COSTED FLIGHT BUILDUP

TABLE 4.3.1.2-9

I-8.7-7

FLIGHT OPERATIONS BUILDUP - 110A-1

The methodology used to establish the 110A-1 flight buildup is keyed to achieving all flights defined by the 100% payload capture analysis after the second year of operations. The primary factors considered include: NASA defined Shuttle/Tug launch constraints. initial ETR ground crew launch capabilities, and flight mode buildup.

Shuttle/Tug launch constraints affect the first year of operations and allow only 3 flights. During the second year of operations the allowable Shuttle/Tug launches exceed the payload capture traffic model.

Initial ground crew launch capability is based on a 90% learning factor applied to the minimum ground crew for Tug launch to launch processing during mature turnaround at the 100th flight. The 15 flight ground crew launch capability shown in the second year can only be achieved if the ground crew had been able to achieve the experience associated with 12 flights in the first year. However, since Shuttle/Tug launches are limited to only 3 flights in 1980, the full benefits of potential ground crew learning cannot be realized. Therefore, 1981 is limited to 12 launches since it is equivalent to the first year of full ground crew activity. We recommend that the minimum ground crew be retained for the first two years to limit the initial cost of operations. Additional personnel would be added at the end of 1981 in order to accommodate the higher launch rates required in 1982 and 1983.

During the flight buildup period we recommend that flight crew experience be developed by starting with the simplest flight mode and then progressively introducing the more complex flight modes required for 1982. For example, in 1980 the Tug is limited to single payload deploy missions. During the second year some multi payload deploy and single payload deploy with apogee kick stage flights are introduced.

Our recommended flight buildup for 110A-1, including 3 flights in 1980 and 12 flights in 1981, encompasses 218 total flights through 1990 or 12 less than 100% payload capture traffic.

PROGRAM SENSITIVITY TO IOC SHIFT - 110A-1

Two programmatic options are available for implementing program concept 110A-1 under a 2 year delay. First the baseline schedule could be shifted 2 years and start at October 77 ATP. The second option uses a schedule stretch out from the original 75 ATP to the delayed 81 IOC milestone. Both schedule options assume that the original flight build-up is delayed. We examined the implications of IOC shift with respect to operations, production and development.

IOC delay results in 79 undeployed payloads for either the shift or stretch development schedule options.

Considering vehicle production two different factors should be addressed. They include schedule implications on manufacturing learning and the availability of existing hardware. For the schedule shift option, manufacturing learning can be more efficiently transferred from test article fabrication to vehicle production, than in a stretchout situation. Basic draw back of schedule shift is that the delay in ATP may make the availability of planned existing hardware questionable. On the other hand the stretch option allows early contractual arrangements for vendor support.

The impact of IOC delay on development was reviewed with respect to the following: schedule, type of contractor support available to NASA/DOD for defining Tug/Shuttle systems and interfaces, vehicle test, facilities SR&T and cost. For the first two years of the stretched schedule, Tug/Shuttle systems and interfaces would be defined by the government with support of a prime contractor. This is a vital period for assuring that the two vehicles are compatible as illustrated by the Apollo LM/CSM relationship. The impact on vehicle test, facilities and SR&T are similar for both schedule options. Assuming that the initial period of schedule stretch is devoted to systems engineering studies, we estimate that cost of stretch-out will be $7M. Peak funding occurs in 1981 and is $63M for the schedule stretch option.

8.9 Risk Assessment

In making an assessment of the risk associated with each configuration in each capability option we have considered the type of technology items associated with each vehicle and the impact that it would have on the program if, for one reason or another, the item would be unavailable and an alternative solution would be required. The impact is defined, usually, in terms of added weight, lost performance and total program cost increase; in some cases the impact can be decreased weight or reduced cost.

It is assumed that all of the weight increases and all of the cost increases will occur simultaneously without benefit of any offsetting decreases in either weight or cost. For example in configuration 110A-1 we have assumed that the +4 lb. weight impact of abandoning spun aluminum tanks in favor of welded aluminum tanks is combined with a $10.0 million cost increase as a result of abandoning aluminum tanks in favor of titanium tanks due to materials compatibility or fracture mechanics issues.

Taking the summation of all the weight increases, these are converted to costs by using the $75K/lb. figure derived when we were first selecting subsystem options for incorporation with 110A-1. The $75K/lb. number represents the last step (actually the slope of the line) in our subsystems synthesis process which provides a curve of Δ weight versus Δ total program costs as we added lighter and more costly subsystems options to achieve a behicle with 3500 lb. deploy capability. In this manner we arrived at a estimate of the costs expected if we had to recover the weight growth.

In similar fashion we then summed all of the potential cost increases, ignoring any offsetting cost decreases, and added these to the dollars representing the weight increases. The 110A-1 has no projected performance loss since it uses the OME 7.5K engine; the assumption is that the basic OME will have been developed to meet its weight, performance and reusability goals for the Shuttle Orbiter. In the case of configurations which use the Class I engine, for example 410AD-2, we have assumed that a 3 second Isp performance loss is possible. To convert this performance loss to costs we use the payload sensitivity factor to loss in Isp (97 lbs/sec), divide this by the payload sensitivity to inert weight and then multiply by $111/lb. to convert it to costs.

Taking all of the costs and adding them together we get a total low cost risk value of $15.3M for 110A-1 which ranges to a high value of 94.3M for 320A-3A/320AE-3A.

8.10 RISK ASSESSMENT (continued)

Where no suitable alternative exists (for example the Class I engine, or the laser radar, or the Space Storable SRM) we have identified that item as both a cost and a schedule risk without attempting to quantify the risk. In general, we are relying on the successful completion of the proposed SR&T programs to reduce or eliminate the risk of schedule slippage.

Taking configuration 110A as an example:

110A-1: This is an extremely low risk program with only two items representing a technical risk, the spun-form aluminum tanks and the prestressed filament reinforced (PFR) helium tanks. Both of these items are low risk and both have suitable, low risk alternatives available.

The incorporation of separate tanks (rather than the nested tanks used in the other configurations) further reduces the risk associated with this configuration. Level III (rather than Level IIB) autonomy also reduces the risk since there is no reliance on the 621B Navigation Satellite program. The OME 7.5K engine is the lowest risk engine program available, so its use on 110A-1 further reduces risk. The use of scaled-up LM batteries rather than fuel cells with their associated cryogenic storage tanks and valves is again the lowest risk approach available for providing electrical power. The all-aluminum structure is the lowest cost/lowest risk approach available. The short mission duration (34 hours) eliminates the need for multi-layer insulation (MLI) on most of the external surfaces there minimizing the risk of damage to the MLI during vehicle ground operations.

Since the 110A-1 does not have to communicate with payloads it has the the lowest risk communications equipment, a dedicated frequency station, to develop. Although our current approach includes making the communications equipment compatible with the NASA Tracking and Data Relay Satellite System (TDRSS) an option which can further reduce risk, is to eliminate the requirement for this equipment to meet the spread spectrum and CCIR interference requirements associated with TDRSS. The modifications of an existing IMU (the Carousel VB) and an existing computer (the CDC 469) are again the lowest risk approach identified in the GN&C and DMS areas.

Although the use of an apogee kick stage (AKS) to deploy heavier payloads reduces the sensitivity of the configuration to inert weight growth or I_{sp} loss, it does add complication to flight operations, increasing risk. Elimination of the AKS can further reduce the risk of this configuration.

R

110A-1 RISK ASSESSMENT

TECHNOLOGY ITEM	
TECHNOLOGY ITEM IMPACT	
• SPUN-FORM AL TANKS	+4 LB
• PFR TANK	+48 LB
• MATERIALS COMPATIBILITY	-32 LB
• FRACTURE MECHANICS	
• HEAT PIPES	+5 LB

VEHICLE SENSITIVITY (DEPLOY)	PLAIN	WITH AKS
$\frac{\partial P/L}{\partial W \text{ FIXED}}$ (LB/LB)	-3.83	-2.32
$\frac{\partial P/L}{\partial ISP}$ (LB/SEC)	117	90.2

EXTREMELY LOW RISK PROGRAM

I-19-2

- TECHNICAL RISK
  - POTENTIAL WT IMPACT: +57 LB ≈ 132 LB OF PAYLOAD (W/AKS)
  - POTENTIAL ISP LOSS: MIN WITH OME 7.5K ENG
  - USE OF AKS MINIMIZES VEHICLE SENSITIVITIES & RISK
  - OPEN WEIGHT REDUCTION OPTIONS: FUEL CELLS, GRAPHITE COMPOSITE
- SCHEDULE RISK
  - PROPOSED SR&T PROGRAMS (COMPLETED PRIOR TO ATP) PROTECT AGAINST SCHEDULE SLIP
- COST RISK
  - POTENTIAL Δ COST $15.3 M

110A-1 RISK ASSESSMENT

The technology items and their potential impact are shown on the opposite chart. If the spun-form aluminum tank does not meet its goals, a welded gore aluminum tank adds 4 lbs to the vehicle. Similarly if the prestressed filament reinforced (PFR) tank is replaced by a 6Al4V titanium tank, 48 lbs are added. If materials compatibility or fracture mechanics data indicate the need to change propellant tank material from aluminum to titanium a 32 lb weight reduction would be offset by a $10M cost increase. If heat pipes were replaced by adding louvers and electrical heaters a 5 lb weight increase would result. To recover the minor impact on payload capability due to these possible weight increases, fuel cells and graphite composites are open options.

The use of the OME 7.5K engine provides high confidence that the weight, performance and reusability goals will be met because the basic engine will have been developed for use in the Shuttle Orbiter. As a result there is no projected potential weight or Isp loss with this engine.

Schedule risk is minimized by the proposed SR&T programs which provide the feasibility of the approach 4 months prior to ATP.

Converting all of the potential weight increases to a total program cost at a $75K/lb value and adding the potential cost increase items, yields a total cost risk of $15.3M for 110A-1.

RISK ASSESSMENT 110A-1

TOTAL COST RISK ---------- $15.25M

Section 8.10 Supporting Research and Technology

This section includes a summary matrix chart which identifies all of the SR & T items and where they are applied to each configuration in each capability option.

Following the summary matrix there are individual tables for each configuration which summarize the technology items for that particular configuration and give a very brief synopsis of the type of SR & T program proposed and the estimated funding and schedule requirements. The text following each table is the facing page text prepared for the main presentation.

Following the tables for each configuration, an additional form is filled out for each technology item providing status information, justification for the proposed SR & T program, objectives, technical approach, and a more detailed schedule showing when the proposed program must be completed in order to support the particular configuration.

In dealing with the subject of SR & T we have identified two distinct groups - one where technology is needed and the other where there is no doubt that the technology is available and it is a straightforward engineering task to accumulate data that will preclude making a "false start" where several alternates are under study; we have called the latter group "desired data".

The storable Tug will benefit from the fact that the APOLLO IM program has used similar materials, propellants, equipments and procedures; the Shuttle Orbiter will expand on this data base for the Tug. The low number of identified SR & T items and the modest sums projected are based on the assumption that several existing or planned efforts related to the Shuttle will continue to provide data. These include the planned propellant and materials compatibility testing in support of the Shuttle Orbital Maneuvering Subsystem, its engines, tanks and components both at NASA/WSTF and at the Shuttle contractor's facilities. In addition, we have identified the Air Force funded efforts to develop the advanced Micron IMU for aircraft programs, as an effort which we would build-on rather than to start from scratch.

We have not attempted to detail the SR & T programs required on the Class I engine (with or without the two position nozzle) except to point out the uncertainty associated with the anticipated engine life and the predicted performance of very high expansion ratios within the mixture ratio of interest. The engine contractor will provide the proposed SR & T efforts required on the engine and we will provide comments on same at NASA's request.

The overall "message" which we hope will become obvious to the reader is that there are no real "show-stoppers" among the SR & T items identified.

TECHNOLOGY REQUIREMENTS AND DESIRED DATA - 110A-1

The upper part of the facing chart contains the supporting research and technology (SR&T) items required for 110A-1; the lower part of the chart contains what we have termed as "desired data". The distinction between the two is that the "desired data" items do not require technology but are considered straightforward engineering development tasks to produce design data prior to Tug program go-ahead (ATP); this will preclude impacting Tug schedules should the data indicate the desireability of an alternative approach, (vis., titanium propellant tanks rather than aluminum).

The total SR&T funds requested for 110A-1 is $325K to be expended over a 12 month period culminating 4 months prior to Tug ATP. The low funding request is consistent with the high percantage of existing state-of-the-art materials, equipment designs, and lubrication and testing procedures incorporated in 110A-1.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Main Propulsion (Discipline)

TITLE Prestressed Filament Reinforced (PFR) Tanks WBS No. 320-03-04-02

STATUS Structural Composites Industries, Inc. (SCI) and Arde-Portland, Inc. are under contract to LeRC to demonstrate the feasibility of the PFR tanks. This program will result in the construction of a 24 in. diam. Ardeform PFR tank of the type assumed by our study. If successful the basic technology will be proven.

JUSTIFICATION
A PFR ambient helium storage tank is comparable with the weight of a SHe tank and its associated heat exchanger. It provides a simple and less operationally complex system compared to the SHe tank. The PFR tank also provides a leak-before-burst design which results in increased Tug safety.

OBJECTIVES
Design, fabricate, and test 3 to 6 PFR tanks to demonstrate that current manufacturing and quality control techniques are adequate to produce a reliable, low weight tank suitable for containing gaseous helium (or hydrogen and oxygen in the case of fuel cell reactant tanks). The program will resemble a pre-qualification test program which will demonstrate the ability of the PFR tank to undergo the dynamic loading, compatibility, environmental exposure and etc. tests required for acceptance as a flight item.

TECHNICAL APPROACH

Fabricate 3 to 6 tanks and subject them to a pre-qualification test program to demonstrate the maturity of the design.

MANPOWER 2 man years FUNDING $125,000

SPECIALIZED FACILITIES
Available at tank manufacturers

TITLE SPIN FORMING OF 2219-T 81 DOMES FOR TANKS

WBS No. 320-05-01-01-02

STATUS Hot technique of spin forming 2219 is feasible. However, the technique has not been demonstrated nor have design allowables been established.

JUSTIFICATION A weight savings can be achieved if 2219 aluminum alloy can be spun to achieve a temper of at least T81

OBJECTIVES To demonstrate a combination of hot and cold spin forming to achieve a minimum of T81 temper in 2219 spun domes

TECHNICAL APPROACH Small scale, approximately 5 foot domes will not be hot spun approximately to size. Domes will then be heat treated to the unstable "W" condition and spun cold to size to achieve a T-31 temper. After heat treatment to T81 scale domes will be sectioned for mechanical property evaluation and thickness control.

TITLE Material Compatibility

WBS No. 320-03-01-01

STATUS Material compatibility of Ti-6AL-4V STA and 2219-T87 Aluminum alloy in the presence of MMH at temperatures up to 150°F is required. Compatibility of N_2O_4 with 2219-T87 is also required.

JUSTIFICATION Compatibility of propellants with tankage material must be assessed to obtain the reuse life of the tanks under cyclic loads.

OBJECTIVES The objective of the program is to obtain the static and fatigue properties of the tankage parent and weldment materials under cyclic exposure to propellants and load.

I-8.10-4

TECHNICAL APPROACH Static and fatigue properties of candidate materials specimens will be obtained prior to and after exposure to the propellants. Tests will be performed at R.T. and 150°F.

TITLE Fracture Mechanics Test Data

WBS No. 326-03-01-01-02

STATUS Fracture mechanics test data for thin gage (.020 to .040) for Titanium 6AL-4V STA and 2219-T87 aluminum alloy exposed to N_2O_4 and MMH at temperatures up to 200°F is not available.

JUSTIFICATION Fracture mechanics data for thin gage tank material are required to assess the fracture mode and life cycle of the tug propellant tanks.

OBJECTIVES The objectives of the program are to obtain K_{ic}, K_{th} and flaw growth data for parent and weldment materials in the induced thermal environment up to 200°F. Data to be obtained prior to and after exposure to the candidate propellants. In addition to fracture mechanics data, NDE techniques are to be employed on the test specimens to assess flaw detection capability.

I-8-10-11

TECHNICAL APPROACH Standard fracture elemental specimens are to be employed. Tests are to be employed. Tests are to be conducted at room temperature and at 150 and 200°F. Surface flaws of various sizes are to be used and NDE techniques are to be employed to document size where practical.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Thermal Control
(Discipline)

TITLE: SPACE TUG HEAT PIPES

WBS No. 320-04-02

STATUS: Heat pipes (HP) are currently being used in both ground and space application. The variable conductance heat pipe (VCHP) principle is particularly attractive for Tug application but requires further development.

JUSTIFICATION: The fuel cell and certain high power density avionics units carried on the Space Tug require active cooling. Trade studies which have examined pumped loop radiators, sublimators and various heat pipes have indicated the obvious merits of the variable conductance heat pipe. A VCHP radiator could interface with the pumped loop heat transport system of the fuel cell, eliminating the cost and complexity of a selective stagnation radiator with its associated unreliable automatic bypass valves. A VCHP header, a heat transport device, could provide for high power density avionics heat transport without recourse to the active loop.

I-8.10-13

OBJECTIVES: Emphasis will be placed on experimentally obtaining the large turn down ratios which appear theoretically achievable and in developing predictive techniques.

TECHNICAL APPROACH: Design, fabricate and test a VCHP radiator and VCHP header and experimentally determine performance with emphasis on turn down ratio and shut off heat flux levels.

MANPOWER: 5580 manhours

FUNDING: $100K

8.11.14 SENSITIVITY TASK RESULTS SUMMARY

8.11.1- Ground/Onboard Autonomy Trade Study

The results of our autonomy trade study is presented in Figure 1 and concludes the following:

- Autonomy level IV is best suited to Option 1 concept 110A-1
- Autonomy level II is best suited for Options 2 and 3 where Option 3 starts with level III and evolves to level II.

The level I systems degraded performance resulting from the slow convergence characteristics of the Horizon Scanner/Star Tracker system makes this system unattractive. Our performance studies to date on this level I system have been preliminary in nature and we recommend that NASA and DOD initiate SR&T studies which combine a detail navigation analysis with a complete vehicle performance evaluation.

The level II system selected in our baselines requires the use of the 621B NAV SAT. This introduces significant schedule risk and technology issues. This NAV SAT system has sufficient coverage for spacecraft below 2000 N.M., introducing as a result the need for dedicated ground beacons (1-way doppler) for high altitude TUG operations. It is recommended that the interferometer approach which utilizes undedicated RF sources as landmarks be considered as an option.

The level III system is a compromise approach. It introduces high development and operating cost for software for both the ground and on-board computer systems.

The level IV system is attractive for Option I due to low development costs. The high ground involvement and costs precludes the use of this approach for the more complex Option 2 and 3 programs.

Figure 2 summarizes the cost sensitivities for the three concepts evaluated. Figure 3 outlines the weights and performance. Figures 4 thru 5 lists the weights, DDT&E costs and production costs of the avionics systems used in the sensitivity evaluation.

I-8.1.1-13

8.11.2 - RELIABILITY/REDUNDANCY SENSITIVITY ANALYSIS

OBJECTIVE

I. DETERMINE THE IMPACT ON REDUNDANCY REQUIREMENTS OF A .97 RELIABILITY LEVEL FOR RETRIEVE AND DEPLOY MISSIONS OF 72 AND 36 HOURS.

II. DETERMINE IF PROGRAMMATIC COST SAVINGS CAN BE REALIZED BY ALTERING THE .97 RELIABILITY/REDUNDANCY LEVEL.

GRUMMAN

I. REDUNDANCY SENSITIVITY TO MISSION

ASSUMPTIONS

- o RELIABILITY REFERENCE MISSION OF 168 HOURS (144 TUG + 24 ORBITER) IS THE BASELINE FOR ESTABLISHING REDUNDANCY REQUIREMENTS.

- o TO ACHIEVE .97 FOR THE 410AD-2 CONFIGURATION, 67 LBS OF REDUNDANCY IS INCLUDED

  - IMU
  - OX VENT VALVE
  - APS VENT VALVE
  - FUEL VENT VALVE
  - COMPUTER
  - APS ELECTRONICS
  - 2 RECEIVERS
  - 4 THRUSTER ISOLATION VALVES

- o ALL ABOVE REDUNDANCY IS SAFETY ESSENTIAL EXCEPT THE IMU

GRUMMAN

APPROACH

- REMOVE REDUNDANCY IN A WEIGHT-EFFECTIVE MANNER TO MEET SAFETY OR .97 RELIABILITY GOAL.

- MEASURE COST AND WEIGHT SAVINGS IF SAFETY CONSTRAINT WERE LIFTED.

GRUMMAN

RESULTS

- IF SAFETY CONSTRAINT RETAINED, A REDUNDANT 10 LB IMU CAN BE REMOVED FOR BOTH MISSIONS WITH A TEN TUG COST SAVINGS OF $2.2 MILLION. RELIABILITY IS .9902 AND .9825 FOR RETRIEVE AND DEPLOY MISSIONS - WELL ABOVE .97 RELIABILITY TARGET.

- IF SAFETY CONSTRAINT WERE LIFTED:

  DEPLOY MISSION (36 HRS)

  - ALL REDUNDANCY CAN BE REMOVED
  - WEIGHT SAVINGS OF 67 LBS PER VEHICLE
  - TEN TUG COST SAVINGS OF $12.3 MILLION
  - RELIABILITY OF .9803

  RETRIEVE MISSION (72 HRS)

  - ALL REDUNDANCY EXCEPT 4 THRUSTER ISOLATION VALVES CAN BE REMOVED
  - WEIGHT SAVINGS OF 61 LBS PER VEHICLE
  - TEN TUG COST SAVINGS OF $11.8 MILLION
  - RELIABILITY OF .9707

GRUMMAN

II. PROGRAMMATIC COST SENSTIVITY TO REDUNDANCY/RELIABILITY

ASSUMPTIONS

- BASELINE CONFIGURATION IS 410AD-2 WITH REDUNDANCY REQUIRED TO PROVIDE .97 RELIABILITY FOR 168 HR (144 TUG + 24 ORBITER) MISSION.

- TUG CARRYING COSTS FOR ADDITIONAL WEIGHT
  - $100,000 $/LB FOR MINIMUM DDT&E LOWER PERFORMANCE VEHICLES
  - $400,000 $/LB FOR HIGH PERFORMANCE VEHICLES

GRUMMAN

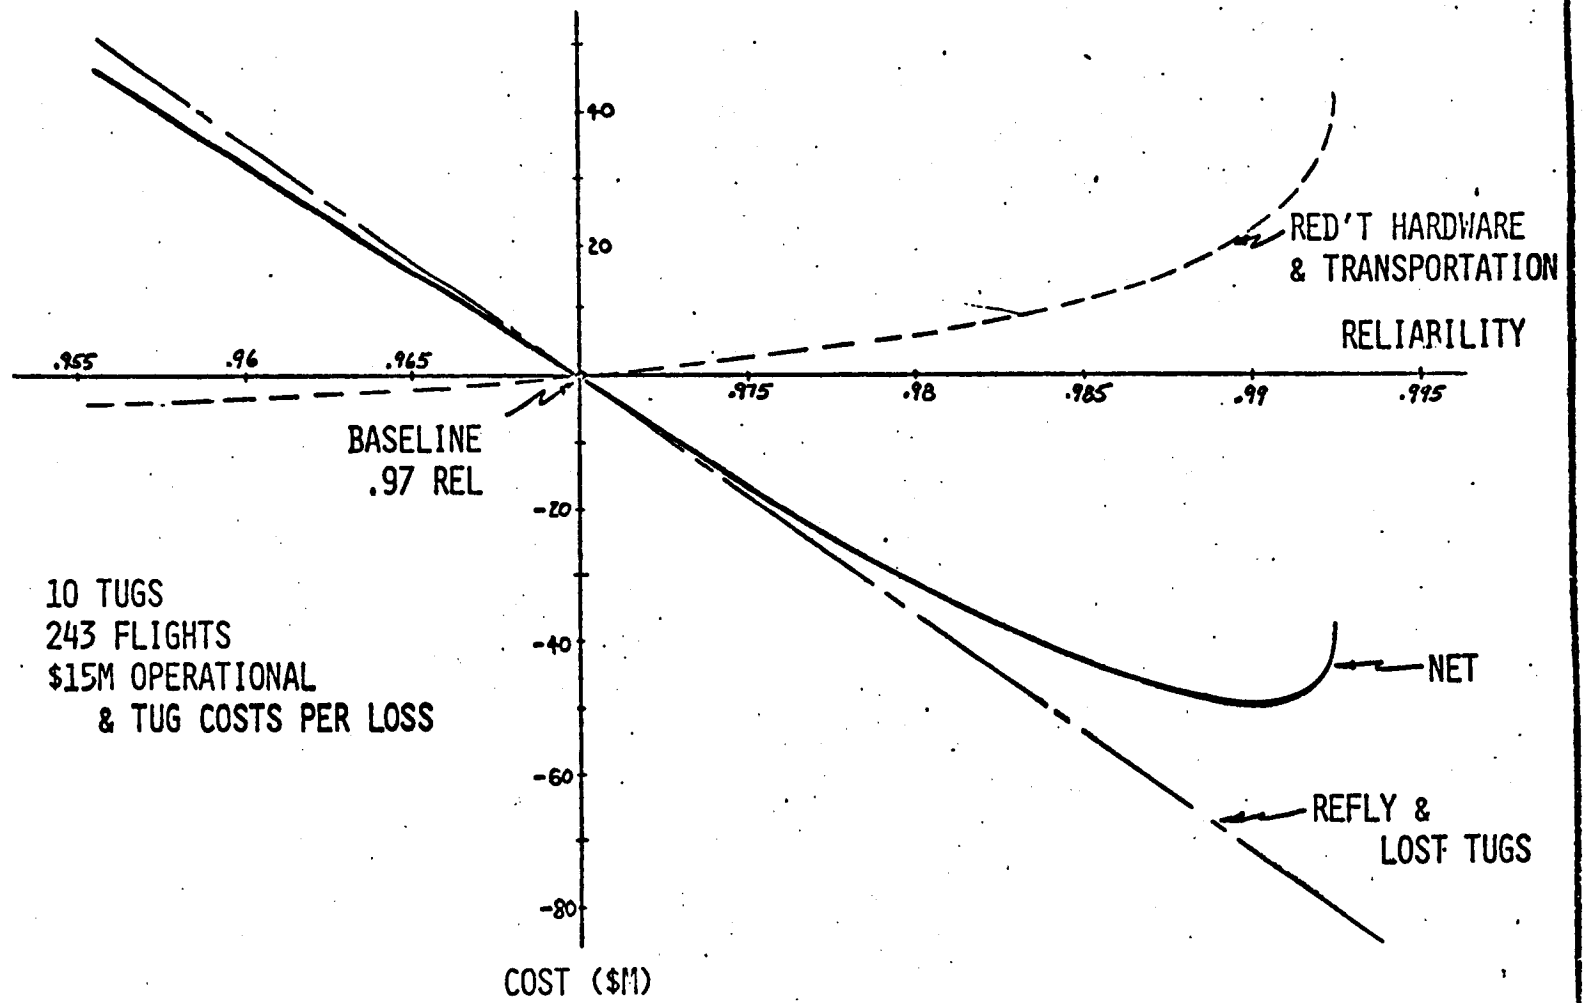
APPROACH

- o COMPARE THE PROGRAMMATIC COST DELTA's DUE TO INCREASING OR DECREASING THE REDUNDANCY/RELIABILITY LEVEL.
  - MISSION OPERATIONAL AND LOST TUG COSTS
    = Δ UNRELIABILITY X NUMBER MISSION X (TUG + OPERATIONAL COSTS/FLT)
    (243) ($15M)
  - REDUNDANT HARDWARE COSTS
    = HARDWARE COST X NUMBER OF VEHICLES IN FLEET
    (10)
  - TRANSPORTATION COSTS
    = WEIGHT OF REDUNDANT HARDWARE X CARRYING COST PER LB.
    ($100,000 TO $400,000)

GRUMMAN

PROGRAMMATIC COST VARIATION WITH RELIABILITY LEVEL

o $100,000/LB CARRYING COSTS



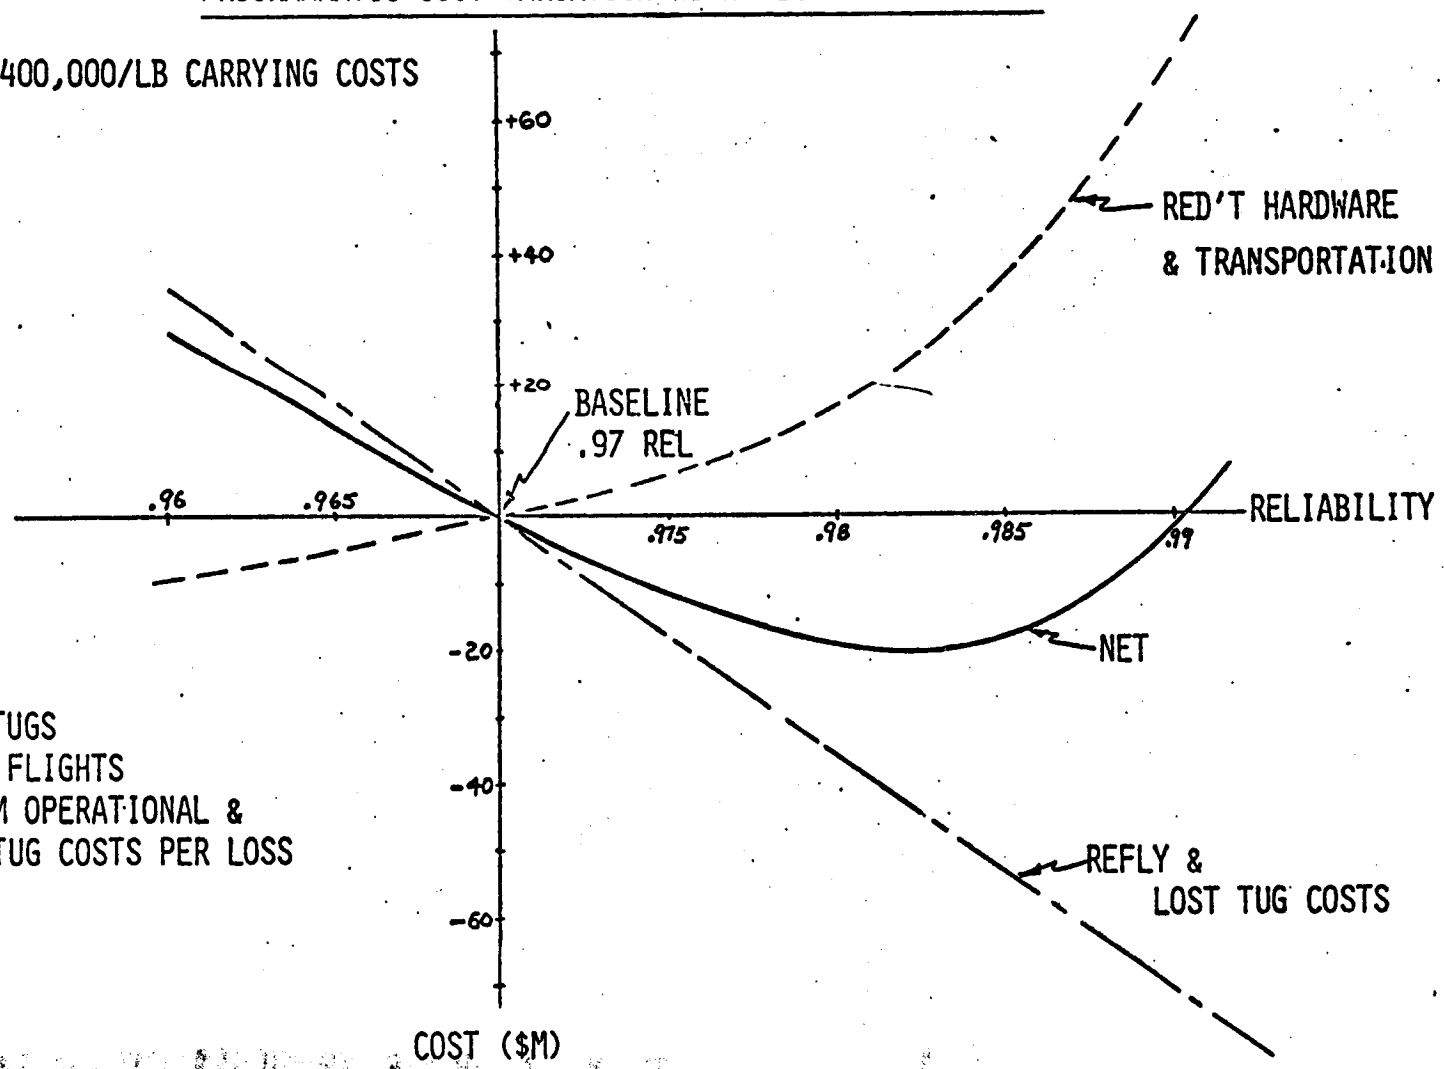
10 TUGS
243 FLIGHTS
$15M OPERATIONAL
& TUG COSTS PER LOSS

SAVINGS OF $55M WITH ADDITIONAL REDUNDANCY AT .991 RELIABILITY

GRUMMAN

PROGRAMMATIC COST VARIATION WITH RELIABILITY LEVEL

o $400,000/LB CARRYING COSTS



10 TUGS
243 FLIGHTS
$15M OPERATIONAL &
TUG COSTS PER LOSS

SAVINGS OF $20M WITH ADDITIONAL REDUNDANCY AT .982 RELIABILITY

GRUMMAN

RELIABILITY GOAL BASED ON PROGRAMMATIC COST

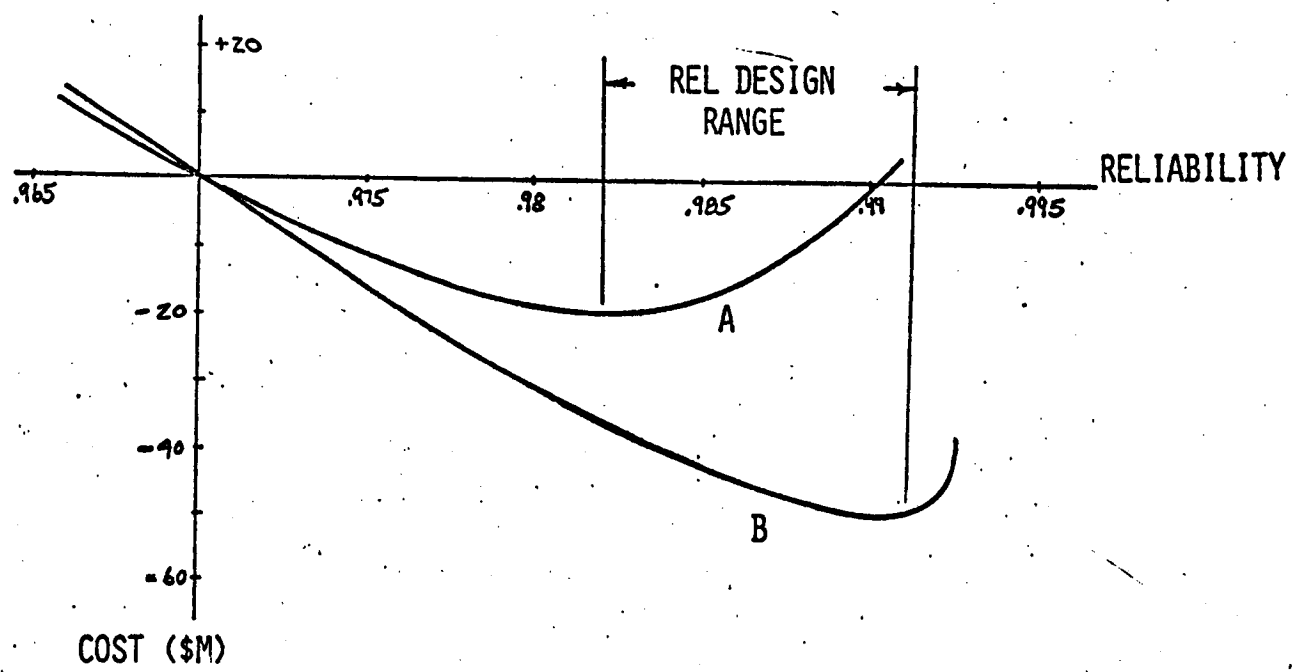
BASELINE - 410A-2 CONFIGURATION

.97 RELIABILITY

TRANSPORTATION COSTS

A- $400,000/LB

B- $100,000/LB



COST-EFFECTIVE RELIABILITY RANGE .982 - .991

GRUMMAN

EQUIPMENT REDUNDANCY ANALYSIS

- THE SYSTEM LEVEL ANALYSIS CAN BE PERFORMED ON AN INDIVIDUAL EQUIPMENT BASIS WITH COMPARABLE RESULTS.

- INDIVIDUAL COST-EFFECTIVE EQUIPMENT REDUNDANCY LEVELS CAN THUS BE DEFINED AS EACH INDIVIDUAL DESIGN IS HARDENED WHILE OTHER DESIGNS ARE STILL SOFT.

- ECONOMIC REDUNDANCY SELECTION CRITERION
  - ADD REDUNDANCY IF

$$\Delta \text{ UNRELIABILITY} > \frac{\$ \text{ REDUNDANT HARDWARE} + \$ \text{ TRANSPORTATION}}{\$ \text{ MISSION AND } \$ \text{ LOST TUG}}$$

GRUMMAN

ILLUSTRATION OF EQUIPMENT LEVEL ANALYSIS ON STAR TRACKER

HARDWARE COST =	81K
WEIGHT =	17 LBS
NUMBER OF VEHICLES =	10
NUMBER OF FLIGHTS =	243
COST OF MISSION & TUG LOST =	$15M
COST PER LB =	$100K TO $400K

FOR $100K PER LB

$$\Delta \text{ UNREL.} > \frac{\$81K \times 10 + 17 \times \$100K}{243 \times \$15\ M}$$

$$> .0007$$

FOR $400K PER LB.

$$\Delta \text{ UNREL.} > \frac{\$81K \times 10 + 17 \times \$400K}{243 \times \$15M}$$

$$> .0021$$

ADD ONE ORDER OF REDUNDANCY TO STAR TRACKER SINCE

$$\Delta \text{ UNREL.} = .0047$$

GRUMMAN

EQUIPMENT REDUNDANCY NOMOGRAPH

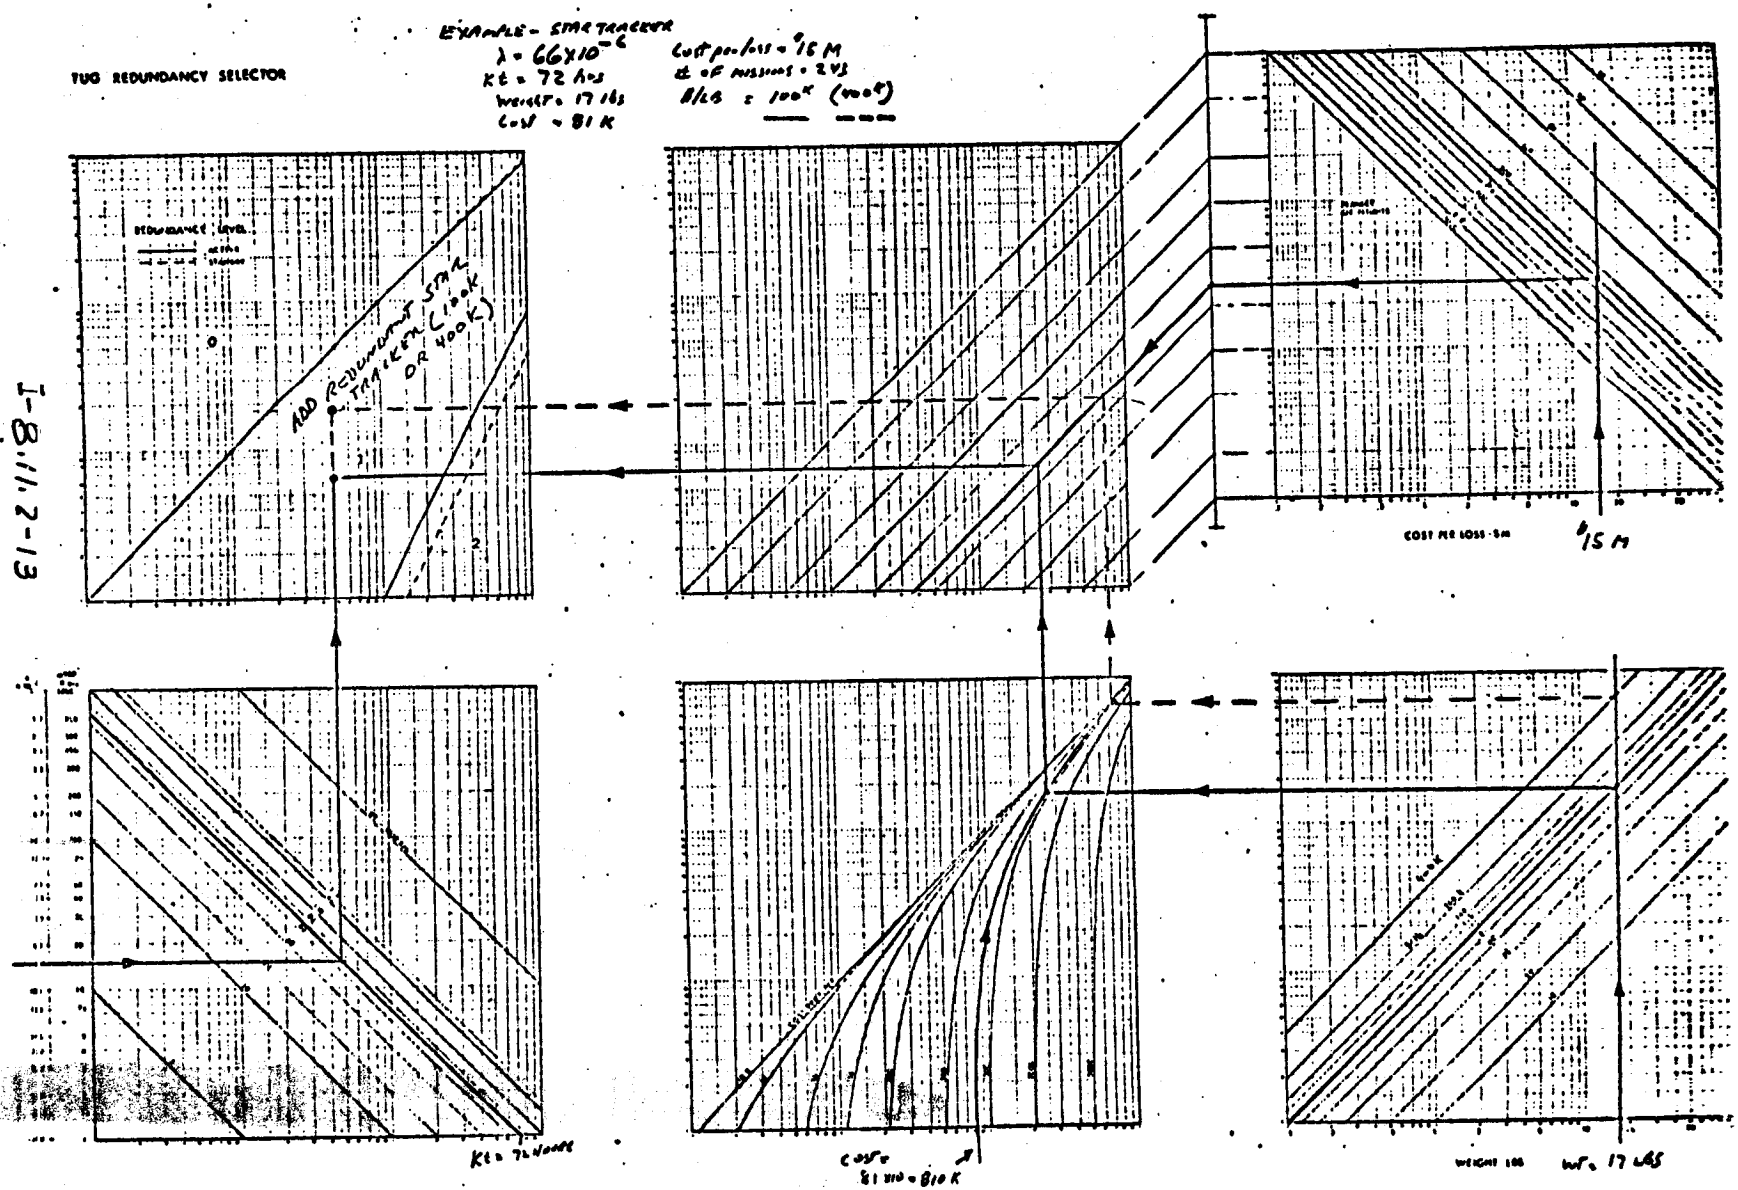
- A NOMOGRAPH HAS BEEN DEVELOPED TO PERFORM "TABLE TOP" ANALYSES, AND IS CONTAINED IN THE NEXT CHART.
- THE STAR TRACKER IS ILLUSTRATED FOR THE TWO TRANSPORTATION COST EXTREMES OF $100K AND $400K.
- DECISION CONFIDENCE CAN BE EASILY ASSESSED BY DETERMINING THE EQUIPMENT PARAMETER (FAILURE RATE, COST, OPERATING TIME, ETC.) RANGES OVER WHICH THE REDUNDANCY LEVEL DOES NOT VARY.

GRUMMAN

TUG REDUNDANCY SELECTOR

EXAMPLE - STAR TRACKER
$\lambda = 66 \times 10^{-6}$
Kt = 72 hrs
WEIGHT = 17 lbs
COST = 81 K

COST PER LOSS = $15 M
OF MISSIONS = 2 YR
B/LS = 100K (400K)



CONCLUSIONS

- o PROGRAMMATIC COST SAVINGS OF $20M TO $55M RELIAZABLE IF ADDITIONAL. REDUNDANCY INCORPORATED.

- o COST EFFECTIVE RELIABILITY DESIGNS RANGE BETWEEN .982 AND .991 FOR 168 HR. REFERENCE MISSION
  - MINIMUM DDT&E TUGS - 0.991
  - HIGH PERFORMANCE TUGS - 0.981

RECOMMENDATIONS:

- o FURTHER STUDY TO DEFINE OPTIMUM RELIABILITY/REDUNDANCY FOR EACH CONFIGURATION USING APPROPRIATE MIX OF DEPLOY, RETRIEVE AND ROUND TRIP MISSIONS.

GRUMMAN

8.11.3 - 30 DAY SERVICING MISSION SENSITIVITY STUDY

OBJECTIVE

- ESTABLISH STORABLE SPACE TUG PERFORMANCE CAPABILITY FOR SERVICING 4 SATELLITES IN GEOSYNCHRONOUS ORBIT ON A SINGLE MISSION

ISSUES

- GUIDELINES AND ASSUMPTIONS
- DELTA-V BUDGET AND CONSUMABLES USAGE
- AUXILIARY PROPULSION SUBSYSTEM (APS) REQUIREMENTS
- ELECTRICAL POWER SUBSYSTEM (EPS) REQUIREMENTS
- CONFIGURATION ARRANGEMENT
- WEIGHT SUMMARY AND PERFORMANCE EVALUATION
- MISSION SUCCESS RELIABILITY EVALUATION
- COST IMPACT
- DEVELOPMENT RISK AND TECHNOLOGY ISSUES

30 DAY SERVICING MISSION

GUIDELINES AND ASSUMPTIONS

- STORABLE TUG PERFORMS 30 DAY MISSION DURING WHICH TIME 4 SATELLITES ARE SERVICED
- MISSION TIMELINE AND MAIN PROPULSION DELTA-V BUDGETS USED FROM MSFC LETTER PD-TUG-E (74-30) DATED 10 AUGUST 1973 WITH THE FOLLOWING EXCEPTION
- RENDEZVOUS AND DOCKING DELTA V WAS MODIFIED TO REFLECT TPI, TPF AND DOCKING MANEUVERS CONSISTENT WITH BASELINE TUG MANEUVER TABLES
- THE OPTION 2 BASELINE CONCEPT, 410AD-2, WAS USED AS THE POINT OF DEPARTURE FOR THIS ANALYSIS
- A 500 LB SERVICE UNIT WAS BASELINED. WEIGHT OF SPACE REPLACEABLE UNITS (SRU) IS ESTABLISHED BY PERFORMANCE ANALYSIS
- TWO SERVICING MODES TO BE CONSIDERED
  - SERVICE MODE I EXPENDS ALL REPLACED SRU'S AT EACH SPACECRAFT SERVICED. TUG RETURNS ONLY WITH 500 LB SERVICE UNIT
  - SERVICE MODE II CARRIES A CONSTANT PAYLOAD (SERVICE UNIT PLUS SRU'S) THROUGHOUT THE MISSION
- NO SPECIFIED MISSION SUCCESS RELIABILITY GOAL FOR SERVICING MISSION. CAPABILITY DETERMINED BY ANALYSIS

PERFORMANCE ANALYSIS FOR SERVICING MISSION: MODE I

TUG DELTA-V BUDGET

30 DAY SERVICING MISSION

AUXILIARY PROPULSION SYSTEM (APS)

- APS SENSITIVITY ISSUES
  - WEIGHT PENALTY OF ADD-ON MONOPROPELLANT SERVICING MISSION KIT
  - EFFECT ON BASELINE APS SELECTION OF DESIGNING TO SERVICING MISSION REQUIREMENTS
- REQUIREMENTS
  - USABLE APS PROPELLANT = 991 LB SERVICE 1, 1020 LB SERVICE 2
  - BASELINE APS USABLE PROPELLANT = 450 LB.
  - TANKS SIZED FOR 110% OF USABLE PROPELLANT DELTA
  - SERVICING MISSION TANKS SIZED FOR 1.1 (991-450) = 595 LBS. PROPELLANT
- WEIGHT PENALTY OF APS SERVICING MISSION KIT
  - ADDITIONAL HARDWARE WEIGHT = 94.7 LB.

    2 HELIUM TANKS @ 16.1 LB EACH = 32.2LB
    5 PROPELLANT TANKS @ 10.5 LB EACH = 52.5 LB
    LINES AND SUPPORTS = 10.0 LB

  - EFFECTIVE PROPELLANT WEIGHT INCREASE = 161 LB
    EFFECTIVE PROP. WT = 27% ACTUAL PROP. WT.

30 DAY SERVICING MISSION

AUXILIARY PROPULSION SYSTEM (APS) (CONT'D)

- SENSITIVITY ISSUE
  - EFFECT ON BASELINE APS SELECTION (MONOPROPELLANT VS BIPROPELLANT) OF DESIGNING TO SERVICING MISSION REQUIREMENTS (1020 LB USABLE APS PROPELLANT)
- RESULTS
  - DESIGNED FOR SERVICING MISSION, OFF LOADED FOR BASELINE PROPELLANT REQUIREMENTS

	EFFECTIVE WEIGHT (LB)	DDT&E COST ($M)	TOTAL PROGRAM COST ($M)
MONOPROPELLANT SYSTEM 24 THRUSTERS, 25 LB THRUST	417	3.1	40.6
BIPROPELLANT SYSTEM 24 THRUSTERS, 25 LB THRUST	391	4.6	46.5

- CONCLUSION: RETAIN MONOPROPELLANT APS DESIGN FOR SERVICING MISSION
  - EQUIVALENT COST PER LB SAVED ON THE BIPROP SYSTEM = $5.9M/26 LB = $227K/LB
  - OTHER SUBSYSTEM IMPROVEMENTS WITH $100-200K COST/LB ARE AVAILABLE AND ARE MORE COST EFFECTIVE.

30 DAY SERVICING MISSION

EPS ASSUMPTIONS AND GUIDELINES

- MISSION TIMELINE DEVELOPED FROM REFERENCE MISSION IN MSFC LETTER PD-TUG-E(74-30) DATED 10 AUGUST 1973.

- PAYLOAD POWER SUPPORT REQUIREMENTS FOR SERVICE MODES I AND II PER AIR FORCE LETTER XRZ DATED 13 AUGUST 1973.

- MODIFIED SHUTTLE FUEL CELL (BASELINED FOR TUG CONFIGURATION 410AD-2) IS A 2.5 KW STACK AT 28VDC AND CAN SUPPORT THE SERVICING MISSION PEAK POWER REQUIREMENTS WITHIN VOLTAGE REGULATION.

- THEREFORE ONLY ADDITIONAL FUEL CELL REACTANTS (AND STORAGE CAPACITY) ARE REQUIRED TO SUPPORT THE 30 DAY SERVICING MISSION.

- THE BASELINE TUG EQUIPMENT DUTY CYCLES CAN BE SELECTIVELY REDUCED CONSISTENT WITH THE LONGER MISSION DURATION. MAJOR REDUCTIONS WERE (SEE TABLE):
  - MINIMAL DMS COMPUTER AND DACU DUTY CYCLES
  - 25% DUTY CYCLE FOR CATALYST HEATERS
  - MAIN ENGINE BROUGHT UP TO TEMPERATURE PRIOR TO BURNS

410AD-2 BASELINE & ON-ORBIT SERVICING

DEVELOPMENT RISK AND TECHNICAL ISSUES

- THERE ARE NO DEVELOPMENT OR TECHNICAL ISSUES ASSOCIATED WITH PROVIDING THE TUG SERVICE KIT HARDWARE TO SUPPORT THE 30 DAY SERVICING MISSION.

- THERE MOST CERTAINLY WILL BE DEVELOPMENT ISSUES ASSOCIATED WITH DESIGN AND OPERATIONAL DEVELOPMENT OF THE SERVICING MODULE AND ASSOCIATED PAYLOAD INTERFACES. THESE WERE NOT CONSIDERED AS PART OF TUG PROGRAM DEFINITION.

GRUMMAN

30 DAY SERVICING MISSION

SUMMARY

- PERFORMANCE CAPABILITY
  - TOTAL SRU DELIVERY CAPABILITY IN SERVICE MODE I IS 686 LB. CAN BE INCREASED TO 2516 LB IF SERVICE UNIT IS NOT RETURNED TO SHUTTLE
  - TOTAL SRU ROUND TRIP CAPABILITY IN SERVICE MODE II IS 96 LB. CAN BE INCREASED TO 263 LB IF HIGHER PERFORMANCE ENGINE IS INCORPORATED IN TUG.
- COST IMPACT TO TUG PROGRAM FOR SERVICE MODES I AND II RESPECTIVELY ARE $8.3 - $8.4M DDT&E AND $18.9 - $19.7M TOTAL PROGRAM COST.
- TUG ADD-ON EQUIPMENT WAS PROVIDED IN KIT FORM AND INTEGRATED WITH SERVICE UNIT INTO A SERVICING MODULE.
- THERE ARE NO TUG PROGRAM DEVELOPMENT OR TECHNICAL ISSUES ASSOCIATED WITH PROVIDING THE SERVICING KIT.

GRUMMAN

8.11.4 - DOD COMMUNICATION REQUIREMENTS SENSITIVITY STUDY

OBJECTIVE

STARTING WITH A COMMUNICATIONS SYSTEM THAT MEETS BASIC NASA REQUIREMENTS, DETERMINE THE IMPACT OF EXPANDING TO THE FULL NASA/DOD CAPABILITY COMMUNICATIONS SYSTEM OF CONCEPT 310RE-3A.

GUIDELINES AND ASSUMPTIONS

DEFINE THE IMPACT IN TWO INCREMENTS, STARTING WITH THE BASIC NASA REQUIREMENTS (STDN COMPATIBLE):

1. ADD TDRS COMPATIBILITY (SPREAD SPECTRUM)
2. ADD DOD COMMUNICATIONS REQUIREMENTS (SGLS COMPATIBILITY PLUS SECURE COMM)

STUDY AREAS

- WEIGHT IMPACT
- PERFORMANCE IMPACT
- COST IMPACT
- DEVELOPMENT RISK AND TECHNOLOGY ISSUES

COMPONENT	BASIC NASA (STDN)			BASIC NASA + TDRS (SPREAD SPECTRUM)			FULL CAPABILITY (SGLS +) (SECURE COMM.)

COMMUNICATIONS REQUIREMENTS SENSITIVITY STUDY
COST COMPARISON

COMMUNICATIONS REQUIREMENTS SENSITIVITY STUDY

DEVELOPMENT RISK AND TECHNOLOGY ISSUES

- From a Tug viewpoint, the technology exists and there is low risk in providing the transition from the Basic NASA requirements to the full capability communications system.

- The most significant issue involved in growth of the communications capability is the development and operation of the TDRS itself.

COMMUNICATIONS CAPABILITY LEVEL	GROWTH IMPACT						
	DELTA WEIGHT (lbs)	DELTA PERFORMANCE (Geosync Payload - lbs)			DELTA COST ($ X 10^{-3})		RISK
		DEPLOY	RETRIEVE	ROUND TRIP	DDT&E	RECURRING

FULL CAPABILITY (SGLS + Secure Comm)	+ 44	- 161	- 60	- 44	+ 7419	+ 467	LOW

COMMUNICATIONS REQUIREMENTS SENSITIVITY STUDY

GROWTH IMPACT SUMMARY

8.11.5 - PAYLOAD COMMAND, CONTROL, AND CHECKOUT SENSITIVITY STUDY

OBJECTIVE:

Determine the impact on the baseline 310RE-3A Tug configuration of providing the payload command, control, and checkout function

GUIDELINES AND ASSUMPTIONS:

- The only subsystem area having significant weight or cost impact is the communications subsystem.
- The TV Assembly was assumed to be required for payload monitoring and support only.
- If there is no requirement for payload support, the DFS will be used for both Tug/Ground and Tug/Orbiter communication, but not simultaneously.

STUDY AREAS:

- Weight Impact
- Performance Impact
- Cost Impact
- Development Risk and Technology Issues

COMPONENT	WITHOUT PAYLOAD SUPPORT			WITH PAYLOAD (310RE-3A Baseline)

PAYLOAD COMMAND, CONTROL, AND CHECKOUT SENSITIVITY STUDY

COST COMPARISON

PAYLOAD COMMAND, CONTROL, AND CHECKOUT SENSITIVITY STUDY

DEVELOPMENT RISK AND TECHNOLOGY ISSUES

- DFS hardware exists for STDN or SGLS compatible systems. Existing hardware can be modified to be STDN and SGLS compatible, but not TDRS compatible

- CSS hardware does not exist since no spacecraft has had to communicate with other spacecraft on the same frequency as the ground. New equipment must be developed.

- Elimination of payload support and the associated requirement for CSS equipment would further reduce the risk of an already low risk subsystem.

PAYLOAD SUPPORT LEVEL	GROWTH IMPACT						
	DELTA WEIGHT (lbs)	DELTA PERFORMANCE (Geosynch Payload - lbs)			DELTA COST ($ x 10^{-3})		RISK
		DEPLOY	RETRIEVE	ROUND TRIP	DDT&E	RECURRING

PAYLOAD COMMAND, CONTROL AND CHECKOUT SENSITIVITY STUDY

GROWTH IMPACT SUMMARY

8.11.6- ELECTRICAL POWER TO PAYLOAD SENSITIVITY STUDY

OBJECTIVE: DETERMINE EFFECT OF PROVIDING 300 WATT ELECTRICAL POWER TO PAYLOAD DURING TUG DEPLOYMENT AND RETRIEVAL OPERATIONS

STUDY PLAN:

- DETERMINE WEIGHT AND COST IMPACT FOR ADDING REQUIREMENT TO PROVIDE 300W OF PAYLOAD SUPPORT POWER DURING PAYLOAD DEPLOYMENT TO CONCEPT 110A-1

- DETERMINE WEIGHT AND COST IMPACT FOR DELETING REQUIREMENT TO PROVIDE 300W OF PAYLOAD SUPPORT POWER DURING PAYLOAD DEPLOYMENT AND RETRIEVAL FOR OTHER FIVE TUG CONCEPTS

ELECTRICAL POWER TO PAYLOAD SENSITIVITY STUDY

GUIDELINES AND ASSUMPTIONS

- 110A-1 DOES NOT PROVIDE PAYLOAD POWER; ALL OTHER VEHICLES PROVIDE 300 W (28VDC) AT PAYLOAD INTERFACE

- EPS "ON" AND PAYLOAD SUPPORT TIMES FOR SIZING EPS BASELINE:

		110A-1	320AE-3A	ALL OTHER CONFIGURATIONS
- EPS ON TIME	HRS	34	123	117
- PAYLOAD SUPPORT TIME	HRS	-0-	57	100

- PAYLOAD SUPPORT TIME DELTAS:

110A-1	+ 11 HOURS
320AE-3A	- 57 HOURS
ALL OTHERS	-100 HOURS

- PAYLOAD POWER REQUIREMENTS AT TUG POWER SOURCE INCLUDE 10% FACTOR FOR DISTRIBUTION AND CONTROL.

I-8.11.7-19

8.11.8 – SPIN STABILIZED PAYLOAD RETRIEVAL SENSITIVITY STUDY

OBJECTIVE: DETERMINE EFFECT ON TUG PROGRAM IF TUG IS REQUIRED TO DESPIN STABILIZED PAYLOADS WHICH ARE CANDIDATES FOR RETRIEVAL

APPROACH

- TOPSS STUDY (FINAL REPORT DATED 5 MARCH 1973) RECOMMENDED THAT REUSABLE DESPIN KIT ON TUG BE UTILIZED TO DESPIN PAYLOADS
- TUG APS WOULD NULL RESIDUAL RATES
- DESPIN KIT WAS ESTIMATED TO WEIGH 90 LB.

RESULTS

- MOST SIGNIFICANT IMPACT IS THAT TUG PAYLOAD RETRIEVAL CAPABILITY IS REDUCED BY 123 LB
- DESPIN KIT WAS ASSUMED TO BE GFE
- TUG/DESPIN KIT INTERFACE IS NOT SIGNIFICANTLY MORE COMPLEX THAN TUG/PAYLOAD INTERFACE
- TUG APS PROPELLANT REQUIREMENTS TO NULL RESIDUAL RATES IS SMALL (LESS THAN 2 LB)
- TUG PROGRAM COST IMPACT IS SMALL. DEVELOPMENT OF GFE DESPIN KIT AND PAYLOAD/DESPIN KIT INTEGRATION WAS NOT ESTIMATED

8.11.9- RENDEZVOUS AND DOCKING SENSITIVITY STUDY

OBJECTIVE: ESTABLISH IMPACT ON STORABLE TUG CONCEPTS OF PROVIDING RETRIEVAL CAPABILITY

APPROACH

- USING CONCEPT 110A-1 (DEPLOYMENT CAPABILITY ONLY) AS A REFERENCE DEFINE THE WEIGHT, DDT&E COST, AND DEVELOPMENT RISK IMPACT OF ADDING RETRIEVAL USING THE FOLLOWING THREE MODES:
  - (1) - ADD RETRIEVAL HARDWARE TO 110A-1 CORE VEHICLE
  - (2) - ADD (1) ABOVE PLUS DEORBIT KICK STAGE
  - (3) - ADD (1) ABOVE PLUS RETRIEVAL DELAY MODULE

(3)	ADD RETRIEVAL CAPABILITY PLUS RDM	+ 79

T-8119-3

GRUMMAN

RENDEZVOUS & DOCKING SENSITIVITY STUDY

DEVELOPMENT RISK & TECHNOLOGY

- ADDING RETRIEVAL CAPABILITY TO 110A-1 HAS THE FOLLOWING IMPACT ON DEVELOPMENT RISK:
  - INCREASED MISSION DURATION REQUIRES DEVELOPMENT OF FUEL CELL & CRYO STORAGE TANKS TO REPLACE BATTERY. THESE ITEMS ARE MORE DIFFICULT TO DEVELOP THAN A BATTERY, HENCE INCREASED RISK.
  - FUEL CELLS REQUIRE ACTIVE COOLING LOOPS WITH THEIR ASSOCIATED PLUMBING & VALVES. THESE ITEMS ARE MORE DIFFICULT TO DEVELOP AND ARE INHERENTLY LESS RELIABLE THAN HEAT PIPES, HENCE INCREASED RISK.
  - RETRIEVAL REQUIRES ADDITION OF LASER RADAR WHICH IS A TECHNOLOGY ITEM CURRENTLY UNDER DEVELOPMENT AT ITT.
  - RETRIEVAL REQUIRES TUG/PAYLOAD COMMUNICATIONS, THUS ADDING THE CHANNEL SELECTABLE STATION (CSS) TO THE DEDICATED FREQUENCY STATION (DFS) ALREADY ON 110A-1. THE CSS IS MORE COMPLEX THAN THE DFS, HENCE INCREASED RISK.

- RETRIEVAL REQUIRING DEVELOPMENT OF EITHER A DEORBIT KICK STAGE (DKS) OR A RETRIEVAL DELAY MODULE (RDM):
  - THE DKS IS A STAGE INCORPORATING A SRM WHICH MUST BE ABLE TO SURVIVE 5 YEARS IN SPACE WITHOUT DEGRADATION OF ITS PROPELLANT GRAIN; THIS REQUIRES SUPPORTING TECHNOLOGY INVOLVING INCREASED RISK
  - THE RDM INVOLVES LESS RISK THAN THE DKS SINCE IT UTILIZES EXISTING TECHNOLOGY EQUIPMENT

GRUMMAN

T-8119-4

RENDEZVOUS AND DOCKING SENSITIVITY STUDY

SUMMARY

- ADDING RETRIEVAL CAPABILITY TO A TUG DESIGNED FOR DEPLOYEMENT ADDS AT LEAST 350 LB TO THE DRY WEIGHT OF THE TUG
- ADDED DRY WEIGHT REDUCES DEPLOYMENT CAPABILITY OF TUG BY AT LEAST 900 LB, EVEN WHEN SELECTED RETRIEVAL EQUIPMENT IS LEFT ON THE GROUND
- THE DDT&E COST OF ADDING RETRIEVAL CAPABILITY IS A MINIMUM OF $54M AND COULD BE AS HIGH AS $90M IF A DKS IS REQUIRED TO IMPROVE PAYLOAD RETRIEVAL PERFORMANCE
- DEVELOPMENT OF A LASER RADAR AND A DKS, IF REQUIRED ARE THE KEY TECHNOLOGY ITEMS

GRUMMAN

NESTED TANK/SEPARATE TANK WEIGHT STUDY

CONFIGURATION 310-3A

- WELDED GORE TITANIUM TANK MATERIAL
- GRAPHITE COMPOSITE HONEYCOMB OUTER SHELL STRUCTURE
- NESTED DOMES SEPARATED BY A NON-METALLIC MESH
- BOTH CONFIGURATIONS SUPPORTED AT THE SAME ORBITER ATTACHMENT LOCATIONS
- THE GEOMETRY AND STRUCTURAL ARRANGEMENT DETAILS FOR THE SEPARATE TANK CONFIGURATION ARE SIMILAR TO TUG 110A-1 WITH WELDED TITANIUM TANKS SUBSTITUTED FOR ALUMINUM TANKS (SPUN ALUMINUM DOMES AND WELDED ALUMINUM CYLINDER) AND COMPOSITE HONEYCOMB SUBSTITUTED FOR THE HONEYCOMB SHELL
- THE SEPARATE TANK CONFIGURATION IS 70 LBS HEAVIER AND 34 INCHES LONGER THAN THE COMPARABLE NESTED DOME CONFIGURATION

CONFIGURATION 110A-1

- THE ALL-ALUMINUM SEPARATE TANK CONFIGURATION IS 129 LBS HEAVIER AND 34 INCHES LONGER THAN A COMPARABLE NESTED DOME CONFIGURATION

PERFORMANCE AND COST COMPARISON

CONFIGURATION 310-3A/310RE-3A

PERFORMANCE COMPARISON

- SEPARATE TANK CONFIGURATION RESULTS IN 70LB HIGHER TUG DRY WEIGHT
- THIS RESULTS IN A PAYLOAD PERFORMANCE REDUCTION OF:

  256 LB PAYLOAD DELIVERY CAPABILITY

  96 LB PAYLOAD RETRIEVAL CAPABILITY

  70 LB ROUND TRIP CAPABILITY

COST COMPARISON

STRUCTURES AND THERMAL CONTROL COSTS

	DDT&E	FIRST UNIT COST	AVERAGE UNIT	TOTAL PRODUCTION*	TOTAL PROGRAM
NESTED DOME	$ 16.1M	$ 1.6M	$ 1.0M	$ 23.0M	$ 39.1M
SEPARATE TANK	$ 14.9M	$ 1.5M	$ 0.94M	$ 21.6M	$ 36.5M
DIFFERENCE	+ 1.2M	+ $ 0.09M	+ $ 0.06M	+ $ 1.4M	+ $ 2.6M

* CONCEPT 310-3A/310RE-3A HAS FLEET SIZE OF 23 TUGS

SUMMARY

- EQUIVALENT TRANSPORATION COST = $\frac{\$\ 2.6 \times 10^6}{70\ \text{LB}} = \$\ 37\ \text{K/LB}$
- TUG TRANSPORATION COSTS LESS THAN $ 100 K/LB ARE COST EFFECTIVE OPTIONS
- BASED ON COST/WEIGHT CONSIDERATIONS NESTED DOME TANK CONFIGURATION IS ATTRACTIVE OPTION

GRUMMAN

POTENTIAL TANKAGE HAZARDS/IMPACT

HAZARD	SEPARATE	NESTED
LOSS OF MMH PRESSURE	NOT A TANKAGE PROBLEM	
LOSS OF N_2O_4 PRESSURE	NOT A TANKAGE PROBLEM	VENT MMH TANK
VENT FAILS CLOSED	PROVIDE REDUNDANT VENTS	
EITHER TANK LEAKS	VENT, DRAIN "OTHER" TANK CLEAN UP REQUIRED CONTROL MATERIALS FOR COMPATIBILITY	
BOTH TANKS LEAK	PROVIDE VENT AREA THAT PRECLUDES PRESSURE BUILDUP	LIMITED VENT VOLUME MESH CAUSES TIME DELAY IN MIXING

T-811.10-11

DEVELOPMENT RISK AND CRITICAL TECHNICAL AREAS

RELATIVE TO SEPARATE TANKS

- INSTALLATION AND FITTING OF NESTED DOME MEMBRANE INCREASES WELD/ASSEMBLY COMPLEXITY
- TANKS MUST BE ASSEMBLED AND TESTED AT THE SAME TIME INCREASING MANUFACTURING FLOW TIME AND RISK OF SCHEDULE SLIPPAGE.
- LEAK DETECTION MORE DIFFICULT ON NESTED DOME SURFACES
- INSPECTION OF NESTED DOME SURFACES MUST BE DONE FROM INSIDE TANK
- TESTING OF TANKS MORE DIFFICULT
- DELTA - P REQUIRED FOR NESTED BULKHEAD TO PREVENT STRUCTURAL FAILURE

CHANGES TO BASELINE SYSTEM

- FEEDLINE, FILL/DRAIN, ADAPTER, AND SHUTTLE SERVICE LINES INCREASED TO 3.25 IN DIAMETER
- FILL/DRAIN Q.D.'S MUST BE ALL NEW LOW RESISTANCE DESIGN, PRESENT (LM/SPS) DESIGNS HAVE HIGH PRESSURE DROP DUE TO POPPET ARRANGEMENT

FEED SYSTEM WEIGHT PENALTIES

TUG	18 LB. INCREASE
ADAPTER	41 LB. INCREASE
SHUTTLE	60 LB. (TOTAL WEIGHT, PRESENT SYSTEM UNKNOWN)

GRUMMAN

ON-ORBIT DUMP

- IF SYSTEM IS DESIGNED FOR MODE III ABORT CAN PROPELLANT BE DUMPED ON A ONCE-AROUND ABORT?

- YES
  - DUMP TIME INCREASED TO 10 MINUTES
  - 5% RESIDUAL WILL REMAIN IN TANKS
  - REQUIRES ONE SHUTTLE RCS ENGINE TO BURN FOR THE 10 MINUTE DUMP (PLUS A 14% DUTY CYCLE ON A NOSE JET TO YAW COMPENSATE)
  - CONSUMES 2000 LB. SHUTTLE RCS PROPELLANT AND 50% DEPLETES ONE AFT RCS MODULE

GRUMMAN

VEHICLE WEIGHT SAVINGS

- LANDING WITHOUT PROPELLANT LOAD CAN SAVE TANKAGE AND STRUCTURAL WEIGHT
- ABORT LANDING IS THE CRITICAL DESIGN CONDITION WITH FULL PROPELLANT
- STRUCTURAL WEIGHTS ASSOCIATED WITH THE SENSITIVITY ARE MAIN PROPULSION TANKS, TUG FORWARD SUPPORT FRAME AND TUG/SHUTTLE INTERFACE FORWARD FRAME

GRUMMAN

T-8.11.12-9

Engine Sensitivities

NON QUANTITATIVE FACTORS

110A-1

The OME 12K engine represents a greater technical risk than the OME 7.5K. The 12K engine requires strengthening of the injector manifolds, prop valves and gimbal ring. The injector manifold volumes must also be increased. The thrust chamber/injector assy. of the 12K engine has a cycle life capability of 300 cycles as compared with 750 cycles for the OME 7.5K. In both cases, the turbo machinery and gas generator are being designed for 300 cycle life capability.

410AD-2

(1) 8096B-2

o The 8096B-2 represents a lower technical risk than the Class I because the gas generator and turbomachinery are the same basic design as the existing 8096 hardware, whereas, the Class I engine is a totally new design.

o The 8096B-2 presents increased operational/contamination problems. During the initial operational phase (1 year) a flush and purge of the engine is required after each flight. Thereafter, it is required every 4th flight. The 8096 S_1O_2 coating on the T/C walls and hydrocarbons from the turbine exhaust represent contamination problems to the cargo bay during reentry. The 8096 engine requires draining and replacing the gear box lube oil after each flight.

The 8096 engine presents a slightly greater post-flight safety hazard in that start tanks contain GN_2 gas at 1000 psi pressure as compared to 1.5 lb of propellant at 50 psi. in the class I engine.

(2) Class II

o The Class II engine represents the highest technical risk of any of the engine designs. It is the only design which requires an advance

I-8.11.12-10

in the state-of-the-art. It is a staged combustion engine operating at 1200 psia Pc and 3000°F combustion chamber wall temp.

o The Class II engine presents increased operational/contamination problems. In order to perform maintenance/refurbishment the turboprop/thrust chamber (which is an in-line configuration) must be removed from the engine mount.

The baseline Class II engine uses Silicone oil to provide the cooling margin required to operate at the wall temp. of 3000°F. The S_1O_2 coating on the T/C walls, which results from its use, presents a contamination problem to the cargo bay during reentry.

The Class II engine presents a slightly greater post-flight safety hazard in that the start accumulators contain 7.5 lb. of propellants as compared to 1.5 lb. for the class I engine

310-3A

Same as 410AD-2, Item (1).

310-3A/310RE-3A OME 7.5K → Class I

Engine/Vehicle Interfaces

o Thrust mount attachment and pump inlet positions are identical. Pump inlet diameters are close enough to be considered identical. Since OME 7.5K has boost pump on ox. side only (Class I has boost pumps on both sides), a 3.5 inch spool piece must be used for the interim vehicle.

o Provisions for gimbal actuator attach points must be included on the interim vehicle for use with the Class I engine. The OME 7.5K is a throat gimballed engine and gimbal actuators are contained within the engine assy.

o There are minor, easily handled, differences in the positions of the fluid and electrical panels.

NOTE: This concept results in the unusual situation of replacing an engine design with superior cycle life capability (T/C life is 750 cycles vs. 300) with one of lesser capability.

310RE-3A, 310-3B & 310ARE-3B

Same as 410AD-2, Item (1).

510A-3B & 510ADE-3B

o The 8096B-2 represents a higher technical risk than the OME 7.5K engine because it includes modifications to the injector, shortening of the combustion chamber and recontouring the nozzle.

o The remaining items are the same as 410AD-2, Item (1) except the OME 7.5K engine also presents a problem of contaminating the cargo bay with hydrocarbons.

ENGINE SENSITIVITY STUDY - CONCLUSIONS

- o TRANSPORTATION COSTS LESS THAN $100K - $125K/LB INDICATE VIABLE CHANGES
  - 8096B REPLACING OME 7.5 : GOOD CHOICE
  - 8096B REPLACING CLASS I : MARGINAL, CAPTURE ANALYSIS NECESSARY FOR FINAL DECISION
  - OME 12 REPLACING OME 7.5 : BAD CHOICE
  - CLASS II REPLACING CLASS I : BAD CHOICE
- o PHASING OME 7.5 TO CLASS I EASES PRE-1980 DDT&E BY $38M AT A PROGRAM COST PENALTY OF $26M AND A LARGE PHASE I PERFORMANCE DECREMENT.

T-8.11.12-16

GRUMMAN

8.11.13 - USE OF RETRIEVAL DELAY MODULE (RDM) IN OPTION 2

OBJECTIVE: DETERMINE THE COST IMPACT OF UTILIZING A TUG CONCEPT WITH A RDM (SIMILAR TO CONCEPT 310ARE-3B) AS A DIRECT DEVELOPED TUG IN OPTION 2

RESULTS:

CONCEPT	COST ($M) DDT&E	PRODUCTION	OPERATIONS	TOTAL PROGRAM TUG	TUG + SHUTTLE
DIRECT DEVELOPED TUG WITH RDM	336	180	205	721	3569
410AD-2	350	232	207	789	3362
DELTA	-14	-52	- 2	-68	+207

- USE OF TUG WITH RDM IN OPTION 2 RESULTS IN LOWER TUG COSTS BUT HIGHER TUG PLUS SHUTTLE COSTS
- THESE RESULTS ARE SIMILAR TO CONCEPT COMPARISON IN OPTION 3B EXCEPT THAT CONCEPT 510ADE-3B CONTAINED A LOWER TECHNOLOGY, LOWER DDT&E TUG.

GRUMMAN

8.12 DOD ACQUISITION APPROACH

110A-1

The validation phase serves to validate and refine the program characteristics through study and analysis, hardware development and prototype testing. SR&T activities are also initiated during this phase to assure an orderly progression into the Full Scale Development Phase.

During the Full Scale Development Phase the vehicle test program will be implemented to demonstrate by actual performance testing that the contractual requirements have been met and all major problems have been resolved. The major emphasis at this time is our ground test program which utilizes four major test articles/facilities and mockups. These ground test articles, including the Propulsion Test Vehicle, Structural Test Article, Integrated Avionics and Software Development Facilities and the test programs, are geared to providing assurance of a successful flight test program. The flight test program is the final verification of system design and operational capability and includes a dedicated First Orbital Flight (FOF) without payload followed by operational flights. Flight test data will be acquired on five of these operational flights which have been selected and scheduled to demonstrate Tug capability in a build-up fashion. By the completion of the third flight, however, sufficient confidence will have accrued to verify Tug system capability including ground operations and mission turnaround to allow for a production go-ahead. The Full Scale Development Phase will end after the sixth and last flight test. The two flight test vehicles will continue payload flights during the initial part of the operations Phase. Subsequent flights will be performed by vehicles delivered during the Production Deployment Phase.

DOD ACQUISITION APPROACH (AFSCP800-3) 110A-1

Implementing program concept 110A-1 in accordance with DOD full funding requirements (AFSCP800-3) results in a longer development activity plus a delay in the start of production and operations.

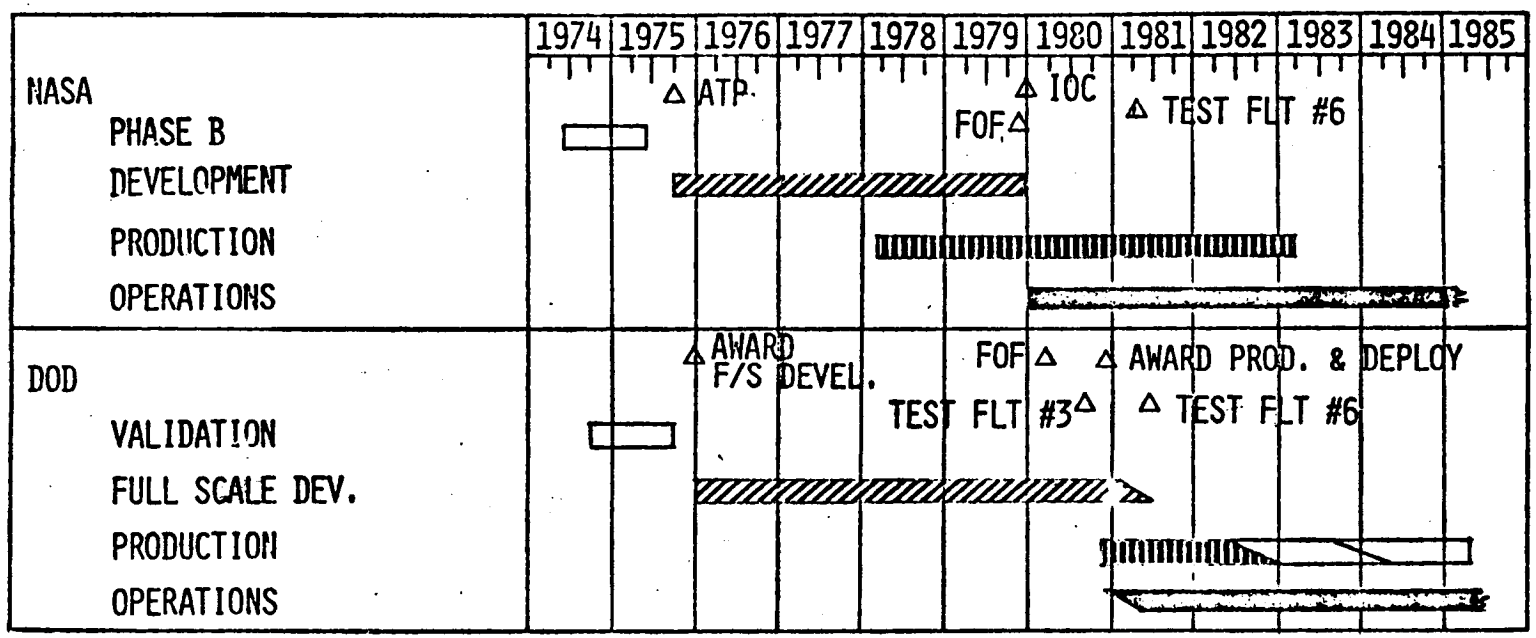
The primary schedule differences between NASA and DOD acquisition programs are as follows:

- DOD Validation Phase constrained to start no sooner than Oct 74 or 3 months after NASA Phase B go ahead.
- Full Scale Development Phase lasts 63 months (1 year longer than the NASA equivalent DDT&E Phase) and includes all test flights (5 of which were costed for NASA as part of initial operations)

In order to obtain DOD approval for full production funding the development program must demonstrate that all performance and operations objectives have been met and related plans for production deployment and operations are well defined.

We have selected the third test flight as the key milestone for demonstrating that all program objectives can be attained. Initial payload deploy operations are performed with the flight test vehicles. The operational fleet will be supplemented with production vehicles as they become available. We recommend that production articles procurement follow a 3 lot buy (3 vehicles per lot) to minimize full funding fiscal requirements.

DOD ACQUISITION APPROACH (AFSCP 800-3) 110A-1



FULL SCALE DEVELOPMENT

- o EXTEND DEVELOPMENT TO INCLUDE 6 TEST FLIGHTS
- o USE FLIGHT TEST VEHICLE FOR INITIAL PAYLOAD OPERATIONS
- o ADD 2ND VEHICLE TO SUPPORT INITITAL OPERATIONS

PRODUCTION/DEPLOYMENT

- o PROVIDE 9 ADDITIONAL VEHICLES (3/3/3-3 LOT BUY)

OPERATIONS

- o DELETE 5 TEST FLIGHTS - 213 TOTAL FLIGHTS
- o TOTAL FLEET-11 MAIN STAGES & 14 APOGEE KICK STAGES

GRUMMAN

8.0 SCHEDULES

8.1.1 SUMMARY PROJECT SCHEDULE

Introduction: The Storable Tug Project schedule was developed to identify the principal project phases and to establish schedule estimates for all hardware and soft ware elements in accordance with the Space Tug Work Breakdown Structure.

The Tug Project Schedule depicts major program milestones and presents project activities at level 5 of the WBS. This schedule establishes the planning baseline for development of the Storable Tug System through design, development, manufacturing, ground test, flight test and operations. It integrates all supporting schedules into an overall project level plan and establishes the sequence and interdependency of activities and events required for the development of an operational Space Tug System.

Groundrules and Assumptions: Following are the ground rules and assumptions used for development of the Storable Tug Project Schedule:

- o ATP is October 1975 at the earliest for Options 1 and 3. ATP for Option 2 to be determined by the contractor.
- o Schedule planning is designed to minimize peak annual funding during DDT&E.
- o Main Stage DDT&E requirements consist of the following major test articles:
  - A structural test article (STA) for dynamic, static and fatigue tests.
  - A main propulsion test vehicle (PTV). Following the completion of live propellant testing the PTV will be refurbished and delivered as an operational flight vehicle.
  - One shipset of Avionics hardware for the Integrated Avionics Test (IAT).
  - A flight test vehicle (MS-1).
- o Operational fleet sizes for each project option are based on a study of traffic capture models.
- o Production rate of vehicles is based on avoiding duplication of major structural assembly tooling and minimizing gaps in manufacturing flow.

- Initial operational capability (IOC) is achieved after completion of one test flight (FOF). IOC dates are as follows:

  Option 1 - December 1979
  Option 2 - December 1983
  Option 3 - December 1979 - initial, December 1983 - evolved.

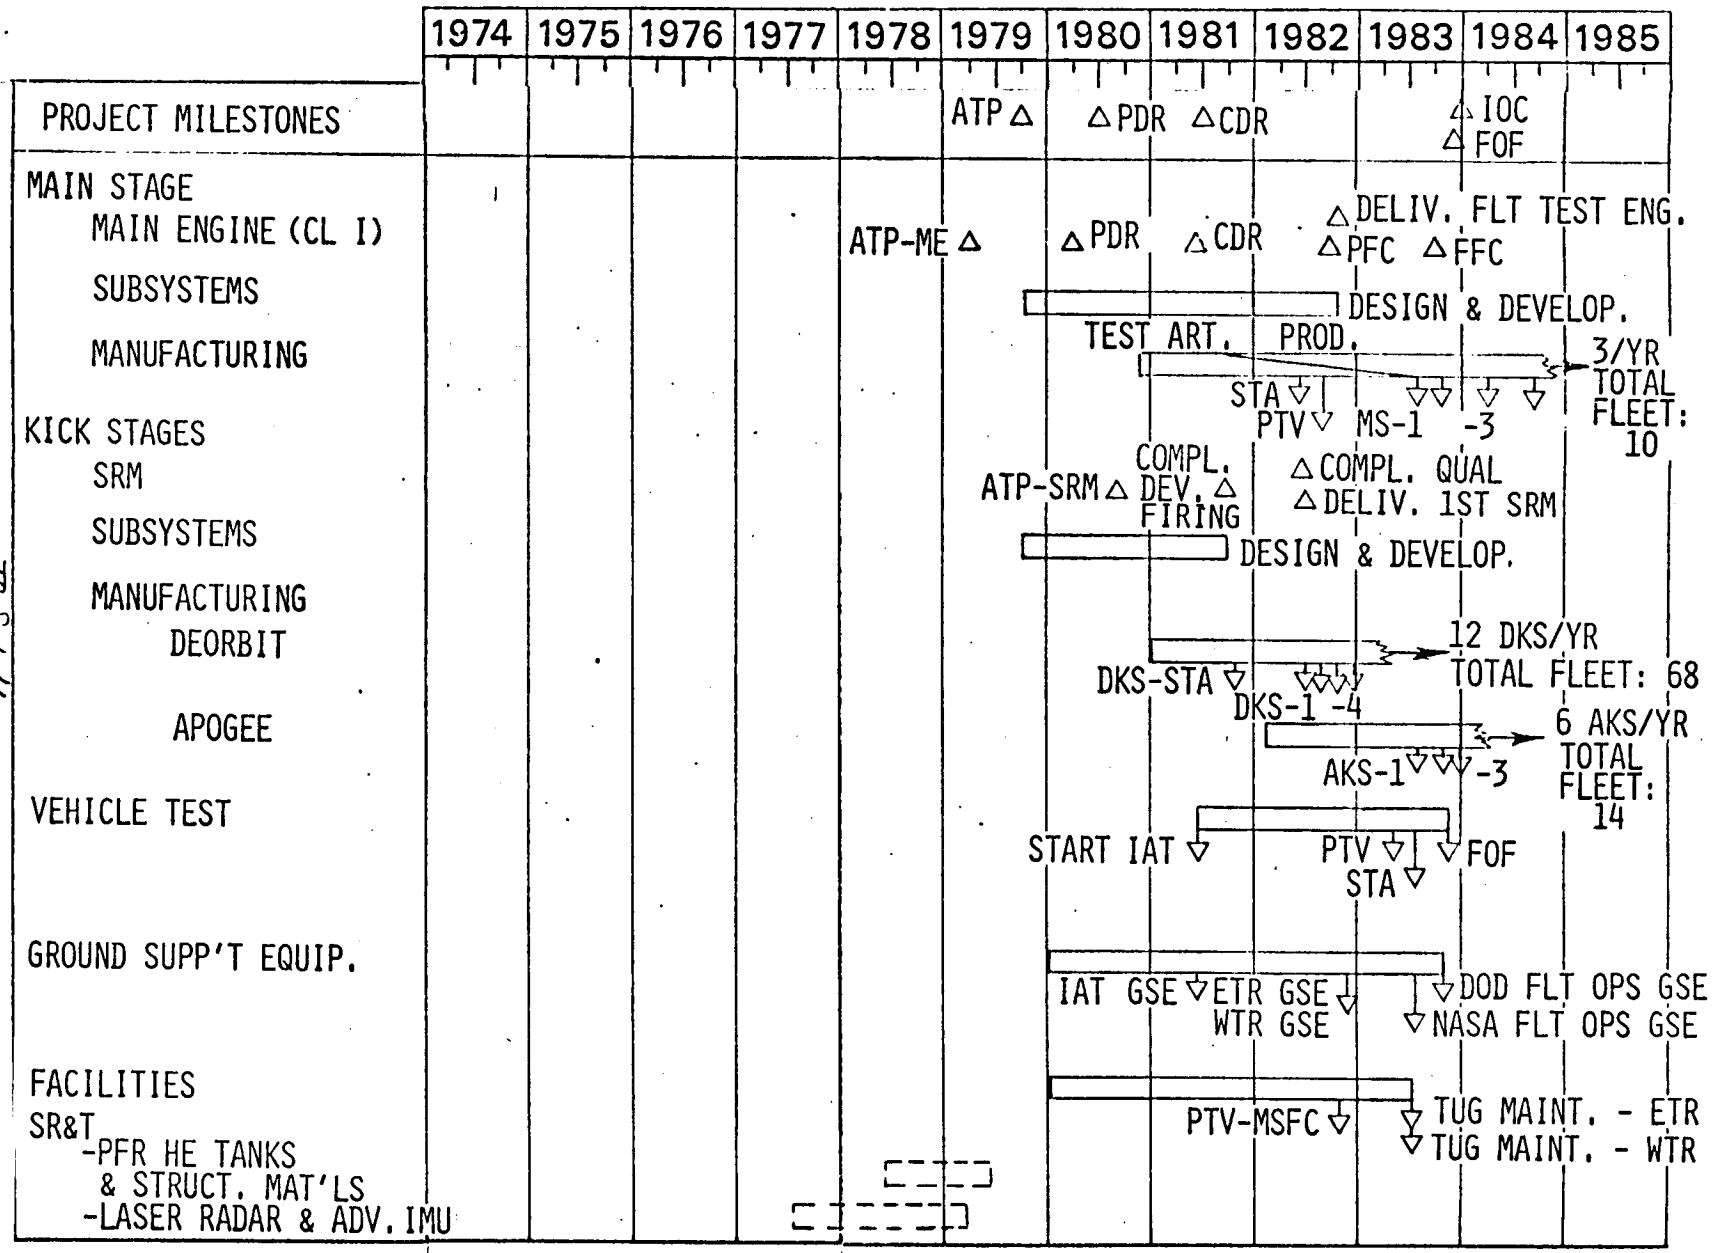
- Maximum number of flights in 1980 is 3, based on the Shuttle traffic model.

Approach: Based on the above groundrules and assumptions a preliminary project milestone schedule was developed to form a baseline for all detail scheduling. Detailed subsystem design and development schedules, manufacturing and factory checkout flows, vehicle test, GSE, facilities, and SR&T Schedules were then developed in conjunction with personnel representing the cognizant management and technical disciplines. These detailed schedules were then summarized and integrated into the Tug Project Schedule through the process of establishing a logical and achievable relationship between the engineering design and development process, procurement of subcontract equipment, hardware fabrication and assembly process and the vehicle test program that minimizes risks and ensures the fulfillment of program objectives. Finally, the major project milestones and activities presented in the Tug Project Schedule were condensed into the Summary Project Schedule.

SUMMARY SCHEDULE - 410AD-2

The primary elements of the 410AD-2 Project Schedule are as described for 110A-1. Authorization to Proceed (ATP) occurs on October 1, 1979 with IOC targeted for January 1, 1984. The design, development and manufacture of the main stage nested dome tanks primarily pace the program. The Class I main engine ATP occurs 6 months before main stage ATP with Final Flight Certification (FFC) occuring two months before main stage first flight. The 410AD-2 main stage major vehicle tests leading to IOC are also as described for 110A-1. Main stage manufacturing begins December 1, 1980 and continues through production of 10 vehicles to support fleet operations. Deorbit Kick Stage (DKS) development begins at the same time as the main stage in order to capture 1986 payload retrieval flights. DKS flights will begin in late 1982 and will be performed with other launch vehicles. Production of Apogee Kick Stages, however, start 13 months after DKS production since AKS operations begin after main stage IOC. DKS vehicle tests start 6 months before the start of main stage vehicle tests and a DKS flight test is planned for September 1, 1982. GSE and Facilities are scheduled to support vehicle test manufacturing ETR/WTR site activation and NASA/DOD Flight Operations Control activations. Both ETR and WTR will be activated to support initial flights in 1983.

410AD-2 SUMMARY PROJECT SCHEDULE



8.1.2 DEVELOPMENT SCHEDULES

8.1.3 PRODUCTION SCHEDULES

The detailed Project Schedule depicts the total development and production phases for the Main Stage and the Auxiliary Stage(s). The detailed Project Schedule is based on a constraint logic that considers overall program objectives and the detailed interaction of constraints on significant program activities. It provides reasonable margins for development problems and minimizes program front-loading.

The detailed Subsystem Schedules provide an order of magnitude increase in detail from the Project Schedule and depict the subsystem activities in both inhouse and subcontractor areas. Subsystem schedule information is presented at WBS level 6 for Structures, Thermal Control and Orbiter Interface, and at WBS level 7 for Propulsion and Avionics subsystems.

8.1.4 OPERATIONS SCHEDULE

Scheduled and planned for concept 410AD-2, option 2 are 30 launches per year with 12 days between launches. Ground servicing as shown on the programmatics/cost operations schedule from land to launch is 10 tug work days and 9 tug/orbiter work days.

8.1.5 FACILITIES SCHEDULE

Included in the storable space tug facilities schedule for concept 410AD-2 are the various tasks to be completed against major program milestones. The fundamental grouping of these tasks are manufacturing, test, maintenance and refurb-ETR, ETR launch, maintenance and refurb-WTR and WTR launch. Under this tug concept facilities maintenance extends into 1991, with most of design/construction/activation ending by 1983 in support of WTR launch requirements.

8.1.6 EVALUATION OF MAJOR SCHEDULE DRIVERS

410AD-2

Our schedule for this project option shows the start of main engine development preceding the Tug ATP by 6 months. This is necessary because of the long development time of the Class I engine (42 months to PFC). Development of the Main Stage subsystems can be achieved in the same overall time span (51 months from ATP to IOC) as for option 1, providing that the SR&T effort for the advanced IMU and the Laser Rend. Radar have been completed prior to phase C/D ATP in October 1979. The critical path for this option may be traced through the following activities:

- Structural design, including the integral, nested tank design.
- Tank fabrication and assembly.
- Vehicle structural assembly.
- Flight test vehicle (MS-1) final assembly, equipment installation and checkout.
- Ship to ETR.
- Prelaunch activity for FOF in December 1983.

Development of the Deorbit Kick Stage will begin concurrently with the Main Stage development in order to make the DKS available for deployment with payloads in 1982, approximately 1½ years prior to the Tug IOC. The Apogee Kick Stage, utilizing common subsystem equipment already developed for the DKS will subsequently be manufactured for deployment in December 1983 (FOF).

8.2 VEHICLE TEST PROGRAM (410AD-2)

8.2.0 Our approach to development of the 410AD-2 Vehicle Test Program is essentially as described in Part I (110A), Paragraph 8.2.0. Since the Deorbit Kick Stage (DKS) must be available for flight approximately fourteen months before main stage first flight, a separate and earlier DKS ground and flight test program is planned. Table 8.2-1 summarizes the design verification approach in terms of test verification requirements and method of requirement satisfaction. Figure 8.2-1 presents a summary schedule of the total 410AD-2 Vehicle Test Program.

8.2.1 Ground Test Articles - Type and Descriptions

8.2.1.1 Propulsion Test Vehicle (PTV)

The 410AD-2 PTV is as described in Part I, Paragraph 8.2.1.1.

8.2.1.2 Structural Test Article (STA)

The description of the main stage STA is the same as that for the 110A-1 and described in Part I, Paragraph 8.2.1.2. The propellant tanks are integral and with nested domes which reduces the overall length to 25 feet.

The auxiliary stage for this configuration is a combined apogee and deorbit kick stage. Its description is otherwise the same as for the 110A-1.

8.2.1.3 Integrated Avionics Testing

8.2.1.3.1 Main Stage Avionics Hardware and Software

Integrated avionics hardware and software testing for the 410AD-2 configuration will be accomplished using an IAT and ASDL facility as described for configuration 110A. However, the 410AD-2 IAT facility and ASDL will have retrieval capability and autonomy level IIB included as part of the initial design.

8.2.1.3.2 Deorbit Kick Stage (DKS)

A breadboard of the DKS wiring and avionics hardware and GSE will be integrated and tested in the main stage IAT facility.

GRUMMAN

Table 8.2-1

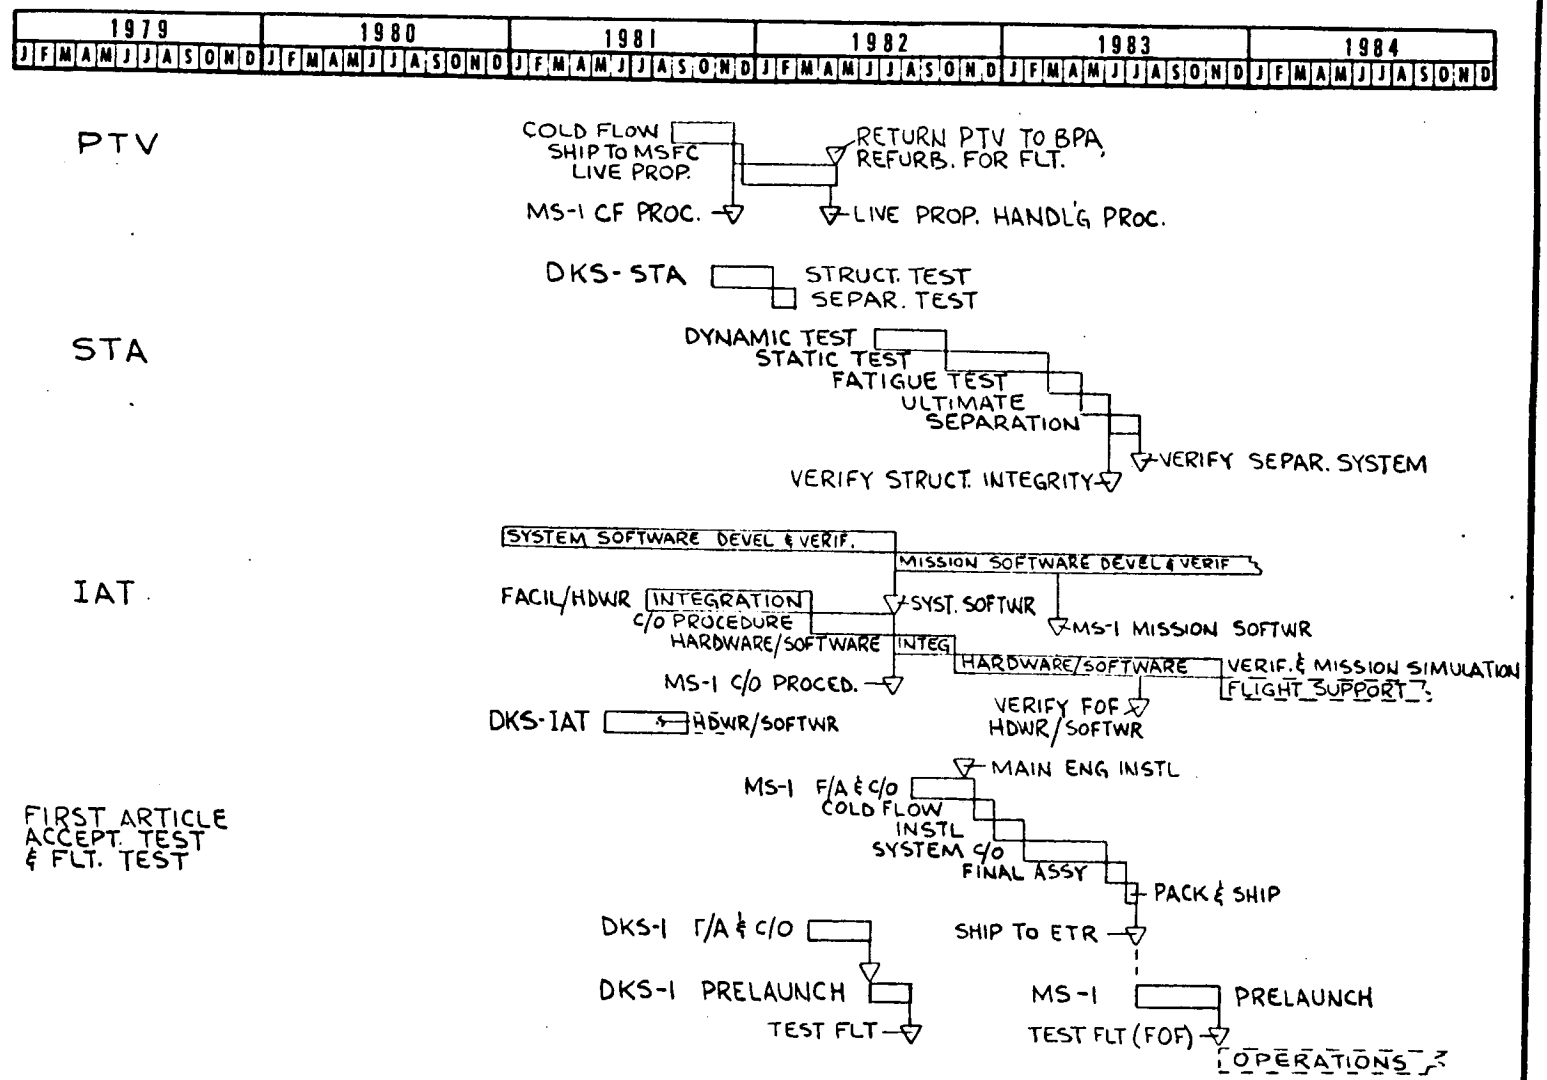

FIG. 8.2-1 410AD-2 VEHICLE TEST SCHEDULE

8.2.1.3.3 Apogee Kick Stage (AKS)

The AKS attitude gyro, velocity meter, sequence programmer, aux. propulsion and thrust vector electronics, instrumentation, and timer/control relays will be the same as for the DKS. Therefore the functional operation of the DKS at these interfaces will be modified to reflect Tug command and control required for the AKS, integrated into the IAT and used as an AKS breadboard for IAT. AKS / Main stage mission software will be developed in the ASDL.

8.2.1.4 Mockups

Mockups will be provided for both the main stage and the kick stages as described in Part I, Paragraph 8.2.1.4. The early deorbit kick stage mockups will be modified and will serve as the later Apogee Kick Stage Mockups.

8.2.2 Flight Test Articles - Description

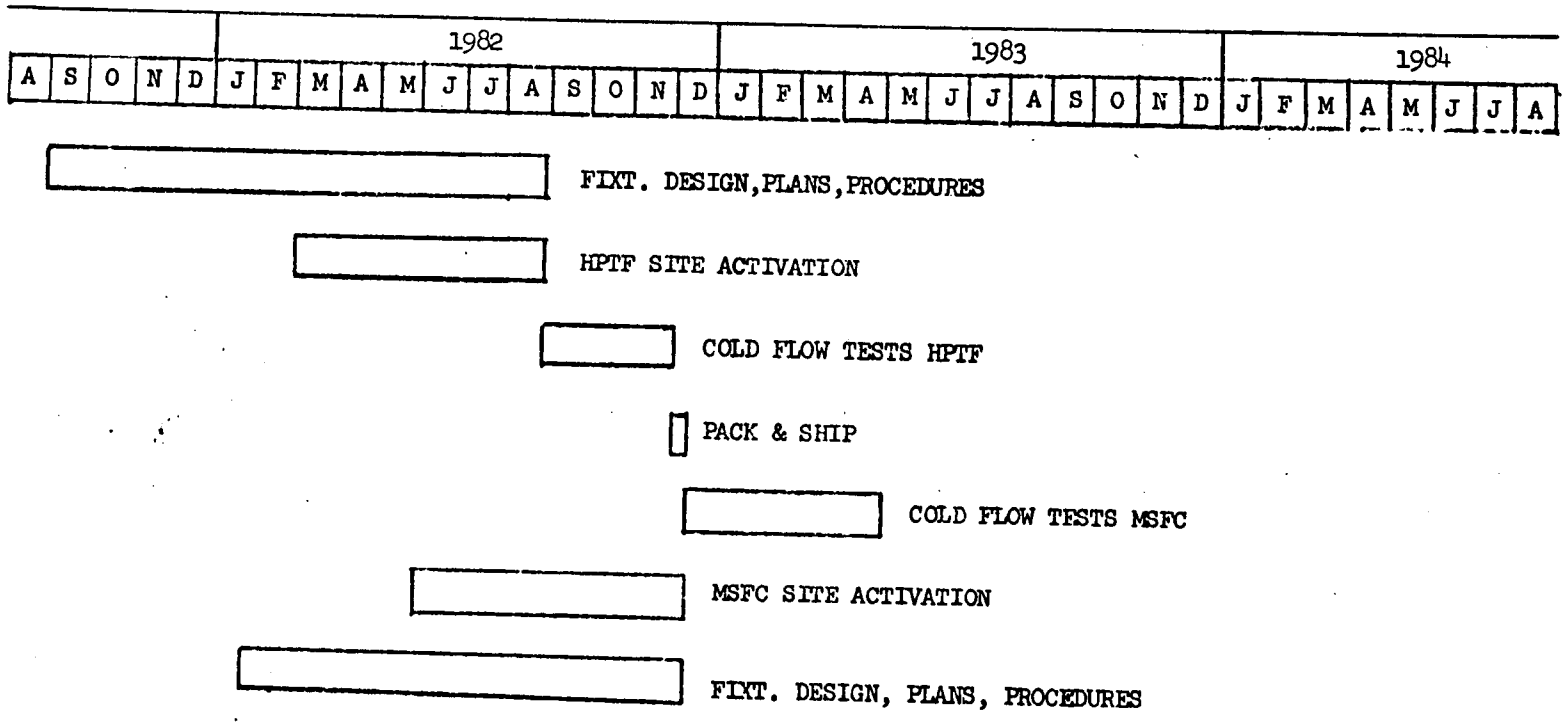
The 410AD-2 main stage flight test article is essentially as described in Part I, Paragraph 8.2.2.1. The deorbit kick stage (DKS) required for the early and separate DKS flight testing will be the first production unit with a DFI system to acquire flight test data. This article must be available for flight test in September 1982.

8.2.3 Ground Test Program

This section describes the major elements of the vehicle ground test program. The test programs described in the following paragraphs include the Propulsion Test Vehicle (PTV), Structural Test Article (STA), Integrated Avionics Testing including software development, and mockups required in support of program requirements.

8.2.3.1 Propulsion Test Vehicle Program

The 410AD-2 Propulsion Test Program is as described in Part I, Paragraph 8.2.3.1. The test schedule and manloading is essentially the same as 110A-1 except it supports the 1983 First Orbital Flight. The test schedule and manloading is shown in Figure 8.2-2. Kick stage SRM development and qualification will be accomplished at the engine contractors facilities as described for 110A-1.



MANPOWER 1 1 2 2 3 6 7 10 16 15 18 24 35 41 44 40 33 29 28 15 7 TOTAL 377 MM

FIGURE 8.2-2 410AD PTV TEST SCHEDULE & MANPOWER

8.2.3.2 Structural Test Article (STA) Program

8.2.3.2.1 Main Stage

The main stage STA program is as described in Part I, Paragraph 8.2.3.2. While the propellant tanks are integral they are again qualified separately from the STA program to allow thorough testing, including burst pressure, without interference with the STA schedule. The STA is used for structural/mechanical interface check-out at the launch site after completion of the test program described for configuration 110A-1. The manloading and test schedule is essentially as shown in Part I, Figure 8.2-3 except that it starts in June 1982.

8.2.3.2.2 Kick Stage

This stage is a combined apogee and deorbit kick stage employing SRM's for propulsion. It is developed 14 months before the main stage for operations with the orbiter or other launch vehicles. The test philosophy is as described in Part I, Paragraph 8.2.3.2.2, as it will be tested with fixtures simulating other payload, main stage or launch vehicle interfaces. The kick stage STA is preserved for additional testing if the need should arise and for structural/mechanical interface checkout at the launch site. The manloading and test schedule for this kick stage is as shown in Part I, Figure 8.2-4 except that it starts in November 1981.

8.2.3.3 Integrated Avionics Test Program

8.2.3.3.1 Main stage Avionic Hardware and Software

The integrated avionics test philosophy and test program for this configuration is basically the same as described in Part I, Paragraph 8.2.3.3. The testing for 410AD-2 will include retrieval avionics hardware and mission software in addition to those tests required for configuration 110A.

Integrated fuel cell reactant tank tests will be required for this configuration and will be performed at the fuel cell subcontractor.

The test schedule and manloading are shown in Figure 8.2-3. It should be noted, however, that DKS development is accomplished early in the program to permit deployment with payloads prior to the availability of the Space Tug.

8.2.3.3.2 Deorbit Kick Stage (DKS)

The test program for the DKS will be similar to that described for the AKS in Part I, Paragraph 8.2.3.3. The major difference is that there is no mission software /hardware tie between the Main stage and the DKS. The test program for the DKS is therefore independent of the MS and consists of breadboard integration, functional verification and GSE and procedures checkout. This will be accomplished in the main stage IAT facility to take advantage of common facility test equipment. The schedule for DKM avionics testing is also shown in Figure 8.2-3.

8.2.3.3.3 Apogee Kick Stage (AKS)

The DKS breadboard will be modified to reflect the AKS configuration and tested in the main stage IAT facility as described for the 110A configuration. Main stage software will include the AKS command and mission requirements. The schedule for AKS avionics testing is also shown in Figure 8.2-3.

8.2.3.4 Mockups

The 410AD-2 mockup program is essentially as described in Part I, Paragraph 8.2.3.4. The DKS mockups, however, must be available in time to support the early development of requirements of the DKS program.

8.2.4 Flight Test Program

This section describes the flight test program for the 410AD-2 configuration. In addition, the section also includes a description of the vehicle level factory and launch site test and checkout approach. In order to maintain continuity the section begins with the checkout and test approach and follows with the discussion of the flight test program.

8.2.4.1 Flight Vehicle Checkout and Test

The philosophy and objectives of the Flight Vehicle Ground test program are the same as those described in Part I, Paragraph 8.2.4.1. The only differences in Factory Testing is the addition of fuel cell checks and the deletion of the RGA-APS Polarity checks (The 410AD-2 doesn't have an RGA Package).

FIG 8.2-3

8.2.4.1 Flight Vehicle Checkout and Test (cont'd)

There are two major differences in the prelaunch tests. A longer countdown demonstration is required to allow practice loading of comsumables for the fuel cells, and the AKS/DKS goes through its first prelaunch flow along and not integrated with a main stage as does the AKS with the 110A-1 main stage.

The factory site facilities and equipment requirements are basically the same as those for 110A-1. An additional RF bench is required to test the RF navigation aids, while the Laser radar will require a checkout or calibration unit. Additional GSE is also required in the HPTF for Fuel Cell testing. The special fixture for RGA-APS polarity tests is not required for this concept. Tug operational facilities are used for prelaunch.

Test schedules and manpower requirements are presented in Figures 8.2-4 and 8.2-5 for the MS vehicle and Figure 8.2-6 and 8.2-7 for the AKS/DKS stage.

8.2.4.2 Flight Test Program

The main stage flight test program is essentially as described in Part I, Paragraph 8.2.4. First Orbital Flight (FOF) is a dedicated flight test and deploys a dummy payload only. The test sequence is modified slightly to include a retrieval demonstration using a DKS to serve as the retrieval target.

Since the DKS is developed and flown earlier than the main stage, a separate and dedicated flight test is planned to verify the capability of the DKS to function during and after extended exposure to orbital environments. This flight will occur in mid-1982 and could be accomplished as part of a normal Shuttle launch or by some other means.

There will be a total of eight flights in the flight test program including the dedicated first flight and seven subsequent operational flights. A DFI system will be added to the main stage and kick stage to obtain flight test data during the flight test program. Operational flights included in the flight test program are:

(2) Single payload deploy
(1) Multi payload deploy
(1) Single payload deploy with kick stage
(1) Retrieve
(1) Round trip
(1) Retrieve/round trip with kick stage

The flight test schedule and cost are shown in figure 8.2-8.

FIG. 8.2-8 FLIGHT TEST PROGRAM SCHEDULE (410-AD2)

8.2.5 Impact of Two Year Earlier IOC

A two year earlier IOC accompanied by an identical two year earlier program start (ATP) will generally not impact the Vehicle Test Program. SR&T requirements, however, may affect the development cycle of the advanced IMU utilized in this configuration. Our development cycle for the IMU is based upon a related on going Air Force SR&T activity which is scheduled for completion at the end of 1977. We have proposed further follow-on SR&T activities to refine the technology to Tug requirements. A two year earlier start in the Tug program will necessarily force the follow-on IMU tasks to be also started earlier and in parallel with the Air Force program. This is necessary to ensure that the development cycle through qualification tests may be accomplished on time. This approach will increase program risk and may necessitate an alternate choice in IMU hardware.

8.2.6 Analysis of Test Program

8.2.6.1 Key Elements

The key elements of the Vehicle Test Program are essentially as described in Part I, Paragraph 8.2.6.1. Early development of the Deorbit Kick Stage, however, requires early structural and integrated avionics testing to support the DKS first flight. First flight of the DKS is a dedicated flight test to verify DKS operations after long term orbital exposure.

8.2.6.2 SR&T Assumptions

410AD-2 SR&T requirements are proposed to provide early confidence in an orderly maturity of Tug design, development and manufacturing approaches once the hardware phase of the program begins. Technology requirements, test programs affected and a brief description of the interaction between the SR&T requirements and the test programs affected is summarized in Table 8.2-2.

8.2.6.3 Reusability Demonstration

Reusability Demonstrations for the 410AD-2 are as described in Part I, Paragraph 8.2.6.3.

8.2.6.4 Life Verification Test

Life Verification Tests for the 410AD-2 are as described in Part I, Paragraph 8.2.6.4.

TECHNOLOGY REQUIREMENTS	TEST PROG. AFFECTED	REMARKS
Main engine life and high performance	o GFE eng. devel. prog. o Flight test prog.	Early life verif. of eng. components and area ratio nozzle performance assure phase C/D engine development. PTV is not affected since eng. is not required. FOF could tolerate slightly reduced eng. performance.
PFR helium tank		Early verif. of low weight PFR tank assure maximum tug performance.
Materials compatibility Data	o Tank qual o STA prog. o PTV prog.	Early verif. of material compatibility with MMH and N_2O_4 assures on-time development of main stage tankage including tank qual. STA and PTV testing.
Fracture Mechanics data	o Tank qual. o STA prog.	Early fracture mechanics data allows on-time development of structural subsystem including tankage quals and STA testing.
Heat Pipes	o Flight test prog.	Early verif. of heat pipe design approach allows on-time developments of Thermal Control Subsystem thereby maximizing Tug performance.
Advanced IMU	o Integrated avionics o Flight Vehicle Factory checkout o STA	Early devel. of Advanced IMU will assure on time devel of software and integration procedures in the IAT LAB for FLT VEH buildup and test and accurate simulation for STA prog.
Graphite Composite	o STA Prog.	Early Devel of graphite composite honecomb face sheets assures that STA program progresses as planned.
Laser Radar	o Integrated Avionics o Flight Vehicle factory checkout o STA	Early devel of light weight low power Laser Radar will assure on time development of software and integration procedures in the IAT LAB for FLT VEH buildup & Test and accurate simulation for STA program.
Long Term Space Storable SRM	o SRM Qual	Early verif. of long term space storable SRM on-time development and qual.

Table 8.2-2.

RETRIEVAL CAPABILITY WITH KICK STAGES INCREASE VEH. AVIONICS & FLT TEST BY $16.8M

410AD-2 GROUND TESTS

TEST	TEST ART.	OBJECTIVES	TEST APPROACH
STRUCTURE o MAIN STG (MS) o DEORBIT KICK STAGE (DKS)	o COMPLETE M.S. PRIM. & SEC. STRUCT. INCL. TUG/ORB. & TUG P.L. ADAPTERS o COMPLETE DKS PRIM. & SEC. STRUCT.	o EVAL. DYN., STATIC STRENGTH, SAFE-LIFE & SEPARATION o VERIFY STRUCT./MECH INTERFACES AT LAUNCH SITE	o VIB./ACOUSTIC TESTS o DES. LIMIT STATIC TESTS o STATIC FATIGUE o ULT. STATIC TESTS o SEP. DEMO. o INTERFACE VALIDAT. DEMO. AT KSC.
PROPULSION (MS)	o FLIGHT WT. MAIN STG. STRUCT. o MAIN ENG. SUPPT. S/S LESS ENG. o ENG. SIMUL. UNIT o PTV REFURB. TO FLIGHT OPS.	o DEMO. OPS OF ASSEM. COMPONENTS o DEVELOP C/O & OPS PROCEDURES o VERIFY SERV/HANDLG PROCEDURES o DEMO. SYS. PERF. & CHARACTERISTICS	o COLD FLOW ONLY o REFEREE FLUIDS PHASE - FILL/DRAIN/FLOW TESTS o LIVE PROPELLANTS PHASE - LOAD CONTROL/ ACCURACY - SYS. COMPAT. & DYN. - PERF.SERV./HANDLG. PROCEDURES

II-2-17

410AD-2 GROUND TESTS

Vehicle Test Program

The vehicle test program for 410AD-2 was developed in a similar manner to that described for 110A-1.

Structural Test Articles

The Structural test program for the 410AD-2 MS is the same as the test program for the 110A-1 MS but is shifted four years later in time. The DKS Structural test article program is basically the same as the MS test program. The AKS structure is the same as the DKS and therefore does not require a separate structural test program.

Propulsion Test Vehicle

The M.S. Propulsion test program for the 410AD-2 configuration is the same as the test program for the 110A-1 except that it is shifted four years later. The DKS propulsion test article program is the same as for the 110A-1 AKS. Since the only difference between the DKS and AKS propulsion system is a reconfiguration in SRM's, no additional AKS propulsion tests are required.

81-E.3-18

410AD-2 GROUND TESTS (CONT'D)

TEST	TEST ARTICLE/FACILITY	OBJECTIVES	APPROACH

LZ-828-19

410AD-2 GROUND TEST (CONTD)

Integrated Avionics Tests

The MS Integrated Avionics Test program for the 410 AD-2 configuration will be basically the same as for the 110A-1 however, the 410AD-2 IAT facility will include retrieval electronics and Level IIb autonomy hardware. The DKS will be integrated in the same facility as the MS IAT to take advantage of the facility simulation and GSE capability. The DKS will be modified to simulate the AKS for MS-AKS IAT Mission Simulations.

Mockups

The MS mockup for this configuration will be the same as the mockups required for 110A. The DKS will also be mocked up and subsequently modified to serve as AKS mockups.

410AD-2 FLIGHT TESTS

TEST ARTICLE	OBJECTIVES	APPROACH
o MAIN STAGE - 1ST PROD. UNIT INCLUDING DFI o DKS - 1ST PROD. UNIT INCLUDING DFI	o THERMO - VERIFY SYS. THERMAL CONTROL o STRUCT - VERIFY LAUNCH/ORBIT/ ENTRY/LANDING LOADS AND DYNAMICS o PROP - VERIFY MPS/APS o AVIONICS - VERIFY AVIONICS OPS o OPS - EVALUATE TUG/ORB, TUG/KS & TUG/PAYLOAD INTERFACES - EVALUATE SYSTEM PERFORMANCE CAPABILITY - DEMO PAYLOAD DEPLOY & RETRIEVE o DKS - DEMO SYS. FLIGHT TEST COST = $24.44M

TOTAL VEHICLE TEST = $49.60M

GRUMMAN

II-2.2-21

410AD-2 FLIGHT TESTS

Eight flights are included in the 410AD-2 flight test program. The main stage flight test program is essentially as described for configuration 110A-1. The test sequence is modified slightly to include a retrieval demonstration using a DKS to serve as the retrieval target.

Since the DKS is developed and flown earlier than the main stage, a separate and dedicated flight test is planned to verify the capability of the DKS to function during and after extended exposure to orbital environments. This flight will occur in mid-1982 and could be accomplished as part of a normal Shuttle launch or by some other means.

PART II

8.3 Facilities Plan - Option 2 - Concept 410AD-2

8.3.1 Manufacturing Facility

Same as concept 110A-1 except 34,900 sq. ft. of floor space is required for fabrication and assembly of the TUG.

8.3.2 Test Facilities

Same as concept 110A-1 except 1AT will require 1300 sq. ft. of floor space at JSC.

8.3.3 Operations Facilities

Same as concept 110A-1 except TUG Maintenance Facility at ETR will have 4 horizontal stations in 12,000 sq. ft. addition to the Shuttle OMS Facility. The Kickstage SRM Processing Facility will require 2,800 sq. ft. of floor space.

8.3.4 Impact of 2 Year Early IOC

Examination of the facility schedule in Section 8.1 and the following Facility Funding Requirement Data Sheet indicates that a two year early IOC from December '83 to December '81 with a corresponding two year early ATP would require activation of Manufacturing, Test, ETR and Mission Control facilities two years earlier. Therefore, approximately $4.3 million of facility DDT & E costs must be expended two years earlier. Assuming that WTR would now become operational in 1983 as in the 110A-1 concept, approximately $2.7 million for WTR facilities must be expended one year earlier.

T-8.3-2

8.4 Vehicle Manufacturing

This section establishes the manufacturing requirements for the 410AD-2 spacecraft including the assembly sequence, tooling, schedule, manufacturing test, special processes and facilities.

The 410AD-2 spacecraft consists of a main stage and apogee or deorbit kick stages (AKS/DKS). The main stage employs a graphite/epoxy outer shell and nested titanium propellant tanks. The kick stage is structurally the same as the AKS described in Part I and varies only in the number of solid rocket motors and equipment complement required.

8.4.1 Plan/Flow/Time

The manufacturing sequence identifies the major manufacturing tasks from parts fabrication through assembly, installation, checkout and delivery and the manufacturing flow defines the time phasing of these tasks. The calendar relationship of program milestones to tooling delivery, operation sheet planning, work order release and assembly of the major test articles and flight vehicles is shown in a master manufacturing schedule.

8.4.1.1 Main Stage

The assembly breakdown of the main stage is shown in figure 8.4-1 and the description of the major assemblies, equipment installations, and test/checkout operations is provided in Table 8.4-1. The manufacturing flow and master schedule are shown in Figures 8.4-3 and 8.4-4 respectively.

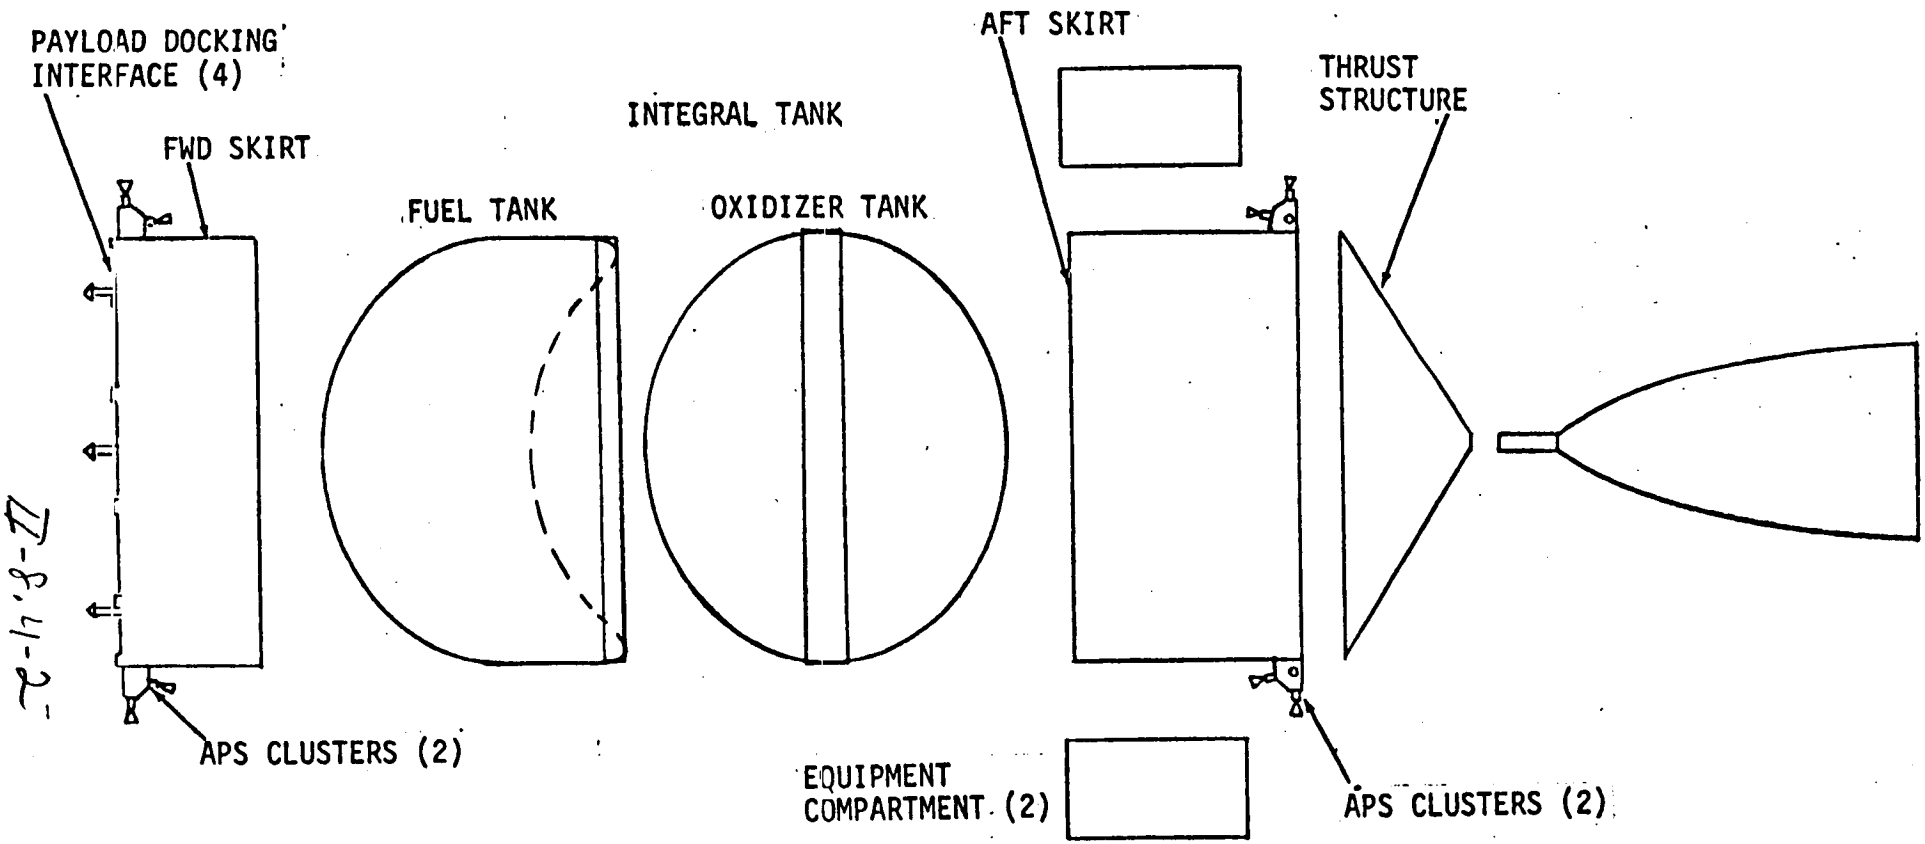

Figure 8.4-1 Assembly Breakdown Main Stage

TABLE 8.4-1

MANUFACTURING SEQUENCE

410AD-2, 310-3A, 310-3B

MAIN STAGE

MAJOR ASSEMBLIES

Forward Skirt Subassembly
- o Outer shell - aluminum honeycomb with graphite epoxy composite skins or stiffened aluminum sheet for 510A-3B
- o Fwd Frame - Payload/kick stage interface & APS support
- o Intermediate Frame
- o Support Frame - Orbiter pick-up

Fuel & Oxidizer Tanks
- o See Nested Dome Propellant Tank Manufacturing Sequence and Fig. 8.4-2

Aft Skirt Subassembly
- o Outer Shell- Aluminum honeycomb with graphite epoxy composite skins or stiffened aluminum sheet for 510A-3B
- o Intermediate Frame
- o Aft Frame - Adapter interface, APS support & thrust structure attachment

Thrust Structure Subassembly
- o Conical shell - stiffened aluminum sheet
- o Fwd ring frame
- o Engine gimbal support
- o Base heat shield

Other
- o Equipment compartment subassembly
- o APS clusters (2 fwd/2 aft)
- o Probe drogue interfaces (4 fwd./4 aft)

STRUCTURAL ASSEMBLY

Join propellant tanks and aft skirt assembly
Install MLI insulation blankets
Join fwd skirt and tank assemblies
Install thrust structure
Install equipment compartment tank supports, equipment shelves and secondary structure

INSTALLATIONS

Main Propulsion System (MPS)
- o Engine - Class I
- o Helium Tank
- o Gimbal actuators (2)
- o Pressurization & propellant feedlines
- o Fill, Vent, Drain Lines
- o Control/Relief valves, filters, regulators, flex joints, quick disconnects, etc.
- o Low level sensors (fuel & OX)

INSTALLATIONS (Cont)

Auxiliary Propulsion System (APS)

- Propellant Tanks (2)
- Helium Tanks (2)
- Thrusters (24) - 25# (310-3A/3B 16 @ 25#)
- Pressurization & Propellant Feedlines
- Fill, Vent, Drain Lines
- Control/Relief Valves, Filters, Regulators, Quick Disconnects, etc.
- Acquisition Bladders
- Thruster Heaters

Thermal Control

- Insulation Blankets - MLI
- Alzak Skins
- Base Heat Shield - Thrust Structure
- Silver Backed Teflon Tape - Saddle Bags
- Radiator & Associated Plumbing

Astrionics

Electrical Power (EPS)

- Fuel Cell
- Cryo Hydrogen Tank
- Cryo Oxygen Tank
- Emergency Battery
- Distribution & Control Boxes
- Cable/Harnesses - Approx. 10,000 ft. & 120 connectors

Guidance, Navigation & Control (GN&C)

- Intertial Measuring Unit (IMU)
- Star Tracker (2)
- Rate Gyro Unit
- Accelerometer
- APS Control Electronics
- Main Engine Control Electronics

Added For Deorbit & Retrieval Missions:

- Laser Rendezvous Radar
- Satellite Receiver
- Doppler Receiver
- "L" Band Antennas (4)
- Combined Doppler Detector

Data Management (DMS)

- Computer (2)
- Controller/TM Formatter
- Data Acquisition Units (3)
- Sensors (190)
- Tape Recorder

(Cont)

INSTALLATIONS (Cont)

Astrionics (Cont)

Communications

- Transciever
- Power Amplifier (2)
- Signal Processor
- Diplexer (2)
- Antenna Switch
- OMNI Antenna (2)
- Aux. Transmitter
- Power Splitter
- TV Assembly

TEST AND CHECKOUT

In-Process Manufacturing Verification

- Fluid Line Leak Checks
- Electrical Harness Continuity, Dielectric and Insulation Resistance
- Dimensions, Finish, Identification and Markings
- Cleanliness
- Workmanship

Acceptance Test

- Cryo Proof Propellant tanks
- Proof/Leak Check Fluid Lines
- Flow Calibration
- Electrical Circuit Functional and EMI
- Thrust Vector and Gimbal Actuator Alignment
- Functional Performance
- Fit & Clearance Checks
- RGA/APS Polarity Test
- Mission Simulation
- Cleanliness Verification
- Weight and CG Determination

PACK AND SHIP

Apply Pad Pressures To Fluid Systems

Install Protective Devices and Covers

Clear Acceptance Paperwork

Install in Shipping Container

TOOLING REQUIREMENTS (Cont)

410AD-2, 310-3A, 310-3B

PART/ASSEMBLY	OPERATION	TOOL/GSE
EQUIPMENT COMPARTMENT (Cont)		
Fittings	Machine	Holding Fixtures
FLUIDS ASSEMBLIES		
Tubing	Form	Standard bending dies & set-up gages (SUGS)
	Weld connectors	Standard Orbital welding equipment adapters & welding schedules
Assembly	Assemble fluid lines and purchased components such as valves, filters, regulators	Assembly fixtures and standard cryofit and brazing tools.
ELECTRICAL HARNESSING		
	Wire cutting and prep	Standard cutting, stripping, marking tools
	Assembly	Harness boards
INSTALLATIONS		
	Install subassemblies and components	Installation fixtures
FINAL ASSEMBLY		
	Structural Assembly Installations Handling Transportation Shipping	Final assembly fixture Work stand Slings (2) (GSE) Dolly (GSE) Container (GSE)

8.4.3 Facilities

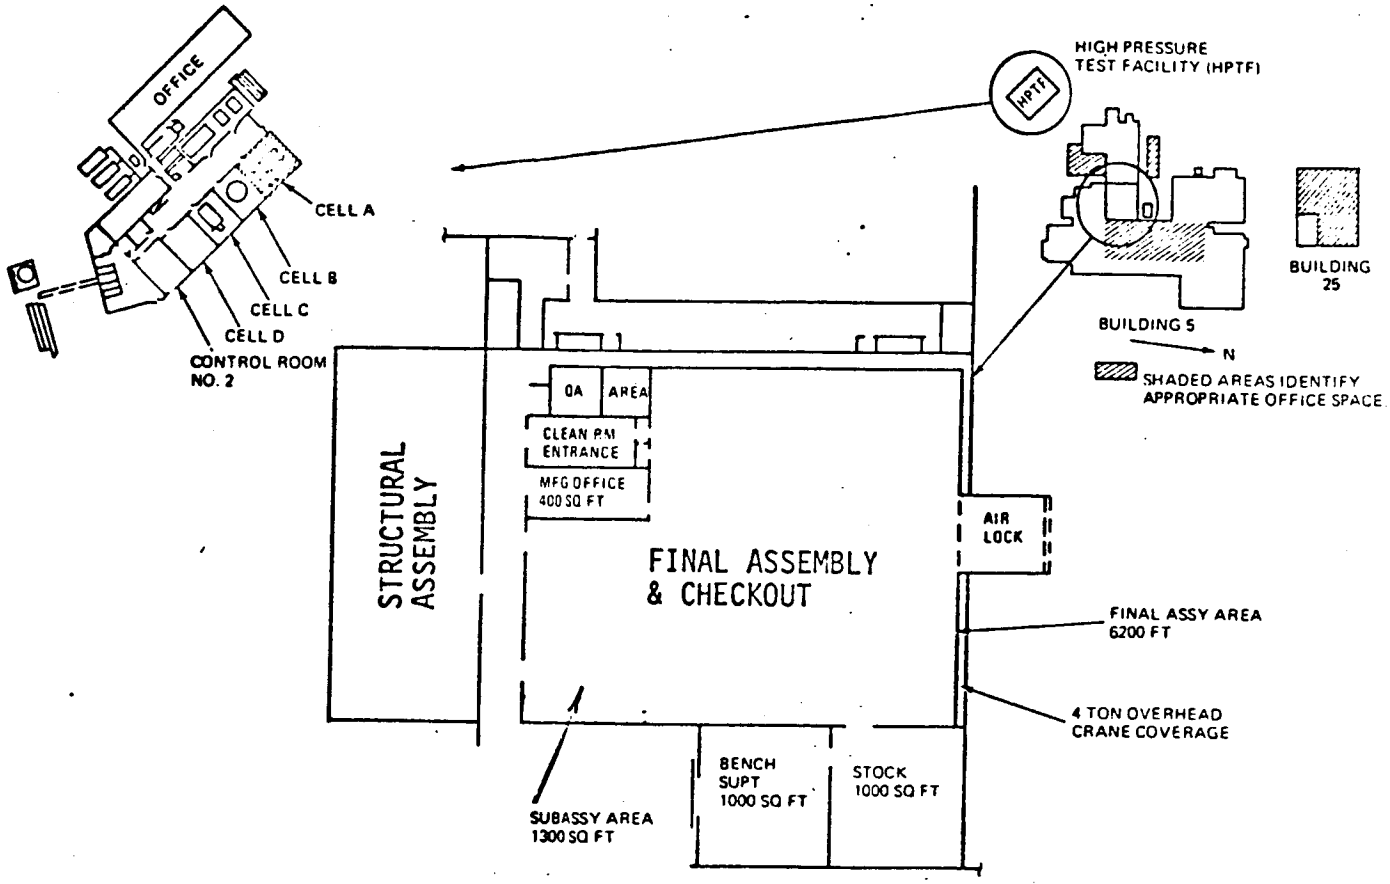
The Tug Spacecraft will be assembled in our existing Plant #5 Spacecraft Assembly Facility. This area, developed for the OAO, has the controlled environment necessary for contamination-free propulsion system assembly and is adjacent to the LM High Pressure Test Facility (HPTF) for fluid system calibration and acceptance test. All structural assembly will be accomplished adjacent to final assembly. The floor plan layout of the area and the floor space requirements are shown in Figure 8.4-5.

Subassembly and acceptance testing of fluid system modules will be accomplished in the Plant #2 Laminar flow clean room which has 4 booths and provisions for component cleaning, tube welding, x-ray inspection and high pressure component test.

The HPTF contains 4 test cells equipped with fluid distribution systems, instrumentation, remote controls and data reduction equipment for safely conducting high pressure fluid system testing.

The propellant tanks will be fabricated in the Plant #3 welding area. This area, developed for LM cabin welding has stake and boom welding equipment and provisions for dye penetrant, X-ray and ultrasonic inspection of pressure vessel quality welds.

Parts will be fabricated in specialized work areas in Plant #2 and #3 such as the press department, chemmilling, heat treat, machine shop and finishing facility.



Final Assembly Facility

FLOOR SPACE UTILIZATION

ACTIVITY	MAIN STAGE	KICK STAGE
FINAL ASSY & C/O	5,900 sq. ft.	10,900 sq. ft.

TANK ASSY. (PL. #3)	3,800	-
TOTAL	18,000 sq. ft.	17,200 sq. ft.

Figure 8.4-5 II-8.4-17

8.4.4 Special Requirements

8.4.4.1 Critical Processes

Identification and control of critical processes are essential for assuring spacecraft integrity. Grumman corporate procedure M-120 and M-311 discipline the identification and documentation of the control requirement and provide for implementation through detailed shop instructions, inspection procedures and verification records. All processes are validated before being used in production. Personnel are trained, qualified, and certified for performing selected processes.

Our existing Manufacturing Engineering Process Standards (MEPS) for welding, brazing, crimping, finishing, structural bonding, contamination control etc. will apply to the majority of the Space Tug process requirements.

Special attention will be given to defining the critical process requirements for the titanium propellant tanks and the composite honeycomb outer shell.

Ten foot diameter titanium tanks have not been fabricated before and titanium tanks such as the 54" LM tanks are normally fabricated by welding machined forgings. Because of the high cost of developing 10 foot diameter forgings we are proposing to fabricate the tank domes of welded gore sections. Special processes will be required for tolerance control of weld joint fit-up, welding equipment power settings, repair procedures, heat treating, gore forming, chemical milling and finishing.

The outer shell of the spacecraft is designed of honeycomb panels with .012 inch thick graphite epoxy skins. We have extensive composites experience from our aircraft programs but expect that special techniques will be required to fabricate the thin skins which will be layed-up from .0025 inch graphite epoxy tape which is still in the development stage.

8.4.4.2 Vehicle Modification and Repair

In general, minor maintenance and repair of the spacecraft will be accomplished at the operational site. Activities requiring major modification to structure, subsystem installations or MPS tanks which require special tooling or facilities will be accomplished in the final assembly facility in Plant #5 Bethpage.

If extensive modification is required the major structural sections can be disassembled. The forward skirt attaches to the fuel tank frame with mechanical fasteners which can be removed to expose the forward end of the tank. The aft skirt joins the two tanks at the main frame of the aft tank and the fuel tank Y ring. Removing the mechanical fasteners at these points allows separating the tanks and removing them from the structure. To accomplish this level of dis-assembly for tank replacement the vehicle will be designed with mechanical joint connectors such as the Gamah or flange connectors used on LM spacecraft. Raychem cryofit fittings used on F-14 hydraulic systems and brazed fittings used on LM will also be used in applications where replacement or repair of subsystems is anticipated. Electrical harnesses and cables will also have end connectors to allow disconnecting equipment or disassembly of themajor spacecraft sections.

8.4.5 Summary Analysis/Philosophy

The primary manufacturing responsibility in this program phase has been to analyze the various configurations to determine the most cost effective combination of equipment, facilities, resources and schedule required to produce them. Initially the major cost drivers were identified and trade-off studies were conducted to provide inputs to the designers and the costing group. Producibility support was also provided to the designers to assure a cost effective balanced manufacturing program.

The integral titanium nested dome propellant tank is the major cost driver and manufacturing technology challenge in this configuration. We have reviewed Saturn, Titan, Centaur and LM manufacturing methods to establish minimum material gages, fabrication processes, tolerances and assembly procedures. Because of the large diameter (10 feet) we have elected to assemble the tank domes from welded gore sections instead of the usual one piece machined forgings.

Systems installation and checkout is the other main cost driver in this configuration. To reduce the impact of these activities on cost and schedule we will modularize subsystems as much as possible. This allows off-line build-up and parallel flow of the modules such as the helium pressurization unit and APS control valve package to provide better accessibility, more efficient work distribution and man loading, improved workmanship/quality and reduced total flow time. Modularization is of special importance for a reusable vehicle since the entire unit can be removed for maintenance and repair without impacting availability of the spacecraft.

8.4.6 Impact of IOC Date Two Years Earlier

Moving IOC two years earlier to December 1981 will require moving program start (ATP) at least an equivalent time. There is adequate time in the manufacturing schedule to meet the program milestones therefore any stretchout or reduction of elapsed time will be inefficient.

8.4.7 GSE Requirements

Ground support equipment is used to perform acceptance tests in the factory flow and to detect or diagnose malfunctions or monitor the functional performance status of systems, subsystems or equipment. The GSE is listed below and is described in volume 6 appendix E. Special handling equipment associated with manufacturing operations is identified in the tooling section 8.4.2.

Weight and C.G. equipment
LRU handling fixture
Induction brazing unit
Engine dolly
Battery container
Theodolite
Navigation base alignment gage
APS tank dolly
Auxiliary crane control
Vacuum test cart
GN_2 manifold and oxidizer storage unit
Pressurization Maintenance Unit (PMU)
Nitrogen conditioning cart
Transporter GN_2 storage
Cryo and blow-down equipment
Propellant loading control assembly (PLCA)
Propellant system checkout cart
Propellant system helium distribution assembly
Leak detector
APS transfer control assembly
GN_2 regulator unit
Communications test station S-band
Battery charger
Ground power supply
APS valve controller
Load bank
S-band uplink monitor
Communications test station L-band

8.5 SPECIAL PROGRAMMATICS

410AD-2 SPECIAL PROGRAMMATICS

The facing chart summarizes the salient features defined for implementing and managing Program 410AD-2 and indicates specific areas for government participation.

The main factors derived from our analysis of 410AD-2 include: defining the initial flight build up based on initial ground crew launch capability; timing DKS development for concurrent start to capture 1986 retrievals; performing early DKS flights with other launch vehicles; advancing Main Engine go ahead 6 months before the main stage to avoid a critical path; refurbishing the propulsion test article for operational use; and defining a fall back position for every identified risk.

Specific areas for government participation include: establishing Tug/Shuttle interface requirements before Orbiter design freeze; providing payload interface design requirements and mission model data; initiating required activities for Support Research and Technology; providing GFE systems and components (e.g., main engines, and DOD secure comm); supporting propulsion system testing and development and supporting integrated avionics hardware testing and related software development; providing required facilities and performing vehicle ground operations, flight operations and logistic support operations.

410AD-2 SPECIAL PROGRAMMATICS

- o PROGRAM IMPLEMENTATION AND MANAGEMENT
  - FLIGHT BUILD-UP SET BY ETR GROUND CREW LAUNCH CAPABILITY
  - DKS TIMED FOR CONCURRENT START TO CAPTURE 86 RETRIEVALS
  - EARLY DKS FLIGHTS PERFORMED WITH OTHER LAUNCH VEHICLES
  - MAIN ENGINE ATP ADVANCED 6 MONTHS TO AVOID CRITICAL PATH
  - PROPULSION ARTICLE REFURBED FOR FLIGHT
  - FALL BACK POSITION SHOWN FOR EVERY IDENTIFIED RISK

- o AREAS FOR GOVERNMENT PARTICIPATION
  - FIRM TUG/SHUTTLE INTERFACES BEFORE ORBITER PDR
  - PROVIDE PAYLOAD INTERFACE DESIGN REQUIREMENTS & MISSION MODEL DATA
  - INITIATE REQUIRED SR&T
  - SUPPORT SYSTEM TEST - AVIONICS HARDWARE/SOFTWARE, PROPULSION
  - PROVIDE GFE SYSTEMS & COMPONENTS, FACILITIES & LOGISTIC SUPPORT
  - PERFORM VEHICLE GROUND AND FLIGHT OPERATIONS

GRUMMAN

8.6 COST DATA

Included in this report are cost data for DDT & E,Production and Operation Phases of Concept 410AD-2. In sufficing reporting requriements this section is divided as follows:

- Storable Space Tug System Project expected cost--Spares Cost (INT 7 OPS)--First Unit Cost (Data Forms A1,2 and 3, subparagraph No's 8.6.1, 8.6.2 & 8.6.3) (Computer P/O)

- Storable Space Tug Funding Schedules--DDT 7 E,Production and Operations (Data Forms C, subparagraph 8.6.4,8.6.5, 8.6.6 and 8.6.7.

- First Unit Production Cost per WBS (including Avionics to level 7). Main Stage and Auxiliary Stage(s), (subparagraph 8.6.8).

- 410AD-2 Average Cost/Flight (subparagraph 8.6.9).

- Storable Space Tug System Project Cost Estimate data by SOW-DDT & E, Production and Operations. (Data Form T (SOW'S) subparagraph 8.6.10).

- Form B (Technical Characteristics) subparagraph 8.6.11.

TABLE 4.3.2.2-9 CONCEPT 410AD-2 COSTED FLIGHT BUILDUP

 D-8.7-8

FLIGHT OPERATIONS BUILDUP 410AD-2

The methodology used to establish the 410AD-2 flight buildup is also keyed to achieveing all flights defined by the 100% payload capture analysis after the second year of operations. As in110A-1, the primary factors considered include: NASA defined Shuttle/Tug launch constraints, initial ETR ground crew launch capabilities, and flight mode buildup. In option 2 however, the Shuttle/Tug launch constraints do not apply.

Initial ground crew launch capability is based on a 90% learning factor applied to the minimum ETR ground crew required to support 29 flights in the third year. As a consequence only 20 ETR flights can be achieved in 1984 and 27 in 1985. The minimum WTR ground crew can accomplish all flights planned at WTR.

During the flight buildup period we recommend similiar to 110A-1, that flight crew experience be developed by starting with the simplest flight mode and then progressively introducing the more complex flight modes required for 1986.

Our recommended flight buildup for 410AD-2, including 25 flights in1984 and 33 flights in 1985, encompasses 245 total flights through 1990 or 17 less than 100% payload capture traffic.

PROGRAM SENSITIVITY TO IOC SHIFT - 410AD-2

Two programmatic options are available for implementing program 410AD-2 with a 2 year earlier IOC. First the baseline schedule could be shifted 2 years and start at October 77 ATP. The second option uses a schedule stretch out from October 75 ATP to the earlier 81 IOC milestone. Both schedule options assume that the original flight build up is advanced. As in 110A-1, we examined the implications of IOC shift with respect to operations, production and development.

IOC delay results in additional payloads captured (66 deployed and 18 retrieved).

Considering vehicle production two different factors should be addressed. They include schedule implications on manufacturing learning and the availability of existing hardware. For the schedule shift option, manufacturing learning can be more efficiently transferred from test article fabrication to vehicle production than in a stretchout situation. However as in 110A-1 the stretch option allows early contractual arrangements for vendor support of existing hardware.

The impact of advancing IOC on development was also reviewed with respect to schedule, type of contractor support available to NASA/DOD for defining Tug/Shuttle systems and interfaces, vehicle test, facilities SR&T and cost. As noted in 110A-1, for the first two years of stretched schedule, Tug/Shuttle systems and interfaces would be defined by the government with support of a prime contractor. This is an important period for assuring that the two vehicles are compatible as illustrated by the Apollo LM/CSM relationship. The impact on vehicle test and facilities are similar for both schedule options. However, it should be noted that the advanced IMU SR&T requirement would conflict with a similar DOD program. This would require a design change to the Carousel IMU. Assuming that the initial period of schedule stretch is devoted to systems engineering studies we estimate that cost of stretch out will be $14M. Peak funding occurs in 1980 and is $119M for the schedule stretch option.

8.9 Risk Assessment

In making an assessment of the risk associated with each configuration in each capability option we have considered the type of technology items associated with each vehicle and the impact that it would have on the program if, for one reason or another, the item would be unavailable and an alternative solution would be required. The impact is defined, usually, in terms of added weight, lost performance and total program cost increase; in some cases the impact can be decreased weight or reduced cost.

It is assumed that all of the weight increases and all of the cost increases will occur simultaneously without benefit of any offsetting decreases in either weight or cost. For example in configuration 110A-1 we have assumed that the +4 lb. weight impact of abandoning spun aluminum tanks in favor of welded aluminum tanks is combined with a $10.0 million cost increase as a result of abandoning aluminum tanks in favor of titanium tanks due to materials compatibility or fracture mechanics issues.

Taking the summation of all the weight increases, these are converted to costs by using the $75K/lb. figure derived when we were first selecting subsystem options for incorporation with 110A-1. The $75K/lb. number represents the last step (actually the slope of the line) in our subsystems synthesis process which provides a curve of Δ weight versus Δ total program costs as we added lighter and more costly subsystems options to achieve a behicle with 3500 lb. deploy capability. In this manner we arrived at a estimate of the costs expected if we had to recover the weight growth.

In similar fashion we then summed all of the potential cost increases, ignoring any offsetting cost decreases, and added these to the dollars representing the weight increases. The 110A-1 has no projected performance loss since it uses the OME 7.5K engine; the assumption is that the basic OME will have been developed to meet its weight, performance and reusability goals for the Shuttle Orbiter. In the case of configurations which use the Class I engine, for example 410AD-2, we have assumed that a 3 second Isp performance loss is possible. To convert this performance loss to costs we use the payload sensitivity factor to loss in Isp (97 lbs/sec), divide this by the payload sensitivity to inert weight and then multiply by $111/lb. to convert it to costs.

Taking all of the costs and adding them together we get a total low cost risk value of $15.3M for 110A-1 which ranges to a high value of 94.3M for 320A-3A/320AE-3A.

410AD-2 RISK ASSESSMENT

TECHNOLOGY ITEM IMPACT	
• CLASS I ENG	-3 SEC ISP

  - POTENTIAL Δ COST $23.9M

MODERATE RISK PROGRAM

II-3.4-2

410AD-2 RISK ASSESSMENT

The technology items and their potential impact are shown on the opposite page. If the prestressed filament reinforced (PFR) helium tank fails to meet its goals, a 6A14V titanium tank adds 48 lbs to the vehicle. If the advanced (Micron) IMU is unavailable, a Carousel VB IMU plus a rate gyro unit adds 30 lbs. If the graphite composite shell fails to meet its objectives, an aluminum honeycomb shell adds 38 lbs. The laser radar and space storable SRM are items for which no attractive alternate exists, hence they represent both a schedule and cost risk. If materials compatibility or fracture mechanics data indicate the need to change propellant tank material from titanium to either aluminum or stainless steel, the added weight would be +13 lbs and + 3 lbs respectively. If the heat pipes are replaced by incorporating high heat rejection items on the active loop, there are no weight changes. To recover the weight impact on payload capability due to these possible weight increases, the advanced fuel cell is an open option.

The Class I engine is a new design based on current technology with the exception of the uncertainty in engine life and in the predicted performance with the high expansion ratio nozzles used. It is estimated this engine can miss its performance goals by -3 seconds Isp.

Schedule risk is minimized by the proposed SR&T programs which provide the feasibility of the approach 4 months prior to ATP.

Converting the potential Isp loss and weight increases to a total program cost at a $111K/lb value and adding the potential cost increase items yields a total cost risk of $23.9M for 410AD-2.

RISK ASSESSMENT 410AD-2

BASELINE	ALTERNATIVE	WEIGHT LBS	TOTAL PROGRAM COST, $M

TOTAL COST RISK ---------- $23.87

Section 8.10 Supporting Research and Technology

This section includes a summary matrix chart which identifies all of the SR & T items and where they are applied to each configuration in each capability option.

Following the summary matrix there are individual tables for each configuration which summarize the technology items for that particular configuration and give a very brief synopsis of the type of SR & T program proposed and the estimated funding and schedule requirements. The text following each table is the facing page text prepared for the main presentation.

Following the tables for each configuration, an additional form is filled out for each technology item providing status information, justification for the proposed SR & T program, objectives, technical approach, and a more detailed schedule showing when the proposed program must be completed in order to support the particular configuration.

In dealing with the subject of SR & T we have identified two distinct groups - one where technology is needed and the other where there is no doubt that the technology is available and it is a straightforward engineering task to accumulate data that will preclude making a "false start" where several alternates are under study; we have called the latter group "desired data".

The storable Tug will benefit from the fact that the APOLLO LM program has used similar materials, propellants, equipments and procedures; the Shuttle Orbiter will expand on this data base for the Tug. The low number of identified SR & T items and the modest sums projected are based on the assumption that several existing or planned efforts related to the Shuttle will continue to provide data. These include the planned propellant and materials compatibility testing in support of the Shuttle Orbital Maneuvering Subsystem, its engines, tanks and components both at NASA/WSTF and at the Shuttle contractor's facilities. In addition, we have identified the Air Force funded efforts to develop the advanced Micron IMU for aircraft programs, as an effort which we would build-on rather than to start from scratch.

We have not attempted to detail the SR & T programs required on the Class I engine (with or without the two position nozzle) except to point out the uncertainty associated with the anticipated engine life and the predicted performance of very high expansion ratios within the mixture ratio of interest. The engine contractor will provide the proposed SR & T efforts required on the engine and we will provide comments on same at NASA's request.

The overall "message" which we hope will become obvious to the reader is that there are no real "show-stoppers" among the SR & T items identified.

TECHNOLOGY REQUIREMENTS AND DESIRED DATA - 410AD-2

The upper part of the facing chart contains the supporting research and technology (SR&T) items required for 410AD-2; the lower part of the chart contains what we have termed as "desired data". The distinction between the two is that the "desired data" items do not require technology but are considered straightforward engineering development tasks to produce design data prior to Tug program go-ahead (ATP); this will preclude impacting Tug schedules should the data indicate the desirability of an alternative approach.

Excluding the SR&T on the Class I engine, the total SR&T funds requested for 410AD-2 is $1,390K to be expended over an 18 month period culminating 4 months prior to Tug ATP. The advanced (Micron) IMU) is the long lead item (18 months) also excluding the Class I engine.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Avionics (GN&C)
(Discipline)

TITLE Low Weight/Power, (Rendezvous and Docking) Laser Radar WBS No. 320-03-03-02

STATUS ITT-Gilfillan has been under NASA Contracts since 1964 to design, develop, build, and test various spaceborne laser radar systems. The third generation system will be delivered in late November 1973.

JUSTIFICATION The application of the above developed technology to meet specific space tug rendezvous and docking requirements is desired.

In addition in order to improve the payload capability of the storable tug, low weight Avionics equipments (specifically, low weight/low power laser radar) are required.

OBJECTIVES To design, develop, fabricate, and test a low weight, low power, rendezvous and docking laser radar.

S-018-D

TECHNICAL APPROACH Using Tug requirements, design for light weight, low power by using new components, lighter mirror drives and improved optics

TITLE Prestressed Filament Reinforced (PFR) Tanks WBS No. 320-03-04-02

STATUS Structural Composites Industries, Inc. (SCI) and Arde-Portland, Inc. are under contract to LeRC to demonstrate the feasibility of the PFR tanks. This program will result in the construction of a 24 in. diam. Ardeform PFR tank of the type assumed by our study. If successful the basic technology will be proven.

JUSTIFICATION

A PFR ambient helium storage tank is comparable with the weight of a SHe tank and its associated heat exchanger. It provides a simple and less operationally complex system compared to the SHe tank. The PFR tank also provides a leak-before-burst design which results in increased Tug safety.

OBJECTIVES

Design, fabricate, and test 3 to 6 PFR tanks to demonstrate that current manufacturing and quality control techniques are adequate to produce a reliable, low weight tank suitable for containing gaseous helium (or hydrogen and oxygen in the case of fuel cell reactant tanks). The program will resemble a pre-qualification test program which will demonstrate the ability of the PFR tank to undergo the dynamic loading, compatibility, environmental exposure and etc. tests required for acceptance as a flight item.

L-8-10-7

TECHNICAL APPROACH

Fabricate 3 to 6 tanks and subject them to a pre-qualification test program to demonstrate the maturity of the design.

STORABLE SPACE TUG SUPPORTING RESEARCH AND TECHNOLOGY - Main Propulsion (MPS)
(Discipline)

TITLE Long-Term SRM Space Storage

WBS No. 320-04-8-2,9-2

STATUS In 1963, Battelle Memorial conducted long-term space storage tests (hard vacuum, thermal and radiation) on SRM propellants, motor components and assembled motors. The testing was performed on PBAA and polyurethane propellants. Some accelerated thermal testing at -160°F has been conducted by UTC on HTPB during the past year.

JUSTIFICATION Some of the Storable Tug missions use deorbit SRM's; these impose a requirement for long-term space storage (3-6 yrs) on SRM's. The effects of hard vacuum and low temperature on the reliability and performance of the SRM must be considered. Radiation is not a consideration because the payloads requiring deorbit kick stages are not exposed to the Van Allen radiation belt for any significant duration.

OBJECTIVES

To demonstrate that long-term exposure to hard vacuum and low temperature will not affect the performance of present day propellants such as CTPB and HTPB.

D-810-13

TECHNICAL APPROACH

Expose propellant tensile bars, propellant burning strands and propellant additives to thermal vacuum conditions and conduct weight/vapor loss, tensile strength, and burning rate tests after exposure.

TITLE Material Compatibility WBS No. 320-03-01-01-02

STATUS Material compatibility of Ti-6AL-4V STA and 2219-T87 Aluminum alloy in the presence of MMH at temperatures up to 150°F is required. Compatibility of N_2O_4 with 2219-T87 is also required.

JUSTIFICATION Compatibility of propellants with tankage material must be assessed to obtain the reuse life of the tanks under cyclic loads.

OBJECTIVES The objective of the program is to obtain the static and fatigue properties of the tankage parent and weldment materials under cyclic exposure to propellants and load.

TECHNICAL APPROACH Static and fatigue properties of candidate materials specimens will be obtained prior to and after exposure to the propellants. Tests will be performed at R.T. and 150°F.

TITLE Fracture Mechanics Test Data

WBS No. 320-03-01-01/02

STATUS Fracture mechanics test data for thin gage (.020 to .040) for Titanium 6AL-4V STA and 2219-T87 aluminum alloy exposed to N_2O_4 and MMH at temperatures up to 200°F is not available.

JUSTIFICATION Fracture mechanics data for thin gage tank material are required to assess the fracture mode and life cycle of the tug propellant tanks.

OBJECTIVES The objectives of the program are to obtain K_{ic}, K_{th} and flaw growth data for parent and weldment materials in the induced thermal environment up to 200°F. Data to be obtained prior to and after exposure to the candidate propellants. In addition to fracture mechanics data, NDE techniques are to be employed on the test specimens to assess flaw detection capability.

TECHNICAL APPROACH Standard fracture elemental specimens are to be employed. Tests are to be employed. Tests are to be conducted at room temperature and at 150 and 200°F. Surface flaws of various sizes are to be used and NDE techniques are to be employed to document size where practical.

TITLE SPACE TUG HEAT PIPES

WBS No. 320-04-02

STATUS

Heat pipes (HP) are currently being used in both ground and space application. The variable conductance heat pipe (VCHP) principle is particularly attractive for Tug application but requires further development.

JUSTIFICATION

The fuel cell and certain high power density avionics units carried on the Space Tug require active cooling. Trade studies which have examined pumped loop radiators, sublimators and various heat pipes have indicated the obvious merits of the variable conductance heat pipe. A VCHP radiator could interface with the pumped loop heat transport system of the fuel cell, eliminating the cost and complexity of a selective stagnation radiator with its associated unreliable automatic bypass valves. A VCHP header, a heat transport device, could provide for high power density avionics heat transport without recourse to the active loop.

11-8-10-71

OBJECTIVES

Emphasis will be placed on experimentally obtaining the large turn down ratios which appear theoretically achievable and in developing predictive techniques.

TECHNICAL APPROACH

Design, fabricate and test a VCHP radiator and VCHP header and experimentally determine performance with emphasis on turn down ratio and shut off heat flux levels.
