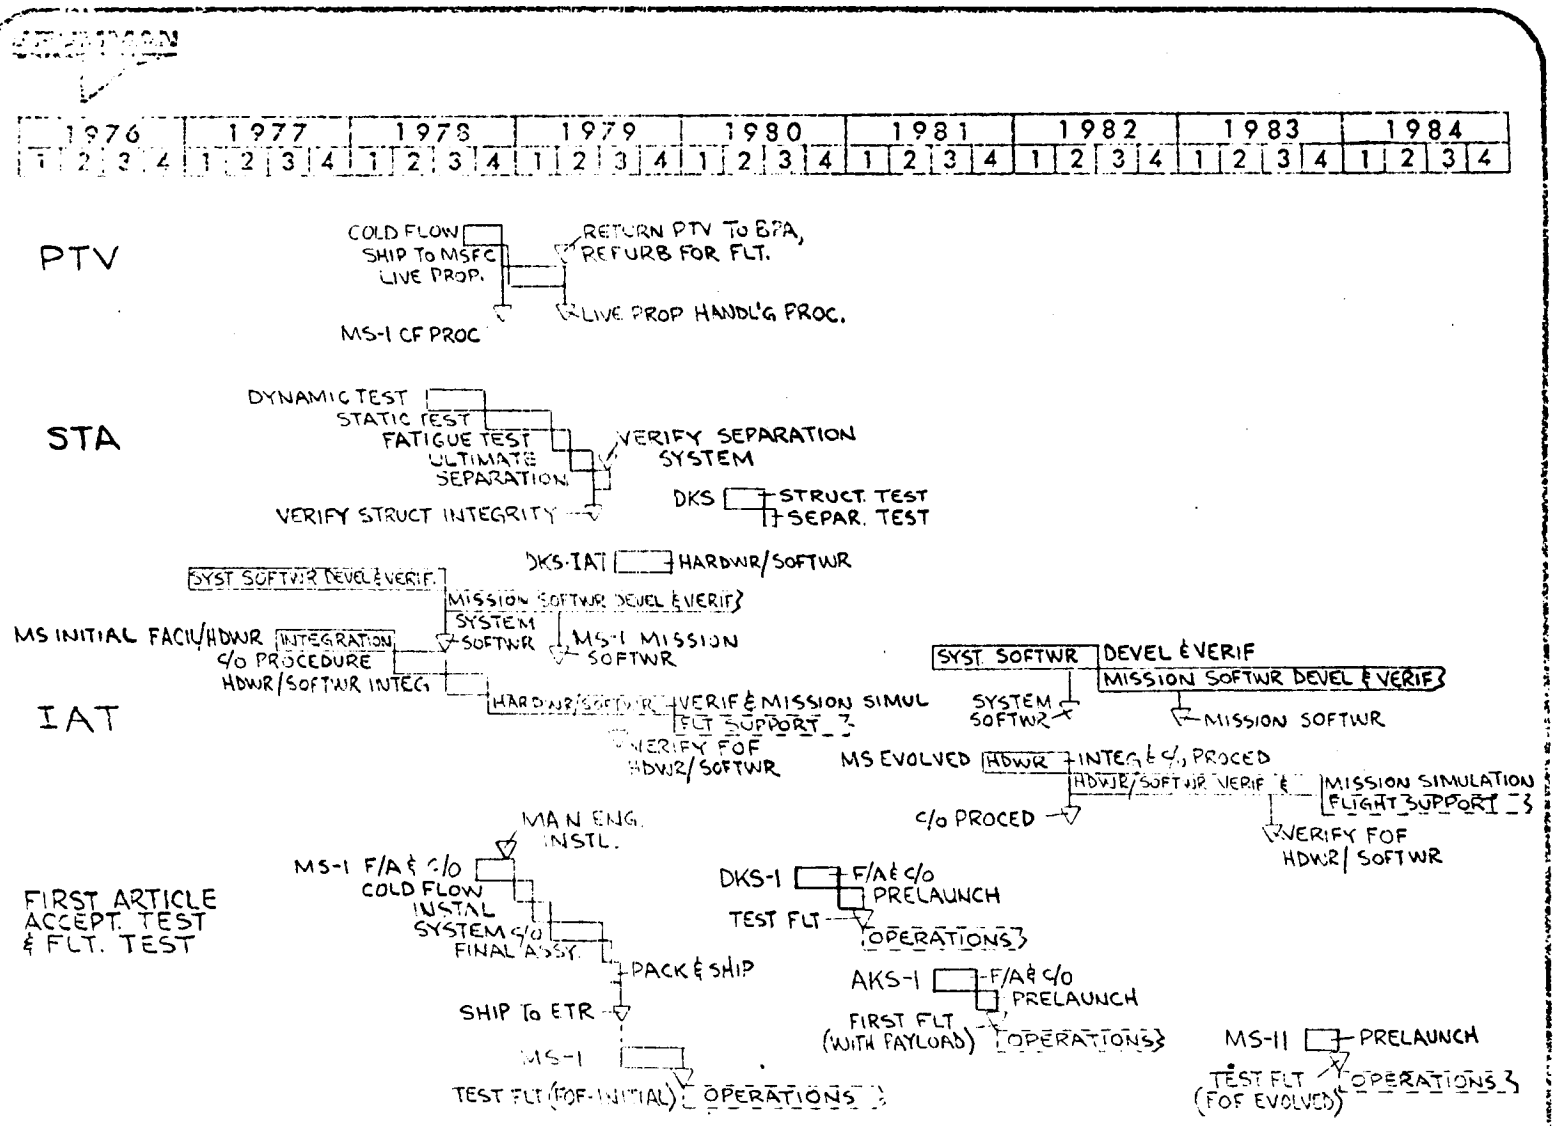

FIG. 8.2-1 510A-3B/510ADE-3B VEHICLE TEST SCHEDULE

8.2.3 Ground Test Program

This section describes the major elements of the vehicle ground test program. The test program described in the following paragraphs include the propulsion test vehicle (PTV), Structural Test Article (STA), Integrated Avionics Testing including software development, and mock-ups required in support of program requirements.

8.2.3.1 Propulsion Test Vehicle (PTV) Program

The Main Propulsion System and Auxiliary Propulsion System test program for the 510A-3B configuration is the same as described in Part I, paragraph 8.2.3.1

The DKS/AKS SRM test program will be conducted at the engine manufacturer as described for the 110A configuration AKS in Part I, paragraph 8.2.3.1.1

8.2.3.2 Structural Test Articles

The main stage structural test program, is the same as described in Part II, paragraph 8.2.3.2. The main stage test schedule and manloading is the same as shown in Part I, Figure 8.2-3 except that it is shifted three months later.

The DKS/AKS auxiliary stage begins as a Deorbit kick stage and later is flown with AKS capability only. Since there are no structural changes required, only one STA is provided. The structural tests are all performed for the most critical conditions for either AKS, DKS or combined AKS/DKS. Hence the initial test program satisfies all requirements for all configurations. In other respects the test program is the same as described for the 110A configuration AKS in Part I, paragraph 8.2.3.2.2. The schedule and manloading is the same as for the 110A AKS except that it starts in 2/80 instead of 12/80 because of the early flight requirements of the DKS.

8.2.3.3 Integrated Avionics Test Program

The mainstage integrated avionics test aprogram for the 510A-3B/510ADE-3B configuration is the same as described in Part III paragraph 8.2.3.3

The DKS/AKS integrated avionics test program is the same as described in Part II, paragraph 8.2.3.3.

The schedule and manloading for integrated avionics testing is shown in figure 8.2-2.

8.2.4 Flight Test Program

8.2.4.1 Flight Vehicle Test and Checkout

The Main Stage (MS) factory and prelaunch flow, schedule and manpower requirements are the same as described in Part III, paragraph 8.2.4.1.

The AKS/DKS factory and prelaunch flow, schedule and manpower requirements are shown in Figures 8.2-3 and 8.2-4.

8.2.4.2 Flight Test

Eight flights are planned for the 510A-3B/510ADE-3B configuration flight test program.

The main stage (MS) and Apogee kick stage (AKS) flight test program for configuration 510A-3B is essentially as described in Part I, paragraph 8.2.4, with the AKS not tested until late 1981.

The MS flight test program for configuration 510ADE-3B is the same as described in Part III, paragraph 8.2.4 using the DKS as the retrieval target.

Since the DKS is developed and flown earlier than the main stage, a separate and dedicated flight test is planned to verify the capability of the DKS to function during and after extended exposure to orbital environments. This flight will occur in early 1981 and could be accomplished as part of a normal shuttle launch or by some other means.

The schedule and test costs for the flight test program is shown in Figure 8.2-5.

8.2.5 Analysis of the Test Program

8.2.5.1 Key Elements

The key elements of the 510-3B/510ADE-3B configuration Vehicle Test Program, are the same as described in Parts II and III, Paragraph 8.2.6.1

8.2.5.2 SR&T Assumptions

The basic assumptions for the 510-3B/510ADE-3B SR&T requirements are described in Part I, paragraph 8.2.6.2.- SR&T requirements. Test programs affected and a brief description of the interaction with the test programs affected is summarized in Table 8.2-2

  - LAUNCH OPS: $1.61 M
  - FLIGHT OPS: $2.30 M
- CONSUMABLES (FOF ONLY): $62 K

FIGURE 8.2-5 -FLIGHT TEST PROGRAM SCHEDULE (510A-3B/510 ADE-3B)

TECHNOLOGY REQUIREMENTS	TEST PROG. AFFECTED	REMARKS
Main engine life and high performance	- GFE eng. devel. prog. - Flight test prog.	Early life verif. of eng. components and area ration nozzle performance assures phase C/D engine development. PTV is not affected since eng. is not required. FOF could tolerate slightly reduced eng. performance.
PFR helium tank		Early verif. of low weight PFR tank assures maximum tug performance.
Materials compatibility Data	- Tank Qual. - STA prog. - PTV prog.	Early verif. of material compatibility with MMH and N_2O_4 assures on-time development of main stage tankage including tank qual. STA and PTV testing.
Fracture Mechanics Data	- Tank Qual. - STA prog.	Early fracture mechanics data allows on-time development of structural subsystem including tankage quals and STA testing.
Heat Pipes	- Flight test prog.	Early verif. of heat pipe design approach allows on time developments of Thermal Control Subsystem thereby maximizing Tug performance
Advanced IMU	- Integrated avionics - Flight Vehicle Factory checkout - STA	Early devel. of Advanced IMU will assure on time devel. of software and integration procedures in the IAT LAB for FLT VEH buildup and test and accurate simulation for STA prog.
Laser Radar	- Integrated Avionics - Flight Vehicle factory checkout - STA	Early devel. of light weight low power Laser Radar will assure on time development of software and integration procedures in the IAT LAB for FLT VEH buildup and test and accurate simulation for STA program.
Long Term Space Storable SRM	- SRM Qual.	Early verif. of long term space storable SRM assures an on-time development and qual.
Spun-form 2219-T81 tanks	- STA test program	Early verification of manufacturing techniques and and material property data allows on-time development of struct. subsystem including qual. on STA

TABLE 8.2-2 SR&T ASSUMPTIONS

8.2.5.3 Reusability Demonstration

Reusability demonstrations for the 510-3B/510ADE-3B configuration are the same as described in Part I, paragraph 8.2.6.3

8.2.5.4 Life Verification Tests

The Life Verification Test requirements for the 510-3B/510ADE-3B configuration are the same as described in Part I, paragraph 8.2.6.4.

510A-3B/510ADE-3B GROUND TESTS

TEST	TEST ART.	OBJECTIVES	APPROACH
STRUCTURES o 510-3B ONLY - MAIN STG (MS) - APOGEE KICK STAGE (AKS)/ DEORBIT KICK STAGE (DKS)	o COMPLETE M.S. PRIM & SEC. STRUCT. INCL. TUG/ORB, TUG/AKS TUG/P.L. 510A-3B/510ADE-3B GROUND TESTS

Vehicle Test Program

The vehicle test program for 510A-3B/510ADE-3B was developed in a similar manner to that described for 110A-1

Structural Test Articles

The Structural test program for the 510A-3B is the same as that described for the 110A-1. The DKS Structural test philosophy is basically the same as the MS test program. The AKS structure is the same as the DKS and therefore does not require a separate structural test program. The 510A-3B STA will be configured to include the evolved 310ADE-3B avionic retrieval hardware and mechanical interfaces with test loads enveloping both configurations.

Propulsion Test Vehicle

The M.S. Propulsion test program for the 510A-3B configuration is the same as that described for the 110A-1. The DKS propulsion test philosophy is also the same as for the 110A-1 AKS. Since the only difference between the DKS and AKS propulsion system is a reconfiguration in SRM's no additional DKS propulsion tests are required.

510A/510ADE GROUND TESTS (CONT'D)

TEST	DESCRIPTION	OBJECTIVES	APPROACH
INTEGRATED AVIONICS o INTEG. AVIONIC TEST (IAT) FACILITY - MS - DKS - AKS o AVIONICS SOFTWARE DEVELOPMENT LAB (ASDL) - MS	o IAT - SHIP SET OF AVIONICS - COMPUTER SIMULATION - SENSOR STIMULUS - FACTORY & LAUNCH GSE o ASDL - COMPUTER FACILITY WITH MATH MODEL SIMULATION OF MS HARDWARE	o VERIFY HARDWARE/ SOFTWARE PRIOR TO VEHICLE INSTALLATION & FOF o VERIFY EVOLVED RETRIEVAL HARDWARE/SOFTWARE PRIOR TO VEHICLE INSTALLATION & FOR 83 IOC.	o IAT - SUBSYSTEM INTEG. & END-TO-END FUNCTIONAL VERIFICATION - VERIFY FACTORY C/O PROCED - HARDWARE/SOFTWARE VERIF. - MISSION SIMULATION - INTEGRATE & VERIFY RETRIEVAL CAPABILITY HARDWARE/SOFTWARE - RETRIEVAL MISSION SIMULATION o ASDL SOFTWARE VERIFICATION FOR BASIC & EVOLVED CONFIGURATION
MOCKUPS o MS o DKS o AKS	o WOOD & CARDBOARD MOCKUP OF THE TUG MS, DKS & AKS STRUCTURE INCLUDING EQUIPMENT FOR PDR. o WOOD & METAL MOCKUP OF MS, DKS & AKS STRUCT. & COMPONENTS FOR CDR	EVALUATE EQUIPMENT ACCESSIBILITY & MAINTAINABILITY. EVALUATE SHUTTLE & PAYLOAD INTERFACE AND LINES RUN PRIOR TO FAB OF FINAL HARDWARE	o COMPONENT INSTALLATION o ESTABLISH LINE LENGTHS. FOR FINAL HARDWARE FAB. o DEMONSTRATE MAINTAINABILITY - ASSESSMENT & DEMOS OF EQUIPMENT CLEARANCES - CONNECTOR & MOUNTING ACCESSIBILITY DEMO o SHUTTLE & PAYLOAD INTERFACE ASSESSMENT

GROUND TEST COST = $26.85M

510A-3B/510ADE-3B GROUND TESTS (CONT'D)

Integrated Avionics Tests

The MS Integrated Avionics Test program for the 510A configuration will be the same as the 110A-1 test program. The DKS will be integrated in the same facility as the MS IAT to take advantage of the facility simulation and GSE capability. The DKS will be modified to simulate the AKS for MS-AKS IAT Mission Simulations. The IAT and ASDL facilities will initially be configured for the basic mission hardware and software including autonomy level III A. As the retrieval capability and autonomy level II B is evolved the IAT hardware and ASDL software will be updated and the evolved system verifications and mission simulation performed.

Mockups

The MS mockups for this configuration will be the same as those required for 110A. The DKS will also require mockup which will be modified at a later date to serve as AKS mockups.

510A-3B/510ADE-3B FLIGHT TESTS

TEST ARTICLE	OBJECTIVES	APPROACH
o MAIN STAGE (510A-3B) - 1ST PROD. UNIT INCLUDING DFI o MAIN STAGE (510ADE-3B) - 1ST PROD. UNIT INCLUDING DFI o DKS 1ST PROD. UNIT INCLUDING DFI.	INITIAL IOC o THERMO-VERIFY SYS. RETRIEVAL DEMO WITH DKS PERFORMED UPON RETURN TO 160NM ORBIT o ONE DEDICATED FLIGHT TEST OF DKS IN 1982

FLIGHT TEST COST = $23.04M

TOTAL VEHICLE TEST = $49.91M

GRUMMAN

510A-3B/510ADE-3B FLIGHT TESTS

Nine flights are included in the 510A-3B/510ADE-3B flight test program.

The main stage flight test program is essentially as described for configuration 110A-1. The test sequence for the evolved configuration includes a retrieval demonstration as described in 310RE-3A using a DKS to serve as the retrieval target.

Since the DKS is developed and flown earlier than the main stage a separate and dedicated flight test is planned to verify the capability of the DKS to function during and after extended exposure to orbital environments. This flight will occur in early 1981 and could be accomplished as part of a normal Shuttle launch or by some other means.

8.3 Facilities Plan - Option 3B - Concept 510A-3B/510 ADE-3B

8.3.1 Manufacturing Facilities

Same as concept 110A-1 except 39,200 sq. ft. of floor space is required for fabrication and assembly of the TUG.

8.3.2 Test Facilities

Same as concept 110A-1 except 1AT will require 1300 sq. ft. of floor space at JSC.

8.3.3 Operations Facilities

Same as concept 110A-1 except TUG Maintenance Facility at ETR will have 4 horizontal stations in a 12,000 sq. ft. addition to the Shuttle OMS Facility. The Kickstage SRM Processing Facility will require 2800 sq. ft. of floor space.

8.4 Vehicle Manufacturing

This section establishes the manufacturing requirements for the 510A-3B/510ADE-3B spacecraft including the assembly sequence, tooling, schedule, manufacturing test, special processes and facilities.

The 510A-3B spacecraft consists of a main stage and an apogee kick stage (AKS) with phased introduction of a deorbit kick stage (DKS). The configuration is essentially the same as the 310 and 410 configurations except that the OMS engine is used and lower construction cost is achieved by using aluminum propellant tanks and a stiffened sheet outer shell. Use of the OME increases the length of the orbiter adapter and relocates the forward support pickup structure.

8.4.1 Plan/Flow/Time

The manufacturing sequence for the main stage and propellant tanks are included in the Part II Section 8.4 manufacturing discussion. The kick stage is essentially standard for all configurations and is discussed in Part I Section 8.4.1.2.

The manufacturing flow and master schedule are shown in figures 8.4-1 and 8.4-2 respectively.

8.4.2 Tooling Requirements (including GSE)

Tooling requirements for the main stage are shown in Figure 8.4-1. The kick stage requirements are the same as those discussed in Part I Section 8.4.2.2.

8.4.3 Facilities Requirements

See Part II section 8.4.3

8.4.4 Special Requirements

See Part I Section 8.4.4

8.4.5 Summary Analysis/Philosophy

8.4 Vehicle Manufacturing

This section establishes the manufacturing requirements for the 510A-3B/510ADE-3B spacecraft including the assembly sequence, tooling, schedule, manufacturing test, special processes and facilities.

The 510A-3B spacecraft consists of a main stage and an apogee kick stage (AKS) with phased introduction of a deorbit kick stage (DKS). The configuration is essentially the same as the 310 and 410 configurations except that the OMS engine is used and lower construction cost is achieved by using aluminum propellant tanks and a stiffened sheet outer shell. Use of the OME increases the length of the orbiter adapter and relocates the forward support pickup structure.

8.4.1 Plan/Flow/Time

The manufacturing sequence for the main stage and propellant tanks are included in the Part II Section 8.4 manufacturing discussion. The kick stage is essentially standard for all configurations and is discussed in Part I Section 8.4.1.2.

The manufacturing flow and master schedule are shown in figures 8.4-1 and 8.4-2 respectively.

8.4.2 Tooling Requirements (including GSE)

Tooling requirements for the main stage are shown in Figure 8.4-1. The kick stage requirements are the same as those discussed in Part I Section 8.4.2.2.

8.4.3 Facilities Requirements

5.5 510A-3B/510ADE-3B SPECIAL PROGRAMMATICS

The main features defined for implementing and managing Program 510A-3B/510ADE-3B include: defining the initial/evolved flight build up based on Shuttle/Tug launch constraint and ground crew launch capability; timing DKS development to capture 1984 retrievals: implementing 3 lot vehicle production (deploy, deploy-upgrade, and retrieve); refurbishing the propulsion test article for operational use; and defining a fall back position for every identified risk.

Specific areas for government participation include: establishing Tug/Shuttle interface requirements before Orbiter design freeze; providing payload interface design requirements and mission model data; initiating required activities for supporting Research and Technology; providing GFE systems and components (eg: main engines, and DOD secure comm); supporting propulsion system testing and development and supporting integrated avionics hardware testing and related software development; providing required facilities; and performing vehicle ground operations, flight operations, and logistic support operations.

510A-3B/510ADE-3B SPECIAL PROGRAMMATICS

- o PROGRAM IMPLEMENTATION AND MANAGEMENT
  - INITIAL/EVOLVED FLIGHT BUILD-UP SET BY SHUTTLE/TUG LAUNCH CONSTRAINT AND GROUND CREW LAUNCH CAPABILITY
  - 3 LOT PRODUCTION (DEPLOY, DEPLOY-UPGRADE AND RETRIEVE) TO AVOID MFG GAP
  - DKS TIMED TO CAPTURE '84 RETRIEVALS
  - PROPULSION ARTICLE REFURBED FOR FLIGHT
  - FALL BACK POSITION SHOWN FOR EVERY IDENTIFIED RISK

- o AREAS FOR GOVERNMENT PARTICIPATION
  - FIRM TUG/SHUTTLE INTERFACES BEFORE ORBITER PDR
  - PROVIDE PAYLOAD INTERFACE DESIGN REQUIREMENTS AND MISSION MODEL DATA
  - INITIATE REQUIRED SR&T
  - SUPPORT SYSTEM TEST - AVIONIC HARDWARE/SOFTWARE, PROPULSION
  - PROVIDE GFE SYSTEMS AND COMPONENTS, FACILITIES AND LOGISTIC SUPPORT
  - PERFORM VEHICLE GROUND AND FLIGHT OPERATIONS

GRUMMAN

8.6 COST DATA

Included in this section are the cost data for an evolved tug configuration 510A-3B-510ADE-3B. Cost data are provided for the initial program 510A-3B and the combined total evolved program.

- Initial Program 510A-3B
  - Storable Space Tug System Project Expected Cost-Spares Cost (INT & OPS)-First Unit Cost (Data Forms A1, 2 and 3, subparagraph No's 8.6.1, 8.6.2 and 8.6.3) (Computer P/O)
  - Storable Space Tug Funding Schedules-DDT & E, Production and Operations (Date Form C, subparagraph 8.6.4, 8.6.5, 8.6.6 and 8.6.7)
  - Form B (Technical Characteristics subparagraph 8.6.11)
- Combined Evolved Program 510A-3B/510ADE-3B
  - Same as initial program plus:
    - Average Cost/Flight (subparagraph 8.6.9)

8.7 FLIGHT SCHEDULE

Included in support of our flight schedule definition for concept 510A-3B/510ADE-3B are the following tasks:

- Fleet size and Vehicle Usage
- Kick Stage Usage
- Flight Element Requirements
- Kick Stage Definition
- Payload Flown
- 510A-3B/510ADE-3B Flight Operations Buildup
- Programmatic Data Summary Storable Tug Concept 510A-3A/510ADE-3A

510A-3B/510ADE-3B FLIGHT OPERATIONS BUILDUP

As in the prior programs the 510A-3B/510ADE-3B flight buildup was defined considering: NASA defined Shuttle/Tug launch constraints, initial and evolved ETR ground crew launch capabilities, and flight mode buildup.

Our recommended flight buildup for 510A-3B/510ADE-3B, including 3 flights in 1980, 18 flights in 1981, and 38 flights in 1984, encompasses 336 total flights through 1990 or 25 less than 100% payload capture traffic.

8.9 Risk Assessment

In making an assessment of the risk associated with each configuration in each capability option we have considered the type of technology items associated with each vehicle and the impact that it would have on the program if for one reason or another, the item would be unavailable and an alternative solution would be required. The impact is defined, usually, in terms of added weight, lost performance and total program cost increase; in some cases the impact can be decreased weight or reduced cost.

It is assumed that all of the weight increases and all of the cost increases will occur simultaneously without benefit of any offsetting decreases in either weight or cost. For example in configuration 110A-1 we have assumed that the +4 lb. weight impact of abandoning spun aluminum tanks in favor of welded aluminum tanks is combined with a $10.0 million cost increase as a result of abandoning aluminum tanks in favor of titanium tanks due to materials compatibility or fracture mechanics issues.

Taking the summation of all the weight increases, these are converted to costs by using the $75K/lb. figure derived when we were first selecting subsystem options for incorporation with 110A-1. The $75K/lb. number represents the last step (actually the slope of the line) in our subsystems synthesis process which provides a curve of Δ weight versus Δ total program costs as we added lighter and more costly subsystems options to achieve a behicle with 3500 lb. deploy capability. In this manner we arrived at a estimate of the costs expected if we had to recover the weight growth.

In similar fashion we then summed all of the potential cost increases, ignoring any offsetting cost decreases, and added these to the dollars representing the weight increases. The 110A-1 has no projected performance loss since it uses the OME 7.5K engine; the assumption is that the basic OME will have been developed to meet its weight, performance and reusability goals for the Shuttle Orbiter. In the case of configurations which use the Class I engine, for example 410AD-2, we have assumed that a 3 second Isp performance loss is possible. To convert this performance loss to costs we use the payload sensitivity factor to loss in Isp (97 lbs/sec), divide this by the payload sensitivity to inert weight and then multiply by $111/lb. to convert it to costs.

Taking all of the costs and adding them together we get a total low cost risk value of $15.3M for 110A-1 which ranges to a high value of 94.3M for 320A-3A/320AE-3A.

51CA-3B/51OADE-3B RISK ASSESSMENT

TECHNOLOGY ITEM IMPACT	
• SPUN-FORM AL TANK	+4 LB
• PFR TANK	+48 LB
• ADV IMU	+30 LB
• LASER RADAR	COST/SCHED
• SPACE STORABLE SRM	COST/SCHED
• MATERIALS COMPATIBILITY	-13 LB
• FRACTURE MECHANICS	
• HEAT PIPES	SCHED

VEHICLE SENSITIVITY (DEPLOY)	PLAIN	WITH AKS
$\frac{\partial P/L}{\partial W \text{ FIXED}}$ (LB/LB)	-3.52	-2.44
$\frac{\partial P/L}{\partial \text{ ISP}}$ (LB/SEC)	112	92

- TECHNICAL RISK
  - POTENTIAL WT IMPACT: +82 LB ≈ 200 LB OF PAYLOAD (W/AKS)
  - POTENTIAL ISP LOSS: MIN WITH ONE 7.5K ENG
  - OPEN WEIGHT REDUCTION OPTIONS: GRAPHITE COMPOSITE, ADV. FUEL CELL
- SCHEDULE RISK
  - PROPOSED SR&T PROGRAMS (COMPL PRIOR TO ATP) PROTECT AGAINST SCHEDULE SLIP
  - AVAILABILITY OF 621 B SATELLITES
- COST RISK
  - POTENTIAL Δ COST $15.9 M

LOW RISK PROGRAM

510A-3B/510ADE-3B RISK ASSESSMENT

The technology items and their potential impact are shown on the opposite chart. If the Spun-form aluminum tank does not meet its goals, a welded gore aluminum tank adds 4 lbs. to the vehicle, similarly if the prestressed filament reinforced tank is replaced by a 6Al4V titanium tank, 48 lbs. are added. If the advanced (Micron) IMU is unavailable, a Carousel VB IMU plus a rate gyro unit adds 30 lbs. There are no attractive alternatives for the lasar radar and the space storable SRM, hence, they represent both a schedule and cost risk. If materials compatibility or fracture mechanics data indicate the need to change propellant tank material, a change from aluminum to titanium results in a 13 lb. weight reduction but increases costs by $10M. If high heat rejection items are placed on the active loop rather than on heat pipes there are no weight changes. To recover the weight impact on payload capability due to these possible weight increases, graphite composites and the advanced fuel cell remain open options.

The use of the OME 7.5K engine provides high confidence that the weight, performance and reusability goals will be met because the basic engine will have been developed for use in the Shuttle Orbiter. As a result there is no projected potential weight or Isp loss with this engine.

Schedule risk is minimized by the proposed SR & T programs which provide the feasibility of the approach by ATP; however, the availability of the 621B Navigation Satellites remains a schedule risk.

Converting the potential Isp loss and weight increases to a total program cost at a $111K/lb value and adding the potential cost increase items, yields a total cost risk of $15.8M for 510A-3B/510ADE-3B.

RISK ASSESSMENT 510A-3B/510ADE-3B

TOTAL COST RISK ----------$15.87M

Section 8.10 Supporting Research and Technology

This section includes a summary matrix chart which identifies all of the SR & T items and where they are applied to each configuration in each capability option.

Following the summary matrix there are individual tables for each configuration which summarize the technology items for that particular configuration and give a very brief synopsis of the type of SR & T program proposed and the estimated funding and schedule requirements. The text following each table is the facing page text prepared for the main presentation.

Following the tables for each configuration, an additional form is filled out for each technology item providing status information, justification for the proposed SR & T program, objectives, technical approach, and a more detailed schedule showing when the proposed program must be completed in order to support the particular configuration.

In dealing with the subject of SR & T we have identified two distinct groups - one where technology is needed and the other where there is no doubt that the technology is available and it is a straightforward engineering task to accumulate data that will preclude making a "false start" where several alternates are under study; we have called the latter group "desired data".

The storable Tug will benefit from the fact that the APOLLO LM program has used similar materials, propellants, equipments and procedures; the Shuttle Orbiter will expand on this data base for the Tug. The low number of identified SR & T items and the modest sums projected are based on the assumption that several existing or planned efforts related to the Shuttle will continue to provide data. These include the planned propellant and materials compatibility testing in support of the Shuttle Orbital Maneuvering Subsystem, its engines, tanks and components both at NASA/WSTF and at the Shuttle contractor's facilities. In addition, we have identified the Air Force funded efforts to develop the advanced Micron IMU for aircraft programs, as an effort which we would build-on rather than to start from scratch.

We have not attempted to detail the SR & T programs required on the Class I engine (with or without the two position nozzle) except to point out the uncertainty associated with the anticipated engine life and the predicted performance of very high expansion ratios within the mixture ratio of interest. The engine contractor will provide the proposed SR & T efforts required on the engine and we will provide comments on same at NASA's request.

The overall "message" which we hope will become obvious to the reader is that there are no real "show-stoppers" among the SR & T items identified.

TECHNOLOGY REQUIREMENTS AND DESIRED DATA - 510A-3B/510ADE-3B

The upper part of the facing chart contains the supporting research and technology (SR&T) items required for 510A-3B/510ADE-3B; the lower part of the chart contains what we have termed as "desired data". The distinction between the two is that the "desired data" items do not require technology but are considered straightforward engineering development tasks to produce design data prior to Tug program go-ahead (ATP); this will preclude impacting Tug schedules should the data indicate the desirability of an alternative approach, (vis., titanium propellant tanks rather than aluminum).

The total SR&T funds requested for 510A-3B/510ADE-3B is $1,425 K) to be expended over an 18 month period culminating at Tug ATP or prior to go-ahead on the evolved Tug. The advanced (Micron) IMU is the long lead item (18 months).

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Avionics (C&C)
(Discipline)

TITLE Low Weight/Power, (Rendezvous and Docking) Laser Radar

WBS No. 320-03-03-02

STATUS ITT-Gilfillan has been under NASA Contracts since 1964 to design, develop, build, and test various spaceborne laser radar systems. The third generation system will be delivered in late November 1973.

JUSTIFICATION The application of the above developed technology to meet specific space tug rendezvous and docking requirements is desired.

In addition in order to improve the payload capability of the storable tug, low weight Avionics equipments (specifically, low weight/low power laser radar) are required.

OBJECTIVES To design, develop, fabricate, and test a low weight, low power, rendezvous and docking laser radar.

II-88-9

TECHNICAL APPROACH Using Tug requirements, design for light weight, low power by using new components, lighter mirror drives and improved optics

TITLE Prestressed Filament Reinforced (PFR) Tanks

WBS No. 320-03-04-02

STATUS Structural Composites Industries, Inc. (SCI) and Arde-Portland, Inc. are under contract to LeRC to demonstrate the feasibility of the PFR tanks. This program will result in the construction of a 24 in. diam. Ardeform PFR tank of the type assumed by our study. If successful the basic technology will be proven.

JUSTIFICATION

A PFR ambient helium storage tank is comparable with the weight of a SHe tank and its associated heat exchanger. It provides a simple and less operationally complex system compared to the SHe tank. The PFR tank also provides a leak-before-burst design which results in increased Tug safety.

OBJECTIVES

Design, fabricate, and test 3 to 6 PFR tanks to demonstrate that current manufacturing and quality control techniques are adequate to produce a reliable, low weight tank suitable for containing gaseous helium (or hydrogen and oxygen in the case of fuel cell reactant tanks). The program will resemble a pre-qualification test program which will demonstrate the ability of the PFR tank to undergo the dynamic loading, compatibility, environmental exposure and etc. tests required for acceptance as a flight item.

TECHNICAL APPROACH

Fabricate 3 to 6 tanks and subject them to a pre-qualification test program to demonstrate the maturity of the design.

MANPOWER 2 man years

FUNDING $125,000

TITLE SPIN FORMING OF 2219-T 81 DOMES FOR TANKS WBS No. 320-03-01-01-02

STATUS Hot technique of spin forming 2219 is feasible. However, the technique has not been demonstrated nor have design allowables been established.

JUSTIFICATION A weight savings can be achieved if 2219 aluminum alloy can be spun to achieve a temper of at least T81

OBJECTIVES To demonstrate a combination of hot and cold spin forming to achieve a minimum of T81 temper in 2219 spun domes

91-63-IX

TECHNICAL APPROACH Small scale, approximately 5 foot domes will not be hot spun approximately to size. Domes will then be heat treated to the unstable "W" condition and spun cold to size to achieve a T-31 temper. After heat treatment to T81 scale domes will be sectioned for mechanical property evaluation and thickness control.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Main Propulsion (MPS)
(Discipline)

WBS No. 320-04-8-2, 9-2

TITLE Long-Term SRM Space Storage

STATUS In 1963, Battelle Memorial conducted long-term space storage tests (hard vacuum, thermal and radiation) on SRM propellants, motor components and assembled motors. The testing was performed on PBAA and polyurethane propellants. Some accelerated thermal testing at -160°F has been conducted by UTC on HTPB during the past year.

JUSTIFICATION Some of the Storable Tug missions use deorbit SRM's; these impose a requirement for long-term space storage (3-6 yrs) on SRM's. The effects of hard vacuum and low temperature on the reliability and performance of the SRM must be considered. Radiation is not a consideration because the payloads requiring deorbit kick stages are not exposed to the Van Allen radiation belt for any significant duration.

OBJECTIVES
To demonstrate that long-term exposure to hard vacuum and low temperature will not affect the performance of present day propellants such as CTPB and HTPB.

VI-8,4-18

TECHNICAL APPROACH
Expose propellant tensile bars, propellant burning strands and propellant additives to thermal vacuum conditions and conduct weight/vapor loss, tensile strength, and burning rate tests after exposure.

TITLE Material Compatibility WBS No. 320-03-01-01-02

STATUS Material compatibility of Ti-6AL-4V STA and 2219-T87 Aluminum alloy in the presence of MMH at temperatures up to 150°F is required. Compatibility of N_2O_4 with 2219-T87 is also required.

JUSTIFICATION Compatibility of propellants with tankage material must be assessed to obtain the reuse life of the tanks under cyclic loads.

OBJECTIVES The objective of the program is to obtain the static and fatigue properties of the tankage parent and weldment materials under cyclic exposure to propellants and load.

VI-8.4-20

TECHNICAL APPROACH Static and fatigue properties of candidate materials specimens will be obtained prior to and after exposure to the propellants. Tests will be performed at R.T. and 150°F.

TITLE Fracture Mechanics Test Data WBS No. 320-03-01-01-02

STATUS Fracture mechanics test data for thin gage (.020 to .040) for Titanium 6AL-4V STA and 2219-T87 aluminum alloy exposed to N_2O_4 and MMH at temperatures up to 200°F is not available.

JUSTIFICATION Fracture mechanics data for thin gage tank material are required to assess the fracture mode and life cycle of the tug propellant tanks.

OBJECTIVES The objectives of the program are to obtain K_{ic}, K_{th} and flaw growth data for parent and weldment materials in the induced thermal environment up to 200°F. Data to be obtained prior to and after exposure to the candidate propellants. In addition to fracture mechanics data, NDE techniques are to be employed on the test specimens to assess flaw detection capability.

VI-89-22

TECHNICAL APPROACH Standard fracture elemental specimens are to be employed. Tests are to be employed. Tests are to be conducted at room temperature and at 150 and 200°F. Surface flaws of various sizes are to be used and NDE techniques are to be employed to document size where practical.

TITLE SPACE TUG HEAT PIPES

WBS No. 320-04-02

STATUS

Heat pipes (HP) are currently being used in both ground and space application. The variable conductance heat pipe (VCHP) principle is particularly attractive for Tug application but requires further development.

JUSTIFICATION

The fuel cell and certain high power density avionics units carried on the Space Tug require active cooling. Trade studies which have examined pumped loop radiators, sublimators and various heat pipes have indicated the obvious merits of the variable conductance heat pipe. A VCHP radiator could interface with the pumped loop heat transport system of the fuel cell, eliminating the cost and complexity of a selective stagnation radiator with its associated unreliable automatic bypass valves. A VCHP header, a heat transport device, could provide for high power density avionics heat transport without recourse to the active loop.

VI-5.9-24

OBJECTIVES

Emphasis will be placed on experimentally obtaining the large turn down ratios which appear theoretically achievable and in developing predictive techniques.

TECHNICAL APPROACH

Design, fabricate and test a VCHP radiator and VCHP header and experimentally determine performance with emphasis on turn down ratio and shut off heat flux levels.
