INTRODUCTION

WHAT NASA SCIENTIFIC AND TECHNICAL REPORTS AND PUBLICATIONS FOR 1969 IS

NASA Scientific and Technical Reports and Publications for 1969, a Selected Listing, (NASA SP-7035) combines in a single publication a selective listing of NASA reports which were printed and widely distributed and announced in *Scientific and Technical Aerospace Reports (STAR)* and significant articles which were announced in *International Aerospace Abstracts (IAA).* The documents listed from *STAR,* which abstracts report literature for the aerospace sciences, include the following NASA report series: Special Publications (NASA SP-), Technical Reports (NASA TR R-), Technical Notes (NASA TN D-), Technical Memorandums (NASA TM X-), Technical Translations (NASA TT F-), and Contractor Reports (NASA CR-). The documents listed from *IAA,* which abstracts journal literature for the aerospace sciences, include those which carry an author affiliation from NASA Headquarters or a NASA Center, or which were basic documents for a conference or symposium in which a NASA-authored paper was included. NASA-generated reports and articles announced in *STAR* or *IAA* during 1969 but omitted from this volume can be located through the annual indexes to *STAR* and *IAA.*

HOW NASA SCIENTIFIC AND TECHNICAL REPORTS AND PUBLICATIONS FOR 1969 IS ORGANIZED

The arrangement of abstracts in this publication is similar to that of *STAR* and *IAA,* i.e., by NASA subject categories. In each subject category, *IAA* references are arranged in accession number order followed by *STAR* references also in accession number order. The first section contains the bibliographic citations and abstracts; the second section contains five indexes (subject, personal author, corporate source, report/accession number, and accession/report number), each arranged with the "A" accessions before the "N" accessions.

STAR Entries

AVAILABILITY OF DOCUMENTS

Documents listed are available on initial distribution without charge to:

1. NASA Offices, Centers, contractors, subcontractors, grantees, and consultants:
2. Other U.S. Government agencies and their contractors:
3. Libraries in the United States that have arrangements with NASA to maintain collections of NASA documents for public use;
4. Other organizations in the United States having a need for NASA documents in work related to the aerospace program; and
5. Foreign government or academic organizations that have established appropriate reciprocal arrangements with NASA.

NASA documents that have been microfiched(1) (identified by the # sign in the citation) are available on microfiche without charge at any time to the same organizations, described above, that are eligible to receive full-sized copy on initial distribution.

HOW TO OBTAIN MICROFICHE

If you are registered with NASA and eligible to receive reports as described above, send the completed *Document Request* (Facility Form 492) to:

NASA Scientific and Technical Information Facility
P.O. Box 33
College Park, Maryland 20740

If you are not registered with NASA and wish to receive information concerning registration, request *Registration Form—Technical Publications* (Facility Form 713) from the NASA Scientific and Technical Information Facility at the address given above. Others may obtain microfiche copies by purchase as described in the following paragraphs.

(1) A microfiche is a transparent sheet of film, 105 × 148 mm in size, containing up to 72 pages of information reduced to micro images (not to exceed 20:1 reduction).

PUBLIC SALE OF DOCUMENTS

All documents listed with a Clearinghouse for Federal Scientific and Technical Information (CFSTI) availability statement or a Superintendent of Documents, U.S. Government Printing Office (GPO) availability statement in the citation may be purchased from the U.S. Government sales agency cited, at the address given below.

Publications with a CFSTI availability statement are sold in hard copy and in microfiche copy by:

Clearinghouse for Federal Scientific and Technical Information
(CFSTI)
Springfield, Virginia 22151

The following unit price has been established by CFSTI: $3 for hard copy, $0.65 for microfiche.

Publications with a GPO availability statement in the citation are sold in hard copy by:

Superintendent of Documents, U.S. Government Printing Office
(GPO)
Washington, D.C. 20402.

NASA documents available from GPO are also available from CFSTI at the GPO price given in the citation.

COSATI SUBJECT CATEGORY CODE

In the citation of each document is a code, e.g., CSCL 25A, that indicates the subject category assigned to it from the *COSATI Subject Category List* (first edition, December 1964) published by the Committee on Scientific and Technical Information of the Federal Council for Science and Technology.

IAA Entries

All cited documents are available from the AIAA Technical INFORMATION Service as follows: Paper copies are available at $3.00 per document up to a maximum of 20 pages. The charge for each additional page is $0.25. Microfiche are available at the rate of $0.50 per microfiche for documents identified by the symbol # following the accession number. A number of publications, because of their special characteristics, are available only for reference in the AIAA Technical Information Service Library. Minimum air-mail postage to foreign countries is $1.00.

Please refer to the accession number, e.g., A69-13193, when requesting documents. Address all inquiries and requests to:

Technical Information Service
American Institute of Aeronautics and Astronautics, Inc.
750 Third Avenue, New York, N.Y. 10017

INDEXING VOCABULARY

The Preliminary Edition of the *NASA Thesaurus* (December 1967) (NASA SP-7030) is used as the authority for the indexing vocabulary that appears in the subject index. The *NASA Thesaurus* should be consulted in examining the current indexing vocabulary, including associated cross-reference structure. Only the subject terms that have been selected to describe the documents abstracted in this publication appear in the subject index. Copies of the *NASA Thesaurus* may be obtained from the Clearinghouse for Federal Scientific and Technical Information or the Superintendent of Documents, U.S. Government Printing Office at $8.50 for the three-volume set.

TABLE OF CONTENTS

Subject Categories

Abstracts in the journal are grouped under the following categories:

page:

01 AERODYNAMICS
Includes aerodynamics of bodies, combinations, internal flow in ducts and turbomachinery; wings, rotors, and control surfaces. For applications see: 02 Aircraft and 31 Space Vehicles. For related information see also: 12 Fluid Mechanics; and 33 Thermodynamics and Combustion. 1

02 AIRCRAFT
Includes fixed-wing airplanes, helicopters, gliders, balloons, ornithopters, etc; and specific types of complete aircraft (e.g., ground effect machines, STOL, and VTOL); flight tests; operating problems (e.g., sonic boom); safety and safety devices; economics; and stability and control. For basic research see: 01 Aerodynamics. For related information see also: 31 Space Vehicles; and 32 Structural Mechanics. 25

03 AUXILIARY SYSTEMS
Includes fuel cells, energy conversion cells, and solar cells; auxiliary gas turbines; hydraulic, pneumatic and electrical systems; actuators; and inverters. For related information see also: 09 Electronic Equipment; 22 Nuclear Engineering; and 28 Propulsion Systems. 41

04 BIOSCIENCES
Includes aerospace medicine, exobiology, radiation effects on biological systems; physiological and psychological factors. For related information see also: 05 Biotechnology. 65

05 BIOTECHNOLOGY
Includes life support systems, human engineering; protective clothing and equipment; crew training and evaluation, and piloting. For related information see also: 04 Biosciences. 81

06 CHEMISTRY
Includes chemical analysis and identification (e.g., spectroscopy). For applications see: 17 Materials, Metallic; 18 Materials, Nonmetallic; and 27 Propellants. 99

07 COMMUNICATIONS
Includes communications equipment and techniques; noise; radio and communications blackout; modulation telemetry; tracking radar and optical observation; and wave propagation. For basic research see: 23 Physics, General; and 21 Navigation. 107

08 COMPUTERS
Includes computer operation and programming; and data processing. For basic research see: 19 Mathematics. 129

09 ELECTRONIC EQUIPMENT
Includes electronic test equipment and maintainability; component parts, e.g., electron tubes, tunnel diodes, transistors; integrated circuitry; microminiaturization. For basic research see: 10 Electronics. For related information see also: 07 Communications and 21 Navigation. 139

10 ELECTRONICS
Includes circuit theory; and feedback and control theory. For applications see: 09 Electronic Equipment. For related information see: Specific Physics Categories. 153

11 FACILITIES, RESEARCH AND SUPPORT
Includes airports; lunar and planetary bases including associated vehicles; ground support systems; related logistics; simulators; test facilities (e.g., rocket engine test stands, shock tubes, and wind tunnels); test ranges; and tracking stations. 159

12 FLUID MECHANICS
Includes boundary-layer flow; compressible flow; gas dynamics; hydrodynamics; and turbulence. For related information see also: 01 Aerodynamics; and 33 Thermodynamics and Combustion. 175

13 GEOPHYSICS
Includes aeronomy; upper and lower atmosphere studies; oceanography; cartography; and geodesy. For related information see also: 20 Meteorology; 29 Space Radiation; and 30 Space Sciences. 195

14 INSTRUMENTATION AND PHOTOGRAPHY
Includes design, installation, and testing of instrumentation systems; gyroscopes; measuring instruments and gages; recorders; transducers; aerial photography; and telescopes and cameras. 217

15 MACHINE ELEMENTS AND PROCESSES
Includes bearings, seals, pumps, and other mechanical equipment; lubrication, friction, and wear; manufacturing processes and quality control; reliability; drafting; and materials fabrication, handling, and inspection. 235

16 MASERS
Includes applications of masers and lasers. For basic research see: 26 Physics, Solid-State. 259

17 MATERIALS, METALLIC
Includes cermets; corrosion; physical and mechanical properties of materials; metallurgy; and applications as structural materials. For basic research see : 06 Chemistry. For related information see also: 18 Materials, Nonmetallic; and 32 Structural Mechanics. 261

18 MATERIALS, NONMETALLIC
Includes corrosion; physical and mechanical properties of materials (e.g., plastics); and elastomers, hydraulic fluids, etc. For basic research see: 06 Chemistry. For related information see also: 17 Materials, Metallic; 27 Propellants; and 32 Structural Mechanics. 275

19 MATHEMATICS
Includes calculation methods and theory; and numerical analysis. For applications see: 08 Computers. 283

20 METEOROLOGY
Includes climatology; weather forecasting; and visibility studies. For related information see also: 13 Geophysics; and 30 Space Sciences. 289

21 NAVIGATION
Includes guidance; autopilots; star and planet tracking; inertial platforms; and air traffic control. For related information see also: 07 Communications. 295

22 NUCLEAR ENGINEERING
Includes nuclear reactors and nuclear heat sources used for propulsion and auxiliary power. For basic research see: 24 Physics, Atomic, Molecular, and Nuclear. For related information see also: 03 Auxiliary Systems; and 28 Propulsion Systems. 307

23 PHYSICS, GENERAL
Includes acoustics, cryogenics, mechanics, and optics. For astrophysics see: 30 Space Sciences. For geophysics and related information see also: 13 Geophysics, 20 Meteorology, and 29 Space Radiation. 315

24 PHYSICS, ATOMIC, MOLECULAR, AND NUCLEAR
Includes atomic, molecular and nuclear physics. For applications see: 22 Nuclear Engineering. For related information see also: 29 Space Radiation. 321

25 PHYSICS, PLASMA
Includes magnetohydrodynamics. For applications see: 28 Propulsion Systems. 333

26 PHYSICS, SOLID-STATE
Includes semiconductor theory; and superconductivity. For applications see: 16 Masers. For related information see also: 10 Electronics. 343

27 PROPELLANTS
Includes fuels; igniters; and oxidizers. For basic research see: 06 Chemistry; and 33 Thermodynamics and Combustion. For related information see also: 28 Propulsion Systems. 351

28 PROPULSION SYSTEMS
Includes air breathing, electric, liquid, solid, and magnetohydrodynamic propulsion. For nuclear propulsion see: 22 Nuclear Engineering. For basic research see: 23 Physics, General; and 33 Thermodynamics and Combustion. For applications see: 31 Space Vehicles. For related information see also: 27 Propellants. 355

29 SPACE RADIATION
Includes cosmic radiation; solar flares; solar radiation; and Van Allen radiation belts. For related information see also: 13 Geophysics; and 24 Physics, Atomic, Molecular, and Nuclear. 371

30 SPACE SCIENCES
Includes astronomy and astrophysics; cosmology; lunar and planetary flight and exploration; and theoretical analysis of orbits and trajectories. For related information see also: 11 Facilities, Research and Support; and 31 Space Vehicles. 389

31 SPACE VEHICLES

Includes launch vehicles; manned space capsules; clustered and multistage rockets; satellites; sounding rockets and probes; and operating problems. For basic research see: 30 Space Sciences. For related information see also: 28 Propulsion Systems; and 32 Structural Mechanics. 443

32 STRUCTURAL MECHANICS

Includes structural element design and weight analysis; fatigue; thermal stress; impact phenomena; vibration; flutter; inflatable structures; and structural tests. For related information see also: 17 Materials, Metallic; and 18 Materials, Nonmetallic. 461

33 THERMODYNAMICS AND COMBUSTION

Includes ablation, cooling, heating, heat transfer, thermal balance, and other thermal effects; and combustion theory. For related information see also: 12 Fluid Mechanics; and 27 Propellants. 483

34 GENERAL

Includes reports of a broad nature related to industrial applications and technology, and to basic research; defense aspects; law and related legal matters; and legislative hearings and documents. 501

A69-12520 *#
HYPERSONIC VISCOUS INTERACTION ON SLENDER CONES.
C. C. Horstman and M. I. Kussoy (NASA, Ames Research Center, Moffett Field, Calif.).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N. Y., Jan. 22-24, 1968, Paper 68-2.)
AIAA Journal, vol. 6, Dec. 1968, p. 2364-2371. 34 refs.

Results of an experimental investigation conducted to obtain surface measurements and flowfield properties about slender cones in the viscous interaction regime. The measurements, obtained for the most part on a 3° half-angle cone in helium at Mach 41, included surface pressures and heat transfer, shock-wave shapes, and detailed shock-layer surveys (to obtain velocity and density profiles) at angles of attack up to 15°. Surface pressures were successfully correlated with published data for a wide range of test conditions by means of a strong interaction parameter. At angle of attack the pressure and heat-transfer distribution on the sharp 3° cone displayed a blunted-cone type of overexpansion on the windward side. Measured density and pitot pressure profiles through the shock layer indicated pressures were below the Rankine-Hugoniot values over the entire model length at zero and 10° angle of attack on the leeward side. At zero angle of attack, measured velocity profiles deviated from the usual calculated laminar boundary-layer profiles. Surface heat-transfer measurements at zero angle of attack fell significantly below both weak and strong interaction predictions but were successfully correlated with previous published merged flow results. (Author)

A69-12522 *#
FLOW PHENOMENA AND SEPARATION OVER DELTA WINGS WITH TRAILING-EDGE FLAPS AT MACH 6.
Allen H. Whitehead, Jr. and J. Wayne Keyes (NASA, Langley Research Center, Hampton, Va.).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N. Y., Jan. 22-24, 1968, Paper 68-97.)
AIAA Journal, vol. 6, Dec. 1968, p. 2380-2387. 26 refs.

Results of an experimental investigation conducted to obtain surface measurements and flowfield properties about slender cones in the viscous interaction regime. The measurements, obtained for the most part on a 3° half-angle cone in helium at Mach 41, included surface pressures and heat transfer, shock-wave shapes, and detailed shock-layer surveys (to obtain velocity and density profiles) at angles of attack up to 15°. AERODYNAMICS OF BODIES OF REVOLUTION IN CONING MOTION.
Murray Tobak, Lewis B. Schiff (NASA, Ames Research Center, Moffett Field, Calif.), and Victor L. Peterson (NASA, Ames Research Center, Hypersonic Aerodynamics Branch, Moffett Field, Calif.).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N. Y., Jan. 22-24, 1968, Paper 68-20.)
AIAA Journal, vol. 7, Jan. 1969, p. 95-99. 9 refs.

Nonlinear functional analysis is used to show that the moments for an arbitrary motion about the center of gravity may be compounded of the sum of contributions from four simple motions, three of which are standard. The fourth, lunar motion, is investigated experimentally with an apparatus designed to reproduce the lunar motion in a wind tunnel. Photographs of the vortices on the leeward side of the body reveal that they become asymmetrically disposed with respect to the angle-of-attack plane during lunar motion. This makes them a potent source of "Magnus-type" moment. The contribution of the vortices to Magnus moment appears to be proportional to their contribution to pitching moment during steady planar motion multiplied by the turning rate of the angle-of-attack plane during lunar motion. The moment is a potential causative agent in the occurrence of large-amplitude circular limit motions. (Author)

SOME TOPICS IN HYPERSONIC BODY SHAPING.
E. S. Love (NASA, Langley Research Center, Aero-Physics Div., Hampton, Va.), W. C. Woods, G. C. Ashby, Jr. (NASA, Langley Research Center, Aero-Physics Div., Hypersonic Fluid Mechanics Branch, Hampton, Va.), and R. W. Rainey (NASA, Langley Research Center, Aero-Physics Div., Hypersonic Aerodynamics

Branch, Hampton, Va.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-181. 19 p. 36 refs.
Members, $1.00; nonmembers, $1.50.

Some topics related to hypersonic body shaping for minimum drag and improved performance are presented. Implications of the most frequently assumed pressure laws are reviewed from the view of practical flight regimes, and solutions expressed in exponential residuals are presented for inviscid minimum drag power-law bodies (simple and complex) for a wide range of fineness ratios. Experimental results from Mach 6 to 20 are presented for a series of trapezoidal bodies; the cross-section of the body giving best lift-drag ratio differs from that indicated in earlier work. A simple "$\sin^2$-deficiency method" is presented for predicting pressures on blunt shapes; the method appears to yield results comparable to more elaborate methods requiring machine computation. (Author)

A69-18161 *#
A NEW METHOD FOR EXTRACTING AERODYNAMIC COEFFICIENT FROM FREE-FLIGHT DATA.
Gary T. Chapman and Donn B. Kirk (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-134. 7 p. 7 refs.
Members, $1.00; nonmembers, $1.50.

Description of a method for obtaining aerodynamic coefficients from the observed motion of a body in flight. The method eliminates the need for closed-form solutions by employing numerical solutions to the equations of motion. This makes possible a far more general treatment. A least-squares technique employing differential corrections must be used; for this purpose, partial derivatives of each dependent variable with respect to each unknown coefficient, including all initial conditions, must be known accurately at every data station. Application of the method of parametric differentiation yields the required accuracy in these partial derivatives, and rapid convergence of the solution is usually obtained. The method is applied to four examples of varying complexity, and the diversity of its application is demonstrated. M.G.

A69-18167 *#
ON THE SINGULARITY METHOD OF SUBSONIC LIFTING-SURFACE THEORY.
Siegfried Wagner (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-37. 14 p. 16 refs.
Members, $1.00; nonmembers, $1.50.

Extension of the lifting-surface theory at steady subsonic flow [due to Multhopp (1955) and Truckenbrodt (1953)] to the leading edge of wings. An optimal number of integration stations for spanwise integration is calculated. The positions of these integration stations are not identical with the spanwise distribution of the control points where the tangential flow condition is fulfilled. The new integration procedure, along with an accurate treatment of the singularities, allows an improved prediction of the loading of wings with complicated planforms such as double-delta and variable-sweep wings. A method for calculating the spanwise distribution of the leading-edge-suction force and of the induced drag is developed and is applied to the computation of the loading of a variable-sweep wing. A comparison with measurements and existing theories shows that the spanwise distribution of lift, pitching moment, induced drag, and leading-edge-suction force can be computed more accurately by the present method. M.G.

A69-18176 *#
THEORETICAL AND EXPERIMENTAL STUDY OF SUPERSONIC STEADY FLOW AROUND INCLINED BODIES OF REVOLUTION.
John V. Rakich and Joseph W. Cleary (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-187. 10 p. 20 refs.
Members, $1.00; nonmembers, $1.50.

Description of a three-dimensional method of characteristics and critical assessment of numerical results by comparison with the results of hypersonic wind-tunnel experiments. Calculations for a 15° half-angle sphere-cone have been performed for angles of attack up to $\alpha = 20°$, and have been carried downstream 45 nose radii for $\alpha = 10°$. Comparisons with pointed-cone calculations show that effects of bluntness persist at this distance. Pitot-pressure distributions in the flowfield are in good agreement with experiment except on the leeward side of the body far from the nose, where low-energy, viscous fluid accumulates. Oil-film studies of surface streamlines demonstrate the large viscous crossflow in the boundary layer. Theoretical upwash angles around a Sears-Haack body are compared with classical slender-body theory, indicating nonlinearities due to Mach number, which may reduce the interference lift of wing-body combinations. (Author)

A69-18184 *#
CONE DRAG IN RAREFIED HYPERSONIC FLOW.
M. I. Kussoy and C. C. Horstman (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-140. 7 p. 17 refs.
Members, $1.00; nonmembers, $1.50.

Experimental drag coefficients for spheres and sharp cones in rarefied hypersonic air flow are presented. These data were obtained using a free-flight technique in a shock tunnel. The test conditions were: (1) Mach number from 15 to 24.3, (2) Reynolds number per inch from 480 to 2730, (3) mean free path from 0.016 to 0.127 in., and (4) cone semivertex angles from 2.5 to 25°. When compared with hypersonic viscous interaction and near-free molecule theories (both computed for the present range of test conditions), the cone drag is over-estimated. However, applying the viscous-interaction parameter of Mirels and Ellinwood, a correlation of cone drag for each cone angle in terms of Mach number and free-stream Reynolds number is developed. A correlation of average local skin-friction coefficient (deduced from the present data) for individual cone angles is also developed in terms of Mach number and free-stream Reynolds number. The ratio of skin friction to heat-transfer coefficient is shown to be a function only of cone angle. (Author)

A69-21972 *#
NEW FEATURES OF THE METHOD OF INTEGRAL RELATIONS FOR THE BLUNT BODY PROBLEM.
Jerry C. South, Jr. (NASA, Langley Research Center, Applied Mechanics Branch, Hampton, Va.).
AIAA Journal, vol. 7, Feb. 1969, p. 369-371. 5 refs.

Description of two new features of the one-strip method of integral relations in its application to the inviscid, supersonic blunt-body problem. The features are: (1) the adaptation of the method to blunt power-law bodies with infinite curvature at the nose, and (2) the use of intermediate parameter perturbations to aid in the construction of highly unstable saddle-point solutions. The present study considers the adaptation of the simplest (one-strip) approximation of the method to hypersonic, ideal-gas flow over axisymmetric power-law bodies. B.H.

A69-22495 *#
PROGRAMS FOR COMPUTATION OF VELOCITIES AND STREAMLINES ON A BLADE-TO-BLADE SURFACE OF A TURBOMACHINE.
Theodore Katsanis and W. D. McNally (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Mechanical Engineers, Annual Gas Turbine Conference and Products Show, 14th, Cleveland, Ohio, Mar. 9-13, 1969, Paper 69-GT-48. 8 p. 13 refs.
Members, $0.75; nonmembers, $1.50.

Description of Fortran programs that give the solution to the two-dimensional, subsonic, nonviscous flow problem on a blade-to-

blade surface of revolution of a turbine. Flow may be axial, radial, or mixed. There may be a change in stream channel thickness in the through-flow direction. Either single, tandem, or slotted blades may be handled as well as blade rows with splitter vanes. Also, small regions may be magnified to give more detail where desired, such as around a leading or trailing edge or through a slot. The method is based on a finite-difference solution of the stream-function equations. Numerical examples are shown to illustrate the type of blades which can be analyzed, and to show results which can be obtained. Results are compared with experimental data. (Author)

A69-22521 *#
SOME MEASUREMENT PROBLEMS ENCOUNTERED WHEN DETER MINING THE PERFORMANCE OF CERTAIN TURBINE STATOR BLADES FROM TOTAL PRESSURE SURVEYS.
Thomas P. Moffitt, Herman W. Prust, Jr., and Harold J. Schum (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Mechanical Engineers, Annual Gas Turbine Conference and Products Show, 14th, Cleveland, Ohio, Mar. 9-13, 1969, Paper 69-GT-103. 8 p.
Members, $0.75; nonmembers, $1.50.

Discussion of the problems encountered in determining turbine stator blade performance from total-pressure surveys downstream of the blade row. The stator blades were suitable for turbine cooling and incorporated thick trailing edges having a large included wedge angle between the suction and pressure surfaces. Blade performance was rated in terms of kinetic energy loss coefficients, which relate the frictional and mixing losses to the ideal kinetic energy that could be developed at a given overall pressure ratio. The loss coefficients were calculated from the results of total-pressure surveys and flow conditions as determined by measurements at the inlet and outlet of the blade row. For the type of blading involved, it was determined that these loss coefficients were sensitive to the size of support stem of the total-pressure probe used and the size and axial location of the probe sensing element. The effect of these variables on the results obtained are presented, and desirable manners of taking survey data for this type of blading are discussed. (Author)

A69-25378 *#
A CLOSED-FORM SOLUTION TO OBLIQUE SHOCK-WAVE PROPERTIES.
Vincent R. Mascitti (NASA, Langley Research Center, Advanced Configuration Group, Hampton, Va.).
Journal of Aircraft, vol. 6, Jan.-Feb. 1969, p. 66.

Development of a method for direct computation of oblique shock-wave properties with freestream Mach numbers and flow-deflection angle as the independent variables. It is shown that this problem has an explicit solution, which is presented in general terms. F.R.L.

A69-26762 *#
REINGESTION CHARACTERISTICS AND INLET FLOW DISTORTION OF V/STOL LIFT-ENGINE FIGHTER CONFIGURATIONS.
Jerry V. Kirk and Jerry P. Barrack (NASA, Ames Research Center, Full-Scale and Systems Research Div., Moffett Field, Calif.).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N.Y., Jan. 22-24, 1968, Paper 68-78.)
Journal of Aircraft, vol. 6, Mar.-Apr. 1969, p. 116-122.

Study of short-path reingestion of exhaust gas and inlet-flow distortion in V/STOL lift engines. Reingestion during hover was studied on a static-test facility and inlet-flow distortion was studied in a 40 x 80 ft wind tunnel. Factors affecting exhaust-gas reingestion, engine surge, and hover performance are presented and discussed. Inlet-flow distortion and total pressure recovery during transition from hover to wing-supported flight are shown for two types of lift-engine configurations. The effects of an inlet vane and engine tilt are shown for a range of flight speeds, power settings, and aircraft angles of attack. R.B.S.

A69-31881 *#
UNUSUAL BOUNDARY-LAYER TRANSITION RESULTS ON CONES IN HYPERSONIC FLOW.
George G. Mateer and Howard K. Larson (NASA, Ames Research Center, Moffett Field, Calif.).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N.Y., Jan. 22-24, 1968, Paper 68-40.)

Nonablating, 5° and 15° half-angle cones were tested as part of a program to study the effects of subliming ablation on boundary-layer transition. The results of wind-tunnel tests showed that the measured transition Reynolds numbers (1) were independent of the local unit Reynolds number, (2) were equal to those usually observed or higher, and (3) decreased as the boundary-layer edge Mach number increased from 5 to 6.8. The first two of these unusual results may be due in part to a unique feature of the wind tunnel: a low-molecular weight helium-air boundary layer. Data are presented which show a significant effect of wind-tunnel boundary-layer molecular weight on model boundary-layer transition. In addition, a new correlation of transition results for cones is presented which shows that the dependence of transition on boundary-layer edge Mach number extends over a range of edge Mach numbers from 3 to 8. These tests were conducted at nominally constant values of free-stream Mach number (7.4), wall-to-total temperature ratio (0.4), and total temperature (1500°R). The only tunnel condition varied was total pressure, 200 to 1800 psia, which produced a corresponding variation in free-stream unit Reynolds number of $0.9\text{-}8.0 \times 10^6$ per foot. Transition was defined from measurements of heat transfer to the model surface. Preliminary results from 5° camphor cones indicate no significant effect of camphor ablation on transition at an edge Mach number of 6.8. (Author)

FLIGHT AND WIND TUNNEL INVESTIGATION OF INSTALLATION EFFECTS ON SUPERSONIC CRUISE EXHAUST NOZZLES AT TRANSONIC SPEEDS.
Fred A. Wilcox, Nick E. Samanich, and Bernard J. Blaha (NASA, Lewis Research Center, Cleveland, Ohio).
American Institute of Aeronautics and Astronautics, Propulsion Joint Specialist Conference, 5th, U.S. Air Force Academy, Colorado Springs, Colo., June 9-13, 1969, Paper 69-427. 8 p. 5 refs.
Members, $1.00; nonmembers, $1.50.

Discussion of a combination wind tunnel and flight research program, initiated by the NASA Lewis Research Center, for the purpose of investigating the effect of the location of power plants in aft-mounted wing nacelles in future supersonic-cruise aircraft. This investigation is based on the use of an F-106 aircraft which has been modified to carry two aft-mounted nacelles housing J-85 afterburning turbojet engines. Flight tests are now underway with a variety of exhaust nozzle concepts. Some of the significant results obtained from the flight and wind tunnel program are discussed. P.v.T.

BALLISTICS RANGE BOUNDARY-LAYER TRANSITION MEASUREMENTS ON CONES AT HYPERSONIC SPEEDS.
Norman W. Sheetz, Jr. (U.S. Navy, Naval Ordnance Laboratory, Corona, Calif.).
IN: VISCOUS DRAG REDUCTION; PROCEEDINGS OF THE SYMPOSIUM, DALLAS, TEX., SEPTEMBER 24, 25, 1968. [A69-33247 17-12]
Symposium sponsored by the U.S. Navy and NASA.
Edited by C. S. Wells.
New York, Plenum Press, 1969, p. 53-83. 38 refs.

Investigation of the effect of a number of parameters on the boundary-layer transition on conical bodies. These parameters include Mach number, cone angle, nose bluntness, and the ratio of wall-to-recovery temperature. The tests were conducted on 3, 5, 6.3, and 9° half-angle cones. The test Mach number varied from 3 to 15, while the ambient temperature ranged from 80 to 800°F. The free-stream Reynolds number based on tip radius varied from near

zero to 10^5. The data show a stabilizing, and apparently linear, effect on the boundary layer as the free-stream Mach number is increased. B.H.

AMPLIFIED LAMINAR BOUNDARY LAYER OSCILLATIONS AND TRANSITION AT THE FRONT ATTACHMENT LINE OF A 45° SWEPT FLAT-NOSED WING WITH AND WITHOUT BOUNDARY LAYER SUCTION.
W. Pfenninger and J. W. Bacon, Jr. (Northrop Corp., Beverly Hills, Calif.).
IN: VISCOUS DRAG REDUCTION; PROCEEDINGS OF THE SYMPOSIUM, DALLAS, TEX., SEPTEMBER 24, 25, 1968. [A69-33247 17-12]
Symposium sponsored by the U.S. Navy and NASA.
Edited by C. S. Wells.
New York, Plenum Press, 1969, p. 85-105. 8 refs.

Discussion of experiments performed in the Northrop 7 x 10 ft tunnel, in which transition at the attachment line of a 45° swept flat-nose wing was observed. For a wing with suction through closely spaced chordwise slots, the wind tunnel screen turbulence was found to induce regular amplified attachment-line boundary layer oscillations. The oscillations were generally modulated and superimposed on random low-frequency oscillations induced by free-stream large-scale eddies. The high-frequency boundary-layer velocity fluctuations arising near the attachment line were found to grow, leading finally to turbulent spots in combination with the random low-frequency oscillations. Without suction, transition started at attached line transition Reynolds numbers of 240 and 310 at potential flow velocity/kinematic viscosity ratios of 5.5×10^6 and 3.5×10^6, respectively. V.P.

NONGRAY RADIATING FLOW ABOUT SMOOTH SYMMETRIC BODIES WITH LARGE BLOWING.
W. B. Olstad (NASA, Langley Research Center, Gas Physics Section, Hampton, Va.).
American Institute of Aeronautics and Astronautics, Thermophysics Conference, 4th, San Francisco, Calif., June 16-18, 1969, Paper 69-637. 14 p. 16 refs.
Members, $1.00; nonmembers, $1.50.

Modification of a simplified flowfield technique developed by Maslen (1964) to account for radiation and large blowing. Radiation cooling and nongray absorption (including the contribution of atomic lines) were taken into account. Results were obtained for a series of blunted cones traveling at speeds from 10.7 to 15.2 km/sec at an altitude of 60.96 km in the earth atmosphere. It is shown that the radiative heating distributions depend strongly on whether the primary source of radiation is the entropy layer or the flow external to the entropy layer. It is also shown that the entropy layer can be significantly affected by radiation cooling. The reduction of radiative heating by blowing cold air from the body surface is also discussed. (Author)

EFFECTS OF MASS ADDITION OF VARIOUS GASES ON THE HEAT TRANSFER AND SURFACE PRESSURES ON A BLUNT CONE IN HYPERSONIC FLOW.
C. C. Pappas and George Lee (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Fluid and Plasma Dynamics Conference, San Francisco, Calif., June 16-18, 1969, Paper 69-716. 5 p.
Members, $1.00; nonmembers, $1.50.

Surface effects of uniform mass addition of the gases helium, air, argon, helium-argon mixtures, and three freons (with molecular weight to 200). Surface heat transfer and pressure were obtained over the whole length of the blunt conical body. Tests were conducted on a cold porous wall in a hypersonic air stream of Mach number 13.4, total enthalpy 2100 Btu/lb, and Reynolds number of 31,000 per foot. The effect of lowering molecular weight was to decrease the heat transfer everywhere and increase surface pressure on the afterbody, except for the freon gases which show little effect of molecular weight on heat transfer. Agreement between theory and experiment was good for the stagnation point heat transfer, except for the freon gases. A nonsimilar boundary-layer theory coupled to an inviscid surface pressure prediction was in good agreement with experimental heat transfer and pressure. (Author)

American Institute of Aeronautics and Astronautics and Canadian Aeronautics and Space Institute, Subsonic Aero- and Hydro-Dynamics Meeting, Ottawa, Canada, July 2, 3, 1969, AIAA Paper 69-742.
17 p. 5 refs.
Members, $1.00; nonmembers, $1.50.

Flight characteristics during landing and wing deployment are presented for three lifting entry spacecraft concepts having hypersonic (L/D)s of approximately 1.0, 2.0, and 3.0. The types of variable geometry studied include foldout; switchblade; and a single-pivot, two-position skewed wing. Detailed static subsonic wind-tunnel data obtained on each vehicle were used to estimate the dynamic stability characteristics. Wind-tunnel data were obtained for various wing deployment positions. The spacecraft concepts studied are dynamically stable throughout the subsonic flight envelope, but stability augmentation is required to provide acceptable handling qualities with the center of gravity of the vehicles located by detailed preliminary design. Wing deployment transients are minor and the piloting task during wing deployment consists of a simple push-over maneuver. For the configurations investigated, landing characteristics are comparable to present day high-performance fighter aircraft. (Author)

Results of a series of investigations involving a 0.0226-scale Lockheed C-5A aircraft model conducted in the Ames Research Center, NASA, 11- by 11-ft, Arnold Engineering Development Center 16-ft, and Cornell Aeronautical Laboratory 8-ft Transonic Wind Tunnels at high subsonic speeds. The objectives of the investigations were to: (1) identify areas of agreement and disagreement in the data from the different facilities; (2) determine corroborative explanations where differences existed; (3) prescribe and verify test and data reduction procedures to improve the quality of wind-tunnel test results; and (4) identify problems requiring further research. Of significance, the identical wing-fuselage combination was maintained throughout the initial test entries in the three facilities, along with the same sting and balance combination. Standard test techniques at each facility were employed. Comparisons of static force, moment, and model base pressure for the wing-fuselage configuration are presented. In spite of precautions taken, procedural errors were experienced. Beyond corrections for the procedural errors, however, there remain significant differences in the data from the three facilities. An analysis of factors influencing the quality of data from the Ames facility is suggestive of the need for continuing critical appraisal of generally accepted test procedures, instrumentation tolerances, and corrections to wind-tunnel data. EXPERIMENTAL AERODYNAMICS OF A ROTOR ENTRY VEHICLE.

Alan D. Levin and Ronald C. Smith (NASA, Ames Research Center, Moffett Field, Calif.).

(American Institute of Aeronautics and Astronautics, Aerodynamic Deceleration Systems Conference, El Centro, Calif., Sept. 23-25, 1968, Paper 68-950.)

Journal of Aircraft, vol. 6, July-Aug. 1969, p. 330-335. 11 refs.

An unpowered rotor entry vehicle model has been tested at Mach numbers 0.10 to 3.54 at angles of attack from 15° to 90°. The tests included variations of blade collective and cyclic pitch angles. A summary of the autorotative equilibrium rotor speed, forces, and moments is presented. The results indicate that adding the rotor to the capsule improved vehicle performance throughout most of the Mach number range. Maximum lift-to-drag ratio was substantially improved at low Mach numbers. Large pitching moments were produced by the rotor requiring the use of flaps for longitudinal trim. Control phasing was unusual compared to the predicted response of an "ideal rotor," but did not change grossly with forward flight speed. (Author)

EXPERIMENTAL INVESTIGATION OF SEPARATED FLOW OVER A CAVITY AT HYPERSONIC SPEED.

Mansop Hahn (NASA, Ames Research Center, Moffett Field, Calif.).

(American Institute of Aeronautics and Astronautics, Fluid and Plasma Dynamics Conference, Los Angeles, Calif., June 24-26, 1968, Paper 68-672.)

AIAA Journal, vol. 7, June 1969, p. 1092-1098. 13 refs.

Research supported by the National Research Council and NASA.

An experimental investigation of flow details (velocity and temperature) and wall heat transfer within the separated flow region of an annular cavity at a free-stream Mach number of 7.3 is discussed. Tests were conducted at a total temperature of 1110 K and a wall-to-total temperature ratio of 0.26. Free-stream Reynolds number per meter ranged from 1.6 to 6.3×10^{6}. Effects of Reynolds number and cavity length-to-depth ratio on the distribution of temperature and heat-transfer rate are examined for both separated laminar and transitional flows. For laminar flow, typical results show that the velocity along the dividing streamline gradually increases downstream and approaches 35% of the outer-edge velocity. For both laminar and transitional flows, cavity gas temperature increased toward the reattachment region, which was consistent with the measured distribution of the heat-transfer rate on the cavity wall. The magnitude of the temperature varied with Reynolds number and cavity length-to-depth ratio. The ratio of integrated heat-transfer rate in laminar separated flow to that in corresponding attached flow was less than the theoretical limiting value of Chapman and varied with Reynolds number and cavity length-to-depth ratio. Discussion of three fields of rotor aerodynamic research–namely, comparison of theoretical and experimental data, rotor-blade flow visualization, and development of ways of using more blade-section camber. More thorough theory/data comparisons are recommended. It is suggested that a technique for obtaining flow visualization in cross sections around the retreating blade should be devised for use in solving high tip-speed ratio, high section angle-of-attack rotor aerodynamic problems. It is stressed that improved aerodynamic characteristics might be obtained by making the trailing edge "self-adaptive" (flexible) and thus permitting increased camber. P.G.

HYPERSONIC VISCOUS INTERACTION ON SHARP AND BLUNT INCLINED PLATES.

Joseph H. Kemp, Jr. (NASA, Ames Research Center, Moffett Field, Calif.).

(American Institute of Aeronautics and Astronautics, Fluid and Plasma Dynamics Conference, Los Angeles, Calif., June 24-26, 1968, Paper 68-720.)

An approximate analysis is presented for the effect of arbitrarily distributed blowing on the laminar boundary-layer flow and pressure distribution around two-dimensional or axisymmetric hypersonic blunt bodies. The analysis is based on a simplified integral method solution coupled with a Newtonian model of the inviscid flow around the effective body shape defined by the dividing streamline between the blown and free-stream gas. Numerical results for a hemispherically blunted cone with various injection levels, including the case of strong blowing, are given for three different types of blowing distributions encountered in practice. Significant increases in the local pressure are found when blowing is continued around the nose into the afterbody region. (Author)

DOWNSTREAM COOLING EFFECTIVENESS OF MASSIVE UPSTREAM TRANSPIRATION FROM A SLENDER CONE.

James C. Dunavant (NASA, Langley Research Center, Aerophysics Div., Hampton, Va.) and James C. Mulligan (North Carolina State University, Mechanical and Aerospace Engineering Dept., Raleigh, N.C.).

AIAA Journal, vol. 7, Sept. 1969, p. 1796, 1797.

Results of measurements of the radiation equilibrium temperature downstream of a transpiration-cooled gas flow section near a slender-cone vertex in a continuous flow hypersonic tunnel with the blowing rate exceeding blowoff and with a nominal freestream Mach number of 10. A simple lumped parameter formulated from approximate theoretical considerations is shown to provide a basis for the correlations characterizing the cooling effectiveness of such a system. A comparison of the experimental and theoretical results shows a fair agreement for a helium flow at low- and middle-range Reynolds numbers. V.Z.

CALCULATED AND EXPERIMENTAL HINGE MOMENTS ON A TRAILING-EDGE FLAP OF A 75° SWEPT DELTA WING AT MACH 6

J. Wayne Keyes and George C. Ashby, Jr. Washington Dec. 1967 28 p refs

(NASA-TN-D-4268) Avail: CFSTI CSCL 01A

The hinge moment characteristics of a trailing-edge flap on a 75° swept delta wing have been investigated at a Mach number of 6.0 and a Reynolds number of 4.03×10^6 (based on the root chord of the delta wing). This investigation was conducted at angles of attack from 30° to 90° and flap-deflection angles from 0° to 30°. The boundary layer in the area of the wing–flap junction was considered to be transitional for angles of attack up to approximately 60° and laminar for angles of attack from 60° to 90°. Both a sharp and blunt leading-edge wing and two flap aspect ratios were used in the investigation. Although the flow on the wing and flap was found to be complex, a meaningful analysis of the data can be made for the nonseparated case if the local flow regime over the wing and flap is properly classified (subsonic or supersonic) for each angle of attack and flap-deflection angle. The slope of the hinge moment curves changed at approximately the same angle of attack that the flow regimes were predicted to change when tangent–cone and oblique shock theories were used. Boundary layer separation over the flap was not extensive for flap deflections less than 20°. The type of boundary layer could have a strong influence on the hinge moments for flap deflection angles large enough to cause boundary layer separation. Author

A METHOD FOR DETERMINING SURFACE PRESSURES ON BLUNT BODIES OF REVOLUTION AT SMALL ANGLES OF ATTACK IN SUPERSONIC FLOW

Charlie M. Jackson, Jr., Wallace C. Sawyer, and Rudeen S. Smith Washington Nov. 1968 104 p refs

(NASA-TN-D-4865) Avail: CFSTI CSCL 01A

Existing theoretical techniques have been modified and combined to provide a method for computing surface pressure distributions on blunt bodies with spherical nose caps and arbitrary afterbody shapes. The method consists basically of modified Newtonian theory in the stagnation region with second-order shock-expansion theory used when the surface flow becomes supersonic. The second-order shock-expansion theory is most conveniently applied to rotationally symmetric bodies; therefore, to use this theory at small angles of attack, the body meridian lines are used to generate equivalent bodies of revolution from which the meridian pressure distributions are obtained. A complete, consistent set of experimental surface pressure data is presented for two typical blunt reentry configurations to permit evaluation. The test conditions provide surface pressure distributions for six Mach numbers from 1.50 to 4.63 and four angles of attack from 0° to 12° for each model. A comparison of the present theoretical method with these experimental data indicates that this method gives adequate engineering estimates of the surface pressures on

blunt bodies at moderate angles of attack except where flow separation or detached secondary shock waves are present. Author

EFFECT OF POROUS BLEED IN A HIGH PERFORMANCE AXISYMMETRIC, MIXED COMPRESSION INLET AT MACH 2.50
Robert W. Cubbison, Edward T. Meleason, and David F. Johnson Washington Nov. 1968 37 p refs
(NASA-TM-X-1692) Avail: CFSTI CSCL 01C

A study to determine the effect of boundary layer bleed location and the amount of total bleed flow on the performance of a mixed compression, axisymmetric, reflecting-shock inlet was conducted in the Lewis 10- by 10-Foot Supersonic Wind Tunnel at Mach 2.498. Best overall inlet performance was obtained with 2.5 percent supercritical bleed located just downstream of the last cowl and centerbody shock reflection points in the supersonic diffuser. Critical pressure recovery was 0.899 with 16.5 percent distortion, and the subcritical operating range was 7.8 percent of engine corrected airflow. Distortion considerations may dictate either more bleed or use of vortex generators. Author

A NUMERICAL SOLUTION FOR THE MINIMUM INDUCED DRAG, AND THE CORRESPONDING LOADING, OF NONPLANAR WINGS Final Report
J. L. Lundry Washington NASA Nov. 1968 39 p refs
(Contract NAS1-7484)
(NASA-CR-1218; DAC-66900) Avail: CFSTI CSCL 20D

A numerical procedure has been developed for the accurate computation of the minimum induced drag, and the associated loading, of nonplanar wings. The minimum induced drag and the loading are determined by the solution of a potential problem about the shed vortex wake in the Trefftz plane. The potential problem is analyzed in an auxiliary mapping plane that is related to the physical plane by the Schwarz–Christoffel transformation; the procedure can therefore be applied to configurations with front views that can be approximated by straight line segments. The success of the method depends on an iteration that converges satisfactorily for most cases. Comparisons of results of the method with results of known test cases show that errors in the minimum induced drag and in the corresponding loading are of the order of 10^{-4} when the method is programmed in single precision arithmetic for an IBM 7094. EFFECT OF VARIABLE STATOR AREA ON PERFORMANCE OF A SINGLE-STAGE TURBINE SUITABLE FOR AIR COOLING. 6: TURBINE PERFORMANCE WITH 70-PERCENT DESIGN STATOR AREA
Harold J. Schum, Edward M. Szanca, and Herman W. Prust, Jr. Washington Nov. 1968 24 p refs
(NASA-TM-X-1697) Avail: CFSTI CSCL 21E

The performance of this turbine is compared with those obtained for the design and the 130-percent design-stator-area turbines. Whereas the design turbine yielded an efficiency of 0.923 at its equivalent design operating condition, the closed turbine produced an efficiency of only 0.840 at the same operating point. This compares with 0.897 for the open turbine. The large loss of efficiency for the closed turbine is attributed mainly to the high velocities at the stator exit, incidence to the rotor, and substantially reduced reaction across the rotor. AERODYNAMIC CHARACTERISTICS OF 0.25-SCALE MODEL OF TOMAHAWK LAUNCH VEHICLE AT MACH NUMBERS FROM 2.30 TO 4.63
Lloyd S. Jernell Washington Nov. 1968 62 p refs
(NASA-TM-X-1684) Avail: CFSTI CSCL 01A

An investigation of several configurations of a 0.25-scale model of the Tomahawk launch vehicle has been conducted in the Langley Unitary Plan wind tunnel at Mach numbers from 2.30 to 4.63. The investigation included the effects of body fineness ratio, fin planform geometry, and fin cant angle for an angle of attack range of about $-4°$ to $21°$ at roll angles from $0°$ to $67°$. The results indicate that for the moment reference center employed, each configuration experienced pitch-up at angles of attack of approximately $8°$ to $10°$ at a Mach number of 2.30, with the angle of pitch-up decreasing with increasing Mach number. The larger fins delay pitch-up to a slightly higher angle of attack at all test Mach numbers. Canting the basic fins $1°$ was effective in producing rolling moment throughout the ranges of angle of attack and Mach number. Varying the roll angle resulted in large variations in the lateral force and moments above angles of attack of about $4°$ because of the effects of the forebody vortices acting on the fins. Author

EFFECTS OF ANGLE OF ATTACK AND BLUNTNESS ON THE SHOCK-LAYER PROPERTIES OF A 15° CONE AT A MACH NUMBER OF 10.6
Joseph W. Cleary Washington Nov. 1968 40 p refs
(NASA-TN-D-4909) Avail: CFSTI CSCL 01A

An experimental investigation was conducted to determine the effects of varying angle of attack and nose bluntness ratio on the shock layer properties of a typical conical entry body. Distributions of pitot and static pressures were measured across the shock layer of a cone with $15°$ semiapex. The measurements were obtained from wing-tunnel tests in air at a Mach number of 10.6 and a free stream unit Reynolds number of 1.2×10^6 per foot. Results are presented at fore and aft axial positions for several circumferential angles when at angle of attack. Pitot pressure distributions demonstrate that the flow over the sharp cone was essentially conical except for the separated-flow region on the leeward side. Increasing bluntness ratio not only caused progressive deviations from conical flow but also affected the leeward flow separation pattern. Comparisons with inviscid theory show that because of bluntness, the flow remained attached on the lee side for an axial distance of several nose radii while farther aft, the flow separated in a manner similar to that of the sharp cone. On the windward side where the boundary layer was thin, inviscid theory accurately predicts the more salient properties of shock layers for both sharp and blunted cones. Author

HEAT-TRANSFER AND PRESSURE DISTRIBUTIONS INSIDE THE HINGE-LINE GAP OF A WEDGE-FLAP COMBINATION AT MACH NUMBER 10.4
J. David Dearing and H. Harris Hamilton Washington Nov. 1968 57 p refs
(NASA-TN-D-4911) Avail: CFSTI CSCL 01A

Aerodynamic heating inside the gap separating a control flap from the adjacent support structure has been measured at a nominal free stream Mach number of 10.4. The model, a 10-percent-thick wedge, was fitted with a simple flap whose chord

was 20 percent of the wedge chord. Angle of attack was varied to change the entrance-to-exit pressure ratio and resulted in local Mach numbers ahead of the gap entrance of from 5.9 to 7.9. Laminar, transitional, and turbulent boundary layers on the wedge near the entrance were obtained by combined variations in local Mach numbers and local Reynolds number. The heating in the gap always decreased from entrance to exit and at the gap center never exceeded one-half that on the wedge at the entrance. In general, the gap heating increased with gap width and flap deflection, and rounding the gap entrance and exit lip tended to increase the overall level of heating in the gap over that for the sharp-lip configuration. THE PATH OF A JET DIRECTED AT LARGE ANGLES TO A SUBSONIC FREE STREAM

Richard J. Margason Washington Nov. 1968 54 p refs
(NASA-TN-D-4919) Avail: CFSTI CSCL 20D

An investigation was made of the path and general shape of the wake from a single jet exiting at large angles to the free stream through a range of effective velocity ratios (square root of the ratio of the free-stream dynamic pressure to the jet dynamic pressure). The jet-exit deflection angles ranged, in 30° increments, from 30° to 180° from the free stream. Photographs taken of the wake, which was a mixture of compressed air and water vapor, showed that the jet paths were essentially the same when the jet was exiting upward or downward as well as when the jet was located adjacent to a large surface or located away from adjacent surfaces. The primary variables determining the jet path are the deflection angle of the jet exit and the effective velocity ratio. The results were compared with equations for the jet path from other investigations, and the best empirical fit to these data was determined. Author

A NUMERICAL SOLUTION FOR THE MINIMUM INDUCED DRAG, AND THE CORRESPONDING LOADING, OF NONPLANAR WINGS. 1: USER'S MANUAL FOR COMPUTER PROGRAM 55VD. 2: DESCRIPTIVE MANUAL FOR COMPUTER PROGRAM 55VD

J. L. Lundry Washington NASA Nov. 1968 390 p
(Contract NAS1-7484)
(NASA-CR-1218-Suppl; DAD-66898; DAD-66899) Avail: CFSTI CSCL 01A

A numerical procedure has been developed for the accurate computation of the minimum induced drag, and the associated load distribution, of nonplanar wings. As is well known, the minumum induced drag may be determined by analyzing a potential problem in the Trefftz plane. The procedure solves the potential problem in an auxiliary mapping plane related to the physical plane by the Schwarz–Christoffel transformation for configurations with front views that may be approximated by straight line segments. Previously, the main computational difficulty had been the determination of the mapping constants. The procedure presented here offers a choice of two methods to determine these constants. The procedure has been applied to seven nonplanar lifting configurations, resulting in the development of computer program 55VD in the FORTRAN 4 language for use on an IBM 7094. Program 55VD has been converted to FORTRAN 2.0 for use on the Langley Research Center's CDC 6000 series digital computers. This report is a user's manual for the FORTRAN 2.0 version of program 55VD. PRELIMINARY INVESTIGATION OF DISTORTION DYNAMICS IN A MACH 3 MIXED COMPRESSION INLET

Robert E. Coltrin and Glenn A. Mitchell Washington Dec. 1968 22 p refs
(NASA-TM-X-1706) Avail: CFSTI CSCL 01A

The inlet was operated at critical and supercritical conditions while at 0° angle of attack in the 10- by 10-foot supersonic wind tunnel. The cowl lip diameter was 45.98 cm. Total-pressure sensors with a flat response to 200 Hz were distributed at several diffuser exit locations. The amplitude probability density functions for the total pressures were nearly Gaussian. Frequency analysis showed that the amplitude of the power spectral densities for these pressures dropped by half from 0 to 100 Hz, but was nearly constant at higher frequencies. No periodic components were observed. Author

HYPERSONIC AERODYNAMIC CHARACTERISTICS OF A MODEL OF A LOW-FINENESS-RATIO VARIABLE GEOMETRY LOGISTICS SPACECRAFT CONCEPT

Bernard Spencer, Jr. Washington Dec. 1968 44 p refs
(NASA-TM-X-1701) Avail: CFSTI CSCL 01A

An investigation has been made in the Langley 15-inch hypersonic flow apparatus at a Mach number of 10.03 to determine the static aerodynamic characteristics of a model of a low fineness ratio variable geometry logistics spacecraft concept designed for hypersonic lift drag ratios near 1.0. The variable geometry feature envisioned for the configuration is a fold-down-type wing, stowed in the triangular side areas of the body during entry and deployed at subsonic speeds for improvement in subsonic performance. The variable geometry feature is considered to be retracted for the present hypersonic tests. Author

AN ESTIMATE OF THE SUPERSONIC FLOW FIELD ABOUT AN AXISYMMETRIC BODY WITH AN N WAVE PRESSURE TRACE

Roger W. Luidens Washington Dec. 1968 28 p refs
(NASA-TN-D-4935) Avail: CFSTI CSCL 01A

Linearized flow assumptions and the conservation equations of mass, momentum, and energy are used to estimate the flow field at all distances from a body which produces an N wave pressure trace. The analytical results show good agreement with experimental results for cones and axisymmetric bodies with convex profiles. The influence of the shock wave entropy increase on the attenuation of the shock wave static pressure rise with distance from the body is illustrated. Author

EXPERIMENTAL INVESTIGATION OF ADVANCED CONCEPTS TO INCREASE TURBINE BLADE LOADING. 3: PERFORMANCE EVALUATION OF TANDEM ROTOR BLADE

H. G. Lueders Washington NASA Dec. 1968 43 p refs
(Contract NAS3-7902)
(NASA-CR-1254) Avail: CFSTI CSCL 20D

The overall performance of a single-stage turbine designed with a tandem rotor blade and negative rotor hub reaction was investigated over a range of equivalent speeds and expansion ratios. Surveys of total pressure, flow angle, temperature, and hot-wire data were taken at the rotor trailing edge. The performance of the turbine is compared with the performance of a plain rotor blade turbine. Both turbines have the same design requirements and were tested with the same stator. Author

WIND-TUNNEL INVESTIGATION OF A LARGE JET TRANSPORT MODEL EQUIPPED WITH AN EXTERNAL-FLOW JET FLAP

Lysle P. Parlett, Marvin P. Fink, and Delma C. Freeman, Jr. Washington Dec. 1968 86 p refs

(NASA-TN-D-4926) Avail: CFSTI CSCL 20D

A wind tunnel investigation was carried out to determine the aerodynamic characteristics of a model of a large jet transport aircraft equipped with an external-flow jet-augmented flap. The tests were conducted in the Langley full-scale tunnel by using a model powered by scaled nitrogen-driven, fan-jet engines. The results of the investigation were analyzed for the case of an airplane having a thrust-weight ratio of 0.30 for both takeoff and landing. These results indicated that the model with the external-flow jet flap could achieve a maximum trimmed lift coefficient of approximately 4.0 with this thrust-weight ratio. When this maximum lift coefficient was examined with consideration of reasonable operational safety margins based on flight experience with several powered-lift airplanes, it appeared that a safe operational approach lift coefficient was about 2.2. Based on this analysis, it appeared that the use of the jet flap would provide increases in operational lift coefficient of the airplane and would give substantial improvements in takeoff and landing performance. Static longitudinal stability and trim could be achieved over the entire lift range by the use of a horizontal tail with an area of 22 percent of the wing area. The out-of-trim moments caused by operation with the critical engine out could be trimmed throughout the entire lift range by the use of conventional rudder, aileron, and spoiler controls. Author

THEORY FOR COMPUTING SPAN LOADS AND STABILITY DERIVATIVES DUE TO SIDESLIP, YAWING, AND ROLLING FOR WINGS IN SUBSONIC COMPRESSIBLE FLOW

M. J. Queijo Washington Dec. 1968 78 p refs

(NASA-TN-D-4929) Avail: CFSTI CSCL 20D

A method of computing span loads and some of the resulting aerodynamic derivatives for wings in sideslip, yawing, and rolling flight is derived. The method is applicable to wings of arbitrary planform, and accounts for compressibility effects. The span-load computations require that angle-of-attack span-load distributions be available for the wing under consideration. The theory developed is a consistent approach, based on the use of a vortex system, for determining the various wing parameters. Author

EFFECT OF BLEED-SYSTEM BACK PRESSURE AND POROUS AREA ON THE PERFORMANCE OF AN AXISYMMETRIC MIXED-COMPRESSION INLET AT MACH 2.50

Bobby W. Sanders and Robert W. Cubbison Washington Dec. 1968 33 p refs

(NASA-TM-X-1710) Avail: CFSTI CSCL 21E

Two bleed geometries that had about a 2.75 to 1 ratio in total porous area were tested with different bleed-exit areas to provide various back pressures. With bleed-exit areas providing the same supercritical bleed mass flow, the higher porous-area configuration provided higher total-pressure recovery at critical inlet operation. For the same supercritical bleed mass flow the more porous configuration also obtained a reduction in bleed drag of 42.5 percent but at a complete loss of subcritical stability margin. However, by proper control of the bleed-exit areas, the engine corrected airflow could be decreased 13.18 percent from that at critical operation without incurring an unstart. Author

EXPERIMENTAL INVESTIGATION IN AN ANNULAR CASCADE SECTOR OF HIGHLY LOADED TURBINE STATOR BLADING. VOLUME 1: ANALYSIS AND DESIGN

James L. Bettner Washington NASA Dec. 1968 169 p refs

(Contract NAS3-9404)

(NASA-CR-1219) Avail: CFSTI CSCL 21E

An analytical and experimental program was initiated to investigate the application of boundary layer control concepts to highly loaded turbine stator blades in an annular cascade. A plain blade was designed which forms the performance base line for the program. Four boundary layer control concepts were investigated—vortex generators, tangential jet blowing, tandem airfoils, and jet flap. The stator blades were designed to a suction surface diffusion factor of 0.4. Author

A MATHEMATICAL ANALYSIS OF SUPERSONIC INLET DYNAMICS

Ross G. Willoh Washington Dec. 1968 45 p refs

(NASA-TN-D-4969) Avail: CFSTI CSCL 21E

An approximate mathematical analysis of supersonic inlet dynamics is presented. The subsonic duct is subdivided into constant-area sections which are represented by one-dimensional wave equations. The movable normal shock is used as the upstream boundary condition, and a choked station is assumed for the downstream boundary condition. The analysis leads to a closed-form matrix solution for the shock-position transfer function. Analytical results are presented and compared with experimental data. Author

DESIGN OF SUPERSONIC INLETS BY A COMPUTER PROGRAM INCORPORATING THE METHOD OF CHARACTERISTICS

Bernhard H. Anderson Washington Jan. 1969 118 p refs

(NASA-TN-D-4960) Avail: CFSTI CSCL 20D

A FORTRAN IV computer program which incorporates the method of characteristics was written to assist in the design of supersonic inlets. The computer program was written with the intention of studying many types of inlet configurations with a minimum of computer time. Particular attention was given to a discussion of a reformulation of the boundary value problem to introduce throat Mach number and flow angle as direct program input quantities. Comparison between the computer results and experimental data indicates good agreement for a number of different configurations. Author

EFFECT OF UNIT REYNOLDS NUMBER, NOSE BLUNTNESS, ANGLE OF ATTACK, AND ROUGHNESS ON TRANSITION ON A 5° HALF-ANGLE CONE AT MACH 8
P. Calvin Stainback Washington Jan. 1969 78 p refs
(NASA-TN-D-4961) Avail: CFSTI CSCL 01A

A 5° half-angle cone has been tested at a nominal free-stream Mach number of 8 over a range of local, sharp cone unit Reynolds numbers from about 4.5×10^6 per meter (1.3×10^6 per foot) to 4.5×10^7 per meter (1.3×10^7 per foot) in a conventional blowdown tunnel. The nominal ratio of wall temperature to free-stream total temperature was about 0.4. The purpose of the investigation was to determine the effect of unit Reynolds number, nose bluntness, angle of attack, and roughness on the beginning of transition and on laminar and turbulent heating. The results obtained with the smooth models indicated that there was an increase in the transition Reynolds number with increasing unit Reynolds number and a rearward movement of the location of transitions with increasing nose bluntness and angle of attack for the windward ray. Although the hypersonic laminar boundary layer could be tripped with various types of roughness elements, large three-dimensional elements caused circumferential nonuniformities in the heat-transfer distribution around the cone for large distances into the turbulent boundary-layer region. The local transition Reynolds numbers for all bluntnesses (including the sharp tip cone) were correlated reasonably well as a single function of local unit Reynolds number if the local flow quantities were obtained from boundary-layer solutions with variable stream entropy effects included. Also, the agreement between laminar transfer data and theory, in the form of Stanton number as a function of Reynolds number, appeared to be improved if variable-entropy effects were taken into account. PRELIMINARY STUDY OF EFFECTS OF REYNOLDS NUMBER AND BOUNDARY-LAYER TRANSITION LOCATION ON SHOCK-INDUCED SEPARATION
James A. Blackwell, Jr. Washington Jan. 1969 27 p refs
Paper presented at AGARD Specialists' Meeting on Transonic Aerodyn., Paris, Sep. 1968; sponsored by AGARD
(NASA-TN-D-5003) Avail: CFSTI CSCL 20D

A two-dimensional experimental and theoretical investigation was conducted on an airfoil to determine the effect of Reynolds number and transition location on shock-induced separated flow. The experimental investigation was conducted in the 8-foot transonic pressure tunnel at Mach numbers from 0.60 to 0.80, angles of attack from 0° to 4°, and Reynolds numbers from 3.0×10^6 to 16.8×10^6. Transition locations from 0.05 to 0.50 chord were utilized. The results indicate that variation of the Reynolds number from full-scale values to the usual wind-tunnel values results in substantial changes in the shock location, trailing-edge pressure recovery, and boundary-layer losses at the trailing edge. By properly fixing the boundary-layer transition point on the wind-tunnel model, full-scale results can be simulated at the usual wind-tunnel Reynolds numbers. The required location of the transition point can be predicted theoretically with acceptable accuracy by simulating the boundary-layer characteristics at the airfoil trailing edge. Author

PREDICTION OF LIFT AND DRAG FOR SLENDER SHARP-EDGE DELTA WINGS IN GROUND PROXIMITY
Charles H. Fox, Jr. Washington Jan. 1969 36 p
(NASA-TN-D-4891) Avail: CFSTI CSCL 01A

A method of predicting the lift and drag of slender planar sharp-edge delta wings in ground proximity is described, and the results are compared with experimental data. The method utilizes a vortex-lattice computer program incorporating an image technique to compute the potential-flow normal-force and axial-force characteristics of delta wings in ground proximity. A recently published vortex-lift concept in free air based on a leading-edge-suction analogy is utilized, and a method is presented for combining it with the results of the potential-flow theory in ground proximity. A comparison of the theoretical and experimental lift and drag for delta wings with a wide range of aspect ratios is presented at selected angles of attack. The comparison indicates that this method provides a reasonably good prediction of the lift and drag in ground proximity for aspect ratios less than 2.0 in the angle-of-attack range from 5° to 16° Author

EXPERIMENTAL SURFACE-PRESSURE DISTRIBUTIONS ON A 9° SPHERICALLY BLUNTED CONE AT MACH NUMBERS FROM 1.50 TO 4.63
Wallace C. Sawyer and Rudeen S. Smith Washington Jan. 1969 60 p refs
(NASA-TM-X-1730) Avail: CFSTI CSCL 20D

An investigation was conducted in a wind tunnel to determine the pressure distributions on a 9° spherically blunted cone at Mach numbers from 1.50 to 4.63 with Reynolds numbers of 2.25×10^6 and 3.00×10^6 per foot (7.38×10^6 and 9.84×10^6 per meter). Angle of attack was varied from 0° to 12°. The surface pressures were integrated in order to obtain forebody forces and moments. The experimental surface pressures and integral forces and moments were compared with an existing theoretical method which predicts surface pressures and aerodynamic characteristics. Comparison of the experimental and theoretical results showed good agreement for surface pressures at moderate angles of attack except at the lower Mach numbers. Comparison of the results for forces and moments generally showed good agreement. The process of integrating surface pressures has been programmed for high speed digital computation. The program is written so that it will apply to arbitrary bodies of revolution. For convenience, the program is presented with the necessary operating details. Author

ROUGHNESS DRAG DUE TO TWO-DIMENSIONAL FABRICATION-TYPE SURFACE ROUGHNESS ON AN OGIVE CYLINDER FROM FORCE TESTS AT TRANSONIC SPEEDS
K. R. Czarnecki and William J. Monta Washington Jan. 1969 48 p refs
(NASA-TN-D-5004) Avail: CFSTI CSCL 20D

An investigation has been made in the transonic Mach number range from 0.70 to 1.20 and over a range of free stream Reynolds number per foot from about 0.8×10^6 to 6.0×10^6 (2.6×10^6 to 19.7×10^6 per meter) to determine by means of force tests the roughness drag due to essentially two dimensional fabrication-type surface roughness immersed in a turbulent boundary layer. Six types of surface roughness, including step, wave, crease, and swept configurations, were investigated. The tests were made on an ogive cylinder of fineness ratio 12.2, the roughness elements covering the cylindrical portion of the models. Some force test data obtained previously on the these models at Mach numbers of 1.61 and 2.01 have been included as an aid to the analysis, and a comparison is made of the force test results with those results obtained from the pressure distribution investigations and with supersonic wave drag theory. The investigation indicated that roughness elements submerged in a turbulent boundary layer had drag characteristics very much like those of bodies in a uniform free stream as the Mach number was increased or the roughness sweep angle was changed. There was, however, a strong influence of change in Reynolds number of boundary layer thickness on the drag characteristics when substantial wave drag was present. Author

DEVELOPMENT OF AIR BEARING LIFT PADS

Dan H. Dane and Herman T. Blaise Washington Jan. 1969 21 p (NASA-TM-X-1724) Avail: CFSTI CSCL 01C

If a loaded air pad would float 0.317 cm (0.125 in.) above the floor, the drag would be almost zero, and the floor surface would not affect the performance of the air pad. Raising a precision air bearing or bladder air bearing higher than the air film layer by supplying more air to the pads produces unacceptable vibrations. Lowering the volume of air from a ground effects machine to get the desired effect produces statically unstable conditions. To provide a frictionless lift capacity on rough floors, a mathematical model of an air bearing lift pad (air pad) that floats 0.317 cm off the surface was devised, manufactured, and successfully tested. Three of these air bearing lift pads were assembled into a cushion air pad platform that had a load carrying capacity exceeding 45.4 kg (100 lb) over a rough floor with less than 0.284 N (1 oz) friction drag. Seven upgraded units were designed and manufactured to support 136 kg (300 lb) for the serpentuator testing program and for general simulation use. Author

A PARAMETRIC STUDY OF BLADE-MOTION STABILITY BOUNDARIES FOR AN ARTICULATED ROTOR

Julian L. Jenkins, Jr. Washington Feb. 1969 29 p refs (NASA-TN-D-5032) Avail: CFSTI CSCL 01C

The blade-motion stability and response sensitivity of a fully articulated rotor (flapping and lead-lag degrees of freedom) was examined by using a numerical solution to the coupled, nonlinear, rigid-blade equations of motion. The effect of initial conditions on the tip-speed ratio for divergent motion is indicated by varying the initial azimuth angle for introducing a disturbance and by varying the disturbance amplitude at the critical aximuth angle. Methods of extending the divergence boundary of an articulated rotor are examined. The effects of blade-root pocket cutout, hinge restraint (spring and damping), flapping-hinge cant angle, and hinge offset are evaluated individually, and a representative combination of these parameters was chosen to indicate the overall effectiveness on blade-motion stability and response. Author

AERODYNAMIC FORCES ON A STATIONARY AND OSCILLATING CIRCULAR CYLINDER AT HIGH REYNOLDS NUMBERS

George W. Jones, Jr., Joseph J. Cincotta (Martin Co., Baltimore, Md.), and Robert W. Walker Washington Feb. 1969 65 p refs (NASA-TR-R-300) Avail: CFSTI CSCL 20D

A wind-tunnel investigation was made of the steady drag and unsteady lift forces on a stationary and oscillating circular cylinder in two-dimensional flow at high Reynolds numbers and at Mach numbers up to 0.6. The experimental data were obtained in the Langley transonic dynamics tunnel from tests of a 3-foot diameter cylinder instrumented to measure directly the unsteady lift and mean drag forces on the cylinder. The cylinder could be held fixed or oscillated laterally to the flow at frequencies from 3 to 20 hertz. For the stationary cylinder, the static pressure distributions, the mean drag coefficients at M 0.2, and the Strouhal number of the unsteady lift forces follow the trends established by previous investigators up to the limits of Reynolds number investigated. At higher Reynolds numbers, each of these parameters remains essentially constant. The unsteady lift force can be categorized into three regimes dependent upon Reynolds number: wide-band random, narrow-band random, and quasi-periodic. Oscillation of the cylinder in the lift direction has no significant effect on the mean drag coefficient. An unsteady lift due to cylinder motion, exists only when the cylinder is oscillated at or relatively near the aerodynamic Strouhal frequency for the stationary cylinder. Author

***AERODYNAMIC DATA ON LARGE SEMISPAN TILTING* WING WITH 0.4-DIAMETER CHORD, SINGLE-SLOTTED FLAP, AND SINGLE PROPELLER 0.22 CHORD BELOW WING**

Marvin P. Fink Washington Jan. 1969 205 p refs (NASA-TN-D-5016) Avail: CFSTI CSCL 20D

A study was made in the full-scale tunnel to determine the longitudinal aerodynamic characteristics of a large-scale semispan V/STOL tilt-wing configuration with a single propeller which was tested for modes of rotation. The wing had a ratio of chord to propeller diameter of 0.4, a 40-percent-chord single-slotted flap, an aspect ratio of 6.14 (3.07 for the semispan), a taper ratio of 1.0, and an NACA 4420 airfoil section. The direction of propeller rotation was found to have a very significant effect on the lift and descent capability (as determined from drag-lift ratios attainable without stalling of any part of the wing within the propeller slipstream) and that up-at-the-tip rotation gave the more favorable results. The use of flow-control devices was very effective in increasing the descent capability and lift for down-at-the-tip propeller rotation where the characteristics without such devices were poor but was much less effective for up-at-the-tip propeller rotation. For the most favorable combination of the configuration variables, descent angles of nearly 27° were achieved over the entire test range of power conditions. Author

PERFORMANCE OF A TOWED, 48-INCH-DIAMETER (121.92-cm) BALLUTE DECELERATOR TESTED IN FREE FLIGHT AT MACH NUMBERS FROM 4.2 TO 0.4

J. W. Usry Washington Feb. 1969 34 p refs Film supplement number L-1002 to this report is available on loan from NASA. Langley Research Center, Langley Station, Va. (NASA-TN-D-4943) Avail: CFSTI CSCL 01C

A ballute decelerator inflated by ram air was tested in free flight to determine the inflation, drag, and stability characteristics. The decelerator has a 40-inch (101.6-cm) envelope equatorial diameter and a 10-percent burble fence. It was towed 13.5 feet (4.12 m) aft of a cone-cylinder-flare payload with a maximum diameter of 18.21 inches (46.25 cm). The decelerator was deployed at an altitude of 115,000 feet (35.1 km) at a velocity of 4400 ft/sec (1342 m/sec) and inflated at a Mach number of 4.2 and a free-stream dynamic pressure of 163 lb/ft^2 (7.8 kN/m^2). The time from the beginning of inflation of the decelerator to full inflation was 0.42 second. Longitudinal loads during inflation were of the same order of magnitude as the steady-state drag load. The decelerator appeared to have excellent stability characteristics in pitch and yaw during and after inflation. Roll rates of both bodies increased after deployment from a minimum of about 2.6 radians/sec just prior to inflation to a maximum of about 6.8 radians/sec for the decelerator and about 5.8 radians/sec for the payload. The drag coefficient of the decelerator varied from about 1.45 at a Mach number of 1.25 to 0.67 at a Mach number of 4.2 Author

TWO DIMENSIONAL INVISCID JET FLOW FROM TWO NOZZLES AT AN ANGLE TO A PLANE SURFACE

Marvin E. Goldstein and Robert Siegel Washington Feb. 1969 45 p refs

(NASA-TN-D-5064) Avail: CFSTI CSCL 20D

Conformal mapping was used to obtain the free streamlines and wall pressure coefficient for jets issuing from two nozzles and striking a surface. The jet nozzle exit planes are at an angle to the surface and can be spaced an arbitrary distance apart and an arbitrary distance from the surface. The effect of nozzle position and tilt angle on the extent of the flow back between the nozzles is shown. The back flow results from a collision between part of the flow from each jet that has been turned by striking the plate. Author

FORTRAN PROGRAMS FOR CALCULATING WIND-TUNNEL BOUNDARY INTERFERENCE

Harry H. Heyson Washington Feb. 1969 74 p refs

(NASA-TM-X-1740) Avail: CFSTI CSCL 20D

Boundary-interference programs, developed in NASA TR R-302, are presented without comment. These programs should be utilized only after careful consideration of the assumptions and procedures given in that report. A systematic computer procedure is developed for calculating the wind tunnel interference factors for arbitrary configurations from the interference calculations for a vanishingly small model. The method is not limited to any one tunnel configuration since it is necessary only to substitute a subroutine appropriate to the tunnel for that given herein. The underlying theory (subroutine DLTAS) in the present computer programs is directly applicable to models which produce large wake deflections, such as V/STOL models. These programs may also be used directly for more conventional testing at moderate lift coefficients by means of the few simple modifications. No sample calculations or check cases are provided. THEORETICAL ANALYSIS OF FLOW IN VTOL LIFT FAN INLETS WITHOUT CROSSFLOW

Norbert O. Stockman and Seymour Lieblein Washington Feb. 1969 39 p refs

(NASA-TN-D-5065) Avail: CFSTI CSCL 20D

A method based on the Douglas incompressible potential-flow computer program has been used for the theoretical analysis of the axisymmetric flow in VTOL lift fan or engine inlets in static operation (no crossflow). The usefulness of the method for predicting flow in real inlets without flow separation was indicated by good agreement between theoretical results and limited available experimental compressible data. Example solutions were given for several different inlet configurations in which shroud curvature and depth, centerbody size and location, and inlet boundaries (type of installation) were varied. The application of the method to the design of an actual fan-in-wing inlet was given in some detail. Author

TUFT-GRID SURVEYS AT LOW SPEEDS FOR DELTA WINGS

John D. Bird Washington Feb. 1969 33 p refs

(NASA-TN-D-5045) Avail: CFSTI CSCL 20D

Tuft-grid surveys were made along the chord and in the near wake of 60°, 75°, 82.5°, and 86.5° delta wings at low speeds in the Langley stability tunnel to show the nature of the flow in the vicinity of such wing planforms. The results are presented without a detailed discussion in that the photographs of the flow patterns are felt to be largely self-explanatory. An unusual wake pattern which gave evidence of three asymmetrically arranged trailing vortices was obtained for the 86.5° delta wing at an angle of attack of 25° and zero sideslip. Author

USE OF SUPERPOSITION IN DIGITAL COMPUTERS TO OBTAIN WIND TUNNEL INTERFERENCE FACTORS FOR ARBITRARY CONFIGURATIONS, WITH PARTICULAR REFERENCE TO V/STOL MODELS

Harry H. Heyson Washington Feb. 1969 114 p refs

(NASA-TR-R-302) Avail: CFSTI CSCL 20D

A superposition method utilizing a digital computer is developed to obtain wall interference for arbitrary configurations. A variety of specific configurations are treated. Sample numerical results indicate that a large number of variables, such as wind-tunnel configuration, model configuration, wake deflection, model location, span of wing and tail, load distribution, sweep, angle tail height, may individually or collectively produce substantial effects on wall interference. Interference is particularly severe at the rear rotor of tandem systems; the maximum size of such systems for reasonable wall effects is discussed. Author

PERFORMANCE CHARACTERISTICS FROM MACH 2.58 TO 1.98 OF AN AXISYMMETRIC MIXED-COMPRESSION INLET SYSTEM WITH 60-PERCENT INTERNAL CONTRACTION

Robert W. Cubbison, Edward T. Meleason, and David F. Johnson Washington Feb. 1969 64 p refs

(NASA-TM-X-1739) Avail: CFSTI CSCL 20D

A study has been made in the Lewis 10 by 10 foot supersonic wind tunnel to determine the performance characteristics of an axisymmetric, mixed compression inlet system designed for Mach 2.5. Inlet performance is presented for 0° and maximum unstart angle of attack. Diffuser static pressure distributions and compressor face total pressure profiles are shown for several operating conditions. Data presented show effects of Mach number, Reynolds number, bypass flow, and vortex generators on performance. Performance during restart cycles and required area ratios for restart are presented. FULL-SCALE INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A SAILWING OF ASPECT RATIO 5.9

Marvin P. Fink Washington Feb. 1969 32 p refs

(NASA-TN-D-5047) Avail: CFSTI CSCL 20D

An investigation was conducted to determine the aerodynamic characteristics of a full-scale model employing a sailwing having a wing aspect ratio of 5.9. The wing had a rigid leading-edge spar, rigid root and wing-tip ribs, a trailing-edge cable stretched between these ribs, and a fabric covering stretched between the leading and trailing edges. Included in the investigation were tests to determine the effect of a round leading edge as well as a D-spar leading edge on the aerodynamic characteristics of the model. Also, the effects of geometric dihedral on the lateral characteristics were determined. The aerodynamic characteristics of the sailwing compared favorably with those of a conventional wing in terms of maximum lift and maximum lift-drag ratio. The round-spar leading-edge configuration had higher lift coefficients but lower values of maximum lift-drag ratio than those of the D-spar configuration. Increased dihedral caused a decrease in maximum lift for both configurations, produced the expected increase in effective dihedral, and gave little effect on the directional stability characteristics. A NUMERICAL METHOD FOR EVALUATION AND UTILIZATION OF SUPERSONIC NACELLE-WING INTERFERENCE

Robert J. Mack Washington Mar. 1969 27 p refs

(NASA-TN-D-5057) Avail: CFSTI CSCL 01A

A numerical method for calculating (1) the inviscid flow nacelle-wing interference loads on a warped wing surface, (2) a load-compensating reflex camber surface for optimization purposes, and (3) the interference-lift effective-area contribution to sonic-boom pressure disturbances are presented and discussed. Within the limitations of a modified supersonic linearized theory, the numerical method can provide reasonable good estimations of the loads imposed on a wing surface by nacelles mounted nearby. EXPERIMENTAL PRESSURE DISTRIBUTIONS ON A 120° CONE AT MACH NUMBERS FROM 2.96 TO 4.63 AND ANGLES OF ATTACK FROM 0° TO 20°

Robert L. Stallings, Jr. and Dorothy H. Tudor Washington Mar. 1969 77 p refs

(NASA-TN-D-5054) Avail: CFSTI CSCL 01A

A sharp and a blunt 120° cone configuration were tested. The blunt configuration consisted of a spherical segment with a radius of 1/8 the base diameter and which faired into a 120° cone frustum. The tests were conducted at Mach 2.96, 3.95, and 4.63 over a range of angles of attack from 0° to 20°. Pressure distributions and shock shapes obtained on both the sharp and blunt cones at an angle of attack (α) of 0° were in good agreement with an approximate theoretical solution based on the one-strip method of integral relations. Mach number had no effect on pressure distributions expressed in the form of local measured pressures divided by the free-stream pitot pressure ($p_l/p_{t,2}$) for either the shapr or blunt configurations at $\alpha = 0°$. At $\alpha > 0°$, the Mach number effect was confined to the leeward side of both configurations and consisted of a decrease in $p_l/p_{t,2}$ with increasing Mach number. Pressure distributions on the cone frustum of the blunt and sharp configurations were essentially the same throughout the range of test variables. An approximate technique involving a tangent-cone concept is presented for predicting the windward and leeward pressures for $\alpha > 0°$. Results from this method are in fair agreement with experimental results both in the form of pressure distributions and force coefficients. For $\alpha > 0°$, the local pressures around the circumference of both the sharp- and blunt-cone configurations, nondimensionalized by the pressure measured along the windward ray, were in good agreement with an empirically derived second-order polynomial. A METHOD FOR DETERMINING THE TOTAL DRAG OF A POINTED BODY OF REVOLUTION IN SUPERSONIC FLOW WITH TURBULENT BOUNDARY LAYER

Charlie M. Jackson, Jr. and Rudeen S. Smith Washington Mar. 1969 67 p refs

(NASA-TN-D-5046) Avail: CFSTI CSCL 01A

An approximate mathematical model of the inviscid and viscid flow field about a body of revolution was developed by utilizing modifications of the second-order shock-expansion theory and of a theoretical analysis of compressible boundary layer growth with pressure gradient. The area of application of this model is intended to be restricted to the attached bow-shock condition in the supersonic flow region with an all turbulent boundary layer. The viscid–inviscid interaction is accounted for by iteration between the respective theories. The solution of the mathematical model including the iteration and the integration of surface conditions to give wave and friction drags was programmed for digital computation, and the program is included. The viscid and inviscid solutions including interactions were applied to several body shapes over a wide range of test conditions and the resulting total drag estimates generally agreed with the reported experimental values to within 5 percent. In view of the difficulty involved in obtaining precise experimental data, it is believed that the present method is generally as accurate as the current experimental testing techniques. Author

EFFECTS OF CONE ANGLE, BASE FLARE ANGLE, AND CORNER RADIUS ON MACH 3.0 AERODYNAMIC CHARACTERISTICS OF LARGE-ANGLE CONES

William D. Deveikis and James Wayne Sawyer Washington Mar. 1969 47 p refs

(NASA-TN-D-5048) Avail: CFSTI CSCL 01A

A wind tunnel investigation was conducted on large angle cones to determine the effects on static aerodynamic characteristics of cone angles from 110° to 150°, base flare angles from 65° to 90°, and base corner radii to 20 percent of the base radius. The tests were conducted at angles of attack to 12° and at Reynolds numbers, based on maximum body diameter, of approximately 1.1 $\times 10^6$ and 3.0 $\times 10^6$ in a Mach 3.0 stream. All models were statically stable, and aerodynamic centers were located downstream from the base. The static stability was relatively insensitive to cone angle but decreased as the flare angle and corner radius increased. The axial force coefficient increased with cone angle and flare angle but decreased with increasing corner radius. Author

WIND-TUNNEL DATA FROM A 0.16-SCALE V/STOL MODEL WITH DIRECT-LIFT AND LIFT-CRUISE JETS

Matthew M. Winston Washington Mar. 1969 72 p refs

(NASA-TM-X-1758) Avail: CFSTI CSCL 01C

Investigations were conducted on a 0.16-scale V/STOL model in the 17-foot (5.18-meter) test section of the Langley 300-mph 7- by 10-foot tunnel. Six cold-air ejectors were used to simulate four direct-lift and two lift-cruise jet engines. Longitudinal and lateral-directional aerodynamic characteristics were investigated for various model configurations, forward speeds, and power conditions in the transition and cruise flight ranges. In addition to control-effectiveness studies, the effects of power variations for different lift-nozzle settings and the effects of height above the ground were investigated. Author

WIND-TUNNEL FORCE AND PRESSURE TESTS OF ROCKET-ENGINE NOZZLE EXTENSIONS ON THE 0.0667-Scale X-15-2 MODEL AT SUPERSONIC AND HYPERSONIC SPEEDS

Earl J. Montoya and Jack Nugent Washington Mar. 1969 65 p refs

(NASA-TM-X-1759) Avail: CFSTI CSCL 01A

Wind-tunnel force and pressure test results of nozzle extensions on the 0.0667-scale X-15-2 model over the free-stream Mach number range from 2.3 to 8.0 at angles of attack from $-5°$ to 18° and Reynolds numbers of 2.0 $\times 10^6$ per foot (6.56 $\times 10^6$ per meter) and 3.4 $\times 10^6$ per foot (1.12 $\times 10^7$ per meter) are presented. The effects of the presence of an aft-mounted ramjet shape and control-surface deflections are shown. Force data indicate that the addition of the nozzle extensions did not appreciably affect

the overall drag or static margin of the model. On the basis of these results as well as other considerations, a nozzle with an internal expansion ratio of 22.1 was deemed most suitable. The presence of this nozzle extension slightly increased the model base pressure. Fuselage afterbody flows impinged on the nozzle extension and formed a shock wave at the impingement point. Large longitudinal and circumferential pressure variations existed on the nozzle extension. Deflecting the speed brakes and horizontal tails significantly affected the nozzle pressures; whereas, the addition of the model ramjet did not have an effect. Author

CHARACTERISTICS STUDY OF A BICONE MIXED-COMPRESSION INLET FOR MACH 1.80 TO 2.50
Bernhard H. Anderson Washington Mar. 1969 35 p ref
(NASA-TN-D-5084) Avail: CFSTI CSCL 01A

A theoretical design study was made to evaluate the behavior of a bicone mixed compression inlet over the Mach number range 1.800 to 2.500 and to explore the possibilities in overall performance that may be realized by modifications of the external and internal geometries. For the inlet operating on-design, the results indicate three characteristics are required for favorable surface compression distributions and low flow distortion near the throat at off-design Mach numbers. These are (1) low-contour curvature of the internal surfaces, (2) nearly equal compression rates on the cowl and centerbody surfaces, and (3) generally low distortion levels in the flow field upstream of the throat. EXPLORATORY INVESTIGATION OF FLOW FIELD RESULTING FROM FORWARD-FACING NOZZLES EXHAUSTING NEAR A LARGE CYLINDRICAL BODY AT FREE-STREAM MACH NUMBERS OF 3.0 AND 6.0
Robert J. McGhee and James A. Martin Washington Mar. 1969 40 p refs
(NASA-TN-D-5030) Avail: CFSTI CSCL 01A

The investigation showed that the resulting flow field contained extensive regions of boundary layer separation and mixing adjacent to the cylindrical body. The extent of flow separation on the body depended upon the ratio of jet-exit static pressure to free-stream static pressure, jet-exit Mach number, and free-stream Mach number. An extensive wake region, caused by the limited expansion of the jet exhaust flow at the nozzle lip, was observed around the nozzles and body base at all test conditions. Increasing the angle of attack from 0° to 4° had only a minor effect on the flow field. Large local surface pressures resulted from the initial impingement of the nozzle exhaust on the body. The pressure coefficient on the body just forward of the nozzle exit, when based on jet-exit conditions, was independent of the ratio of jet-exit static pressure to free-stream static pressure and free-stream Mach number. ANTENNA EFFECTS ON THE AERODYNAMIC CHARACTERISTICS OF A 0.410-SCALE MODEL OF THE CAJUN ROCKET AT MACH NUMBERS FROM 2.30 TO 4.63
Lloyd S. Jernell Washington Mar. 1969 56 p ref
(NASA-TM-X-1771) Avail: CFSTI CSCL 01A

The effects of several proposed antenna configurations on the aerodynamic characteristics of a 0.410-scale model of the Cajun rocket were investigated in a wind tunnel at Mach numbers form 2.30 to 4.63. Data were obtained at angles of attack to approximately 12° for roll angles of 0°, 22.5°, and 45°. The results indicate that the antenna configurations investigated have no significant effects on either the normal force or pitching moment parameters. The turnstile and Dovap antennas contribute appreciably to the axial force coefficient. The greater values of the induced lateral characteristics are generally produced by the quadraloop and Dovap antennas. Author

MODEL TESTS OF JET INDUCED LIFT EFFECTS ON A VTOL AIRCRAFT IN HOVER
P. K. Shumpert and J. G. Tibbetts Washington NASA Mar. 1969 129 p refs
(Contract NAS1-7891)
(NASA-CR-1297) Avail: CFSTI CSCL 01A

Lift losses and jet decay profiles were measured for 18 nozzle configurations and various airframe configurations at nozzle pressure ratios from 1.4 to 2.3 and at heights from landing gear height to infinity. Outboard-hinged nozzle doors greatly increased the lift losses except near the ground. Increasing nozzle lateral spacing reduced the near-ground losses. Other changes had lesser lift effects. The lift losses out of ground effect correlated well with a jet decay parameter which reflected the amount of jet mixing and the corresponding strength of the induced flow field. After correcting for the effects of differences in the jet decay parameter, the results of the present tests also correlated well with the results of a previous NASA test program which used a similar model. FORTRAN PROGRAM FOR CALCULATING VELOCITIES AND STREAMLINES ON A BLADE-TO-BLADE STREAM SURFACE OF A TANDEM BLADE TURBOMACHINE
Theodore Katsanis and William D. McNally Washington Mar. 1969 114 p refs
(NASA-TN-D-5044) Avail: CFSTI CSCL 20D

A Fortran 4 computer program was written that gives the blade-to-blade solution of the two dimensional, subsonic, compressible (or incompressible), nonviscous flow problem for a circular or straight infinite cascade of tandem or slotted turbomachine blades. The blades may be fixed or rotating. The flow may be axial, radial, or mixed. The results include streamline coordinates, velocity magnitude and direction throughout the passage, and the blade surface velocities. This method is based on the stream function using an iterative solution of nonlinear finite difference equations. Author

REVISED FORTRAN PROGRAM FOR CALCULATING VELOCITIES AND STREAMLINES ON A BLADE TO BLADE STREAM SURFACE OF A TURBOMACHINE
Theodore Katsanis and William D. McNally Washington Apr. 1969 59 p refs
(NASA-TM-X-1764) Avail: CFSTI CSCL 01A

An existing FORTRAN IV computer program for blade-to-blade aerodynamic analysis of turbomachine blades was revised to obtain a simpler program consistent with related programs. The analysis is for two-dimensional, subsonic, compressible or incompressible,

nonviscous flow in a circular or straight infinite cascade of blades, which may be fixed or rotating. The flow may be axial, radial, or mixed, and the stream channel thickness may change in the through-flow direction. The results include streamline coordinates, velocity magnitude and direction throughout the passage, and the blade-surface velocities. This report includes a complete description of the input required by the program and the program listing. Author

EXPERIMENTAL STAGNATION POINT VELOCITY GRADIENTS AND HEAT TRANSFER COEFFICIENTS FOR A FAMILY OF BLUNT BODIES AT MACH 8 AND ANGLES OF ATTACK

James C. Ellison Washington Apr. 1969 24 p refs
(NASA-TN-D-5121) Avail: CFSTI CSCL 01A

Local pressure and heat-transfer measurements were obtained on a family of blunt, axisymmetric bodies having a range of ratios of body radius to nose radius from 0 to 0.707, and ratios of corner radius to body radius of 0 to 0.40. The experimental data were obtained at a Mach number of 8.0 and a Reynolds number of 1.37 $\times$ 10^6, over a range of angles of attack from 0° to 20°. An effective nose radius was determined for each body and employed to calculate the stagnation-point values of the heat-transfer coefficient. The results indicated that the stagnation-point heat-transfer coefficient for a given body geometry varies with the angle of attack, except for the flat-faced body having the largest corner radius. FORTRAN PROGRAM FOR CALCULATING VELOCITIES IN A MAGNIFIED REGION ON A BLADE TO BLADE STREAM SURFACE OF A TURBOMACHINE

Theodore Katsanis and William D. McNally Washington Apr. 1969 83 p refs
(NASA-TN-D-5091) Avail: CFSTI CSCL 20D

A Fortran IV computer program was written to obtain a local detailed solution around a leading or trailing edge or in a slot region for compressible, subsonic, nonviscous flow on a blade-to-blade surface between turbomachine blades. This program allows a coarse-mesh solution for an entire blade-to-blade region to be magnified in a small rectangular region. The results include detailed surface velocities, velocity magnitude and direction, and stream-function values throughout the magnified region. The method is based on the stream function and uses the iterative solution of nonlinear finite-difference equations. Author

WIND TUNNEL INVESTIGATION OF INFLATION OF DISK-GAP-BAND AND MODIFIED RINGSAIL PARACHUTES AT DYNAMIC PRESSURES BETWEEN 0.24 AND 7.07 POUNDS PER SQUARE FOOT

Charles H. Whitlock Washington May 1969 7 p refs
(NASA-TM-X-1786) Avail: CFSTI CSCL 01C

Exploratory wind-tunnel tests of the disk-gap-band and modified ringsail parachute con figurations have been conducted at dynamic pressures between 0.24 and 7.07 lb/ft^2 (11 and 339 N/m^2). Both parachutes exhibited positive inflation characteristics over the range of the tests within technique limitations. The disk-gap-band configuration required less time and distance to inflate than the modified ringsail configuration did. Author

OVERALL PERFORMANCE OF A TANDEM-BLADED INDUCER TESTED IN WATER

Richard F. Soltis, Donald C. Urasek, and Max J. Miller Washington May 1969 39 p refs
(128-31-32-12-22)
(NASA-TN-D-5134) Avail: CFSTI CSCL 01A

A 6.5-inch (16.5-cm) diameter inducer composed of tandem blades was tested. Design values of head rise coefficient and flow coefficient were 0.303 and 0.109, respectively. At design flow the noncavitating measured head rise coefficient was 0.278 at a hydraulic efficiency of 0.88. Cavitation caused the head rise to drop off at a suction specific speed of approximately 20,000. It is speculated that cavitation performance could be improved by reducing the blade thickness in the leading edge regions of both blades. The occurrence of cavitation is illustrated in still photographs and the visual observations are correlated with measured results. Small changes to slot geometry were made and resulted in relatively small changes in performance. Author

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A TWIN-KEEL PARAWING

George M. Ware Washington May 1969 30 p refs
(NASA-TN-D-5199) Avail: CFSTI CSCL 01A

An investigation was conducted in the Langley full scale tunnel to determine the performance and the static stability and control characteristics of a twin keel parawing. The model was essentially an all flexible single keel parawing configuration with a rectangular panel added to form a center section between the triangular outboard panels. The tests showed that the model had a maximum lift-drag ratio of 3.4. The model was longitudinally stable from the minimum angle of attack attainable before nose collapse up to the stall angle, an angle of attack range of about 15°. Changing the length of the aft keel and wing tip lines was effective in trimming the model over the entire unstalled angle of attack range and resulted in a modulation in lift-drag ratio from 2.2 to 3.4. The model was directionally stable, had positive effective dihedral over the unstalled angle of attack range in which the configuration could be trimmed, and had longitudinal stability. At angles of attack above the stall, however, the model became directionally unstable and had negative effective dihedral. Differential deflection of the wing tips produced positive rolling moments and negative yawing moments over the test range of angle of attack when the lines were changed in a direction to lower the right wing tip. EXPERIMENTAL INVESTIGATION IN AN ANNULAR CASCADE SECTOR OF HIGHLY LOADED TURBINE STATOR BLADING. VOLUME 3: PERFORMANCE OF TANDEM BLADE

James L. Bettner Washington May 1969 73 p refs
(Contract NAS3-9404)
(NASA-CR-1341) Avail: CFSTI CSCL 01A

A tandem blade consisting of two airfoils was tested in a six blade annular cascade. The performance of this blade was evaluated and compared with that of a plain blade designed to the same set of velocity triangles and tested in the same cascade. The solidity of the tandem airfoil was approximately 91% of the plain blade. By all modes of performance evaluation, the tandem blade met or exceeded the design requirements. Because of flow separation effects, the plain blade consistently fell short of satisfying the design requirements. The tandem blade surface velocity distribution

and blade loads agreed well with theoretical values. Suction surface diffusion factor requirements were met or exceeded. High speed flow visualization studies showed that flow separation was prevented to the trailing edge of the tandem secondary airfoil. The tandem hub, mean, and tip blade sections were 1.2, 6.2, and 2.7%, respectively, in excess of satisfying the required change in tangential velocity across the blade row, while the comparable plain blade sections were 9.0, 8.5, and 11.1% deficient. NEWTONIAN AERODYNAMICS FOR CIRCULAR CONES MODIFIED TO PRODUCE LIFT AT ZERO ANGLE OF ATTACK

Barbara J. Short Washington May 1969 32 p refs

(NASA-TN-D-5193) Avail: CFSTI CSCL 01A

A parametric study was conducted to determine the theoretical aerodynamic characteristics of right circular cones modified to produce lift at zero angle of attack. In the modification, portions of the cone lying above and behind an inclined plane surface were removed. Newtonian impact theory was used to express force and moment coefficients as functions of the manner in which the cone is terminated by this cutting plane at the base. In addition, relationships were formed that allow limits of acceptable design and performance characteristics to be imposed, such as lower limits of useful volume and lift-drag ratios, assurance of maintaining supersonic flow over the trailing edges, and the permissible range of center-of-gravity locations to assure trim at zero angle of incidence. The configurations studied suggest that it is practical to trim cones at a useful level of lift-drag ratio without inclining the axis of the basic cone relative to the airstream. Author

INVESTIGATION OF A CLASS OF BODIES THAT GENERATE FAR-FIELD SONIC BOOM SHOCK STRENGTH AND IMPULSE INDEPENDENT OF BODY LENGTH AND VOLUME

Raymond L. Barger and Frank L. Jordan, Jr. Washington May 1969 16 p refs

(NASA-TN-D-5148) Avail: CFSTI CSCL 01A

A design method is studied which provides a means of continually increasing the volume of a body without increasing the maximum overpressure or impulse. A sequence of three sonic-boom-generating bodies having length ratios of 1:2.5:4 and volume ratios of 1:7.6:16.6 was designed and tested. The results of the experiments, together with theoretical considerations, indicate that in the far field, the essential signature characteristics (maximum overpressure and impulse) are virtually the same for all three bodies. PRESSURE DISTRIBUTIONS ON 140°, 160°, and 180° CONES AT MACH NUMBERS FROM 2.30 TO 4.63 AND ANGLES OF ATTACK FROM 0° TO 20°

James F. Campbell and Dorothy H. Tudor Washington May 1969 148 p refs

(NASA-TN-D-5204) Avail: CFSTI CSCL 01A

Surface pressure distributions were experimentally obtained on spherically blunted cones with apex angles of 140°, 160°, and 180° (flat disk). The 140° and 160° cones had a ratio of nose radius to base radius of 0.25. Results indicate that an increase in cone angle or angle of attack or both leads to an increase in pressure windward of the measured stagnation point; a decrease in cone angle or an increase in angle of attack leads to a decrease in pressure leeward of the measured stagnation point. Mach number has little effect on the pressure distributions for the cones at zero angle of attack. At angles of attack greater than zero, an increase in Mach number results in a decrease in pressure on the leeward side of all the configurations. A correlation parameter successfully correlates the stagnation point locations for the entire range of test Mach number, cone angle, and angle of attack; an empirical representation of this correlation agrees with the experimental results. Pressure distributions at zero angle of attack agree with a theoretical solution based on the one-strip method of integral relations. Circumferential pressure distributions on large-angle conical bodies can be approximated by second-order polynomials. Author

TRANSONIC AERODYNAMIC CHARACTERISTICS OF HYPERSONIC LOW-WAVE-DRAG ELLIPTICAL BODY-TAIL COMBINATIONS AS AFFECTED BY CHANGES IN STABILIZER CONFIGURATION

Charles H. Fox, Jr. and Bernard Spencer, Jr. Washington May 1969 61 p refs

(NASA-TM-X-1789) Avail: CFSTI CSCL 01A

An investigation has been made in the Langley high-speed 7- by 10-foot tunnel at Mach numbers of 0.89, 0.95, and 1.17 to determine systematically the effects of various combinations of outboard-stabilizer and vertical-tail configurations on the longitudinal and lateral-directional stability and the aerodynamic performance of an elliptical hypersonic low-wave-drag body. The longitudinal area distribution of the body conformed to the theoretical shape required to minimize the zero-lift hypersonic pressure drag under the geometric constraints of given length and volume. The body had an elliptical cross section with a semiaxis ratio of 2 (major axis horizontal) and had an equivalent fineness ratio of 6.14. Base-mounted outboard stabilizers were tested at various dihedral angles alone and in combination with either a single center-line vertical tail or with a vee-tail. The angle of attack was varied from approximately $-4°$ to $18°$ at sideslip angles of 0 and -5 The results of the study indicate that the maximum untrimmed lift-drag ratio is improved considerably by the addition of the outboard stabilizers. The resultant performance is, however, sensitive to changes in the stabilizer dihedral for a given tail configuration. Author

EXPERIMENTAL INVESTIGATION IN AN ANNULAR CASCADE SECTOR OF HIGHLY LOADED TURBINE STATOR BLADING. VOLUME 2: PERFORMANCE OF PLAIN BLADE AND EFFECT OF VORTEX GENERATORS

James L. Bettner Washington NASA May 1969 148 p refs (Contract NAS3-9404)

(NASA-CR-1323; EDR-5315-Vol-2) Avail: CFSTI CSCL 21E

An annular cascade of six blades was designed and fabricated to exhibit the following aerodynamic characteristics: (1) equivalent weight flow per passage, (2) equivalent change in tangential velocity, (3) blade suction surface diffusion factor, Ds: 0.4. The plain blade was tested and the program base-line level of experimental performance was determined. Both flow visualization studies and aerodynamic measurements determined that flow separation occurred on the plain blade suction surface. The region of separated flow on the blade surface exhibited strong radial and circumferential variations. All of the blade configurations of the experimental program were designed for a radially constant suction surface diffusion factor of 0.4; however, plain blade diffusion factors of only

0.330, 0.332 and 0.312 were realized experimentally at the hub, mean, and tip sections, respectively. Also, the hub, mean, and tip sections were 9.0, 8.5, and 11.1% deficient in achieving the required change in tangential velocity across the blade row. Author

CHARTS FOR INTERPOLATION OF LOCAL SKIN FRICTION FROM EXPERIMENTAL TURBULENT VELOCITY PROFILES
Jerry M. Allen and Dorothy H. Tudor Washington 1969 42 p refs
(NASA-SP-3048) Avail: CFSTI CSCL 01A

Charts which allow the easy and rapid determination of local skin friction from experimental turbulent velocity profiles taken in air on smooth surfaces are presented. The charts, calculated from the Fenter–Stalmach law of the wall, cover Mach number range from 0 to 5 and are good for all Reynolds numbers and total temperature levels. Caution should be employed when using these charts with profiles taken under conditions of large heat transfer or pressure gradient because of the lack of reliable experimental verification of the theory under these test conditions. The use of these charts requires that the experimental profile be plotted on translucent paper to the same scale as the charts presented in this report and overlaid on the proper chart. Author

HYPERSONIC FLUTTER ANALYSIS USING MEASURED STATIC AERODYNAMIC DERIVATIVES, AND COMPARISON WITH EXPERIMENT
Robert C. Goetz Washington May 1969 52 p refs
(NASA-TN-D-5233) Avail: CFSTI CSCL 01A

A two-part investigation was conducted, the final intent being to evaluate a quasi-steady flutter analysis technique, using measured static aerodynamic derivatives, at hypersonic speeds. In the first part, static force and moment data were obtained for a series of square-planform double-wedge airfoils with both sharp and circularly blunted leading edges. Aerodynamic characteristics were obtained in helium flow over an angle-of-attack range of $-2°$ to 8° at Mach numbers of 6.8 and 15.3. The results indicate that increasing the leading-edge bluntness greatly increases the drag and decreases the lift at a given angle of attack at both Mach numbers. At a Mach number of 6.8 the aerodynamic center was found to shift forward with increase in bluntness, while at a Mach number of 15.3 there was a slight rearward shift. In the second part of the investigation, a two-degree-of-freedom quasi-steady flutter analysis, including rate terms, is formulated for these airfoils in terms of the experimentally determined slope of the lift curve and location of the aerodynamic center. These comparisons indicate that the pitch-rate term has a significant effect upon the flutter solution and should be included in the quasi-steady analysis. Author

EXPERIMENTAL DATA FOR TWO 1400-FEET PER SECOND TIP SPEED COMPRESSOR ROTORS OPERATED WITH INLET FLOW DISTORTIONS
Everett E. Bailey and Robert S. Ruggeri Washington May 1969 74 p refs Avail: CFSTI CSCL 01A

Data for two 1400-feet-per-second tip speed rotors operated with radial and circumferential flow distortions are presented for a range of equivalent rotor speeds from .50 to 100 percent. Rotor design pressure ratios were 1.6 and 1.76. Data are presented mostly in tabular form, and include radial and circumferential distributions of inlet and discharge total pressures and temperatures, and various wall static pressure measurements along the hub and outer casing. Uniform inlet flow data are included for comparison. Observations of flow conditions at near-stall, with and without distortion, are made. The desirability of comparing distortion data at zero stall margin is discussed. Author

JET EFFECTS ON BOATTAIL PRESSURE DRAG OF ISOLATED EJECTOR NOZZLES AT MACH NUMBERS FROM 0.60 TO 1.47
Douglas E. Harrington Washington May 1969 88 p refs
(NASA-TM-X-1785) Avail: CFSTI CSCL 20D

The cylindrical ejector nozzles were operated over a range of pressure ratios from approximately 1.0 (jet off) to 11 Results were obtained with both 15°and 10°boattail angles. The 15°configurations utilized different radii of curvature at the boattail juncture with a cylindrical forebody. Subsonically, the jet caused large reductions in boattail pressure drag whether the jet was under or overexpanded. A jet boundary simulator was effective in duplicating a fully expanded jet with an exit static-pressure ratio of one. Author

EXPERIMENTAL INVESTIGATION OF THE TURBULENT BOUNDARY LAYER ON A TYPICAL SUBSONIC TRANSPORT FUSELAGE
Richard D. Samuels Washington Jun. 1969 88 p refs
(NASA-TN-D-5242) Avail: CFSTI CSCL 01A

It was determined that the velocity profile can be approximated by use of the widely accepted two-dimensional power-law representation. The velocity index reflects the effects of longitudinal pressure gradient, unit Reynolds number, angle of attack, and to an undetermined degree both the inviscid and the boundary-layer cross flow. The fuselage was more nearly axisymmetric at the forward stations than at the aft stations; consequently, there was little difference found in the boundary-layer parameters with respect to circumferential locations over the forward portions of the fuselage but large deviations in the parameters were noted over the aft portion. For the small angles of attack ($-2°$ to 2°), the various boundary-layer thicknesses varied linearly with angle of attack along the top and bottom center lines of the fuselage, but no definite trends were established for stations along the side. No regions of separated flow were detected on the fuselage. Nash's method for calculating the turbulent boundary layer on a body of revolution when applied to a body having a circumference equal to that of the actual fuselage gave reasonable agreement at an angle of attack of 0° with experiment for all the boundary-layer parameters at all stations for which measurements were made. AERODYNAMIC INVESTIGATION OF SHARP CONE-CYLINDER SPIKES ON 120 DEGREE BLUNTED CONES AT MACH NUMBERS OF 3.00, 4.50, AND 6.00
Robert J. McGhee and W. Frank Staylor Washington Jun. 1969 42 p refs
(NASA-TN-D-5201) Avail: CFSTI CSCL 01A

Some effects of sharp cone-cylinder spikes located at the apex of two 120° spherically blunted cones were investigated at free stream Mach numbers of 3.00, 4.50, and 6.00 at angles of attack of 0°, 2°, and 5°. Spikes of various lengths, diameters, and tip angles were tested, and surface-pressure distributions and schlieren photographs were obtained for the models. The free-stream Reynolds numbers were 6.89, 2.95 and 3.64 $\times$ 10^6 per meter at free-stream Mach numbers of 3.00, 4.50, and 6.00, respectively. Several distinct types of flow which occurred on the spikes were found to be a function of the parameter l/δ, the ratio of the spike-cylinder length to the bow-shock stand-off distance at the stagnation point. For spike lengths of $l/\delta < 0.8$, subsonic steady flow existed over the entire model with a small region of separated flow near the spike. The bow shock was detached and unsteady in the vicinity of the spike for $0.8 < l/\delta < 1.0$. The bow shock attached to the spike tip at about $l/\delta = 1.1$ and remained steady until flow oscillation again occurred at $l/\delta > 2.2$. A region of relatively low pressure separated flow occurred behind the attached bow shock and was followed by a high reattachment pressure near the intersection of the attached spike shock and detached body shock. TRANSONIC AERODYNAMIC CHARACTERISTICS OF TWO HYPERSONIC CRUISE CONFIGURATIONS
Richard A. Langhans Washington Jun. 1969 98 p refs
(NASA-TM-X-1816) Avail: CFSTI CSCL 01A

An investigation was conducted in the 8-foot transonic pressure tunnel to determine the aerodynamic characteristics of two hypersonic cruise airplane configurations. The investigation was conducted at Mach numbers ranging from 0.80 to 1.20, angles of attack from approximately $-5°$ to 15°, and constant Reynolds number per meter of 13.12 $\times$ 10^6. The results of the investigation show the distinct wing-body configuration is longitudinally unstable for the chosen center-of-gravity location and has a pitch-up tendency. This configuration is directionally stable and has positive effective dihedral. The blended wing-body configuration is longitudinally stable at Mach numbers greater than 0.90 and unstable at Mach numbers from 0.80 to 0.90. This configuration is directionally stable and has positive effective dihedral. Author

AN EXPERIMENTAL AND THEORETICAL INVESTIGATION OF A SYMMETRICAL AND A CAMBERED DELTA WING CONFIGURATION AT MACH NUMBERS FROM 2.0 TO 10.7
Walter P. Nelms, Jr., Ralph L. Carmichael, and Charles R. Castellano Washington Jun. 1969 34 p refs
(NASA-TN-D-5272) Avail: CFSTI CSCL 01A

The effect of wing camber on the longitudinal aerodynamic characteristics was studied for a configuration representative of an airplane designed to cruise at hypersonic speeds. A 70° swept delta wing with a symmetrical section and 4-percent thickness ratio was compared to one of identical planform and thickness which was cambered so as to have a flat lower surface. Experiment data were obtained at eight Mach numbers from 1.99 to 10.70 and compared with estimates from three different theoretical procedures. It was found that a configuration with a flat-bottomed wing was in no way superior to a similar configuration with a symmetrical wing section. In fact, at the lowest Mach numbers of this study the flat-bottomed wing had a large negative pitching moment at zero lift, which would indicate fairly substantial values of trim drag. The characteristics could be predicted with fair accuracy by the tangent-wedge/tangent-cone procedure. Author

USE OF TETRAFLUOROMETHANE TO SIMULATE REAL-GAS EFFECTS ON THE HYPERSONIC AERODYNAMICS OF BLUNT VEHICLES
Robert A. Jones and James L. Hunt Washington Jun. 1969 134 p refs
(NASA-TR-R-312) Avail: CFSTI CSCL 01A

An experimental and theoretical study was made of the use of CF_4 in low hypersonic flows as a means of simulating the flow field over the forebody of blunt configurations in hypersonic flight where dissociation of the gas in the shock layer gives large density ratios across the shock wave. A pilot model hypersonic CF_4 blowdown tunnel was built and studied. With this facility a normal-shock density ratio of 12.1 was obtained at a Mach number of 6 with stagnation conditions of 1650 N/cm^2 and 736°K. The results indicate that flow fields over the forebody of blunt configurations for real-gas conditions resulting in normal-shock density ratios up to 17 can be simulated by this method. A computer program for isentropic flow of CF_4 as well as flow across normal and oblique shocks was set up. Plots of various flow parameters are presented as a function of free-stream Mach number for various stagnation temperatures. A method for computing axisymmetric nozzle contours which includes a correction for boundary-layer displacement thickness is described. Author

MEASUREMENTS OF MUTUAL INTERFERENCE HEATING FOR A PROBE ANTENNA MOUNTED ON AN APOLLO REENTRY CONFIGURATION
Robert A. Jones and James L. Hunt Washington Jun. 1969 38 p refs
(NASA-TM-X-1787) Avail: CFSTI CSCL 01A

A study was made at a Mach number of 8 to determine the interference heating effects of a probe antenna located on the windward afterbody of an Apollo model at a 25° angle of attack and protruding ahead of the undisturbed main bow shock. The interference heating effects were observed to occur only on the windward part of the afterbody. The presence of the probe antenna resulted in peak heating rated as large as 23 times the local value for a model without a probe or 2.3 times the reference heat transfer coefficient, which was the calculated heat transfer at the stagnation point of the Apollo model at an angle of attack of 0° This interference heating to the afterbody was very sensitive to Reynolds number with the highest heating rates occurring at the highest Reynolds numbers. The maximum interference heating rates to the probe occurred at the point where the slip-flow line emanating from the intersection of the body bow shock and the probe shock impinged on the lower edge of the probe. The value of this maximum heat transfer rate to the probe was 15.5 times

the reference value or 1.3 times the estimated value for the probe leading edge subjected to the undistrubed local flow conditions immediately behind the body bow shock. Author

ANALYSIS OF TWO DIMENSIONAL INVISCID MODEL OF JET IMPINGEMENT UNDER VERTICAL-TAKEOFF AIRPLANE
Robert Siegel and Marvin E. Goldstein Washington Jul. 1969 36 p refs
(NASA-TN-D-5288) Avail: CFSTI CSCL 01A

Conformal mapping was used to obtain the free streamline pattern and surface pressure distribution for downward jet flow issuing from two parallel slot nozzles. After striking the ground, a portion of the flow from each jet moves along the ground toward the centerline between the jets. When these two portions collide, an upflow results which strikes a plate above the ground simulating the undersurface of an airplane fuselage. Typical flow patterns are shown to illustrate the effect on the free streamlines of nozzle height, nozzle spacing, plate height, plate width, and plate angle. Author

CHARACTERISTIC DESIGN STUDY OF MIXED-COMPRESSION TWO-DIMENSIONAL INLETS WITH LOW-ANGLE COWLS FOR THE MACH NUMBER RANGE 2.70 TO 1.80
Bernhard H. Anderson Washington Jul. 1969 37 p refs
(NASA-TN-D-5330) Avail: CFSTI CSCL 01A

An analytical study was performed to evaluate the effects of several design variables at off-design Mach numbers. Major improvements were realized in overall surface Mach number distributions at off-design conditions by decreasing the internal compression rate in two ways: (1) extending the overall supersonic compression length to avoid surface inflection point, and (2) requiring greater compressive turning by the cowl lip shock. Decreasing the compression rate provided nearly equal cowl and centerbody Mach numbers and Mach number gradients on design. Author

INFLATION AND PERFORMANCE OF THREE PARACHUTE CONFIGURATIONS FROM SUPERSONIC FLIGHT TESTS IN A LOW-DENSITY ENVIRONMENT
Charles H. Whitlock and Richard J. Bendura Washington Jul. 1969 53 p refs
(NASA-TN-D-5296) Avail: CFSTI CSCL 01C

Ten flight tests of modified-ringsail, disk-gap-band, and cross parachute configurations with deployment initiated at Mach numbers and dynamic pressures corresponding to conditions expected during entry into a Martian atmosphere have been completed. Comparison of flight results indicates that theoretical snatch force values were never exceeded when the deployment techniques of these tests were used. Opening loads showed no definite trend with Mach number. Values for filing times compared favorably with generally accepted empirical curves based on 15-percent geometric porosity. Canopy stability was good when Mach numbers were below 1.4 for the modified-ringsail and disk-gap-band configurations. At higher Mach numbers, one test of the disk-gap-band configuration showed canopy fluctuations. The cross-parachute canopies did not achieve a stable configuration during the data period. Comparison of the drag coefficients indicates that the cross parachute produced the highest values and the modified-ringsail values were slightly higher than those of the disk-gap-band configuration. SUBSONIC SPHERE DRAG MEASUREMENTS AT INTERMEDIATE REYNOLDS NUMBERS
Kenneth R. Sivier and J. A. Nicholls Washington NASA Jul. 1969 79 p refs
(Grant NGR-23-005-003)
(NASA-CR-1392) Avail: CFSTI CSCL 01A

The drag of spheres, at subsonic Mach numbers and Reynolds numbers from 25 to 4000, was studied in a continuous wind tunnel using a one-component, magnetic support-and-balance system. The low turbulence incompressible results verified this experimental approach, especially at Reynolds numbers below 300 where the spherical models were not disturbed by unsteady lateral forces. Measurements were also made to evaluate the effects of compressibility, slip flow (Knudsen numbers up to 0.04), sphere surface roughness, and free-stream turbulence (intensities up to 8%). Author

INVESTIGATION OF A 0.3-SCALE JET-TRANSPORT MODEL HAVING A JET-AUGMENTED *BOUNDARY-LAYER-CONTROL* FLAP WITH *DIRECT-LIFT* CONTROL CAPABILITY
Kiyoshi Aoyagi, Stanley O. Dickinson, and Paul T. Soderman (Army Aeron. Res. Lab.) Washington Jul. 1969 86 p refs
(NASA-TN-D-5129) Avail: CFSTI CSCL 01B

An investigation was conducted to define a trailing edge flap system for a large scale subsonic jet transport model that would provide high lift at low-thrust-to-weight ratios (0.05 to 0.10) and direct lift control. The model has a 35° swept wing of aspect ratio 6.43 and four pod-mounted engines under the wing. The flap system was externally jet-augmented from the exhaust of the inboard jet engines. The flap system consisted of a main flap with blowing boundary layer control and a small auxiliary flap for providing direct lift control. Results were obtained with three boundary layer control arrangements and two different auxiliary flap chords at several main and auxiliary flap deflections. Three-component longitudinal data and descent capabilities of the model with the resultant flap system are presented. The results of descent performance computations indicate that the resultant flap system is capable of providing ±0.2 g incremental acceleration normal to the flight path at an approach speed of 117 knots(1 g flight wing loading = 53 psf) or a 4° change in flight-path angle with a thrust-to-weight ratio of 0.05. A STUDY OF HELIUM PENETRATION AND SPREADING IN A MACH 2 AIRSTREAM USING A DELTA WING INJECTOR

Louis A. Povinelli, Frederick P. Povinelli, and Martin Hersch Washington Jul. 1969 17 p refs

(NASA-TN-D-5322) Avail: CFSTI CSCL 01B

Experiments were conducted to determine if vortices could aid the penetration and spreading of helium in a Mach 2 airstream. A half-delta-wing injector, having a 30° semiapex angle and a 12° angle of attack, was used. This delta configuration was designed to produce leading edge vortices into which helium was injected. A flat plate of the same blockage area and at the same angle of attack was also run for comparison. Measured helium concentration showed that the half-delta injector was more effective than the angled flat plate in achieving greater penetration along the vortex position. The spreading was also larger with the delta injector. Author

SHOCK SHAPES AND PRESSURE DISTRIBUTIONS FOR LARGE ANGLE POINTED CONES IN HELIUM AT MACH NUMBERS OF 8 AND 20

David A. Stewart and Mamoru Inouye Washington Jul. 1969 22 p refs

(NASA-TN-D-5343) Avail: CFSTI CSCL 01A

Bow-wave shapes and surface pressures were measured in helium at Mach numbers 8 and 20 on pointed cones with semivertex angles from 52° to 90°. For large cone angles ($\geq 65°$) the bow wave was nearly spherical, the bow-wave shape and surface pressure distribution were predicted adequately by both the method of integral relations and the method of Kaattari, and the bow-wave shape was not influenced by cone angle or a small amount of bluntness. For cone angles approaching shock attachment (attachment $< \sigma < 65°$) where the bow wave was no longer spherical, the method of integral relations adequately predicted the shock shape and surface pressure distribution. The Kaattari method was not applicable for these conditions. Author

ANALYTICAL INVESTIGATION OF TWO-DIMENSIONAL LOSS CHARACTERISTICS OF SUPERSONIC TURBINE STATOR BLADES

Louis J. Goldman and Michael R. Vanco Washington Jul. 1969 22 p refs

(NASA-TM-X-1823) Avail: CFSTI CSCL 01A

An analysis was conducted to determine the loss characteristics of two-dimensional, minimum length, supersonic nozzles with sharp-edged throats. Boundary layer characteristics were calculated and used to obtain the conditions downstream of the nozzles after the flow had mixed to a uniform state. Subsonic, sonic, and supersonic aftermixing axial Mach number solutions were obtained for this model. The loss characteristics were investigated for nozzles designed over an exit Mach number range of 1.5 to 5.0. The effect of nozzle flow angle, throat Reynolds number, and specific heat ratio on losses were studied. Author

EFFECTS OF WING PLANFORM ON THE STATIC AERODYNAMICS OF A CRUCIFORM WING-BODY MISSILE FOR MACH NUMBERS UP TO 4.63

M. Leroy Spearman and Charles D. Trescot, Jr. Washington Jul 1969 140 p refs

(NASA-TM-X-1839) Avail: CFSTI CSCL 01A

Wind tunnel tests were made to determine the longitudinal and lateral aerodynamic characteristics of a cruciform wing–body missile configuration with various wing planforms. The planforms included a family of delta wings and a family of rectangular wings having a constant root chord but varying spans. In addition, a cranked-tip planform was included, and some limited tests were made to determine the longitudinal location effects for a rectangular wing. All configurations were tested at Mach numbers from 1.50 to 4.63 and, in addition, limited transonic results were obtained in the 8-foot transonic pressure tunnel for the body alone and the body with one of the rectangular wing planforms. The results are summarized in the form of various pertinent aerodynamic parameters as a function of Mach number. The summary of results is useful in demonstrating the importance of certain parameters, and should be useful in providing a source of systematic experimental data for future correlation with analytical techniques. EXPERIMENTAL FLOW PROPERTIES IN THE WAKE OF A 120° CONE AT MACH NUMBER 2.20

James F. Campbell and Josephine W. Grow Washington Jul. 1969 55 p refs

(NASA-TN-D-5365) Avail: CFSTI CSCL 01A

An investigation has been conducted to obtain flow properties in the wake of a 120° cone at a free-stream Mach number of 2.20 Free-stream Reynolds number based on model (base) diameter was 0.66×10^6 for the study. Measured total and static pressures were used to calculate the appropriate flow properties which are presented in tabular form. Results typical of the tabulated data indicate that the largest gradients in the flow properties occur at the location in the wake near the neck-down or recompression region. The wake profiles tend to smooth out farther downstream to the extent that static pressure becomes essentially constant across the wake. Velocity distributions at these distances were predicted empirically by considering velocity as a power-law function of longitudinal distance from the cone and as an exponential function of radial distance from the wake center. Author

SUPERSONIC AERODYNAMIC CHARACTERISTICS AND SHOCK STANDOFF DISTANCES FOR LARGE-ANGLE CONES WITH AND WITHOUT CYLINDRICAL AFTERBODIES
James F. Campbell Washington Aug. 1969 97 p refs
(NASA-TN-D-5334) Avail: CFSTI CSCL 01A

Results of this study indicated that all the cone configurations were statically stable with the moment center located at the cone base. Addition of cylindrical afterbody sections resulted in increases in stability throughout the Mach number range. Axial force increased as cone semiapex angle was increased, a maximum being approached for the flat disk. Throughout the angle-of-attack range, addition of cylindrical afterbody sections resulted in reductions in axial force that were not more than 4 percent for all combinations of cone semiapex angles and cylinder lengths and were less than 3 percent for most combinations. Normal force and lift decreased as cone semiapex angle was increased, minimum values being obtained for the flat disk; an increase in these forces resulted when cylindrical afterbody sections were added. Shock standoff distance for any body with a detached shock wave appeared to be uniquely dependent on the inverse square of the density ratio across a normal shock. This dependence allowed shock standoff distance for the conical bodies to be adequately predicted within the test range of cone semiapex angles and Mach numbers. Author

WIND-TUNNEL INVESTIGATION OF AN STOL AIRCRAFT CONFIGURATION EQUIPPED WITH AN EXTERNAL-FLOW JET FLAP
Lysle P. Parlett and James P. Shivers Washington Aug. 1969 86 p refs
(NASA-TN-D-5364) Avail: CFSTI CSCL 01A

The present investigation was performed to provide information on the static longitudinal and lateral characteristics of a proposed short take-off and landing (STOL) transport configuration utilizing the jet-flap principle. Longitudinal tests were conducted at engine gross-thrust coefficients of from 0 to 3.4 through a range of angle of attack which included the stall; and lateral tests were made, both power-off and power-on, through a sideslip range of $\pm 30^\circ$ at angles of attack of 0° and 10°. Untrimmed lift coefficients up to 7.8 were attained at a gross-thrust coefficient of 2.83 in the tail-off condition. With the tail on, nearly all high-lift conditions were characterized by a marked longitudinal instability which began at an angle of attack of 7°. The instability was apparently caused by the tip vortices which, under the influence of the highly loaded center section of the wing, were drawn into the region of the horizontal tail. The tail-on configuration was directionally stable and had positive dihedral effect at all flap and power settings tested; and in the take-off and landing conditions increasing power increased directional stability and decreased dihedral effect. With one outboard engine not operating, the model could be trimmed laterally and directionally up to lift coefficients of 4.2 in the take-off condition and 5.7 in the landing condition. Author

AERODYNAMIC INTERFERENCE EFFECTS CAUSED BY PARALLEL-STAGED SIMPLE AERODYNAMIC CONFIGURATIONS AT MACH NUMBERS OF 3 AND 6
John P. Decker Washington Aug. 1969 85 p refs
(NASA-TN-D-5379) Avail: CFSTI CSCL 01A

A wind tunnel investigation has been conducted to examine the aerodynamic interference effects associated with simple three dimensional aerodynamic configurations placed parallel and in close proximity to each other. The configurations were 10° half-cone bodies that varied in length and were tested with and without simple delta wings. The flat surfaces of the configurations were adjacent to each other during testing. The effects of vertical spacing and relative incidence angle between the configurations were measured, and the resulting data were used to determine the influence of relative body size, nose bluntness, and lifting surfaces on the longitudinal aerodynamic characteristics of the lower configuration at Mach numbers of 3 and 6. Increasing the size of the upper configuration generally caused a progressive decrease in the normal-force-curve slope and a progressive decrease in the static longitudinal stability of the lower configuration. For the upper configuration larger than the lower configuration, the data suggest some form of progressive blanketing since the normal-force-curve slope decreases to zero and even negative values at some of the vertical spacings investigated. Increasing the incidence angle of the upper configuration generally caused nose-up increments in the pitching-moment coefficient and negative increments in the normal-force coefficient of the lower configuration. RECIRCULATION EFFECTS PRODUCED BY A PAIR OF HEATED JETS IMPINGING ON A GROUND PLANE
Gordon R. Hall and Kenneth H. Rogers Washington NASA May 1969 115 p refs
(Contract NAS1-7834)
(NASA-CR-1307) Avail: CFSTI CSCL 01A

An experimental investigation of the recirculation effects resulting from the interaction of a pair of heated jets, a quiescent environment, a ground plane, and a pair of inlets was performed. Upwash blockage surfaces were also used for selected tests. Inlet temperature rise and upwash flow characteristics were determined for a wide range of model geometries and inlet/nozzle flow conditions. Details of the near flow field structure were obtained. Inlet temperature rise and induced aerodynamic forces have been related to the character of the near flow field. The results of the investigation lead to several significant conclusions which relate directly to model simulation of full scale recirculation phenomena. Author

AERODYNAMIC CHARACTERISTICS IN PITCH OF A 1/7-SCALE MODEL OF A TWO- AND THREE-STAGE ROCKET CONFIGURATION AT MACH NUMBERS OF 0.4 TO 4.63
William F. Hinson, Richard A. Langhans, and Roger H. Fournier Washington Aug. 1969 40 p refs
(NASA-TM-D-5378) Avail: CFSTI CSCL 01A

An investigation has been conducted to determine the longitudinal stability characteristics of the upper two- and three-stage combinations of a four-stage solid-propellant unguided rocket research vehicle. The stages tested were stabilized by trapezoidal cruciform fins. Test Mach number range for the three-stage configuration was 0.4 to 1.0; for the two-stage configuration, 0.4 to 4.63. Angle-of-attack range was approximately -4^0 to 14^0. Reynolds number ranged from 1.5×10^6 to 3.4×10^6 per foot (4.92×10^6 to 11.14×10^6 per meter). The general aerodynamic characteristics of normal-force, pitching-moment, and drag coefficients as a function of angle of attack and Mach number are presented. Author

AERODYNAMIC EFFECTS OF BULBOUS BASES
Lars E. Ericsson and J. Peter Reding Washington NASA Aug. 1969 116 p refs
(Contract NAS1-6450)
(NASA-CR-1339; LMSC-4-17-68-4) Avail: CFSTI CSCL 01A

An exploratory study has been made of the effect that a bulbous base can have on the aerodynamic characteristics of blunt space capsules and slender reentry bodies. It is found that the base has a profound effect and can cause drastic loss of dynamic stability. A careful examination of available experimental data reveals that the often complex effects of bulbous bases can be explained using quasi-steady separated flow concepts. In general, a bulbous base adversely affects the vehicle dynamics but increases the static stability. Support interference is a serious problem that can prevent simulation in dynamic wind tunnel tests of full-scale vehicle dynamics. A possible means of measuring and correcting for this dynamic sting interference is outlined. Author

PRESSURES AND HEAT TRANSFER ON A 75 DEGREE SWEPT DELTA WING WITH TRAILING-EDGE FLAP AT MACH 6 AND ANGLES OF ATTACK TO 90 DEGREES
J. Wayne Keyes Washington Sep. 1969 46 p refs
(NASA-TN-D-5418) Avail: CFSTI CSCL 01A

An investigation has been made of the effects of deflecting a flap on the flow field on a 75° swept delta wing with sealed gap for angles of attack from 0° to 90°. Pressure and heat-transfer measurements were made with the free-stream Reynolds number (based on wing root chord) varying from 1.3×10^6 to 5.6×10^6 for 0° angle of attack and at 3.4×10^6 for angles greater than 0°. Flap deflections from 0° to 40° were investigated. In general, center line calculations based on existing two-dimensional methods were in good agreement with the trends of the pressure and heat-transfer distributions if the flow pattern characteristic of the angle-of-attack range and the type of boundary layer are taken into account. BODIES OF REVOLUTION HAVING MINIMUM TOTAL DRAG IN HYPERSONIC FLOW
Waldo I. Oehman and Sylvia A. Wallace Washington Sep. 1969 53 p
(NASA-TN-D-5438) Avail: CFSTI CSCL 01A

The calculus of variations was used to study minimum-drag bodies in hypersonic flow. Newton's formula for pressure drag was assumed, and viscous drag was formulated by use of a variable local skin-friction coefficient. Numerical results are included to assess the effect of the viscous drag for bodies having either given length and base height or given length and volume. The computer program is included for convenience. Author

FORTRAN PROGRAM FOR CALCULATING TRANSONIC VELOCITIES ON A BLADE-TO-BLADE STREAM SURFACE OF A TURBOMACHINE
Theodore Katsanis Washington Sep. 1969 99 p refs
(NASA-TN-D-5427) Avail: CFSTI CSCL 01A

A method was developed to obtain a transonic flow solution on a blade-to-blade surface of a turbomachine. The blade may be fixed or rotating. The flow may be axial, radial, or mixed. The results include velocities on the blade surface and throughout the passage. The transonic solution is obtained by a velocity-gradient method, using information obtained from a finite-difference stream-function solution at a reduced weight flow. Author

FLIGHT-MEASURED AERODYNAMIC DRAG OF TWO LARGE EXTERNAL TANKS ATTACHED TO THE X-15-2 AIRPLANE AT MACH NUMBERS OF 1.6 TO 2.3
David F. Fisher Washington Oct. 1969 15 p refs
(NASA-TM-X-1895) Avail: CFSTI CSCL 01A

Full-scale power-on flight lift and drag measurements were made on the X-15-2 airplane just before and just after two large external fuel tanks were ejected. By subtracting the drag of the airplane after tank ejection from the drag of the airplane before tank ejection, the incremental drag due to the tanks was determined. Analysis of the data showed that the percentage increase of incremental drag due to the tanks was almost equal to the percentage increase in cross-sectional area caused by the tanks. A buildup drag estimate based on free-stream conditions agreed well with the flight data; whereas, the wind -tunnel data, although they had the same general trend of tank drag coefficient with Mach number, were lower than both the estimate and the flight data. EFFECT OF HYPERSONIC RESEARCH ENGINE INSTALLATION ON AERODYNAMIC CHARACTERISTICS OF 0.0667-SCALE MODEL OF X-15A-2 AIRPLANE AT MACH NUMBERS FROM 1.75 TO 4.63

Ernald B. Graves Washington Aug. 1969 186 p ref
(NASA-TM-X-1840) Avail: CFSTI CSCL 01A

An investigation was conducted in a wind tunnel to determine the effect of the proposed hypersonic research engine (HRE) installation on the aerodynamic characteristics of a 0.0667-scale model of the X-15A-2 research vehicle. Test Mach numbers ranged from 1.75 to 4.63 at a constant Reynolds number of 3.0×10^6 per foot (9.84×10^6 per meter). The angle of attack range was from about $-5°$ to $20°$ and the angle of sideslip range was from about $-4°$ to $9°$. Test results indicate that the installation of the hypersonic research engine on the X-15A-2 research vehicle will not generally produce any significant adverse effects on the static stability and control characteristics of the airplane. As expected, there is a small drag increase due to the presence of the engine. Shock patterns emanating from the leading edges of the wing and landing skid appear to be interacting with the flow field forward of the HRE inlet. This interaction would significantly influence the performance of the HRE. Author

AERODYNAMICS AND FLIGHT DYNAMICS OF TURBOJET AIRCRAFT

T. I. Ligum Sep. 1969 248 p refs Transl. into ENGLISH of the book "Aerodinamika i Dinamika Poleta Turboreaktivnykh Samoletov" Moscow, 1967 p 1-246
(NASA-TT-F-542) Avail: CFSTI CSCL 01A

The physical bases of high-speed aerodynamics, and the influence of air compressibility on the aerodynamic characteristics of wings and aircraft are presented. Primary attention is turned to passenger jets. The following areas are covered: takeoff characteristics of jets and methods of improving them; best climbing modes; horizontal flight; the descent; the landing approach; turns and corners; controllability and stability; icing and its influence on flying characteristics; and the characteristics of modern jet engines. DEVELOPMENT OF THREE-DIMENSIONAL PRESSURE-DISTRIBUTION FUNCTIONS FOR LIFTING SURFACES WITH TRAILING-EDGE CONTROLS BASED ON THE INTEGRAL EQUATION FOR SUBSONIC FLOW

Alfredo Navarro Crespo and Herbert J. Cunningham Washington Oct. 1969 74 p refs
(NASA-TN-D-5419) Avail: CFSTI CSCL 01A

For partial-span control surfaces of the trailing-edge flap type with leading-edge hinge and sealed gaps, a series of lifting pressure distributions are developed for deflected and deformed flaps on thin, swept, tapered wings for use in aeroelastic analysis. Solutions for the steady case are presented that overcome the fundamental problem of determining the nature and distribution of the pressure singularity along the flap leading edge and provide an advanced basis for extension to the oscillating case of flutter. LARGE-SCALE WIND-TUNNEL INVESTIGATION OF AN M1-L LIFTING BODY WITH AN INFLATABLE AND A RIGID AFTERBODY

Kenneth W. Mort and Michael D. Falarski (Army Aeron. Res. Lab.) Washington Oct. 1969 29 p refs
(NASA-TN-D-5468; A-2894) Avail: CFSTI CSCL 01A

The M1-L lifting body concept employs a high volumetric efficiency forebody and an inflatable afterbody that is deployed to provide lift-to-drag ratios sufficient for horizontal landings. The purpose of the investigation described here was to determine the low-speed aerodynamic characteristics of a large-scale model with an inflatable afterbody. In addition, a model with a rigid afterbody was tested as a datum for aeroelastic characteristics. Deployment of the inflatable afterbody increased the maximum lift-to-drag ratio (L/D) from less than 1 to slightly more than 2. This value was about 15 to 20 percent less than that for the model with the rigid afterbody. Because a maximum L/D of about 2-1/2 is the minimum value required to accomplish a horizontal landing, this 20-percent reduction appeared to be the most significant effect of flexibility. Studies indicated that deployment of the inflatable afterbody is mechanically feasible. Author

SUPERSONIC LIFTING CAPABILITIES OF LARGE-ANGLE CONES

James F. Campbell and Dorothy T. Howell Washington Oct. 1969 66 p refs
(NASA-TN-D-5499) Avail: CFSTI CSCL 01A

Experimental data were obtained on wind-tunnel models at Mach numbers from 1.41 to 4.63 for a Reynolds number of 0.8×10^6 based on model base diameter. Cone semiapex angles ranged from $40°$ to $90°$ (disk). Results indicated that transverse displacement of the center of gravity vertically from the vehicle longitudinal center line is an effective method of producing trim lift on large-angle cones, the trim lifting capability increasing with increase in cone semiapex angle. An increase in cone semiapex angle decreases the transverse center-of-gravity displacement required to achieve a given value of trim lift-drag ratio, and correspondingly lowers trim angle of attack, and increases trim drag. Transverse displacement of the center of gravity up to 4 percent of the base diameter from the longitudinal center line results in continual decreases in trim drag to values that are about 80 percent of the trim drag obtained for the center of gravity located on the longitudinal center line. For all combinations of cone semiapex angle and transverse center-of-gravity location, trim drag is essentially constant at Mach numbers greater than 2. Rearward longitudinal displacement of the center of gravity from the cone base to 10 percent of the base diameter has little or no effect on the trim aerodynamic characteristics obtained by transverse center-of-gravity shift for cones with semiapex angles equal to or greater than $70°$. PRESSURE DISTRIBUTION OF A LARGE SEMISPAN TILTING WING WITH 0.4-DIAMETER-CHORD, SINGLE-SLOTTED FLAP, AND A SINGLE PROPELLER 0.22 CHORD BELOW WING

Marvin P. Fink and Charles C. Smith, Jr. Washington Oct. 1969

01 AERODYNAMICS

380 p refs
(NASA-TN-D-5481) Avail: CFSTI CSCL 01A

The model consisted of a semispan wing-propeller combination and half fuselage. The tests were made for both up-at-the-tip modes of propeller rotation, with and without a leading edge slat and with and without fences. The tests consisted of the measurement of the wing surface pressures over a range of angles of attack from 5° to 80° for thrust coefficients of 0.90, 0.80, 0.60, and 0.30 for flap deflections at 0°, 20°, 40°, and 60°. The data are presented in tabulated form with only a minimum of analysis. Author

AIRCRAFT WITHOUT WINGS.

C. A. Syvertson (NASA, Ames Research Center, Moffett Field, Calif.).

Science Journal, vol. 4, Dec. 1968, p. 46-51.

Discussion of the M2-F1 and M2-F2 wingless aircraft, which will enable astronauts to make their own landings at an airport of their own choice. These aircraft are of the lifting-body type, and the basic shape from which they were evolved was a cone. At modest cost, these vehicles are capable of reconciling the very different demands of hypersonic atmosphere entry and conventional airfield landing. It is suggested that the lifting body aircraft offers an attractive, proven alternative to purely ballistic manned capsules.

Light aircraft that encounter the trailing vortex system generated by heavy transport aircraft can experience high roll rates, loss of altitude, and large structural loads. Envelopes of vortex system velocities, duration, and movement for various wind conditions have been determined. Specific operational procedures for the takeoff, landing, and en route phases of flight are suggested to enable the light aircraft pilot to avoid the wake turbulence of heavy aircraft.

V/STOL SESSION INTRODUCTORY AND REVIEW PAPER.

John P. Campbell (NASA, Langley Research Center, Hampton, Va.).

(New York Academy of Sciences, International Congress on Subsonic Aeronautics, New York, N.Y., Apr. 3-6, 1967.)

New York Academy of Sciences, Annals, vol. 154, Nov. 22, 1968, p. 843-855. 7 refs.

Description of the basic characteristics of V/STOL aircraft with emphasis on propeller, ducted fan, and turbojet types. An illustration of the basic tradeoffs between hovering capability and cruising speed is given for the various V/STOL types. It is shown that the compound helicopter achieves higher speeds by unloading the rotor and using an additional means of propulsion for cruising flight. It is concluded that the various V/STOL types afford a wide range of capabilities to satisfy a variety of mission requirements and that at least two or three V/STOL types in addition to the helicopter will eventually see wide-spread operational use.

NASA RESEARCH ON FLEXIBLE WINGS.

Francis M. Rogallo (NASA, Langley Research Center, Hampton, Va.).

(New York Academy of Sciences, International Congress on Subsonic Aeronautics, New York, N.Y., Apr. 3-6, 1967.)

New York Academy of Sciences, Annals, vol. 154, Nov. 22, 1968, p. 953-961. 16 refs.

Review of the presently known characteristics and possible future applications of flexible wings. Among the various flexible wings, the all-flexible wing is exciting much interest because - for the same gross weight and steady sink speed - it requires only 1/10 as much area as the conventional parachute. Stiffened high-performance flexible wings show promise of becoming economical, lightweight, rugged, stowable wings for cargo tow gliders, and a variety for sports gliders; they may also be useful in the recovery of boosters and hypersonic aircraft. Attempts to use stiffened flexible wings were not encouraging because a greater performance is needed than that provided by the rigid or inflated frame of wings of conical shape used. Wind-tunnel results show that the maximum lift-drag ratio of the single-keel wing is about 2-1/2 while that of the twin-keel wing is about 3.

LIFTING-BODY RESEARCH VEHICLES IN A LOW-SPEED FLIGHT TEST PROGRAM.

John G. McTigue and Bertha M. Ryan (NASA, Flight Research Center, Edwards AFB, Calif.).

(New York Academy of Sciences, International Congress on Subsonic Aeronautics, New York, N.Y., Apr. 3-6, 1967.)

New York Academy of Sciences, Annals, vol. 154, Nov. 22, 1968, p. 1014-1032.

Discussion of a multiphased flight study to determine the handling qualities of lifting-body entry vehicles. Although manned orbital experience with ballistic shapes has been successful, the recovery of such vehicles leaves much to be desired. The maneuverability footprint at the time of retrofire for the Mercury and Gemini vehicles is extremely limited in comparison to the larger footprint of a lifting body with a maximum hypersonic lift-to-drag ratio of 1 to 1.3. In addition, the lifting body would provide a horizontal landing capability on prepared landing sites anywhere within the continental U.S. on a single orbit. Predictions based on small-scale wind-tunnel data are not always satisfactory, while predictions based on data obtained in full-scale wind tunnels with the actual flight vehicles are closer to the flight data for low-speed conditions. Fourteen glide flights on the M2-F2 have shown that the longitudinal handling qualities are good. It is hoped that the use of lifting bodies for space missions can be recommended within two years.

EXPERIENCE USING BALAKRISHNAN'S EPSILON TECHNIQUE TO COMPUTE OPTIMUM FLIGHT PROFILES.

Lawrence W. Taylor, Jr., Harriet J. Smith, and Kenneth W. Iliff (NASA, Flight Research Center, Edwards AFB, Calif.).

American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-75. 8 p. 12 refs.

Members, $1.00; nonmembers, $1.50.

Grant No. NGR-05-007-122.

A technique for computing optimum profiles is developed which differs from the classical gradient method in that a term representing the constraint of satisfying the equations of motion is included in the cost function to be minimized. Although the number of unknown independent functions is increased to include the state variables, the dimensionality of the gradient of the modified cost is greatly re-

duced, resulting in considerable savings in complexity and time. The unknown control and state variables are expressed in a functional expansion to facilitate solution by means of Newton's method. The effects of weighting terms and the number of functions on the convergence properties are discussed. Comparisons are made of solutions using the classical gradient method, dynamic programming, and Balakrishnan's epsilon technique. (Author)

THE DYNAMIC RESPONSE OF A FLEXIBLE ROTOR BLADE TO A TIP-VORTEX INDUCED MOVING FORCE.
John F. Ward and William J. Snyder (NASA, Langley Research Center, Hampton, Va.).
American Institute of Aeronautics and Astronautics and American Helicopter Society, VTOL Research, Design, and Operations Meeting, Georgia Institute of Technology, Atlanta, Ga., Feb. 17-19, 1969, AIAA Paper 69-203. 15 p. 9 refs.
Members, $1.00; nonmembers, $1.50.

Approximate analytical solution of the dynamic response of a flexible rotor blade to a radially moving force. The results are interpreted specifically in terms of helicopter rotor-blade vibration characteristics associated with tip-vortex impingement. These results indicate that low-frequency mode resonant amplification of repetitive impulse loadings can be encountered at moderate to high forward speeds on lifting rotor systems. The resonant conditions are encountered in sequence with increasing forward speed. For blades of conventional design, the resonant frequencies are encountered at noninteger multiples of rotor rotational speed. (Author)

A COMPARISON OF NEWTON-RAPHSON AND OTHER METHODS FOR DETERMINING STABILITY DERIVATIVES FROM FLIGHT DATA.
Lawrence W. Taylor, Jr., Kenneth W. Iliff, and Bruce G. Powers (NASA, Flight Research Center, Edwards AFB, Calif.).
American Institute of Aeronautics and Astronautics, Flight Test, Simulation, and Support Conference, 3rd, Houston, Tex., Mar. 10-12, 1969, Paper 69-315. 16 p. 8 refs.
Members, $1.00; nonmembers, $1.50.

A new technique of determining stability derivatives from flight data is formulated and compared with the simple equations, analog matching, least squares, and Shinbrot methods of analysis. It is shown that the new technique, termed Newton-Raphson, is superior to the others whether flight data or a statistical model is used. Although the new method uses the Newton-Raphson technique, it is also similar to quasi-linearization. The Newton-Raphson technique has been developed to enable the use of a priori (wind tunnel) information and to automatically adjust bias terms and initial conditions to compensate for errors. The technique has been successfully applied to the X-15, XB-70, F-111, and HL-10 vehicles and has application to many other system identification problems. (Author)

THE X-15 PROGRAM IN RETROSPECT.
John V. Becker (NASA, Langley Research Center, Aero-Physics Div., Hampton, Va.).
Raumfahrtforschung, vol. 13, Mar.-Apr. 1969, p. 45-53. 21 refs.
USAF-supported research.

Review of the principal results of 199 flights of the X-15 research aircraft against a background of the original plans and goals. Noteworthy results were obtained in aerospace piloting problems, in validation of ground research and developmental testing facilities, and in the study of heat transfer in the presence of complex flow fields. The ability of the X-15 system to fly out of the atmosphere for a few minutes of space flight, followed by a steep reentry, produced additional data of value to the space program. Considerable detailed research and development efforts in many areas were given impetus, new and unsuspected problems were identified, and new technology was developed in time for urgent but initially unforeseeable applications. FUTURE TECHNOLOGY TRENDS IN AIRBREATHING PROPULSION.
James F. Dugan, Jr. (NASA, Lewis Research Center, Propulsion Section, Cleveland, Ohio).
American Institute of Aeronautics and Astronautics, Aircraft Design and Operations Meeting, Los Angeles, Calif., July 14-16, 1969, Paper 69-774. 11 p. 34 refs.
Members, $1.00; nonmembers, $1.50.

For subsonic jet transports, noise control is a very pressing problem. The means to control this noise at its source (the engine) are assessed. These include designing for high bypass ratio, lining the ducts with acoustic material, using resonators, choking the engine airflow in the inlet or compressor guide vanes, and rotor-stator blade spacing. Further advances in lower SFC and engine weight are forthcoming through higher turbine inlet temperature, higher bypass ratios, new fuels, and advanced materials. The current trends in turbine-blade cooling are discussed along with the use of blowing and suction techniques for achieving higher stage loading in compressors and turbines to reduce their size and weight. The propulsion systems for a possible nuclear-powered subsonic cargo aircraft are briefly reviewed. For V/STOL aircraft, a wide variety of propulsion systems are being evaluated in prototype aircraft. The major types and tradeoffs among engine weight, low fuel consumption, and noise are illustrated. The major trends in hypersonic airbreathing propulsion are in engines that operate in two or more modes and in supersonic combustion. (Author)

RECENT STUDIES ON EFFECTS OF RUNWAY GROOVING ON AIRPLANE OPERATIONS.
Upshur T. Joyner, W. Pelham Phillips, and Thomas J. Yager (NASA, Langley Research Center, Hampton, Va.).
American Institute of Aeronautics and Astronautics, Aircraft Design and Operations Meeting, Los Angeles, Calif., July 14-16, 1969, Paper 69-773. 15 p. 14 refs.
Members, $1.00; nonmembers, $1.50.

Runway grooving is a significant way of improving tire traction in adverse weather conditions, and this technique has been under study by NASA. Various groove patterns have been evaluated for wet traction; one of the better groove patterns (with grooves 1/4 in. wide and 1/4 in. deep on 1 in. centers) was installed on a research runway. Full-scale traction studies were made using a Convair 990A transport and an F-4D fighter aircraft. Braking traction values obtained on the wet grooved runway were substantially higher than those obtained on the wet ungrooved runway. The results from these investigations were used as the basis for calculations of the effects of grooving on aircraft landing field length and takeoff balanced field length under wet conditions. Grooving is shown to be very beneficial on both counts. (Author)

SOME TEST RESULTS FROM THE NASA PLANETARY ENTRY PARACHUTE PROGRAM.
Harold N. Murrow and John C. McFall, Jr. (NASA, Langley Research Center, Hampton, Va.).
(American Institute of Aeronautics and Astronautics, Aerodynamic Deceleration Systems Conference, 2nd, El Centro, Calif., Sept. 23-25, 1968, Paper 68-934.)
Journal of Spacecraft and Rockets, vol. 6, May 1969, p. 621-623. 16 refs.

Results are summarized from the 13-flight test program designed to furnish data applicable to decelerators for use on Mars. During the series, deployment was initiated at Mach numbers between 1.15 and 3.16 in the altitude region of 122,000 to 159,000 ft. Two techniques were employed to achieve the test conditions, one using a rocket vehicle and the other a large helium-filled balloon. The rocket-launched tests were conducted to obtain basic information on the candidate types and the balloon-launched tests to investigate their deployment performance in the wake of a large aeroshell. Three parachute types with diameters from 30 to 85 ft and a 15-ft-diam Ballute were tested. Deployment characteristics and loadings, drag values, and stability characteristics are summarized. Effects of porosity, sterilization, and mortar-type deployments are discussed. A unique "post-reefing" system for minimization of descent time after the data period is described. (Author)

INFLUENCE OF DRAG ON THE MISSION PERFORMANCE OF HYPERSONIC AIRCRAFT.
Lionel L. Levy, Jr. (NASA, Ames Research Center, Moffett Field, Calif.).
Journal of Aircraft, vol. 6, July-Aug. 1969, p. 326-329. 6 refs.

The variations of drag during the climb and cruise phases of representative hypersonic-cruise transport missions were examined in detail for several possible hypersonic aircraft to assess the influence of drag on mission performance. During cruise, the drag due to lift has the most influence on estimates of performance, independent of configuration and altitude. During climb, the dominant drag component depends on configuration and/or flight path. In some cases, the friction drag was estimated to be 20 to 40 per cent of the total, a percentage great enough so that erroneous estimates would significantly affect performance estimates. Increasing the cruise Mach number increases the drag due to lift during both climb and cruise, and decreasing the allowable sonic-boom overpressure increases the drag due to lift during climb. Significant gains in performance can be realized for reasonably small reductions in drag. In one case, it was found that the payload capacity could be increased from 187 to 231 passengers by reducing the total drag 10 per cent throughout the mission. (Author)

DEVELOPMENT STATUS OF ATTACHED INFLATABLE DECELERATORS.
Martin M. Mikulas, Jr. and Herman L. Bohon (NASA, Langley Research Center, Hampton, Va.).
(American Institute of Aeronautics and Astronautics, Aerodynamic Deceleration Systems Conference, 2nd, El Centro, Calif., Sept. 23-25, 1968, Paper 68-929.)
Journal of Spacecraft and Rockets, vol. 6, June 1969, p. 654-660. 6 refs.

An extensive research program encompassing both structural and aerodynamic disciplines has demonstrated the potentiality and workability of attached inflatable decelerators (AIDs) for supersonic application. An AID consists of an inflatable fabric afterbody attached to a payload which can be deployed at supersonic speeds to provide a sizable increase in drag. An analysis for the determination of constant tension (isotensoid) AID shapes and masses is presented, and results are given in the form of plots. Performance data obtained from both subsonic drop tests and supersonic wind-tunnel tests of models designed from the analysis are presented. The most significant results are those obtained in the AEDC 16-S propulsion wind tunnel on two 5-ft-diam models deployed at Mach numbers 2.2 and 3. Both models deployed successfully and experienced flutter-free flight. The internal pressure and total drag agreed well with values obtained from the analysis. (Author)

Description of tests determining the aerostatic and aerodynamic characteristics of the Dart Vee balloon. The physical properties of four Dart Vee balloons (nominal volumes range from 250 to 750 cubic feet) are presented, and their flight characteristics are evaluated. Results of the aerostatic analysis indicate that, due to the permeability of the gas envelope to helium, the balloon experienced a complete loss of super pressure and a loss of approximately ten per cent of its initial usable free lift in a 24 hour period. The results of the aerodynamic analysis indicate that the Dart Vee balloon has a lift to drag ratio of approximately 1.5 and a stall angle of 16.5 degrees. The balloon exhibited a static lift of 7.5 pounds and an aerodynamic lift of 70 pounds measured just prior to an observed instability which occurred at an airspeed of 18 miles per hour. P.G.

LESSONS FROM THE B-70 TO BE APPLIED TO SST SAFETY.
Fitzhugh Fulton (NASA, Edwards, Calif.).
IN: FLIGHT SAFETY FOUNDATION, ANNUAL INTERNATIONAL AIR SAFETY SEMINAR, 21ST, ANAHEIM, CALIF., OCTOBER 8-11; 1968, TECHNICAL SUMMARY. (A69-41127 22-02)
Arlington, Va., Flight Safety Foundation, Inc., 1968, p. 157-169.

Discussion of the North American Rockwell XB-70 aircraft, a very valuable research vehicle that has produced important data that are particularly applicable to the SST program. The XB-70 is a large, delta-wing aircraft with dual vertical tail surfaces, a movable canard surface with trailing-edge flaps, and a movable nose ramp to provide acceptable visibility at low speed and reduced drag at high speed. It has been flown at Mach 3 and at altitudes above 70,000 ft. Flight characteristics vs wind tunnel predictions are compared. The cockpit instrumentation is described in detail and is evaluated. The XB-70 has vertical-tape flight instruments and round-dial engine instruments. Overspeed operation, inlet operation, and flying qualities are considered. Aspects of operation during deceleration and descent are treated, as well as questions of landing-gear reliability and hydraulic-system operation. F.R.L.

FLIGHT EVALUATION OF RADAR-INERTIAL SYSTEMS.
Ronald J. Madigan (NASA, Electronics Research Center, Cambridge, Mass.).
American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-401. 31 p.

Review of the NASA-ERC program for the development of guidance, navigation, and flight control technology for aircraft. The technical approach includes in-flight evaluation of radio-inertial hybrid systems based initially on helicopter flight tests at Wallops Station, Va. Future plans for development and evaluation of advanced navigation and control systems and components are considered. Initial flight tests results of a radar-updated Gemini inertial navigation system during the approach and landing phase are presented. These results describe a range of performance based on deliberate variations of the system up-date and inertial system performance parameters. (Author)

APPLICATION OF QUADRATIC OPTIMIZATION TO HELICOPTER FLIGHT CONTROL.
Donald L. Gray, Paul S. Rempfer, and Lloyd Stevenson (NASA, Electronics Research Center, Cambridge, Mass.).
IN: AMERICAN AUTOMATIC CONTROL COUNCIL, JOINT AUTOMATIC CONTROL CONFERENCE, 10TH, UNIVERSITY OF COLORADO, BOULDER, COLO., AUGUST 5-7, 1969, PREPRINTS OF TECHNICAL PAPERS. (A69-43267 24-10)
New York, American Institute of Chemical Engineers, 1969, p. 240-247. 6 refs.

Application of steady-state linear quadratic optimal control results to flight control of a set of linearized helicopter equations of motion. A commanded step input is to be tracked quickly and smoothly with zero steady-state error, and all feedback gains are assumed to be constant. Potter's (1966) method of finding the steady-state solution to the matrix Riccati equation is used, with simple repeated roots present. The closed-loop system eigenvectors are used as a tool in adjusting the performance index. The resulting optimal feedback control system is simplified to create a suboptimal control feeding back only available state variables. These systems are compared with one designed by the classical means. (Author)

FLIGHT TESTS OF A DIRECT LIFT CONTROL SYSTEM DURING APPROACH AND LANDING
Joseph W. Stickle, James M. Patton, and Robert C. Henry Washington Nov. 1968 46 p refs
(NASA-TN-D-4854) Avail: CFSTI CSCL 01B

The National Aeronautics and Space Administration has recently completed a flight program to evaluate the use of direct lift control (DLC) as an aid to flight path control during approach and landing. The program utilized a U.S. Navy F8-C airplane modified to incorporate symmetrically variable ailerons to augment the primary longitudinal control system. The airplane was also equipped with an airspeed sensing autothrottle and a commercially available cross-pointer-type instrument landing system. Approximately 230 approaches were made along various single- and two-segment approach paths, guidance being provided by a modified AN/GSN-5 radar and instrument landing system data link. Comparisons of flight path deviations and touchdown dispersion between the basic F8-C control system and the direct lift control system were made. The results indicate that direct lift control provides a better control of small flight path errors than the conventional F8-C control system. Direct lift control with a controlled pitch attitude change, provided through an aileron to horizontal tail interconnect, improved piloting performance and reduced workload during the approach and landing task. CALCULATED AND FLIGHT MEASURED HANDLING-QUALITIES FACTORS OF THREE SUBSONIC JET TRANSPORTS
Walter E. McNeill Washington Nov. 1968 32 p refs
(NASA-TN-D-4832) Avail: CFSTI CSCL 01D

As part of a NASA intercenter study of jet transport stability and control problems in severe turbulence, several calculated and flight-measured handling qualities factors of three current jet transports have been reviewed, and compared with various handling qualities criteria. The longitudinal and lateral handling qualities parameters were calculated by means of a digital computer program, for several typical flight conditions within the normal operating envelopes, using aerodynamic and physical data supplied by the manufacturers of the aircraft as the most reliable information available. The calculations did not take account of effects of yaw dampers and automatic pitch trim devices. On the basis of the current military specification and other published criteria, all three transports had satisfactory or acceptable predicted or flight measured longitudinal short period frequency and damping characteristics in the flignt conditions of interest. Except for some cases of speed instability associated with disengagement of Mach trim compensation devices, acceptable longitudinal phugoid characteristics also were calculated for these transports. LOW SUBSONIC FLIGHT AND FORCE INVESTIGATION OF A SUPERSONIC TRANSPORT MODEL WITH A VARIABLE-SWEEP WING
Delma C. Freeman, Jr. Washington Nov. 1966 84 p refs
Film supplement number L-1008 to this report is available on loan
(NASA-TN-D-4726) Avail: CFSTI CSCL 01C

An investigation was conducted in the Langley full scale tunnel to determine the low speed static and dynamic longitudinal and lateral-directional stability characteristics of a 1/20 scale model of a variable sweep wing supersonic commercial air transport configuration. The results of the investigation showed that the dynamic longitudinal stability and control characteristics of the model were generally satisfactory over the test angle of attack range except for the landing configuration at high angles of attack where the model was statically longitudinally unstable. The effects of power were found to be very large and stabilizing on the longitudinal stability of the model. In the wing sweep range from 20° to 42°, the model generally had good lateral-directional characteristics except for flights at the highest lift coefficients where the model diverged in yaw. The angles of attack at which these divergences occurred, were in the range where there was extensive stalling of the movable wing panels, and the airplane would not ordinarily be operated. As the sweep was increased past 42°, there was a marked deterioration in both lateral control effectiveness and Dutch roll damping, and at maximum sweep (Λ = 72°) an unstable Dutch roll oscillation together with very weak roll control made flight almost impossible. AERODYNAMIC CHARACTERISTICS OF TWIN PROPELLER DEFLECTED SLIPSTREAM STOL AIRPLANE MODEL WITH BOUNDARY LAYER CONTROL ON INVERTED V-TAIL
Richard J. Margason and Garl L. Gentry, Jr. Washington Nov. 1968 181 p refs
(NASA-TN-D-4856) Avail: CFSTI CSCL 01C

This report presents stability and control data for a small deflected-slipstream short take-off and landing (STOL) airplane model which had an inverted V-tail equipped with boundary-layer control. The results of the static wind tunnel investigation are promising and indicate that with further development, an inverted V-tail with boundary layer control can be designed which would produce the longitudinal and directional trim required for an engine-out situation with no control input by the pilot. The data also show that the lateral control required for an engine-out situation can be obtained from a spoiler with the attendant lift loss. The airplane can be trimmed with both engines operating with or without the boundary layer control on the tail when the flaps are retracted (0° flap deflection); however, when the flaps are deflected (45° flap deflection), the boundary layer control is needed to obtain trim up to a thrust coefficient of 2.10. The rudder is capable of producing large increments of yawing moment without changing directional stability and without causing cross coupling with rolling moment for both the flaps-retracted and the flaps-deflected configuration. Both flap configurations (flaps retracted and flaps deflected) with and without the boundary layer control on the tail have positive dihedral effect and are directionally stable through most of the test ranges of angles of attack and sideslip. SYNTHESIS METHODS FOR MANUAL AEROSPACE CONTROL SYSTEMS WITH APPLICATIONS TO SST DESIGN
Walter W. Wierwille and James R. Knight Washington NASA Dec. 1968 144 p refs
(Contract NAS1-7141)
(NASA-CR-1208; CAL-IM-2429-B-1) Avail: CFSTI CSCL 01D

Two synthesis approaches were studied: a programming approach and a man-machine performance approach. The programming approach places emphasis on moving the poles or eigenvalues of a closed-loop flight control system toward positions considered most desirable from a handling qualities point of view. These poles or eigenvalues are functions of each adjustable parameter in the compensators and various sensor feedback paths. To adjust the various parameters optimally, a programming procedure was developed that was implemented by means of digital computer programs. Three programs have been developed. The first performs synthesis in a single flight regime, determining optimum fixed values for the adjustable parameters. The second performs synthesis in an arbitrary number of flight regimes simultaneously, again determining a single set of fixed-values for the adjustable parameters. The third program also performs synthesis in an arbitrary number of flight regimes simultaneously, but allows specified parameters to vary from one regime to another. The programming approach was applied to the longitudinal dynamics of an SST for six flight regimes. It was found that all three programs operated effectively in moving the closed-loop system poles. FLIGHT TESTS UNDER IFR WITH AN STOL TRANSPORT AIRCRAFT
Robert C. Innis, Curt A. Holzhauser, and Richard P. Gallant Washington Dec. 1968 65 p refs
(NASA-TN-D-4939) Avail: CFSTI CSCL 01B

An STOL transport was studied in instrument flight. This aircraft was flown on 7-1/2° and 2-1/2° ILS approaches. It could be flown comfortably and accurately on the 7-1/2° ILS at 60 knots to 200 feet above the runway. The descent and deceleration capabilities were more than adequate in the approach and landing configuration, but were not sufficient in the preapproach configuration. The handling characteristics during instrument flight were generally satisfactory, except for moderate heading excursions at low speeds and moderate angle-of-attack excursions at the rear center of gravity. These characteristics, while not satisfactory, were acceptable and are considered general problems of STOL aircraft operations. Author

FLYING QUALITY FACTORS CURRENTLY LIMITING HELICOPTER NAP OF THE EARTH MANEUVERABILITY AS IDENTIFIED BY FLIGHT INVESTIGATION
Henry L. Kelley, Robert J. Pegg, and Robert A. Champine Washington Dec. 1968 49 p refs
(NASA-TN-D-4931) Avail: CFSTI CSCL 01B

A flight investigation utilizing two modern lightweight helicopters was conducted to study the effects of flying qualities on nap-of-the-earth maneuver capability. Variation in flying qualities was provided by the markedly different stability and control characteristics which resulted from the basically different rotor systems of the two test vehicles. Several tasks were used to provide a realistic basis on which to determine the parameters most pertinent to maneuver capability. The results indicate that the initial angular response characteristics about the roll axis and the sensitivity of the height control are of primary importance. For example, the tightness of the initial roll response, as determined by the magnitude of roll-control sensitivity in combination with angular-velocity damping, had a significant influence on the pilot's ability to attain quickly, precisely, and consequently safely, those bank angles necessary to perform the tasks smoothly. Wind velocity and direction, stick-fixed maneuver stability gradients, angular-velocity and control-system coupling, vibration, and power-governing-system characteristics were other factors that significantly influenced the pilot's ability to maneuver the helicopters. A MATHEMATICAL MODEL FOR CALCULATING THE FLIGHT DYNAMICS OF A GENERAL PARACHUTE-PAYLOAD SYSTEM
Joe D. Gamble Washington Dec. 1968 34 p refs
(NASA-TN-D-4859) Avail: CFSTI CSCL 01A

An analysis yielding six-degree-of-freedom equations of motion is presented for predicting the dynamic behavior of a general parachute-payload system. The parachute canopy and associated air-mass are approximated as a rigid body, and separate equations of motion are derived for the canopy and payload subject to the constraint of the risers and suspension lines. The analysis determines the forces and the response of various riser and suspension-line geometries subjected to large displacements, under the assumption that these lines are linearly elastic. The equations are readily adaptable to computer solutions and should be of interest in analyzing the dynamic performance of lifting-parachute payload systems. Author

STUDY OF ADVANCED ELECTRONIC APPLICATIONS TO AERONAUTICAL DISPLAY AND CONTROL PROBLEMS
G. B. Litchford Washington NASA Jan. 1969 140 p refs
(Contract NASw-1541)
(NASA-CR-1240) Avail: CFSTI CSCL 01D

Electronic aids for navigation, ATC, and collision avoidance in the field of general aviation are discussed, with the aim of accomodating the pilot with minimum IFR capability. Low cost electronic air and ground aids are outlined, and time shared VHF Omnirange (VOR) area coverage is evaluated. Data transmission techniques are discussed as to potential, cost, and effectiveness. General aviation use of the national Secondary Surveillance Radar System (SSR) is treated in light of increased air traffic, both commericial airline and general aviation, in altitudes less than 10,000 feet and the corresponding increase in collision potential. Recent developments in the SSR system include a low cost modified airborne transponder which could be installed in general aviation aircraft to effectively combat the risk of collision in dense airspace. Electronic simulation of very low visibility landing guidance and instrument displays is discussed as to presently available equipment and the need for more flexible and complex systems. A summary of the general requirements of computer generated low visibility landing systems concludes the study. A.C.R.

HUMAN SURVIVAL IN AIRCRAFT EMERGENCIES
Charles A. Yost and Ronald W. Oates Washington NASA Jan. 1969 61 p refs
(Contract NASw-1530)
(NASA-CR-1262) Avail: CFSTI CSCL 01B

A general study was performed to outline methods for the improvement of human survival in civilian aircraft emergencies. Survival condition criteria, accident statistics and human tolerance limits were surveyed with respect to those aircraft used in two categories: certificated air carriers and general-private aviation (including official executive aircraft). The methods presented for aircraft occupant survival improvement fall into the general areas of occupant protection through seat design and occupant restraint improvement to withstand impact accelerations which are applied to the aircraft. LARGE SCALE WIND TUNNEL INVESTIGATION TO IMPROVE THE LOW SPEED LONGITUDINAL STABILITY AT HIGH LIFT OF A SUPERSONIC TRANSPORT WITH VARIABLE-SWEEP WINGS

Anthony M. Cook and Dale G. Jones Washington Jan. 1969 57 p refs

(NASA-TN-D-5005) Avail: CFSTI CSCL 01A

An investigation has been made in the Ames 40- by 80-Foot Wind Tunnel to develop techniques to improve the longitudinal stability for a supersonic transport. The model had a wing pivot outboard of the fuselage, a high aspect ratio movable wing panel, and a highly swept, fixed, inboard wing portion (strake). Special efforts were made to minimize the adverse effects of the vortex flow from the highly swept strake leading edge. Flow control devices tested on the strake included increased leading edge radius, leading edge (Krueger-type) flaps, and upper surface vortex generators. Fences on both strake and movable wing panel were also tested. The results show the basic model with a sharp strake leading edge to have pitch-up at an angle of attack as low as 5°. The use of a larger strake leading edge radius together with a strake leading edge flap and a wing fence produced essentially linear pitching moment characteristics to 18° angle of attack, with a stable break at stall. A combination of vortex generators on the strake upper surface, and a wing fence outboard of the pivot also produced acceptable pitching moment characteristics. Author

SUPERSONIC TRANSPORT OPERATING PRACTICES DURING SIMULATED OPERATIONS IN FUTURE AIR TRAFFIC CONTROL SYSTEM ENVIRONMENTS

Milton D. McLaughlin and Richard H. Sawyer Washington Feb. 1969 65 p refs

(NASA-TN-D-5018) Avail: CFSTI CSCL 01B

Operating practices of the supersonic transport (SST) during simulated operations in air traffic control (ATC) system environments conceived for the time period for introduction of the SST into service are presented. An SST flight simulator and the Federal Aviation Administration ATC simulation facilities were used to create the real-time simulations. The SST flight simulator was operated by airline crews and the ATC simulation facilities by experienced air traffic controllers. The test program included departure and arrival operations under instrument flight rule conditions in the New York and Los Angeles terminal areas with two design study configurations of the SST. The design study configurations were representative of variable-sweep and fixed-wing designs. Both designs had a variable-incidence forebody. Author

VARIABILITY IN SONIC-BOOM SIGNATURES MEASURED ALONG AN 8000-FOOT LINEAR ARRAY

Domenic J. Maglieri, Vera Huckel, Herbert R. Henderson, and Norman J. McLeod Washington Feb. 1969. 58 p refs

(NASA-TN-D-5040) Avail: CFSTI CSCL 20A

Systematic measurement studies designed to minimize all effects other than those of the local atmosphere are presented to document the variability of sonic-boom signatures at ground level. Measurements from an 8000-foot (2438-meter) linear microphone array indicate that wavelike overpressure patterns in which the signature shapes progress from peaked to rounded vary with time. Such variations are believed to be attributable to the atmosphere rather than to the airplane motion. Analyses of data for the same instruments, test array, time period, airplane altitude, and airplane type, and for Mach numbers of 1.3 and 1.6, suggest that less variability in pressure, impulse, period, and rise time exists for the Mach number 1.6 data. The probability of equaling or exceeding the ratio of measured to calculated over-pressure, impulse, and time durations for the F-104 fighter airplane has been determined from a sample of more than 2500 data points for different operating conditions, geographical locations, and climatic conditions. The results suggest that the logarithms of these quantities follow a normal distribution. Author

FULL-SCALE WIND-TUNNEL INVESTIGATION OF STATIC LONGITUDINAL AND LATERAL CHARACTERISTICS OF A LIGHT TWIN-ENGINE AIRPLANE

Marvin P. Fink and Delma C. Freeman, Jr. Washington Jan. 1969 217 p refs

(NASA-TN-D-4983) Avail: CFSTI CSCL 01B

An investigation was conducted in the Langley full-scale tunnel to determine the static longitudinal and lateral stability and control characteristics of a full-scale light twin-engine airplane. Hinge moments were also measured for all control and flap surfaces during the investigation. In general, the airplane was found to have stick-fixed longitudinal stability through the stall, but stick-fixed instability could be encountered at some lift coefficients with rearward center of gravity location. The airplane has stick-free stability through the stall, however, for all power, flap, and center of gravity conditions investigated. At angles of attack below the stall, the airplane is directionally stable, has positive effective dihedral, and the variation of the lateral coefficients is fairly linear. At angles of attack above the stall, the airplane is directionally stable, and has positive effective dihedral for all conditions except at a thrust coefficient of 0. However, rolling and yawing moments greater than those produced by full opposite control occur at zero sideslip because of asymmetrical wind stall. Aileron and rudder effectiveness is maintained through the stall. Author

INVESTIGATION OF OPENING CHARACTERISTICS OF AN ALL-FLEXIBLE PARAWING

Thomas G. Gainer Washington Feb. 1969 32 p refs

(NASA-TN-D-5031) Avail: CFSTI CSCL 01C

Opening forces for an all flexible parawing were measured during deployments made in the 17 foot section of a wind tunnel. The wing tested had a nominal keel length of 5 feet, a flat pattern leading edge sweep of 45°, and equal length leading edges and keel. Lift and drag coefficient time histories were obtained by measuring three components of the total force on the wing. Tunnel dynamic pressure was varied from 0.5 to 2.0 pounds per square foot. Two slotted versions of the wing were also tested and some exploratory tests of a reefing technique of shortening one of the keel suspension lines were made. The results indicated that as the wing opened, there was a buildup in both lift and rage coefficient to large values. The ratio of maximum resultant force coefficient to steady state resultant force coefficient (shock factor) was about 3.0. When the resultant force reached a maximum, it was inclined about 48° to the airstream. For the infinite mass conditions of the tests, filling time was about 2.5 times the ratio of keel length to velocity. The complete force time history, including both the opening force and the forces during the transition to steady state angle of attack, could be nondimensionalized with respect to filling time. Opening forces for a 5 foot wing calculated by using the wind-tunnel data were in excellent agreement with drop test data. Author

EXPERIMENTAL VERIFICATION OF SCALE FACTORS FOR PARAWING OPENING CHARACTERISTICS WITH DIMENSIONAL RATIOS FROM 1:1.3 TO 1:3

Robert H. Moore, David L. Eichblatt, and Theodore F. Hughes

Washington Mar. 1969 41 p refs
(NASA-TN-D-5071) Avail: CFSTI CSCL 01C

Verification of an analytical scaling technique by experimental drop tests under controlled conditions is presented in which opening characteristics of full scale flexible parawing and an intermediate scale model are predicted from results of model testing. Two methods of scaling are considered, dynamic similarity and wing loading. Dynamic similarity is derived from comparing similar forces in the equation of motion of scale models to those of a prototype. Wing loading is similar but differs by requiring the payload-weight-per-canopy area of all parawings to be the same. Three scaled, all flexible parawings with keel lengths of 8, 18, and 24 feet were tested at initial opening velocities ranging from 46 to 90 feet per second. Results are presented in the form of comparisons of actual and predicted tension, acceleration, velocity, and distance time histories. Author

POTENTIAL STRUCTURAL MATERIALS AND DESIGN CONCEPTS FOR LIGHT AIRCRAFT
Washington Mar. 1969 142 p refs
(Contract NAS2-4423)
(NASA-CR-1285) Avail: CFSTI CSCL 01C

An investigation of various areas associated with the design of light aircraft and a study of structural materials and concepts is presented. The primary objectives of this two-phase study were: (1) to make a comparative evaluation of a wide variety of materials and structural concepts, presently and potentially available for application to light aircraft, by investigating the affect of design, manufacturing, operational, and material requirements on the cost of this class of aircraft; (2) to apply the more promising materials and structural concepts to the conceptual design of light aircraft; and (3) to identify key problem areas where additional research may increase the potential of promising materials or concepts. This report summarizes the results of the comparative evaluation and shows how these results may be applied to the structural design studies of light aircraft. Author

LARGE-SCALE TESTS OF AN AIRPLANE MODEL WITH A DOUBLE-DELTA WING, INCLUDING LONGITUDINAL AND LATERAL CHARACTERISTICS AND GROUND EFFECTS
Victor R. Corsiglia, David G. Koenig, and Joseph P. Morelli
Washington Mar. 1969 82 p refs
(NASA-TN-D-5102) Avail: CFSTI CSCL 01C

A wind-tunnel investigation has been undertaken to determine the lateral directional, and longitudinal aerodynamic characteristics of a supersonic transport configuration with a double-delta wing of aspect ratio 1.66. Ground effects were also investigated. There was no large reduction in static longitudinal stability at high angles of attack. The trimmed lift coefficient in ground effect, at gear height, was 1.25 times that out of ground effect at the angle of attack for takeoff or landing. Calculations of takeoff performance showed that the takeoff distance can be reduced by increasing the speed beyond that corresponding to the ground limit value of angle of attack. To improve the lift-drag ratio in the takeoff climb, it is desirable to accelerate after lift-off, because the speed for maximum L/D is about 250 knots relative to a takeoff speed of about 190 knots. The improved L/D results in reduced noise at distances greater than 3 miles from brake release and results in more efficient flight. Author

THE USE OF PILOT RATING IN THE EVALUATION OF AIRCRAFT HANDLING QUALITIES
George E. Cooper and Robert P. Harper, Jr. (Cornell Aeron. Lab.)
Washington Apr. 1969 54 p refs
(NASA-TN-D-5153) Avail: CFSTI CSCL 01A

Pilot rating scales and their use in assessing aircraft handling qualities are reviewed historically, and objections that have been raised to limitations of earlier scales are considered in the development of a revised scale. Terminology used in the evaluation of handling qualities is reviewed and new definitions are proposed to improve communication and international understanding. Of particular significance is the new definition of handling qualities, which emphasizes the importance of factors that influence the selection of a rating other than stability and control characteristics. The experimental use of pilot rating is discussed in detail, with special attention devoted to (1) clarifying the difference between mission and task, (2) identifying what the rating applies to, (3) considering the pilot's assessment criteria, and (4) defining the simulation situation. The important elements of the report are then summarized in a suggested Briefing Guide, designed for guidance in planning and executing handling qualities experiments. Author (F.S.)

SONIC BOOM PROPAGATION IN A STRATIFIED ATMOSPHERE, WITH COMPUTER PROGRAM
Wallace D. Hayes, Rudolph C. Haefeli, and H. E. Kulsrud
Washington NASA Apr. 1969 50 p refs
(Contract NAS1-7721)
(NASA-CR-1299) Avail: CFSTI CSCL 20A

This analysis, to some extent a synthesis of established theory but with many new features, is given in sufficient detail to serve as an algorithm for the computation of sonic boom pressure signatures. This algorithm is realized in a FORTRAN computer program. Required inputs include atmospheric properties and horizontal winds as functions of altitude, information on the flight path of the maneuvering aircraft, and aircraft F-functions. Ray tube areas are computed according to geometric acoustic theory, and nonlinear effects are accounted for through an appropriate age variable. The output includes midfield pressure signatures at any altitude. Results from sample calculations are presented and discussed. Author

AN INVESTIGATION OF A DIRECT SIDE-FORCE MANEUVERING SYSTEM ON A DEFLECTED JET VTOL AIRCRAFT
Terrell W. Feistel, Ronald M. Gerdes, and Emmett B. Fry
Washington Apr. 1969 15 p refs
(NASA-TN-D-5175) Avail: CFSTI CSCL 01C

A series of flight and simulator tests were conducted using the X-14A variable stability jet, VTOL research aircraft and an all-axis motion simulator to determine the acceptability of a direct side-force vane for sideward maneuvering without changing bank angle. The side-force vane, immersed in the jet exhaust of the X-14A just below the diverters, deflected the jet sideways through a small angle and was controlled by a device on the pilot's control stick, which could provide either proportional or on-off control. The side-force vane with proportional control was evaluated in flight for the performance of lateral offset maneuvers of 1 to 2 wing spans translation distance. For this task, the use of the vane for translation was preferred over roll when only a low value of roll control power was available, with a higher control power available in roll; the two methods were equally acceptable. HEAVE RESPONSE OF A PLENUM AIR CUSHION INCLUDING PASSIVE AND ACTIVE CONTROL CONCEPTS
Jack D. Leatherwood, Grayson V. Dixon, and David G. Stephens

Washington, May 1969 44 p refs
(NASA-TN-D-5202) Avail: CFSTI CSCL 01C

An analytical and experimental investigation was conducted to determine the heave (vertical) response characteristics of an open-plenum air cushion suspension to simulated guideway inputs. In addition, passive and active control concepts for attenuating undesirable heave responses were considered. Analog computer solutions of the linear and nonlinear equations of motion were obtained and compared with experimental data. Results of analysis and experiment defined cushion resonant response conditions at which guideway inputs may be greatly amplified in the absence of cushion control. With control, however, the analysis suggests that heave responses may be significantly attenuated for a relatively wide range of guideway inputs. Author

DYNAMICS OF THE SPATIAL MOTION OF AN AIRCRAFT
G. S. Byushgens et al Apr. 1969 221 p refs Transl. into ENGLISH of the publ. "Dinamika Prostranstvennogo Dvizheniya Samoleta" Moscow, Mashinostr. Press. 1967
(NASA-TT-F-555) Avail: CFSTI CSCL 01C

Discussed are original concepts of the theory of spatial motion of an aircraft by taking into account cross couplings. Criteria are given here for stabilizing the motion of an aircraft during maneuvers involving intense rolling. To describe the characteristics of aircraft dynamics during spatial maneuvers, the authors employ several concepts and methods involving the qualitative theory of differential equations. The qualitative results obtained in the analysis are illustrated by the results of calculating the aircraft dynamics on digital computers and simulators. Considerable attention is paid to a physical explanation of the results obtained and to a description of the mechanics of aircraft motion in the most common cases of controlled flight. Detailed analysis is given of the reasons and conditions for appearance of the phenomenon of "inertial rotation" of an aircraft involving losses in effective lateral control. Author

TECHNIQUE FOR CALCULATING OPTIMUM TAKEOFF AND CLIMBOUT TRAJECTORIES FOR NOISE ABATEMENT
Heinz Erzberger and Homer Q. Lee Washington May 1969 25 p refs
(NASA-TN-D-5182) Avail: CFSTI CSCL 01C

A procedure was developed for determining optimum takeoff and climbout trajectories for jet aircraft that minimize the noise produced during overflight of communities located along the ground track of the climbout path. The procedure enables one to compute optimum takeoff trajectories for noise abatement for a particular aircraft operating from a particular airport subject to prescribed operational constraints. An important part of the procedure consists in defining appropriate criteria for noisiness of a trajectory. Two criteria are proposed and are used as a basis for calculating noise optimum trajectories: (1) the perceived noise level (in PNdB) measured after a power reduction at the beginning of the noise-sensitive area, and (2) the perceived noise level, averaged along the noise-sensitive ground track of a climbout trajectory. Calculating trajectories that minimize the chosen criterion for noisiness is interpreted as an optimum control problem. The procedure was applied to the calculation of optimum trajectories for a typical, currently in-service jet transport. Author

EVALUATION OF A CONTACT-ANALOG DISPLAY IN LANDING APPROACHES WITH A HELICOPTER
Robert W. Sommer and R. Earl Dunham, Jr. Washington Jun. 1969 25 p refs
(NASA-TN-D-5241) Avail: CFSTI CSCL 01D

The contact-analog presentation included an inclined pathway, fixed in a ground-coordinate system, that provided information for slope and course guidance. The tests were conducted along a 6° glide slope at approach speeds of about 30 knots to a breakout that was followed by a visual slowdown to hover. The tests of the display showed that because of the limited horizontal view of the contact analog (24°) and an incorrect generation of the lateral movement of the pathway, the pilots were constrained to fly within ±100 feet (±30.48 m) laterally of the path center line. The use of the pathway for slope control was found to be difficult because of the limited vertical view of the contact analog (18°) and the necessity of flying an appreciable distance above the pathway to prevent inversion of the pathway. For the slope offset of the present tests (50 feet (15.24 m)), the nearest visible part of the pathway was a considerable distance ahead of the helicopter; thus slope deviations were difficult to detect. The display also presented an unrealistic quality because of the relative motions of the ground grid and the pathway tip. Author

N69-28044*# National Aeronautics and Space Administration. Langley Research Center, Langley Station, Va.
A WIND-TUNNEL AND ANALYTICAL STUDY OF THE CONVERSION FROM WING LIFT TO ROTOR LIFT ON A COMPOSITE-LIFT V/TOL AIRCRAFT
Robert J. Huston and James P. Shivers Washington Jun. 1969 58 p refs
(NASA-TN-D-5256) Avail: CFSTI CSCL 01C

The principal problem associated with the conversion from wing-borne to rotor-borne flight is the possibility of a large attitude disturbance during the first revolution of the rotor. The aircraft disturbance is due to an oscillation of the lift center of pressure in a longitudinal and lateral direction at a frequency that is simply the number of blades multiplied by the rotor rotational speed. The results of a wind tunnel study indicate that large amplitude cyclic pitch is one means of eliminating the source of the aircraft disturbance for a three-bladed rotor/wing aircraft. In addition, the selection of four blades on a rotor-wing aircraft may so substantially reduce the disturbing moments that cyclic pitch is not required to eliminate the moments. The results of an analytical investigation indicate that the disturbance may also be reduced in magnitude by a rapid initial rotor acceleration or by the use of an oscillation of the horizontal tail surfaces (elevons) at the frequency of the lift center of pressure oscillation. However, simultaneous use of the elevons for longitudinal and lateral control will increase the minimum conversion speeds. Author

WIND-TUNNEL INVESTIGATION OF STEADY-STATE AERODYNAMICS OF A COMPOSITE-LIFT VTOL AIRCRAFT MODEL
Matthew M. Winston and Robert J. Huston Washington Jun. 1969 40 p refs
(NASA-TN-D-5232) Avail: CFSTI CSCL 01C

An investigation of a composite-lift VTOL aircraft model with three different rotor/wing configurations was conducted in the Langley full-scale tunnel. The aircraft configuration was one which employed a three-bladed lifting rotor for helicopter flight which could be stopped to become a fixed wing for airplane cruise flight. The aerodynamic and control characteristics were obtained for helicopter flight, and the cruise aerodynamics were obtained for airplane flight. The results indicate only small differences between the three configurations for most of the helicopter-mode operating conditions. Need for improvements in blade design is indicated, and a potential roll control problem at high tip-speed ratios is identified. The results of the airplane-mode cruise investigation indicate the

importance of careful design of composite lifting surfaces in order to achieve good efficiency in both rotary wing and fixed wing flight. Author

AN EXPERIMENTAL INVESTIGATION OF THE MIXING OF COMPRESSIBLE-AIR JETS IN A COAXIAL CONFIGURATION
James M. Eggers and Marvin G. Torrence Washington Jul. 1969 52 p refs
(NASA-TN-D-5315) Avail: CFSTI CSCL 01B

An experimental investigation was made to obtain data on the mixing of parallel, circular, compressible-air jets in a coaxial configuration. A Mach 1. 3 outer jet and a near-sonic central jet, both exhausting to a quiescent atmosphere were studied. Data were also obtained with both jets operating at subsonic Mach numbers. Radial distributions of total pressure, static pressure, and mass fraction concentration (air in air)of the central jet gas were determined at downstream axial stations both in the near-jet jet and far-jet flow fields. Concentration measurements were made by using a tracer-gas technique. The central-jet gas was a 1% mixture of ethylene in air. At each test condition, the total temperature of both jets was approximately 300° K. The Reynolds numbers for the supersonic and subsonic outer-jet flow were approximately 42.1×10^6 and 13.9×10^6 per meter, respectively. Results of the investigation indicate that good correlation with the experimental air mixing data can be obtained by using an eddy viscosity model based on a representative width of the mixing zone and on the center-line mass flow per unit area. The concentration decay in the region well downstream of the concentration potential core was found to be inversely proportional to the square of the axial coordinate. The accuracy of the concentration measurements was found to be significantly affected by sampling technique and sampling probe design. Author

A LABORATORY INVESTIGATION OF N-WAVE FOCUSING
W. D. Beasley, J. D. Brooks, and R. L. Berger Washington Jul. 1969 19 p refs
(NASA-TN-D-5306) Avail: CFSTI CSCL 01C

A laboratory investigation of the focusing of an N-wave at a point and along a line was conducted. The N-wave was created by a spark at the focus of a parabolic mirror which reflected the N-wave as a plane wave and directed it toward the focusing mirror. Microphone traces of the signature were obtained for various positions of the wave relative to the focus, and schlieren photographs of the passage of the N-wave through the line focus were obtained. The results indicated that the wave underwent a componentwise phase shift of $\pi/2$ radians on passing through a line focus and a corresponding shift of π radians on passing through a point focus, in a manner similar to the focusing of light. RESEARCH AND DEVELOPMENT OF A SONIC BOOM SIMULATION DEVICE
Roger Tomboulian Washington NASA Jul. 1969 48 p
(Contract NAS1-7985)
(NASA-CR-1378; GASL-TR-713) Avail: CFSTI CSCL 01C

To fulfill the requirements for a sonic boom simulator, a pilot facility using an air supply, a mass control valve, and a horn (or duct) was successfully constructed and operated. After an extensive program of analysis of the end reflection conditions, a unique solution was developed which permitted the cancellation of the outgoing wave without the need of a large classical absorber. The concept of this end termination is based on the fact that to match the complex acoustical admittance present at the end of the duct, both the resistive and inertial components of the pressure wave must be cancelled. The initial results obtained using this impedance matching device on the end of the duct indicate that the approach is conceptually sound and that a simulator device of reasonable length can be made and yet produce full-scale sonic boom signatures. The initial results obtained from this facility are discussed. Author

FLIGHT-DETERMINED AERODYNAMIC PROPERTIES OF A JET-AUGMENTED, AUXILIARY-FLAP,

DIRECT-LIFT-CONTROL SYSTEM INCLUDING CORRELATION WITH WIND-TUNNEL RESULTS

L. Stewart Rolls, Anthony M. Cook, and Robert C. Innis Washington Jul. 1969 41 p refs Revised
(NASA-TN-D-5128-Rev) Avail: CFSTI CSCL 01C

Flight tests were conducted on the modified Boeing 367-80 prototype, jet-transport aircraft to determine the aerodynamic characteristics of an externally blown auxiliary-flap system. These flight data are compared with data from a similarly modified one-third scale model in the Ames 40- by 80-foot wind tunnel. Flight data for dynamic steps of the auxiliary flaps indicate a lower peak normal acceleration capability than that indicated by the flight data for static steps; the lower peak is attributed to a rate limit of the flap actuator. The pilots reported an improvement in the landing flare and touchdown tasks resulting from the increased vertical response of the direct-lift-control system. Author

N69-32110*# National Aeronautics and Space Administration. Langley Research Center, Langley Station, Va.

SIMULTANEOUS USAGE OF ATTITUDE CONTROL FOR VTOL MANEUVERING DETERMINED BY IN-FLIGHT SIMULATION

Frank R. Niessen Washington Jul. 1969 12 p refs
(NASA-TN-D-5342) Avail: CFSTI CSCL 01C

The amount of simultaneous control a pilot would use in performing various operational tasks in a vehicle with control response characteristics similar to those of a jet VTOL aircraft was measured. The simulation technique used in this study eliminated trim and disturbance effects. The simultaneous control usage for maneuvering was analyzed in terms of relative bleed-air demands. The results indicate that whenever high total usage did occur, it lasted for only a few tenths of a second. No simultaneous complete control demands occurred during any of the maneuvers; furthermore, the largest simultaneous control demands were significantly less than the sum of the individual maximum control demands. ANALYSIS OF LATERAL DIRECTIONAL STABILITY CHARACTERISTICS OF A TWIN JET FIGHTER AIRPLANE AT HIGH ANGLES OF ATTACK

Joseph R. Chambers and Ernie L. Anglin Washington Aug. 1969 48 p refs
(NASA-TN-D-5361) Avail: CFSTI CSCL 01C

An investigation was conducted to determine the factors producing a directional divergence at high angles of attack for a twin-jet swept-wing fighter airplane. The study consisted of static wind tunnel tests, tuft-flow visualization tests, and calculations of the dynamic lateral directional stability characteristics of the airplane. Several modifications to the basic configuration were evaluated in an attempt to delay or eliminate the instability. Author

LABORATORY EXPERIMENTS ON REVERTED RUBBER FRICTION

G. H. Nybakken, R. J. Staples, and S. K. Clark Washington NASA Aug. 1969 58 p refs
(Grant NGR-23-005-010)
(NASA-CR-1398; TR-7) Avail: CFSTI 01C

Laboratory experiments were carried out to explain the mechanism of reverted rubber skidding as was observed on aircraft tires. It was determined that surface heat generation is the cause of this rubber degradation, and that such reverted rubber exhibits remarkably low friction coefficients on wet surfaces, at all speeds, compared to unreverted rubber on dry surfaces. The process of reverted rubber sliding can take place at ambient temperatures, and is not dependent on the simultaneous presence of heat. It is believed to be caused by a thin water film between the soft reverted rubber and the rigid roadway. Author

SPIN-TUNNEL INVESTIGATION OF A 1/20-SCALE MODEL OF A STRAIGHT-WING, TWIN-BOOM, COUNTER-INSURGENCY AIRPLANE

Henry A. Lee Washington Aug. 1969 28 p ref
(NASA-TM-X-1602) Avail: CFSTI CSCL 01C

An investigation has been made to determine the erect and inverted spin and recovery characteristics of a 1/20-scale dynamic model of a straight-wing, twin-boom, counter-insurgency airplane. Tests were made for the normal loading with the center of gravity at 28-percent mean aerodynamic chord and for a forward and rearward position at 17-percent and 30-percent mean aerodynamic chord, respectively. The landing configuration for the normal loading was also investigated. Additional tests were made to determine the effect of the sponsons, the external wing-tip-mounted missiles, external rocket pods, and an external gun pod. The use of rockets as an emergency recovery device was also investigated. The test results indicate that the airplane will spin in the erect attitude for all loading conditions and will spin inverted only for aileron-with control settings. The optimum control technique for recovery from all spins is movement of the rudder to against the spin followed about one-half turn later by neutralization of the longitudinal and lateral controls. Stores mounted on the wings and sponsons will have no appreciable effect on the spin and recovery characteristics. Author

FIXED-BASE SIMULATOR PILOT RATING SURVEYS FOR PREDICTING LATERAL-DIRECTIONAL HANDLING QUALITIES AND PILOT RATING VARIABILITY

Lawrence W. Taylor, Jr., and Kenneth W. Iliff Washington Aug. 1969 115 p refs
(NASA-TN-D-5358) Avail: CFSTI CSCL 01C

Pilot ratings of lateral-directional handling qualities were collected for a wide range of simplified aircraft characteristics through the use of a simple fixed-base simulator with a color contact analog display. The results of the general survey were obtained with an engineer as the subject and are contained in 45 plots involving five parameters. In another survey, utilizing the same simulation, ratings were obtained from many pilots in order to study the variability in pilot ratings among pilots and the differences in pilot rating that result from changes in mission. The standard deviation of individual pilot ratings ranged from 1.0 at the "good" end of the scale to 2.0 in the middle of the scale. Ratings for specific missions were generally numerically higher (more adverse) than those for the general mission for the same vehicle characteristics. Author

GENERAL-AVIATION PILOT REACTIONS TO AND OPINIONS ON GROOVED RUNWAYS
George E. Cranston Washington NASA Aug. 1969 27 p
(Contract NAS1-8668)
(NASA-CR-1428) Avail: CFSTI CSCL 01C

At the time the survey was performed, there were four commercial airports in the continental United States that had at least one grooved runway. Personal interviews were conducted between general-aviation pilots and aviation safety specialists at these sites by using a prepared questionnaire to obtain the data discussed in this paper. The results of the survey and study show that the grooving of runways has a pronounced beneficial effect and provides increased safety for high-speed general-aviation aircraft operations by the reduction of hydroplaning and increasing braking action during wet runway conditions. Pilots operating light, low-speed aircraft did not generally realize these benefits as the runway lengths and widths at these airports far exceeded their operational requirements under all anticipated circumstances involved with this problem. STATIC AND DYNAMIC STABILITY DERIVATIVES OF A MODEL OF A JET TRANSPORT EQUIPPED WITH EXTERNAL-FLOW JET-AUGMENTED FLAPS
Delma C. Freeman, Jr., Sue B. Grafton, and Richard D'Amato Washington Sep. 1969 52 p refs
(NASA-TN-D-5408) Avail: CFSTI CSCL 01C

A wind-tunnel investigation has been made to determine the static and dynamic stability derivatives of a model of a large jet transport equipped with external-flow jet-augmented flaps. The tests were conducted in the Langley full-scale tunnel, and a model powered by scale-model, compressed-air-driven turbofan engines was used. The results of the investigation showed that blowing on the flap system increased the lift curve slope, delayed the stall, and increased the maximum lift coefficient. The data also showed that all model configurations generally had static longitudinal stability over the test angle-of-attack range except those at the higher flap-deflection angles where the effects of power were destabilizing. The results also showed that the model had positive damping in pitch, roll, and yaw throughout the test angle-of-attack range up to and slightly beyond the stall for all test conditions. The application of power in the flap system resulted in appreciable increases in roll damping but produced essentially no effects in pitch and yaw damping. There were essentially no effects due to oscillation frequency on the damping derivatives. Author

SPIN-TUNNEL INVESTIGATION OF A 1/30-SCALE MODEL OF A SUBSONIC ATTACK AIRPLANE
Henry A. Lee Washington Aug. 1969 29 p ref
(NASA-TM-X-1788) Avail: CFSTI CSCL 01C

Spin and recovery characteristics of a single-engine swept-wing model were tested. Several combat loading conditions were tested for a range of center-of-gravity positions. The effects of external stores, assymetrical loading conditions, and dive brakes were determined as well as parachute size requirements for emergency spin recovery. The results indicate that erect spins can be obtained for all normal loading conditions. Satisfactory recoveries can be obtained by the optimum control technique, i.e. simultaneous movement of the rudder to full against the spin, the ailerons to full with the spin (stick left in a left spin), and the elevator to full up (stick back). With dive brakes open, the airplane may not spin. For the asymmetric loading, spins will be possible only when most of the weight of the external stores is on the outboard wing (right wing for a left spin), and recoveries by optimum control will be unsatisfactory. The airplane will spin inverted, but spins may be difficult to obtain. The optimum control technique for recovery from an inverted spin is to neutralize all controls and then move the rudder to oppose the yawing motion. A parachute 25 feet in diameter (laid out flat) with a drag coefficient of 0.48 (based on the laid-out-flat diameter) and a towline length of 27 feet will suffice for emergency spin recovery. Author

VARIATION IN ENGINE NOISE FOR TWO LANDING-APPROACH CONFIGURATIONS OF A JET TRANSPORT AIRCRAFT

Elmor J. Adkins, Norman J. McLeod, and Paul L. Lasagna Washington, D.C. Oct. 1969 15 p refs

(NASA-TM-X-1896) Avail: CFSTI CSCL 01C

A limited flight investigation was conducted to determine the effect of reduced flap deflections on power required and the resulting engine noise for a subsonic jet transport aircraft. Noise levels were measured during level flight at an altitude of 400 feet (122 meters) at approach speeds. Data were obtained during flybys with flap deflections of 50° and 36°. The maximum overall sound pressure level (OASPL) from flybys with 36° of flap deflection averaged 3 decibels (ref. 0.00002 newtons/meter^2) lower than for flybys with 50° of flap deflection. Buffet intensity was reduced by the use of lower-flap deflections. Author

RESULTS OF A FREE-FLIGHT TEST TO DETERMINE THE PERFORMANCE CHARACTERISTICS OF A TOWED, CONICAL DECELERATOR

J. W. Usry Washington 1969 34 p refs Film supplement number L-1049 to this report is available on loan from Langley Research Center

(NASA-TM-X-1833) Avail: CFSTI CSCL 01C

An inflatable fabric decelerator was tested in free flight to determine its drag and stability characteristics. The inflated decelerator approximated an 80° cone with a 48-inch (121.9-cm) base and was towed behind a cone–cylinder–flare payload at a distance of 13.6 feet (4.15 m) from the payload base. The payload had a maximum flare diameter of 18.21 inches (46.25 cm). The decelerator was deployed at an altitude of 112 000 feet (34.14 km) and a velocity of 4560 ft/sec; 1390 m/sec). Inflation occurred at a Mach number of 4.31 and a dynamic pressure of 130 lb/ft^2 (6224 N/m^2). The snatch force after deployment was not more than 500 pounds (2224 N); this low force indicated that the towline assembly design could be simplified for future flights by eliminating the two snubber lines and the nylon sleeve. The shock force due to inflation was 5600 pounds (24.9 kN). After inflation the force in the towline varied between 300 and 1600 pounds (1334 and 7117 N). The oscillatory motion of the decelerator had a high frequency, and the amplitude increased with time. The test was terminated about 1 second after inflation because of a failure at the attachment point of the towline to the decelerator. The results indicated that the decelerator system was unstable and not suitable for use as a supersonic decelerator with the payload used in this experiment under the conditions of the test. A drag coefficient of 0.75 at a Mach number of 4.2 was estimated from the mean value of the force in the towline prior to the failure. Author

A FLIGHT INVESTIGATION OF SYSTEMS DEVELOPED FOR REDUCING PILOT WORKLOAD AND IMPROVING TRACKING ACCURACY DURING NOISE-ABATEMENT LANDING APPROACHES

Clarence C. Flora, Gerhard K. L. Kriechbaum, and Wayne Willich Washington NASA Oct. 1969 70 p refs

(Contract NAS2-4200)

(NASA-CR-1427) Avail: CFSTI CSCL 01C

A two-phase flight test program was conducted using the Boeing 367-80 airplane. Concurrently, a supplemental ground-based flight simulator program was performed. This study was directed at evaluating various systems developed to reduce the pilot workload while maintaining tracking accuracy under simulated instrument conditions during noise-abatement landing approaches. Preliminary results showed that steeper than normal approaches could not be performed at the same pilot workload level as a conventional approach without improvements in the path guidance system, flight instrument displays, and automatic flight controls. The results of further flight evaluations showed that when the pilot was given an appropriate combination of systems aids he was able to perform steep, two-beam or decelerating approaches with workloads and accuracies comparable to those of conventional approaches. FLIGHT EVALUATION OF TIP-TURBINE-DRIVEN FANS FOR LATERAL CONTROL IN A HOVERING VTOL AIRCRAFT

L. Stewart Rolls and Ronald M. Gerdes Washington Oct. 1969 18 p refs

(NASA-TN-D-5491; A-3299) Avail: CFSTI CSCL 01C

A flight evaluation was made of small tip-turbine-driven fans as a means of augmenting the lateral control characteristics of a VTOL aircraft in hover. Two 12.8-inch-diameter fans were designed, constructed, and tested on the X-14A VTOL test vehicle. Although the fans used less bleed air for a given thrust output, they were unacceptable because of the high time constants of the control system. The time constant reductions which can be provided by closing the control loop with rpm feedback are eliminated when a full command is required. Author

FLIGHT TEST RESULTS OF A TRAILING EDGE FLAP DESIGNED FOR DIRECT-LIFT CONTROL

Charles R. Taylor, Jr. Washington NASA Oct. 1969 84 p refs

(Contract NAS2-4200)

(NASA-CR-1426) Avail: CFSTI CSCL 01C

A flight test investigation was conducted with the Boeing 707 prototype to obtain the performance characteristics of a trailing edge flap for direct-lift control (DLC). The flap system consisted of a main flap with blowing boundary layer control (BLC) and a slotted aft auxiliary flap for DLC. The auxiliary flap had a deflection range of 10° up and 30° down with respect to a faired position with the main flap. The DLC-null angle was 10° down from the faired position. Steady-state aerodynamic characteristics of the flap system were obtained from steady trimmed flight at several speeds plus slow deceleration to the stall. Airplane response and dynamics were obtained from step inputs to the auxiliary flap from their null setting. Similar maneuvers using wing spoilers for DLC also were accomplished. The steady-state results showed that lift coefficient increments (ΔC_L) of about 0.30 to 0.40 generally were obtained with 40° of auxiliary flap travel, while increments of 0.52 to 0.60 were noted with 15° of spoiler travel. Thrust impingement and BLC both tended to increase the ΔC_L's of the flaps, whereas higher main flap settings decreased them. Incremental normal accelerations on the order of +0.10 and −0.12 g were obtained with ±20° flap steps from the null flap. Spoiler steps of ±8° from the null spoiler gave +0.22 and −0.10 g increments. EFFECT OF JET TEMPERATURE ON JET AND PURE TONE NOISE RADIATION
Harry E. Plumblee, George A. Wynne, and Ben T. Zinn Washington NASA Nov. 1969 73 p refs
(Contract NAS1-8443)
(NASA-CR-1472) Avail: CFSTI CSCL 01C

A model jet nozzle was tested over a temperature range of 540°R to 1100°R, and sound pressure was measured at enough positions in the far field to calculate sound power. From these tests, the effect of temperature on total sound power was isolated. A prediction technique for sound pressure was modified to sound power and was verified over the temperature test range of this program. The prediction method was then used to determine the effect of temperature, as high as 3500°R, on radiated sound power. It was determined that jet sound power is a nonlinear function of temperature. At high temperatures, significant reductions in jet noise may be achieved. The changes in fan noise characteristics were also measured as the noise propagates through a high-temperature region in the fan duct and subsequently radiates into an ambient medium. It was shown that increasing temperature increases higher-order acoustic duct mode cut-on frequencies. Increasing temperature possibly reduces radiated pure tone noise. Design studies were made concerning the changes required to modify an existing engine to test the jet-heating concept. A combustion instability analysis for annular duct geometry was performed and used in designing components such as the combustion chamber and flameholders, to reduce high frequency combustion instability. STRIKING CHARACTERISTICS AND TIME LAGS OF THE MAGNETRON GAUGE IN HELIUM FROM 1.9×10^{-7} TORR TO 7×10^{-10} TORR.

William S. Lassiter (NASA, Langley Research Center, Hampton, Va.).

Journal of Vacuum Science and Technology, vol. 5, Sept.-Oct. 1968, p. 147-151. 6 refs.

Experimental measurement of the lower limits of operation of the magnetron ionization gauge in helium over the pressure range from 1.9×10^{-7} to 7×10^{-10} torr. The dependence of the striking voltage on the striking magnetic field at the upper branches of the striking characteristic curves deviates slightly from the parabolic dependence predicted by theory. On the lower branches of the striking characteristic curves, the results show that below 10^{-8} torr, the minimum striking voltage decreases with a decrease in pressure instead of increasing, as predicted by theory. Striking time lags are measured below 10^{-8} torr. The time lags increase with a decrease in pressure and are shown to contribute no significant error in the measurements of the striking characteristics. M.G.

LUNAR POWER SYSTEMS - A LONG VIEW.

Fred Schulman (NASA, Nuclear Power Systems Branch) and A. H. Smith (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, Calif.).

Astronautics and Aeronautics, vol. 6, Nov. 1968, p. 62-69. 32 refs.

Discussion of various technology options for lunar-surface power plants, assuming that a Saturn-V-class vehicle is the mode of transportation to the moon. The amount of power that can then be made available on the moon per launch is expected to be that which can be generated by a power plant weighing up to 30,000 lb and packaged in a Saturn V vehicle. In view of the present state of power technology, it is anticipated that the development and delivery of such systems to the moon will be both difficult and costly. It is contended that many years will be required before any of these advanced systems can be made available for lunar uses, unless the present rate of national investment in space power technology is increased. OBSERVATIONS ON CdS SOLAR CELL STABILITY.

A. E. Spakowski and A. F. Forestieri (NASA, Lewis Research Center, Cleveland, Ohio).

Institute of Electrical and Electronics Engineers, Photovoltaic Specialists Conference, Pasadena, Calif., Nov. 19-21, 1968, Paper. 10 p. 8 refs.

Results of thermal cycling tests conducted to study the stability of CdS solar cells. Early 1968 CdS solar cells are more stable than cells tested previously. The improvement appears to result from the general upgrading of process quality control and from tighter performance specifications. It is not believed that mechanical stresses induced during thermal cycling are the primary cause of cell degradation. The degradation however is a strong function of how the cells are electrically loaded during the test. It is believed that this load effect is often responsible for the differences observed when seemingly identical cells are tested. (Author)

SHEATH STRUCTURE IN THE UNIGNITED MODE.

Peter M. Sockol (NASA, Lewis Research Center, Cleveland, Ohio).

Institute of Electrical and Electronics Engineers, Thermionic Conversion Specialists Conference, Framingham, Mass., Oct. 21-23, 1968, Paper. 10 p. 10 refs.

A kinetic theory model of the plasma-sheath transition is used to analyze the sheath structure in the unignited mode of a thermionic converter. The study is confined to conditions in which the mean-free-paths and Debye length are small compared to the diode spacing. The emitter sheath structure is found to be the same as in the isothermal diode. The collector sheath varies from completely continuum to completely collisionless with a noncontinuum presheath as the local Debye length varies from much larger to much smaller than the mean-free-path. Theoretical current-voltage characteristics are compared with experimental ones. (Author)

A COMPARISON OF THE PERFORMANCE OF TWO RHENIUM, NIOBIUM CYLINDRICAL THERMIONIC CONVERTERS.
Richard M. Williams and Thomas J. Kascak (NASA, Lewis Research Center, Cleveland, Ohio).
Institute of Electrical and Electronics Engineers, Thermionic Conversion Specialists Conference, Framingham, Mass., Oct. 21-23, 1968, Paper. 10 p. 6 refs.

The performances of two rhenium, niobium thermionic converters are compared. The major difference between the converters was the surface preparation of the vapor-deposited rhenium emitters: one emitter was mechanically polished, the other was electroetched. The Rasor-Warner correlation was used to compare the emitter work functions, which in each case were within ±0.1 eV of the 5.0 eV vacuum work function curve. Steady-state electrode efficiency and power density measurements were obtained for each converter. The performance of the mechanically polished emitter was superior to that of the electroetched emitter. This indicates that electroetching of vapor-deposited rhenium does not guarantee a performance improvement. (Author)

HIGH-TEMPERATURE CAPACITORS FROM PYROLYTIC BORON NITRIDE.
R. E. Stapleton and R. A. Lindberg (Westinghouse Electric Corp., Aerospace Electrical Div., Advanced Systems Dept., Lima; NASA, Lewis Research Center, Space Power Systems Div., Cleveland, Ohio).
Space/Aeronautics, vol. 50, Dec. 1968, p. 75, 76.

Results of a research program conducted to evaluate the feasibility of fabricating a high-temperature (1100°F) capacitor comparable in size, weight, and electrical characteristics to conventional lower-temperature capacitors. Four high-temperature, high-purity dielectric materials were tested, including single-crystal aluminum oxide, polycrystalline aluminum oxide, hot-pressed beryllium oxide, and pyrolytic boron nitride. Pyrolytic boron nitride was selected as the optimum material yielding the thinnest wafers. The use of alternatingly interconnected thin-film electrodes resulted in a nearly maximum capacitance for a given volume. A high-capacitance unit was fabricated by stacking five wafers on top of each other. Data are given for the dissipation factor and capacitance change with temperature. T.M.

THE EFFECT OF OXYGEN-SUPPLY IMPURITIES ON THE PERFORMANCE OF A HYDROGEN-OXYGEN FUEL CELL.
J. C. Jones (NASA, Manned Spacecraft Center, Houston, Tex.) and J. E. Cox (Houston, University, Houston, Tex.).
Energy Conversion, vol. 8, Nov. 1968, p. 113-115. 7 refs.

Experimental evaluation of the effect of inert diluent impurities in the reactant oxygen supply on the performance of a hydrogen-oxygen fuel cell. The experimental method involved the operation of single cells with three reactant oxygen supply purity levels. Constant load was maintained and change in cell performance was measured as voltage degradation with time during the test run. Inert blanketing of the oxygen electrode may be responsible for the voltage degradation. After each test run, significant immediate voltage recovery was observed when the oxygen electrode was purged. STATUS OF PHOTOVOLTAIC POWER TECHNOLOGY.
Arvin Smith (NASA, Washington, D.C.).
American Society of Mechanical Engineers, Winter Annual Meeting and Energy Systems Exposition, New York, N.Y., Dec. 1-5, 1968, Paper 68-WA/Sol-1. 12 p. 76 refs.
Members, $0.75; nonmembers, $1.50.

Review of the status of photovoltaic power technology primarily from the viewpoint of current and future applications to the exploration and use of space. The photovoltaic-solar cell technology has shown steady improvement in reliability, increased efficiency, reduced cost, increased power per unit of hardware weight, and ability to withstand extremes of the space environment. New developments are underway to increase solar-cell and array size, to reduce stowage volume during boosting into orbit, and to improve resistance to space radiation and thermal cycling. Silicon-cell electrical contacts and interconnections, low-energy proton damage to small exposed cell areas, and instability of CdS thin-film solar cells are examples of problems receiving attention at this time. M.M.

THE PERFORMANCE OF A RHENIUM, NIOBIUM CYLINDRICAL THERMIONIC CONVERTER.
Thomas J. Kascak and Richard M. Williams (NASA, Lewis Research Center, Cleveland, Ohio).
Institute of Electrical and Electronics Engineers, Thermionic Conversion Specialists Conference, Framingham, Mass., Oct. 21-23, 1968, Paper. 10 p. 8 refs.

A cylindrical thermionic converter with a vapor-deposited rhenium emitter and a niobium collector, with a 10 mil interelectrode spacing, was tested under steady-state conditions. The efficiency and power density were measured over an emitter temperature range of 1600 to 2050 K and over a collector temperature range of 873 to 1173 K. The results show that the maximum electrode efficiency increased from 5.2 to 13.4%, and the power density at maximum efficiency increased from 1.2 to 8.1 W/cm^2 as the emitter temperature ranged from 1600 to 2050 K. The maximum power density increased from 1.4 to 8.8 W/cm^2, and the electrode efficiency at maximum power density increased from 4.9 to 12.8% over the emitter temperature range from 1600 to 2050 K. FUEL CELL SYSTEMS FOR MANNED SPACECRAFT.
Hoyt McBryar (NASA, Manned Spacecraft Center, Houston, Tex.).
IN: ELECTROCHEMICAL GENERATORS FOR SPACE APPLICATIONS; CENTRE NATIONAL D'ETUDES SPATIALES, INTERNATIONAL CONVENTION, PARIS, FRANCE, DECEMBER 4-7, 1967, PROCEEDINGS [LES GENERATEURS ELECTROCHIMIQUES POUR APPLICATIONS SPATIALES; CENTRE NATIONAL D'ETUDES SPATIALES, COLLOQUE INTERNATIONAL, PARIS, FRANCE, DECEMBER 4-7, 1967, PROCEEDINGS]. [A69-21034 08-03]
Paris, Dunod Editeur, 1968, p. 1-18.

Description of the requirements for manned-spacecraft electrical power systems. Considerations that led to the selection of fuel cells for Gemini and Apollo - i.e., weight and volume limitations and high-energy yield requirements for payload compatibility are discussed. The Gemini and Apollo fuel cell system design and configuration are presented, with cutaway views showing mounting locations within the respective equipment bays. The interrelations between the fuel cells and other subsystems such as the thermal control (radiator) system and life support system (water production for metabolic use, etc.) are shown and described. The ion-exchange membrane and the Bacon fuel cell concepts are described with illustrations showing fuel cell elements and performance. The crew-critical aspects relative to the fuel cell are given for the Apollo program. M. G.

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL THERMIONIC CONVERSION SPECIALIST CONFERENCE, 7TH, FRAMINGHAM, MASS., OCTOBER 21-23, 1968, CONFERENCE RECORD. [A69-21806 09-03]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 134-140.
NASA-sponsored research.

Six planar geometry thermionic converters with chloride and fluoride vapor-deposited tungsten emitters, niobium collectors, and 8-mil interelectrode spacing were tested to compare performance characteristics. The investigated temperatures range from 1600 to 2000 K. The results show that for emitter temperatures above 1800 K the chloride vapor deposited tungsten emitters which have (110) preferred orientation offer approximately a 50% higher power density than that of the fluoride vapor-deposited tungsten emitters which have (100) preferred orientation. For emitter temperatures lower than 1700 K the chloride vapor-deposited tungsten emitters offer better performance only at low output-voltage. Chemical etching of the fluoride vapor-deposited tungsten improves its performance to the level of chloride vapor-deposited tungsten. A qualitative correlation was observed for the chloride emitter between the degree of orientation, the cesiated work functions, and converter performance. Converter life tests are proceeding to determine performance stability. Approximately 3000 hr have been attained with the fluoride tungsten emitter at 1900 K, 1600 hr on an etched fluoride tungsten emitter at 1900 K and approximately 4000 hr on a chloride tungsten emitter at 2000 K. The life test program is not yet complete. (Author)

ISOTHERMAL DIODE '68.
James F. Morris (NASA, Lewis Research Center, Cleveland, Ohio).
IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL THERMIONIC CONVERSION SPECIALIST CONFERENCE, 7TH, FRAMINGHAM, MASS., OCTOBER 21-23, 1968, CONFERENCE RECORD. [A69-21806 09-03]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 202-208. 48 refs.

Discussion of the isothermal diode as a basis for the study of the internal complex that controls thermionic energy conversion. Nottingham's (1962) theory, which places a sheath with arbitrary exponential variations of charge concentrations between an equilibrium plasma and a field-modified emitter of electrons, ions, and atoms, is discussed. It is shown that in current isothermal-diode theory the self-consistent interactions of the electrode and the ionized gas build the sheath, which strongly affects particle emissions through arrival rates and fields at the emitter face. The improved theory is shown to reveal a need for a virtual Schottky emitter to give equal absolute sheath drops for positive and negative charges, and to prevent net currents at equilibrium. Near-equilibrium calculations are given, showing that the emission sheath properties correlate with the work function minus the plasma potential, the plasma-electron concentration, and the electrode temperature. Parametric results emphasize the great increase in total cesium arrival rates that positive-ion sheaths can cause. The computed trends for cesium and polycrystalline tungsten show some near-equilibrium effects of this system on emitter and sheath functions. B.H.

SHEATH STRUCTURE IN THE UNIGNITED MODE.
Peter M. Sockol (NASA, Lewis Research Center, Cleveland, Ohio).
IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL THERMIONIC CONVERSION SPECIALIST CONFERENCE, 7TH, FRAMINGHAM, MASS., OCTOBER 21-23, 1968, CONFERENCE RECORD. [A69-21806 09-03]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 209-215. 10 refs.

A kinetic theory model of the plasma-sheath transition is used to analyze the sheath structure in the unignited mode of a thermionic converter. The study is confined to conditions in which the mean-free-paths and Debye length are small compared to the diode spacing. The emitter sheath structure is found to be the same as in the isothermal diode. The collector sheath varies from completely continuum to completely collisionless with a noncontinuum presheath as the local Debye length varies from much larger to much smaller than the mean-free-path. Theoretical current-voltage characteristics are compared with experimental ones. (Author)

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL THERMIONIC CONVERSION SPECIALIST CONFERENCE, 7TH, FRAMINGHAM, MASS., OCTOBER 21-23, 1968, CONFERENCE RECORD. [A69-21806 09-03]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 331-341. 12 refs.

Brief discussion of a new theory for gas breakdown in hot cracks, where the theory is specifically applied to the breakdown of a cesium vapor-filled crack in an insulator such as might be found in the trilayer of a thermionic fuel element. The thermionic insulator analysis includes the effect on breakdown caused by certain parameters which might change over extended mission lifetimes or by a change in insulator material. The intent is to produce a breakdown model which (1) can eventually be used to inexpensively screen proposed insulator materials and gas environments and (2) can extrapolate short-term experimental data to long-term mission requirements. The novel feature of the model presented is the inclusion of surface interactions in the equations describing the electron-energy distribution function. This permits the inclusion of thermionic emission from the insulating walls and the absorption and scattering of high-energy electrons by the wall. M.M.

AUXILIARY ELECTRODE CHARGE CONTROL.
Floyd E. Ford (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: U.S. ARMY ELECTRONICS COMMAND, ANNUAL POWER SOURCES CONFERENCE, 22ND, ATLANTIC CITY, N.J., MAY 14-16, 1968, PROCEEDINGS. [A69-23990 10-03]
Red Bank, N.J., Power Sources Conference Publications Committee,

1968, p. 53-57. 5 refs.

Discussion of signal-electrode charge control of nickel-cadmium batteries. It is pointed out that this type of control offers some unique advantages over previous methods. Being in intimate association with the electrochemical process of the cell, the signal-electrode signals the onset of oxygen pressure within a cell and provides a voltage that is linearly related to pressure over a limited region. This signal voltage can provide a unique method for overcharge control. Use of a selected number of signal-electrode-type cells in each battern provides signals that can be used to maintain the capacity of the battery above the rated value and thus optimize overcharge. HIGH-FIELD CRYOGENIC MAGNETS WITH PURE ALUMINUM CONDUCTOR.

Gerald V. Brown (NASA, Lewis Research Center, Cleveland, Ohio).

University of California, Symposium on Engineering Problems of Fusion Research, Los Alamos, N. Mex., Apr. 8-11, 1969, Paper. 8 p. 7 refs.

Discussion of the use of very pure aluminum conductors in high-current-density cryogenic magnets. The need to limit the strain in the aluminum by appropriate structure strength is analyzed. The conclusion is that aluminum with a resistivity ratio above 10,000 could be effectively used if the strain is limited to a few tenths of a percent. Magnetoresistance is a more serious problem at high fields than is strain resistivity. It is shown that average current densities needed to produce fields of 300 kG and over could be obtained even though large amounts of structure are needed to keep the strain low. An examination of the forces in a tape-wound solenoid shows that the problem of the low yield stress of pure aluminum can be solved by making the conductor thin and thus preventing excessive accumulation of force within the conductor. The amount of structure needed in a tape-wound coil is analyzed in terms of a nondimensional parameter containing the conductor current density and the Young's modulus of the structure. The advantage of a high-modulus structure is emphasized. (Author)

VARIABLE-VOLTAGE, DIRECT-CURRENT POWER SUPPLIES FOR ENERGIZING CRYOGENICALLY COOLED AND SUPERCONDUCTIVE ELECTROMAGNETS.

J. C. Laurence, E. H. Meyn, and R. J. Jirberg (NASA, Lewis Research Center, Cleveland, Ohio).

University of California, Symposium on Engineering Problems of Fusion Research, Los Alamos, N. Mex., Apr. 8-11, 1969, Paper. 10 p.

Power supplies for energizing cryogenically cooled and superconductive electromagnets, and their control circuitry are described. The first is a dc generator of the homopolar type with a continuous rating of 0 to 60,000 A at 38 V. Overloads of up to three times the continuous current output are available for a duty cycle of 2 min. Control circuitry provides for complete reversal of the output voltage by reversing the direction of the exciter field. This feature is useful for discharging an electromagnet in the shortest possible time. The second of these converts three-phase, 440 V, 60-Hz power into a variable-voltage (0 to 45 V) direct current (0 to 15,000 A continuous rating). The fundamental ripple frequency is 360 Hz and its peak-to-peak amplitude is less than 18% of the dc output voltage. Variations in the preset dc output voltage under continuous load are limited to ±1% when the ac input power variations are regulated to ±5%. (Author)

FLAT CONDUCTOR CABLE TECHNOLOGY.

Wilhelm Angele (NASA, Marshall Space Flight Center, Astrionics Laboratory, Huntsville, Ala.).

American Society of Mechanical Engineers, Design Engineering Conference and Show, New York, N.Y., May 5-8, 1969, Paper 69-DE-67. 15 p.
Members, $0.75; nonmembers, $1.50.

Short report on the status of flat conductor cable (FCC) technology as of Autumn 1968. The basic design and manufacturing principles are briefly mentioned. Standards and specifications are listed. The highlights of FCC properties, advantages, and limitations are given. FCC harness design, assembly, and installation methods are presented, as well as the results of a large application study. Proposals for future development efforts and an outlook concerning the expanded use and application of FCC are also included. (Author)

FUEL CELL SYSTEMS FOR MANNED SPACECRAFT.

Hoyt McBryar (NASA, Manned Spacecraft Center, Houston, Tex.). IN: ELECTROCHEMICAL GENERATORS FOR SPACE APPLICATIONS; CENTRE NATIONAL D'ETUDES SPATIALES, INTERNATIONAL CONFERENCE, PARIS, FRANCE, DECEMBER 4-7, 1967, PROCEEDINGS [LES GENERATEURS ELECTROCHIMIQUES POUR APPLICATIONS SPATIALES; CENTRE NATIONAL D'ETUDES SPATIALES, COLLOQUE INTERNATIONAL, PARIS, FRANCE, DECEMBER 4-7, 1967, PROCEEDINGS]. [A69-32405 16-03] Paris, Dunod Editeur, 1968, p. 1-18.

Description of the requirements for manned-spacecraft electrical power systems. Considerations that led to the selection of fuel cells for Gemini and Apollo (i.e., weight and volume limitations and high energy yield requirements for payload compatibility) are discussed. The Gemini and Apollo fuel cell system design and configuration are presented, with cutaway views showing mounting locations within the respective equipment bays. The interrelationships of the fuel cells with other subsystems are shown and described. The ion-exchange membrane and the Bacon fuel cell concepts are described with illustrations showing fuel cell elements and performance. Operational and flight-control requirements are described for each system, with distinction being made between astronaut control and monitoring functions, and ground control and monitoring functions. A summary of the Gemini Program is given relative to the fuel cell. Salient elements of the Apollo lunar landing mission are described, supported by a view showing the earth and moon and the trajectory path with significant events indicated along the way. The crew-critical aspects relative to the fuel cell are given.

DEVELOPMENT OF ELECTRIC POWER SUPPLIES FOR ELECTRIC PROPULSION.

Carl E. Johnson (U.S. Atomic Energy Commission, Washington, D.C.), Arvin H. Smith, and Fred Schulman (NASA, Washington, D.C.).

American Institute of Aeronautics and Astronautics, Propulsion Joint Specialist Conference, 5th, U.S. Air Force Academy, Colorado Springs, Colo., June 9-13, 1969, Paper 69-826. 23 p. 14 refs. Members, $1.00; nonmembers, $1.50.

Discussion of developments in solar and nuclear electric power technology for electric propulsion. Solar cell fold-out arrays weighing 50 lb/kWe in full sunlight at 1 AU are now technology ready in size ranges up to 50 kWe. Up to 10 kWe rollout arrays weighing 30 lb/kWe (oriented in full sun at 1 AU) will be technology ready in 1971; 10 lb/kWe in full sun at 1 AU looks like a reasonable technology goal for 10 years from now. In the late 1970s, the technology of nuclear electric power supplies will become available to extend electric propulsion to the 100 to 300 kWe power range. It is noted that this nuclear power technology should achieve specific weights in the 20 to 50 lb/kWe range and retain this weight at large distances from the sun.

AN EXPERIMENTAL INVESTIGATION OF SEVERAL LOW-AREA-RATIO WATER JET PUMPS.

Nelson L. Sanger (NASA, Lewis Research Center, Cleveland, Ohio). American Society of Mechanical Engineers, Applied Mechanics and Fluids Engineering Conference, Chicago, Ill., June 16-19, 1969, Paper. 46 p. 20 refs.

Experimental evaluation of several low-area-ratio jet pumps in water. The principal geometrical variables investigated were area ratio, throat length, and nozzle spacing. Diffuser geometry was also varied, but to a lesser degree. Experimental values of efficiency and head ratio were compared to a one-dimensional theoretical prediction method previously found to be applicable to moderate- and high-area-ratio pumps. Two related cavitation prediction parameters were developed and compared to experimental data.

GAMMA IRRADIATION OF LITHIUM SILICON SOLAR CELLS.

P. H. Fang (NASA, Electronics Research Center, Cambridge, Mass.).

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, PHOTOVOLTAIC SPECIALISTS CONFERENCE, 7TH, PASADENA, CALIF., NOVEMBER 19-21, 1968, CONFERENCE RECORD. (A69-35678 19-03)

New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 113-116.

Radiation damage and recovery properties of various lithium-diffused silicon p-n solar cells were investigated by measuring photovoltaic parameters as a function of the gamma radiation fluence. The 1-MeV electron equivalent flux was roughly equal to a severe radiation condition in space. Two groups of cells were irradiated: one group at 65 deg C and the second group at 35 deg C. In both cases, a continuous degradation was observed. The rate of degradation is, in general, slower than the conventional n-p solar cells. With the variation of the concentration profile of lithium, it is expected that the result will be modified. However, the present knowledge does not seem to provide sufficient information to compare directly the superiority of different types of silicon solar cells. (Author)

AN EXPLORATORY STUDY OF THE INTERPLANETARY ENVIRONMENTAL EFFECTS ON SOLAR-CELL COVER GLASSES.

A. C. Wilbur and D. L. Anderson (NASA, Ames Research Center, Moffett Field, Calif.).

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, PHOTOVOLTAIC SPECIALISTS CONFERENCE, 7TH, PASADENA, CALIF., NOVEMBER 19-21, 1968, CONFERENCE RECORD. (A69-35678 19-03)

New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 184-188. 5 refs.

Exploratory investigation of interplanetary space environment effects on solar-cell cover glasses to study the feasibility of predicting response so that optimum cover-glass systems can be selected for specific space missions. Effects of 3-MeV protons on Corning 0211 microsheet, Corning 7940 silica, antireflection coating, blue interference filters, and blue-red interference filters have been measured. Effects of temperature and of concurrent illumination on radiation damage were investigated. The effects of 2-keV protons on antireflection coatings were also measured. Results are presented as optical transmission spectra. (Author)

SOLAR CELL RADIATION DAMAGE ON SYNCHRONOUS SATELLITE ATS-I.

Ramond C. Waddel (NASA, Goddard Space Flight Center, Spacecraft Technology Div., Greenbelt, Md.).

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, PHOTOVOLTAIC SPECIALISTS CONFERENCE, 7TH, PASADENA, CALIF., NOVEMBER 19-21, 1968, CONFERENCE RECORD. (A69-35678 19-03)

New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 195-205. 14 refs.

Results of a study in which various types of solar cells were monitored during 416.8 days in synchronous orbit on satellite ATS 1. Judging by the remaining percentage of initial maximum power, qualified conclusions were that (1) degradation was greater than expected; (2) optimum base resistivity was 10 ohm-cm; (3) optimum shield thickness was 6 mils; (4) sapphire and silica shields were comparable; (5) silica shields were superior to glass; (6) boron and aluminum doping were comparable; and (7) it was necessary to presume some radiation damage, some drop in illumination, and a development of series resistance to account for the results. (Author)

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, INTERSOCIETY ENERGY CONVERSION ENGINEERING CONFERENCE, 4TH, WASHINGTON, D.C., SEPTEMBER 22-26, 1969, PROCEEDINGS.

Conference co-sponsored by the American Institute of Aeronautics and Astronautics, the American Nuclear Society, the American Society of Mechanical Engineers, the American Chemical Society, the Institute of Electrical and Electronics Engineers, and the Society of Automotive Engineers.

New York, American Institute of Chemical Engineers, 1969. 1186 p. Members, $30; nonmembers, $40.

CONTENTS:

SUMMARIES OF SESSIONS, p. xv-xxxiii.

DYNAMIC CYCLES—RANKINE. I.

ORGANIC RANKINE CYCLE WITH RECIPROCATING ENGINE. D. T. Morgan, E. F. Doyle, and S. S. Kitrilakis (Thermo Electron Corp., Waltham, Mass.), p. 1-10. (See A69-42237 23-03)

JET CONDENSER DEVELOPMENT FOR AN ORGANIC RANKINE-CYCLE POWER CONVERSION SYSTEM. R. Garcia (Aerojet-General Corp., Azusa, Calif.), p. 11-20. (See A69-42238 23-03)

DESIGN OF A PRACTICAL HYDROCARBON BOILER. J. P. Norton (American Air Filter Co., Inc., St. Louis, Mo.), p. 21-25. (See A69-42239 23-03)

SPACE POWER. I.

COMPUTER ANALYSIS OF SPACE POWER SYSTEMS FOR MISSION ANALYSIS. R. D. Arno (NASA, Office of Advanced Research and Technology, Moffett Field, Calif.), p. 26-32. (See A69-42240 23-03)

COMPUTER SIMULATION OF SATELLITE ELECTRIC POWER SYSTEMS. P. Bauer (TRW Systems Group, Redondo Beach, Calif.), p. 33-41.

PERFORMANCE ANALYSIS OF SATELLITE ELECTRIC POWER SYSTEMS BY COMPUTER SIMULATION. M. Schwartzburg (TRW Systems Group, Redondo Beach, Calif.), p. 42-50. (See A69-42241 23-03)

SOLAR CELL POWER SYSTEMS FOR MANNED SPACE STATIONS. H. Weiner (McDonnell Douglas Corp., Santa Monica, Calif.), p. 51-60. 8 refs. (See A69-42242 23-03)

OPTIMIZATION OF BATTERY SUBSYSTEMS FOR EARTH SATELLITE LIFETIMES OF GREATER THAN 5 YEARS. M. Koslover (TRW Systems Group, Redondo Beach, Calif.), p. 61-73. (See A69-42243 23-03)

POWER SYSTEMS FOR THE APOLLO APPLICATIONS PROGRAM. D. L. Daubert, W. H. Gross (Martin Marietta Corp., Denver, Colo.), C. B. Graff (NASA, Marshall Space Flight Center, Huntsville, Ala.), and J. D. Murrell (NASA, Manned Spacecraft Center, Houston, Tex.), p. 74-83. (See A69-42244 23-03)

BIOMEDICAL POWER. I.

ENERGY SYSTEM REQUIREMENTS FOR A HEART ASSIST-DEVICE. P. M. Newgard and G. J. Eilers (Stanford Research Institute, Menlo Park, Calif.), p. 84-88.

ENERGY TRANSMISSION THROUGH INTACT SKIN. L. A. Heimlich, F. H. Christiansen (United Aircraft Corp., Farmington, Conn.), and T. Sato (Yale University, New Haven, Conn.), p. 89-94.

ELECTROMECHANICAL ENERGY CONVERSION FOR ARTIFICIAL HEARTS—A NEW CONCEPT UTILIZING A NUTATING MOTOR. W. S. Kelly and R. D. Crosier (Battelle

Memorial Institute, Richland, Wash.), p. 95-100.

NUCLEAR ELECTRIC POWER SOURCES FOR BIOMEDICAL APPLICATIONS. D. E. Knapp, A. Bennett, J. G. DeStesse, L. C. Olsen, E. W. Saaski, B. I. Griffin, and K. A. Gasper (McDonnell Douglas Corp., Richland, Wash.), p. 101-106.

DEVELOPMENT OF AN IMPLANTABLE ARTIFICIAL HEAT POWER SOURCE EMPLOYING A THERMOCOMPRESSOR. W. R. Martini (McDonnell Douglas Corp., Richland, Wash.), p. 107-114.

DEVELOPMENT OF A STIRLING CYCLE POWER SYSTEM FOR ARTIFICIAL HEARTS. K. E. Buck (Aerojet-General Corp., San Ramon, Calif.), p. 115-121.

THERMIONIC POWER. I.

THERMIONIC REACTOR CONCEPTS. L. K. Price (U.S. Atomic Energy Commission, Washington, D.C.), p. 122-130. 11 refs. (See A69-42245 23-22)

THERMIONIC FUEL ELEMENT DEVELOPMENT. D. S. Beard (U.S. Atomic Energy Commission, Washington, D.C.), p. 131-136. (See A69-42246 23-22)

FRENCH THERMIONIC PROGRAM AND ACCOMPLISHMENTS. B. Devin (Commissariat à l'Energie Atomique, Gif-sur-Yvette, Essonne, France), p. 137-145. 9 refs. (See A69-42247 23-03)

NUCLEAR POWER AND HYBRIDS.

SNAP-21 10-WATT THERMOELECTRIC POWER SYSTEM. F. K. Fox (3M Co., Roseville, Minn.) and L. R. Niendorf (Union Carbide Corp., Linde Div.), p. 146-152. (See A69-42248 23-03)

SNAP-27 PROGRAM REVIEW. A. A. Pitrolo (General Electric Co., Philadelphia, Pa.), B. J. Rock (U.S. Atomic Energy Commission, Washington, D.C.), W. Remini (NASA, Manned Spacecraft Center, Houston, Tex.), and J. A. Leonard (Sandia Corp., Albuquerque, N. Mex.), p. 153-170. (See A69-42249 23-22)

THE ROLE OF NUCLEAR POWER ENERGY CENTERS IN DEVELOPING ECONOMY. J. M. Holmes (Oak Ridge National Laboratory, Oak Ridge, Tenn.), p. 171-175.

CONTROLLED THERMONUCLEAR POWER. B. Myers, R. W. Werner, J. D. Lee, and P. B. Mohr (California, University, Livermore, Calif.), p. 176-187.

THE WESTERN COAL DEPOSITS—A NATIONAL SOURCE OF POWER AND URANIUM. M. Steinberg, J. Powell, and B. Manowitz (Brookhaven National Laboratory, Upton, N.Y.), p. 188-206.

DYNAMIC CYCLES—RANKINE. II.

EFFECT OF PRESSURE RATIO ON THE PERFORMANCE OF SUPERSONIC TURBINE-NOZZLES. R. E. Barber (Barber-Nichols Engineering Co., Arvada, Colo.), p. 207-225. 12 refs. (See A69-42250 23-28)

COMPARATIVE PERFORMANCE ANALYSIS OF SUPER-CRITICAL FLUID POWER CYCLES. A. V. Pradhan, p. 226-236.

OPTIMIZING A 5 BHP STEAM TURBINE DESIGN. P. F. Swenson, Jr. (Swenson Research, Inc., Bedford Heights, Ohio) and E. N. Poulos (Prototherm Research Laboratories, Inc., Cleveland, Ohio), p. 237-252.

DESIGN OF VAPOR TURBINES INCLUDING EFFECTS OF SUPERSATURATION. K. E. Boyd, E. A. Mock, and R. A. Rackley (Garrett Corp., Phoenix, Ariz.), p. 253-260. 13 refs. (See A69-42251 23-22)

ROTARY STEAM ENGINE. P. O. Tauson (Westinghouse Electric Corp., Pittsburgh, Pa.), p. 261-270. (See A69-42252 23-03)

SPACE POWER. II.

IMPACTABLE POWER SUBSYSTEMS FOR MARS LANDERS. M. Swerdling (California Institute of Technology, Pasadena, Calif.), p. 271-283. 10 refs. (See A69-42253 23-03)

THERMAL MODEL OF A 75 WATT(E) SPACE POWER-PLANAR RTG SYSTEM. A. J. Parker, Jr. (Hittman Associates, Inc., Columbia, Md.) and W. S. West (NASA, Goddard Space Flight Center, Greenbelt, Md.), p. 284-299. (See A69-42254 23-03)

STATUS REPORT ON SMALL REACTOR-THERMOELECTRIC POWER SYSTEMS FOR UNMANNED SPACE APPLICATIONS. J. D. Gylfe and J. H. VanOsdol (North American Rockwell Corp., Canoga Park, Calif.), p. 300-307. (See A69-42255 23-22)

25 KWE REACTOR-THERMOELECTRIC POWER SYSTEM FOR MANNED ORBITING SPACE STATIONS. J. D. Gylfe, R. A. Johnson (North American Rockwell Corp., Canoga Park, Calif.), R. A. DuVal (U.S. Atomic Energy Commission, Canoga Park, Calif.), and L. W. Brantley (NASA, Marshall Space Flight Center, Huntsville, Ala.), p. 308-320. (See A69-42256 23-22)

THE COMPACT Co-60 KERNEL FOR SPACE POWER. W. Ruehle and D. L. Forrest (Aerojet-General Corp., San Ramon, Calif.), p. 321-329. (See A69-42257 23-22)

BIOMEDICAL POWER. II.

THE NEW MERCURIC OXIDE-CADMIUM (MERCAD) BATTERY SYSTEM FOR MEDICAL AND IMPLANTATION APPLICATIONS. M. Eisenberg (Electrochimica Corp., Menlo Park, Calif.), p. 330-338.

STUDIES OF IMPLANTABLE NICKEL CADMIUM-CELLS FOR HEART ASSIST DEVICES. R. P. Hamlen, E. G. Siwek (General Electric Co., Schenectady, N.Y.), G. Rampel (General Electric Co., Gainesville, Fla.), L. D. Wechsler, and J. Zampini (General Electric Co., Syracuse, N.Y.), p. 339-345.

AN IMPLANTABLE BIOLOGICAL FUEL CELL WITH AN AIRBREATHING CATHODE. A. J. Appleby, D. Y. C. Ng (Institute of Gas Technology, Chicago, Ill.), S. K. Wolfson, Jr. (Michael Reese Hospital Medical Center, Chicago, Ill.), and H. Weinstein (Illinois Institute of Technology, Chicago, Ill.), p. 346-353.

LIMITATIONS OF BLOOD PLASMA AS A FUEL CELL ELECTROLYTE. M. Beltzer and J. S. Batzold (Esso Research and Engineering Co., Linden, N.J.), p. 354-360.

TROPHICALLY POWERED FUEL CELL POWER SUPPLY FOR THE ARTIFICIAL HEART. S. Messinger and R. F. Drake (American Hospital Supply Corp., Everett, Mass.), p. 361-369.

THERMIONIC POWER. II.

PRESENT STATUS OF DEVELOPMENT OF THERMIONIC DIODES AND THERMIONIC REACTORS IN THE FEDERAL REPUBLIC OF GERMANY. K. Einfeld (Internationaler Atomreaktorbau GmbH, Bensberg, West Germany), p. 370-382. 23 refs. (See A69-42258 23-22)

THE USE OF ION SPUTTERING IN MAKING ELECTRODES FOR THERMIONIC ENERGY CONVERTERS. J. Kramar (Výzkumný Ústav Silnoproudé Elektrotechniky, Běchovice, Czechoslovakia), p. 383-385. (See A69-42259 23-15)

THERMOELECTRIC POWER.

SILICON GERMANIUM AIR-VAC TECHNOLOGY—A STATUS REPORT. R. E. Berlin, L. H. Gnau, and R. S. Nelson (Radio Corporation of America, Harrison, N.J.), p. 386-394.

DESIGN AND PERFORMANCE ANALYSIS OF SILICON-GERMANIUM RTG's. V. Raag (Resalab Scientific, Menlo Park, Calif.), p. 395-399. 6 refs. (See A69-42260 23-22)

PRACTICAL APPLICATIONS OF MULTI-LAYER INSULATIONS. F. Notaro, G. E. Nies (Union Carbide Corp., Tonawanda, N.Y.), and R. Hedel (Radio Corporation of America, Harrison, N.J.), p. 400-407.

THE MULTI-FOIL THERMAL INSULATION DEVELOPMENT PROGRAM—A STATUS REPORT. M. L. Paquin (Thermo Electron Corp., Waltham, Mass.), p. 408-415.

LIFE AND PERFORMANCE CHARACTERISTICS OF Pb-Te COUPLES IN HYDROCARBON FIRED SYSTEMS. A. Herchakowski (U.S. Army, Electronics Command, Fort Monmouth, N.J.), p. 416-419.

FURTHER DEVELOPMENT OF THE STAR THERMOELECTRIC PANEL. N. C. Miller (North American Rockwell Corp., Canoga Park, Calif.), p. 420-424. (See A69-42261 23-22)

A MODEL TO DESCRIBE LONG-TERM PERFORMANCE CHARACTERISTICS OF PRESSURE CONTACTED LEAD-TELLURIDE THERMOELECTRIC GENERATORS. D. R. Field and G. W. Bunde (3M Co., St. Paul, Minn.), p. 425-435. 16 refs. (See A69-42262 23-22)

THE PERFORMANCE EVALUATION AND LIFE TESTING

OF THERMOELECTRIC GENERATORS AT THE JET PROPULSION LABORATORY. P. Rouklove and V. Truscello (California Institute of Technology, Pasadena, Calif.), p. 436-446. (See A69-42263 23-22)

DYNAMIC CYCLES–RANKINE. III.

AN ORGANIC RANKINE CYCLE FOR MANNED SPACE APPLICATIONS. S. D. Diamond and A. M. Taylor (McDonnell Douglas Corp., Santa Monica, Calif.), p. 447-455. 5 refs. (See A69-42264 23-22)

ZIRCONIUM HYDRIDE REACTOR-ORGANIC RANKINE POWER SYSTEMS. J. H. VanOsdol, F. R. Wilson (North American Rockwell Corp., Canoga Park, Calif.), and R. E. Niggemann (Sundstrand Corp., Rockford, Ill.), p. 456-464. (See A69-42265 23-22)

STUDY OF A 300 kWe RANKINE CYCLE ADVANCED NUCLEAR-ELECTRIC SPACE POWER SYSTEM. J. A. Heller, T. A. Moss, and G. J. Barna (NASA, Lewis Research Center, Cleveland, Ohio), p. 465-483. 19 refs. (See A69-42266 23-22)

DESIGN AND PERFORMANCE OF A MOBILE WASTE HEAT ORGANIC RANKINE CYCLE SYSTEM PROVIDING ELECTRIC POWER AND ENVIRONMENTAL CONTROL. E. Kaplan and E. Lodwig (Fairchild Hiller Corp., Bay Shore, N.Y.), p. 484-493. (See A69-42267 23-03)

SPACE POWER. III.

RADIOISOTOPE THERMAL ENERGY SOURCES FOR SPACE STATION LIFE SUPPORT SYSTEMS. R. V. Elms, Jr. and H. H. Greenfield (Lockheed Aircraft Corp., Sunnyvale, Calif.), p. 494-504. 5 refs. (See A69-42268 23-22)

ELECTRICAL/THERMAL INTEGRATION OF DYNAMIC POWER AND LIFE SUPPORT SYSTEMS FOR MANNED SPACECRAFT. C. H. Shinbrot and J. V. Coggi (McDonnell Douglas Corp., Santa Monica, Calif.), p. 505-514. 14 refs. (See A69-42269 23-22)

ISOTEC THERMOELECTRIC GENERATOR FOR SPACE POWER. E. J. Steeger and J. E. Cruver (Gulf General Atomic, Inc., San Diego, Calif.), p. 515-521. (See A69-42270 23-22)

ELECTROCHEMICAL POWER. I.

COMPUTER ANALYSIS OF SPACE POWER SYSTEMS FOR MISSION ANALYSIS.

Roger D. Arno (NASA, Office of Advanced Research and Technology, Mission Analysis Div., Moffett Field, Calif.).

IN: AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, INTERSOCIETY ENERGY CONVERSION ENGINEERING CONFERENCE, 4TH, WASHINGTON, D.C., SEPTEMBER 22-26, 1969, PROCEEDINGS. (A69-42236 23-03)

Conference co-sponsored by the American Institute of Aeronautics and Astronautics, the American Nuclear Society, the American Society of Mechanical Engineers, the American Chemical Society, the Institute of Electrical and Electronics Engineers, and the Society of Automotive Engineers.

New York, American Institute of Chemical Engineers, 1969, p. 26-32.

The sensitivity of a space power system weight to various mission parameters is examined for an automated satellite repair vehicle and, very briefly, for three generations of manned space stations. Primary batteries, solar cells, fuel cells, radioisotope thermoelectric generators, and secondary battery characteristics are described for the low power, short duration repair vehicle. A comparison is made between solar cells, isotope Brayton, reactor Rankine, reactor Brayton, reactor thermoelectric, and advanced reactor systems for a range of mission dates and power levels for space stations. A computer program is used which allows the description of a wide variety of space power systems over a range of mission parameters. (Author)

New York, American Institute of Chemical Engineers, 1969, p. 74-83.

Fuel cell/battery and solar array/battery systems satisfy major power demands of the manned Apollo Applications Program (AAP) space vehicles. This description of major power system design considerations and features provides information for a general understanding of these systems and how they satisfy AAP power requirements. Mission characteristics, spacecraft attitudes, vehicle configurations, and power requirements are major design considerations influencing configuration and operation of the systems. Modular design, multi-kilowatt power capabilities, and long life are distinguishing features of the AAP power systems, which are capable of generating and conditioning power for subsequent distribution to electrical equipment. Contract No. NAS 5-10441.

Description of the preliminary work accomplished on an advanced thermoelectric design concept for NASA. This concept has possible application to deep space missions and may offer additional flexibility in the integration of a power supply with spacecraft. The concept differs from conventional omnidirectional thermal radiator devices in that it uses a planar unidirectional or bidirectional radiator. The accomplishments include design, fabrication, and test of a full size thermal model to establish feasibility of the concept. (Author)

IN: AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, INTERSOCIETY ENERGY CONVERSION ENGINEERING CONFERENCE, 4TH, WASHINGTON, D.C., SEPTEMBER 22-26, 1969, PROCEEDINGS. (A69-42236 23-03)

Conference co-sponsored by the American Institute of Aeronautics and Astronautics, the American Nuclear Society, the American Society of Mechanical Engineers, the American Chemical Society, the Institute of Electrical and Electronics Engineers, and the Society of Automotive Engineers.

New York, American Institute of Chemical Engineers, 1969, p. 567-574. 6 refs.

Description of three integral coverslip developmental efforts for silicon solar cells. The initial approach involved fusing a borosilicate glass on the cell surface. In the other approaches, two types of sputtering were developed: radio frequency sputtering and high-vacuum-ion-beam sputtering. Sputtering work was concentrated on fused silica. Cells coverslipped by these three techniques were subjected to solderability, temperature-humidity, and radiation tests. All cells were solderable by conventional techniques. Several rf sputtered coverslipped cells fractured during temperature-humidity testing. Tests indicate that all sputtered silica coverslips have internal stresses built into the coverslip. These stresses are possibly tolerable in film thicknesses up to 3 mils. Current efforts are directed toward alleviating the problem. (Author)

New York, American Institute of Chemical Engineers, 1969, p. 659-667. 12 refs.

Description of the design and testing of a turboalternator built for a Brayton cycle space power system. The turbine was designed to operate on argon with an inlet temperature of 1225 deg F. The turboalternator shaft is supported by gas-lubricated bearings. Major areas of investigation were: (1) starting and stopping shaft rotation without bearing damage while the journal bearings operated hydrodynamically; (2) maintaining proper bearing clearance during the startup thermal transient; and (3) having good shaft stability under the loads imposed by the alternator magnetic field. Stability is important because gas bearings have very low damping capability. Previous testing at turbine inlet temperatures up to 200 deg F was extended by running the temperature up to 1225 deg F for a total of 1165 hours. Starts and stops, full-load stop transients, short circuits, and loads of 3.5 times rated were investigated with the bearings operating hydrodynamically. (Author)

New York, American Institute of Chemical Engineers, 1969, p. 830-838. 5 refs.

Description of techniques for modularizing static inverters and converters into "building blocks" or modules which can be paralleled to increase the power capacity of aerospace electrical power conditioning systems. Inverter and converter modules provide dc and three-phase, 400-Hz ac power at 2.5 kW per module. Circuit functions include automatic paralleling, control, protection, annunciation, power switching, and high-frequency pulse-width modulation; these circuits can be separately packaged into interchangeable submodules. The circuits and performance test results of two experimental breadboard ac and dc modules, and their applications to modular systems are presented and discussed. (Author)

Conference co-sponsored by the American Institute of Aeronautics and Astronautics, the American Nuclear Society, the American Society of Mechanical Engineers, the American Chemical Society, the Institute of Electrical and Electronics Engineers, and the Society of Automotive Engineers.
New York, American Institute of Chemical Engineers, 1969, p. 1004-1009. 7 refs.

Description of a straightforward technique in which a spacecraft solar cell array is constrained to operate close to its maximum power point over a wide range of environmental conditions. The output of an array temperature sensor is used to vary the duty cycle of a pulse-width-modulated impedance regulator so that array voltage tracks its optimum value. A resistance-type temperature sensor was found to be applicable on most spacecraft missions. However, a solar cell used as a temperature sensor has the advantage of negligible transient errors on lightweight arrays for orbiting spacecraft.(Author)

DESIGN AND ANALYSIS OF A MODULAR SERVOAMPLIFIER FOR FAST-RESPONSE ELECTROHYDRAULIC CONTROL SYSTEMS

John R. Zeller Washington Nov. 1968 23 p refs

(NASA-TN-D-4898) Avail: CFSTI CSCL 09E

A low cost three stage servoamplifier has been developed for use in fast response research servosystems. This device has the capability of improving the low frequency dynamics of the inductive coils of torque motor devices in electrohydraulic servovalves. In addition, this amplifier provides other servosystem functions such as summing, gain (adjustable), and compensation. A dynamic model of the amplifier-coil combination has been included to assist in analytical evaluation. The flexibility of the modular configuration has been demonstrated in several operational research installations. Author

SUMMARY OF ELECTRICAL COMPONENT DEVELOPMENT FOR A 400-HERTZ BRAYTON ENERGY CONVERSION SYSTEM

Charles S. Corcoran and Le Roy J. Yeager Washington Nov. 1968 33 p refs

(NASA-TN-D-4874) Avail: CFSTI CSCL 10B

The major electrical components of a 400 hertz Brayton cycle system are the alternator, the voltage regulator-exciter, and the parasitic loading speed controller. Unique design features of the components are described. The experimental evaluation of the components and subsystem indicates that the alternator has an efficiency of 91.5 percent at design and that the steady stage and transient performance is suitable for a space power system. In addition, bearing reactions caused by magnetic unbalance resulting from an unsymmetrical gap were determined experimentally. The data show that the reactions consist primarily of a constant and a pole frequency component. Author

CALORIMETRIC, OPTICAL, AND VIBRATION INVESTIGATIONS OF STRETCH-FORMED ALUMINUM SOLAR CONCENTRATORS

Marvin D. Rhodes and Conrad M. Willis Washington Nov. 1968 45 p refs

(NASA-TN-D-4889) Avail: CFSTI CSCL 10B

Three stretch-formed aluminum solar concentrators were evaluated. The models represent three phases of a program; all were 1.52-m-diam paraboloids with a nominal rim angle of $\pi/3$ rad. Calorimetric tests were made on each model to determine the improvement in model performance caused by changes in model design and fabrication. Model 3 was superior to the other models in both geometrical accuracy and specular reflectance and is considered suitable for thermionic applications. Optical-ray-trace tests were performed on models 1 and 2 to determine the magnitude and location of surface slope errors. The largest slope errors occurred near the gore seams but the region of high error was only about 8% of the total area. Ray-trace data were also used to calculate geometric efficiency by three methods. Only the random error method gave reasonable results for both models. Vibration tests on model 1 caused failure in the welds of the rim support ring structure, but subsequent calorimetric tests revealed little or no reduction in concentrator efficiency. Author

Cb-1Zr PUMPED SODIUM LOOP

E. E. Hoffman and J. Holowach Washington, D. C. NASA Nov. 1968 264 p refs

(Contract NAS3-2547)

(NASA-CR-1135) Avail: CFSTI CSCL 14B

A forced circulation Cb-1Zr pumped sodium loop was operated for 2650 hours at a maximum circuit temperature of 2065°F. The single phase sodium test was conducted to evaluate a number of components and test procedures prior to the construction and operation of the Cb-1Zr Rankine system corrosion test loop, a two-loop Cb-1Zr facility in which sodium was circulated in the primary or heater circuit and potassium was boiled and circulated in a two-phase secondary loop. Components which were evaluated included metering and isolation valves, slack diaphragm and stressed diaphragm pressure transducers, electrical feedthroughs, and electromagnetic helical induction pump. Detailed chemical and metallurgical evaluations revealed no evidence of corrosion or significant contamination, either from the sodium or the vacuum chamber environment. The specifications, procedures, fabrication techniques, and testing methods employed for the Cb-1Zr pumped sodium loop test were confirmed to be adequate for the Cb-1Zr Rankine system corrosion test loop test system. EXPERIMENTAL INVESTIGATION OF THE DYNAMICS OF WATER REJECTION FROM A MATRIX TYPE OF HYDROGEN-OXYGEN FUEL CELL
Paul R. Prokopius and Robert W. Easter Washington Dec. 1968 24 p refs
(NASA-TN-D-4956) Avail: CFSTI CSCL 10B

An experimental study of water-rejection dynamics was conducted on a matrix type of hydrogen-oxygen fuel cell which employs a hydrogen stream to extract the product water. Step transients were introduced in the hydrogen inlet humitity and in the rate of electrochemical water production. The resulting water-rejection transients were measured as changes in hydrogen outlet humidity. The transient response data were compared to the responses of a mathematical model developed for a Bacon type of cell. Data are presented which illustrate the effects that various initial operating conditions have on the outlet humidity responses for step transients in both inlet humidity and the rate of water production. SUPERCONDUCTIVE MAGNET SYSTEM, 14-TESLA, 15-cm-BORE
E. R. Schrader and P. A. Thompson Washington NASA Jan. 1969 55 p refs
(Contract NAS3-7101)
(NASA-CR-1260) Avail: CFSTI CSCL 09A

A description is presented of the design and construction of a 14-tesla (140-kilogauss) electromagnet with a 15-cm bore and using Nb_3Sn ribbon. A support system was developed in parallel with magnet design and construction. This system contains a standard research helium dewar and commercially available power supplies. A control console and interconnecting cables complete the entire magnet system. The magnet has four electrically separated groups of windings, the power to which can be supplied and controlled individually. This arrangement provides for a wide range of sequential and synchronized control of the electrical modules. Such control is necessary when optimum powering of the magnet is obtained and field produced by the electromagnet is maximized. Author

EFFECTS OF SAMPLE PREPARATION ON PHOTOMICROGRAPHS OF CADMIUM SULFIDE THIN-FILM SOLAR CELLS
John M. Bozek Washington Jan. 1969 14 p
(NASA-TM-X-1722) Avail: CFSTI CSCL 10B

Cross-section photomicrographs of thin film CdS solar cells revealed large, lamellar cracks in the CdS layer. Investigation of these cracks showed that they were caused, or at least aggravated, by the mounting and polishing techniques used, particularly by the absence of firm mounting of the cell sample. Use of an aluminum mechanical sandwich or of a slab epoxy mounting technique yielded cross sectional photomicrographs of the CdS thin film solar cells showing no large, lamellar cracks in the CdS layer. INVERTER-CONVERTER PARALLEL OPERATION
G. W. Ernsberger, H. R. Howell, and J. L. Klingenberger Washington NASA Jan. 1969 107 p refs
(Contract NAS3-2792)
(NASA-CR-1224) Avail: CFSTI CSCL 10B

Mathematical analysis of circuit operation for harmonic-neutralized, static inverters operating in parallel have been developed and experimentally verified. Inverters can be operated in parallel provided that: (a) all inverters operate at exactly the same frequency; (b) the internal voltages of all inverters are in phase at all times; (c) all nominal regulated output voltages are the same; and (d) circuit provisions in each inverter insure load division. Static converters can be operated in parallel provided that: (a) all converters have the same nominal regulated output voltage, and (b) circuit provisions are provided in each voltage regulator circuit to cause the converters to share load current. A METHOD FOR REDUCING THE EQUIVALENT SINK TEMPERATURE OF A VERTICALLY ORIENTED RADIATOR ON THE LUNAR SURFACE
Darl D. Bien and Donald C. Guentert Washington Jan. 1969 17 p refs
(NASA-TM-X-1729) Avail: CFSTI CSCL 13A

An aluminized plastic cover sheet over the lunar surface immediately surrounding a vertical radiator offers a simple, light-weight method for reducing the radiator equivalent sink temperature. A simplified analysis predicts equivalent sink temperature as a function of cover surface coating properties, cover length, and radiator elevation for a radiator in the lunar equatorial plane. Results indicate that equivalent sink temperature can be reduced from over 600°R (333°K) (no cover) to about 400°R (200°K) (with cover). The corresponding reduction in required radiator area

is about 50 percent for a radiator temperature of 700°R (389°K). The effect of operation off the lunar equator is also discussed. *Author*

EVALUATION OF MAGNETIC MATERIALS FOR STATIC INVERTERS AND CONVERTERS
R. M. Frost, R. E. McVay, and D. M. Pavlovic Washington NASA Feb. 1969 175 p refs
(Contract NAS3-2792)
(NASA-CR-1226) Avail: CFSTI CSCL 10B

Magnetic materials for use in static inverters and converters were tested under dc excitation and under 400 to 3200 Hz square-wave voltage excitation. Materials evaluated included: 4%Mo–79%Ni–17%Fe, 50%Ni–50%Fe, magnetically annealed 49%Co–2%V–49%Fe, singly and doubly grain-oriented silicon steel, the latter both stress-relief annealed and magnetic field annealed. Magnetization curves, hysteresis loops, core loss and apparent power were determined for temperatures from −55° to +250°C; constant current flux reset data were obtained at room ambient. The effects of both vacuum exposure at 250°C and several conventional processing steps on magnetic properties were evaluated. *Author*

(NASA-CR-1244) Avail: CFSTI CSCL 10A

A research and development program to develop an electrolytic regenerative hydrogen-oxygen fuel cell concentrated on the development of a capillary matrix bipolar pile fuel cell stack with integral gas storage tankage. Tasks were undertaken to select and develop electrodes and matrix materials for the regenerative fuel cell. A cell stack employing an oxygen electrode, a potassium titanate matrix, and a hydrogen electrode consisting of a platinized sintered porous nickel plaque was found to comprise the best cell construction. Such cells were cycled on a 35-minute discharge/65-minute charge test regime and attained life-times in the 500 to 1000 cycle range with minimal deterioration. A 500-watt 34-cell prototype, assembled at the end of the program, was subjected to a limited number of test cycles and yielded approximately 15 watt hours per pound. The program demonstrated the potential of the regenerative hydrogen-oxygen fuel cell concept and it is apparent that increases in cycle life and energy density can be achieved with additional development. *Author*

DESCRIPTION AND EVALUATION OF DIGITAL-COMPUTER DESIGN-ANALYSIS PROGRAM FOR HOMOPOLAR INDUCTOR ALTERNATORS
David S. Repas and Gary Bollenbacher Washington Mar. 1969 93 p refs
(NASA-TN-D-5072) Avail: CFSTI CSCL 10A

A digital computer program for analyzing the electromagnetic design of homopolar inductor alternators is presented. The program, which is written in FORTRAN 4 programming language, is described in general terms. The calculational methods are either outlined briefly or appropriate references are cited. Instructions for using the program are given, and typical program input and output for a 15-kVA alternator are shown. Calculated results for this and two nearly identical 80-kVA alternators are compared with experimental data. In general, considering the many assumptions and approximations which are made in the calculational methods, it is felt that reasonable agreement was obtained between the test data and calculated results. *Author*

A FORTRAN 4 PROGRAM TO ESTIMATE THE OFF-DESIGN PERFORMANCE OF RADIAL-INFLOW TURBINES
Carroll A. Todd and Samuel M. Futral, Jr. Washington Mar. 1969 49 p refs
(NASA-TN-D-5059) Avail: CFSTI CSCL 10A

This program computes conventional performance parameters at required combinations of speeds and flow rates. Necessary input information consists of flow areas, diameters, blade angles, and an estimate of design point performance. The flow equations and corresponding computer listings are given. A set of example calculations is included. *Author*

DYNAMIC ANALYSIS OF PERMANENT MAGNET STEPPING MOTORS
David J. Robinson Washington Mar. 1969 65 p refs
(NASA-TN-D-5094) Avail: CFSTI CSCL 09C

A dynamic analysis of permanent magnet stepping motors for multistep operation is described. Linearized transfer function for single-step responses are developed. Multistep operation, when the motor is driven by a current source, is analyzed by using phase plane techniques. Failure of the motor to operate for fixed stepping rates and load torques is discussed. Dimensionless curves showing maximum stepping rate as a function of motor parameters and load torque are developed and experimentally verified. The curves allowed the maximum stepping rate of a motor with viscous, inertial, and torque loads to be predicted from simple measurements of the motor parameters. *Author*

NONCAVITATING AND CAVITATING PERFORMANCE OF SEVERAL LOW AREA RATIO WATER JET PUMPS HAVING THROAT LENGTHS OF 3.54 DIAMETERS
Nelson L. Sanger Washington Mar. 1969 35 p refs
(NASA-TN-D-5095) Avail: CFSTI CSCL 10B

Performance of several jet pumps was determined having diffuser included angles of 2.5° and 6° over a range of spacings of the nozzle exit from the throat entrance of 0 to 3.0 throat diameters. The throat length was found to be too short to permit matching with a conventional diffuser (6° included angle) because significant mixing continued into the diffuser entrance. However, due to the low rate of diffusion the pump having the 2.5° diffuser achieved the relatively high efficiencies of 31.5 percent for a nozzle-to-throat area ratio of 0.066, and 38.7 percent for an area ratio of 0.197. *Author*

PERFORMANCE OF THE SNAP-8 LUBRICATION AND COOLANT SUBSYSTEM

H. B. Block, R. Kruchowy, and J. D. Gallagher Washington Mar. 1969 29 p refs

(NASA-TM-X-1731) Avail: CFSTI CSCL 08N

A SNAP-8 system containing all major prototype components except the nuclear reactor and the radiator was assembled and tested for 1445 hours at Lewis Research Center. The overall system consisted of five subsystems. One subsystem lubricated and/or cooled the other four SNAP-8 subsystems. Lubrication and coolant subsystem pump parameters, and component endurance data were examined. Data indicated no degradation in pump performance during the test. Fluid was supplied to the SNAP-8 components at the required flow rate and temperature. None of these components experienced a failure or significant degradation caused by lack of lubrication or cooling. Proper cooling of the mercury pump and the turbine alternator space seals resulted in a very low oil and mercury leakage to the space vacuum simulator. Author

COMPARISON OF BRAYTON AND RANKINE CYCLE MAGNETOGASDYNAMIC SPACE-POWER GENERATION SYSTEMS

Lester D. Nichols Washington Mar. 1969 59 p refs

(NASA-TN-D-5085) Avail: CFSTI CSCL 10B

Idealized Brayton- and Rankine-MHD cycles are considered for use in space. The Brayton-MHD cycle uses neon as the working fluid; the Rankine-MHD uses lithium. Both are seeded with cesium. The systems are restricted to a specified generator length and specific radiator area. It is shown that generally an entrance Mach number of 1.0 provides maximum power output; for the same value of Hall parameter the Rankine-MHD system may be used at a lower temperature than the Brayton-MHD; but at the same maximum temperature the Brayton-MHD generates more power than the Rankine-MHD. Subsonic entrance Mach number is recommended for Brayton-MHD, and supersonic for Rankine-MHD. Author

PERFORMANCE OF AN EXPERIMENTAL SNAP-8 POWER CONVERSION SYSTEM

Robert P. Macosko, William T. Hanna, Sol H. Gorland, and Kent S. Jeffries Washington Mar. 1969 30 p refs

(NASA-TM-X-1732) Avail: CFSTI CSCL 18N

A SNAP-8 experimental power system was operated for 1445 hours over a time span of 1463 hours. Approximately 1100 hours of continuous system operation were achieved. Steady-state system performance did not degrade with time. All SNAP-8 prototype components performed satisfactorily throughout the test with the exception of the parasitic load resistor. Three automatic shutdowns occurred during the course of the test. The automatic protective system employed functioned properly. There was no oil contamination of the mercury loop as a result of the shutdowns. Author

EFFECT OF ROTOR TIP CLEARANCE ON THE PERFORMANCE OF A 5-INCH SINGLE STAGE AXIAL FLOW TURBINE

Donald E. Holeski and Samuel M. Futral, Jr. Washington Mar. 1969 20 p refs

(NASA-TM-X-1757) Avail: CFSTI CSCL 10A

Turbine efficiency decreased linearly with increasing rotor tip clearance. Static efficiency decreased 20 percent (0.79 to 0.63) as rotor tip clearance was increased from 1.2 to 8.0 percent of passage height. Rotor exit flow survey data are presented in addition to performance data. Comparison of data with three reference turbines substantiated the results obtained and indicated that rotor tip clearance effects are larger for a reaction turbine than for an impulse turbine. RESULTS OF ENDURANCE TESTS OF A SNAP 8 TURBINE-ALTERNATOR

Armen S. Asadourian, Robert J. Frye, Robert P. Macosko, and Richard W. Vernon Washington Mar. 1969 20 p refs

(NASA-TM-X-1741) Avail: CFSTI CSCL 18N

The SNAP-8 turbine-alternator was tested with mercury vapor in a system endurance run. Considerable long term endurance and performance information was obtained. The turbine-alternator accumulated 1445 hours (1110 hr continuous) and was subjected to four starts and stops. During the test period, the electrical power output ranged between 36.8 and 45.6 kW. Prolonged operation of the turbine-alternator did not reveal any degradation in performance or operating characteristics. Author

COLD PERFORMANCE EVALUATION OF 4.97-INCH RADIAL-INFLOW TURBINE DESIGN FOR SINGLE-SHAFT BRAYTON CYCLE SPACE-POWER SYSTEM

William J. Nusbaum and Milton G. Kofskey Washington Mar. 1969 24 p refs

(NASA-TN-D-5090) Avail: CFSTI CSCL 10A

Tests were conducted in argon over a range of turbine inlet pressures from 2.95 to 16.40 psia (2.03 to 11.31 N/cm^2 abs) corresponding to a Reynolds number range from 34,950 to 175,800 at equivalent design speed and pressure ratio. Results are presented to show the effect of this change in Reynolds number on turbine performance. Results are also presented in terms of equivalent specific work, mass flow, torque, and efficiency for operation at the design Reynolds number of 76 200 and at speeds ranging from 0 to 110 percent of equivalent design speed with inlet-total- to exit-static-pressure ratios of 1.33 to 2.01. PERFORMANCE OF N/P SILICON AND CADMIUM SULFIDE SOLAR CELLS AS AFFECTED BY HYPERVELOCITY PARTICLE IMPACT

Robert L. Bowman, Michael J. Mirtich, and John R. Jack Washington Mar. 1969 16 p refs

(NASA-TN-D-5133) Avail: CFSTI CSCL 10A

A shock tube was used to accelerate particles to hypervelocities for the purpose of simulating micrometeoroid exposure. Various solar cells were then exposed to this simulated environment. The electrical characteristic curves of the cells before and after exposure were measured. The degradation of N/P Si solar cells covered by the thinnest quartz (6 mils or 0.15 mm) was greatly reduced from that suffered by cells without covers. The studies also demonstrated that encapulated CdS solar cells performed as well as protected silicon for exposure energies less than 0.5 J despite evidence of particle penetration of the encapsulant. CALORIMETRIC EVALUATION OF TWO CONE-COLUMN SOLAR-ENERGY CONCENTRATIONS

Marvin D. Rhodes and Conrad M. Willis Washington Mar. 1969 25 p refs

(NASA-TN-D-5109) Avail: CFSTI CSCL 10B

Two cone-column solar-energy concentrators were evaluated in this investigation. Both models had a rim angle of 0.79 radian and an effective radius of 76 cm. The first model was a simplified version of the cone-column with a rigidized cone. This model had a calorimetric efficiency of about 0.55 at an aperture radius of 8.16 solar-image radii. If this efficiency could be attained with a model utilizing a low-mass membrane cone. The cone-column would be competitive with a petalous concentrator designed for use with a Rankine cycle system. The second model was constructed to study some of the problems associated with the fabrication of an accurate membrane cone. However, the efficiency of this model was only about 0.28 at an aperture radius of 8.16 solar-image radii. The low efficiency of this model is due to markoff and interference of cone gores. The variation in efficiency for misalinement of the concentrator axis with the solar rays indicated that the performance of the cone-column was similar to that of a paraboloid. In addition, it was shown that small variations in misalinement can be compensated for by transverse displacements of the heat receiver. Author

HIGH PERFORMANCE TURBOALTERNATOR AND ASSOCIATED HARDWARE. 1: DESIGN OF TURBOALTERNATOR

R. Cohen, W. K. Gilroy, and W. B. Spencer Washington NASA Mar. 1969 215 p refs

(Contract NAS3-6013)

(NASA-CR-1290; PWA-3070-Vol-1) Avail: CFSTI CSCL 10B

The National Aeronautics and Space Administration is conducting an evaluation of Brayton cycle turbomachinery configurations. As part of this program, a turboalternator has been designed incorporating a two stage axial flow turbine driving an inductor alternator supported on gas bearings. The gas bearing rotor support system was successfully tested in a gas bearing dynamic simulator and in the turboalternator under electrical load and fault conditions to impose magnetic unbalance forces. A total of about 300 hours of operation was accumulated on the gas bearings with about 200 hours under electrical load. A backup gas bearing system was designed and various experimental investigations were conducted to verify certain areas of the turboalternator design in addition to the gas bearing testing. The turboalternator was successfully tested at design conditions in a high temperature loop. Author

EFFECTS OF TEMPERATURE AND ELECTROLYTE CONCENTRATION ON PERFORMANCE OF A FUEL CELL OF THE BACON TYPE

Robert E. Post Washington Apr. 1969 31 p refs

(NASA-TN-D-5154) Avail: CFSTI CSCL 10B

Performance was studied in terms of voltage-current data for temperatures ranging from 300° to 460°F (422 to 511K), KOH concentrations ranging from 70 to 82 wt. %, and reactant pressures of 22.4 psia ($1.54\times10^5 N/m^2$). The effect of increased concentration appeared as an upward displacement of the voltage-current curve and was two or more times that calculated from thermodynamic considerations. The effect of temperature appeared to be consistent with rate-process principles, in that it increased with current and decreased as equilibrium conditions were approached. Author

A PARAMETRIC ANALYSIS OF SURFACE TEMPERATURES OF PARABOLOIDAL SOLAR CONCENTRATORS IN SPACE

Robert J. Platt, Jr. Washington Apr. 1969 68 p refs

(NASA-TN-D-5144) Avail: CFSTI CSCL 10B

A parametric analysis was made of the surface temperatures of a paraboloidal mirror in space and aimed at the sun. The problem is simplified by the assumption of steady-state conditions, the paraboloidal mirror (solar concentrator) being located directly between the earth and the sun. Surface temperatures are plotted for a range of the important parameters for altitudes up to 35,000 kilometers. Additional temperature plots are presented for the case of a solar concentrator approaching the sun. The results indicate that at an irradiance of one solar constant, a concentrator of very low thermal conductance may experience a front surface temperature of 600°K in space, unless a front surface coating is used to increase the emittance. The temperature difference between the front and rear surfaces, which causes thermal distortion of the mirror, may be greatly reduced by proper selection of thermal control surfaces if the concentrator is near the earth. At irradiances of many solar constants, as in the case of a concentrator used with a solar probe, metal construction and high emittance coatings appear to be needed to reduce the front surface temperature and to minimize thermal distortion. INDUCTION HEATING ADVANCES: APPLICATIONS TO 5800°F

A. F. Leatherman and D. E. Stutz 1969 46 p refs

(NASA-SP-5071) Avail: SOD $0.30 CSCL 13A

Induction furnace design and basic heating principles are discussed. Vacuum reaction, vacuum brazing, and protective atmosphere furnaces are described, and radiant heat shielding designs are included. Theoretical considerations are given to induced currents and skin effects, operating frequency, heating coils, and power requirements. Various equipment arrangements are illustrated, and characteristics of components are given. Some of the more important advantages of induction heating are identified as no contact between work load and heat source, very high temperature capability, rapid heating, simplified control of processing, high efficiency, production capabilities, localization of heat, choice of vacuum or atmospheres, and cooler and cleaner working conditions. N.E.N.

CALORIMETRIC EVALUATION OF THREE 1.5-METER-DIAMETER INFLATABLE RIGIDIZED SOLAR CONCENTRATORS
Marvin D. Rhodes Washington Jun. 1969 35 p refs
(NASA-TN-D-5234) Avail: CFSTI CSCL 10B

The calorimetric efficiency of two 1.52-meter-diameter inflatable rigidized solar concentrators has been determined in order to evaluate their potential use with solar dynamic-cycle power systems. The membranes for these models were fabricated by different construction techniques and rigidized in a simulated space-vacuum environment with different foam materials (polyurethane and epoxy). Neither model was capable of satisfying typical design requirements of dynamic-cycle systems. The polyurethane-foam model had the higher calorimetric efficiency of the two models (0.61 at an aperture ratio of 7.6 as compared with 0.43 for the epoxy-syntactic-foam model); however, both models had about the same contour accuracy. In addition, these two models were compared with an epoxy–fiber - glass model rigidized at atmospheric pressure. Failure of all three models to meet the typical design requirements of the Brayton and Rankine cycle systems is due to low geometrical accuracy and low specular reflectance. Author

EFFECTS OF THERMAL-SHOCK CYCLING ON THIN-FILM CADMIUM SULFIDE SOLAR CELLS
John J. Smithrick Washington Jun. 1969 14 p refs
(NASA-TM-X-1819) Avail: CFSTI CSCL 10B

Thermal-shock cycling of Kapton, copper, and molybdenum substrate thin-film cadmium suflide (CdS) solare cells was conducted in an inert atmosphere by heating the cells to 65°C (338°K) and dipping them into liquid nitrogen. The Kapton substrate cells split in the CdS and delaminated. The open-circuit voltage and fill factor did not change; the shortcircuit current and maximum power decreased in direct proportion to the area by delamination. The single copper substrate cell tested did not delaminate or degrade after 1352 cycles. The single molybdenum cell tested did not delaminate after 1352 cycles but did degrade;however, comparable molybdenum substrate cells degrade on shelf storage also. The mode of degradation under thermal shock cycling was different from that observed, by others, under thermal cycling more realistic earth orbit simulation. Author

PRELIMINARY PERFORMANCE CHARACTERISTICS OF A GAS-BEARING TURBOALTERNATOR
James C. Wood, Martin E. Valgora, Roman Kruchowy, Joseph S. Curreri, Dennis A. Perz et al Henry B. Tryon Washington Jun. 1969 22 p refs
(NASA-TM-X-1820) Avail: CFSTI CSCL 10A

This report presents a preliminary evaluation of a Brayton cycle turboalternator using gas-lubricated bearings and operating on argon at a turbine inlet temperature of 1225°F (936°K). The turboalternator was operated successfully through steady-state and transient modes for 1165 total hours, during which time it was started and stopped 24 times. The alternator output was 8.8 kilowatts electric. The temperatures in the turboalternator did not exceed the predicted values when the turboalternator was operating at design conditions. The bearings always operated within the design clearance limits during both steady-state and transient testing. Largest clearance changes were experienced with the thrust bearings during full-load electrical transient tests. Author

DYNAMIC PERFORMANCE ANALYSIS OF A FUEL-CONTROL VALVE FOR USE IN AIRBREATHING ENGINE RESEARCH
Peter G. Batterton and John R. Zeller Washington July 1969 29 p refs
(NASA-TN-D-5331) Avail: CFSTI CSCL 13K

The analysis of a fast-response fuel-control valve for use in turbojet engine research is presented. This analysis includes cases where the valve is (1) closely coupled to the engine spray nozzles, and (2) located some distance from the engine, thus requiring connection by a hydraulic transmission line. The analysis results in a complete nonlinear model and an equivalent linearized model for both cases. The dynamic performance of the analytical models is presented and compared against corresponding experimental fuel-flow response data. A discussion is included which demonstrates how operating conditions affect fuel-flow frequency response. Author

A BRUSHLESS DC TORQUER-DRIVEN REACTION WHEEL FOR SPACECRAFT ATTITUDE CONTROL
R. Fulcher Washington Jul. 1969 20 p refs
(NASA-TN-D-5265) Avail: CFSTI CSCL 10B

A further development of electromechanical direct drive systems for space applications, dc photoelectronic (brushless) commutation techniques have been applied to the design of a reaction wheel. The resulting prototype hardware, which also incorporates optimized mechanical features, is shown to compare favorably on a weight/power basis with currently used ac torquer-driven reaction wheels. Furthermore, full utilization of the brushless commutator has simplified and improved control systems by providing, within the reaction wheel itself, the control electronic functions of bidirectional rotation, torque level control, and power amplification. A test control system using a prototype, brushless reaction wheel on a single-axis platform demonstrated excellent dynamic response and high pointing accuracy (within a few seconds of arc). Life testing of prototype hardware has been underway for 2 years. Author

N69-31844*# National Aeronautics and Space Administration. Lewis Research Center, Cleveland, Ohio.
EFFECTS OF NICKEL ON THE PERFORMANCE OF N ON P SILICON SOLAR CELLS
Cosmo R. Baraona Washington Aug. 1969 18 p refs
(NASA-TN-D-5366) Avail: CFSTI CSCL 10B

Nickel was added to 10-ohm-cm boron-doped silicon by a floating-zone technique. The calculated nickel concentrations were about 10^{14} atoms/cm^3. Solar cells were made by a standard process. Diffusion length, spectral response, and current-voltage characteristics were measured before and after bombardments by 1-MeV electrons with fluences ranging from 1×10^{14} to 1.5×10^{16} per cm^2. Nickel decreases the initial solar cell performance and does not improve the radiation resistance of the cell. The decreased performance is probably caused by nickel precipitation. Author

CHARACTERISTICS OF A THERMIONIC CONVERTER WITH A CHLORIDE VAPOR DEPOSITED TUNGSTEN EMITTER (110) AND A NICKEL COLLECTOR

V. C. Wilson and S. P. Podkulski Washington NASA Aug. 1969 37 p refs
(Contract NAS3-8511)
(NASA-CR-1416; GESP-9001) Avail: CFSTI CSCL 10A

A chloride vapor-deposited (110) tungsten emitter with a vacuum work function of 4.96 eV was built into a 0.005-inch-spaced converter with a nickel collector. The I–V curves for emitter temperatures of 1673°K to 2153°K are presented. The output power versus emitter temperature is compared with three other similar converters. This converter yielded almost the same output power as a converter with a single-crystal (110) tungsten emitter, 0.002-inch spacing and a molybdenum collector. The vapor-deposited (110) tungsten surface was found to be extremely stable. The collector work function was observed to decrease when the device was left at room temperature for one month. Author

N69-34652*# National Aeronautics and Space Administration. Lewis Research Center, Cleveland, Ohio.
ANALYSIS OF DYNAMIC PERFORMANCE LIMITATIONS OF FAST RESPONSE (150 to 200 Hz) ELECTROHYDRAULIC SERVOS
John R. Zeller Washington Aug. 1969 25 p refs
(NASA-TN-D-5388) Avail: CFSTI CSCL 13L

Fast response (150 to 200 Hz) electrohydraulic valve-controlled piston servo systems are used as research tools in experimental dynamics and controls studies. The components within these systems must operate at their limits of capability to achieve these high rates of response. A detailed nonlinear analytical model of these systems was formulated. The accuracy of this model was verified by comparing model dynamic performance against actual experimental data for a specific application. The analysis has led to a new generalized design criterion which in specific applications assists in determining a maximum region of dynamic performance capability. Author

PERFORMANCE CHARACTERISTICS OF A 14.3-KILOVOLT-AMPERE MODIFIED LUNDELL ALTERNATOR FOR 1200 HERTZ BRAYTON-CYCLE SPACE-POWER SYSTEM
David S. Repas and Richard A. Edkin Washington Sept. 1969 28 p refs
(NASA-TN-D-5405) Avail: CFSTI CSCL 10A

The measured performance of the alternator is presented. Test results include alternator saturation curves, losses and efficiency, voltage unbalance, harmonic analysis, machine reactances, and time constants. The peak electromagnetic efficiency of the alternator was 93.6 percent for a unity power factor load of 9.5 kW. For an output of 14.3 kVA at 0.75 power factor lagging, the alternator electromagnetic efficiency was 90.3 percent. Author

N69-35689*# General Electric Co., Schenectady, N.Y.
CHARACTERISTICS OF A THERMIONIC CONVERTER WITH A FLUORIDE VAPOR DEPOSITED TUNGSTEN EMITTER ETCHED TO PREFERENTIALLY EXPOSE THE 110 CRYSTAL PLANES
V. C. Wilson and J. Lawrence Washington NASA Aug. 1969 117 p refs
(Contract NAS3-8511)
(NASA-CR-1381; GEST-2107) Avail: CFSTI CSCL 10A

A variable spaced planar thermionic converter was built with a tungsten emitter, a niobium collector and a niobium guard ring. The tungsten emitting surface was a 0.020-inch-thick layer of fluoride vapor deposited tungsten. X-ray analysis and etch pit studies showed this surface was oriented with a (100) plane parallel to the bulk surface. The surface was etched to expose the (110) planes which are inclined 45 degrees to the (100) planes. The surface was then a mass of peaks, ridges and valleys several microns in depth, and had an exposed area about 40 percent greater than the plane surface. The initial output performance of this surface at low cesium pressures and also at large spacings was better than unetched (100) tungsten. The most output was obtained at 10 mils spacing or more for emitter temperatures from 1700°K to 2000°K. Operation for 21.8 hours at 2155°K reduced the sharpness of the points and ridges and the output performance decreased, particularly at larger spacings. Author

THE IMPROVEMENT OF AN ELECTRONIC POWER SUPPLY FOR GREATER RELIABILITY IN AEROSPACE USE
John P. Quitter and J. W. Schaelchlin (Gen. Dyn./Convair, San Diego, Calif.) Washington Sep. 1969 47 p refs
(NASA-TM-X-1875) Avail: CFSTI CSCL 10A

This report is a brief account of an upgrading program for electronic equipment. Serious design obstacles were overcome that led to the successful development of a highly reliable electronic component for space use. The component discussed is an inverter that provides three-phase 400-Hz power to the Centaur space vehicle. Because of early ground failure and design deficiencies, the inverter has received much engineering attention. This report is concerned with general upgrading of all piece parts used in the inverter, as well as improved mechanical and thermal design. Weaknesses of original piece parts are described, and rationale presented for the choice of better parts. Author

REDUCTION OF RECOVERY TIME IN HIGH-TEMPERATURE CESIUM VAPOR THYRATRONS
A. W. Coolidge, Jr. Washington NASA Sep. 1969 47 p refs
(Contract NAS3-9423)
(NASA-CR-1417) Avail: CFSTI CSCL 10B

An existing cesium vapor thyratron design was modified with the goal of reducing the recovery time from 300 to 100 microseconds. The approach taken was to facilitate ion-electron recombination by reducing the path lengths traversed by the ions after the cessation of current conduction. This included reduction of grid-to-anode spacing, grid-to-cathode spacing, and a reduction in the width of the grid slots. Although the tubes fabricated with these modifications were more difficult to fire and exhibited slightly increased voltage drop, stable operation was achieved for extended time periods in an inverter circuit. Author

ELECTROCHEMICAL CHARACTERIZATION OF NONAQUEOUS SYSTEMS FOR SECONDARY BATTERY

03 AUXILIARY SYSTEMS

APPLICATION
Manny Shaw, O. A. Paez, and Frank A. Ludwig Washington NASA Sep. 1969 229 p refs
(Contract NAS3-8509)
(NASA-CR-1434) Avail: CFSTI CSCL 10B

Approximately one thousand electrode-organic electrolyte combinations have been characterized relative to their use as rechargeable battery systems, using the method of cyclic voltammetry. Electrode systems consisted of silver, copper, nickel, cobalt, zinc, cadmium, indium, iron, molybdenum, chromium, manganese, vanadium, lithium, calcium, and magnesium. In general, the most promising positive metals were silver, copper, zinc, cadmium, and indium. A large majority of the nickel, cobalt, and iron systems exhibited no discharge peaks at all, and in most cases negligible discharge current. Twenty-four recommended systems comprising silver, copper, zinc, and cadmium, were further characterized by constant-current charge and discharge of sintered electrodes. Author

DEVELOPMENT AND INVERTER TESTING OF HIGH TEMPERATURE CESIUM-VAPOR THYRATRONS
A. W. Coolidge, Jr. Washington NASA Sep. 1969 47 p refs
(Contract NAS3-9423)
(NASA-CR-1435) Avail: CFSTI CSCL 09E

Cesium vapor thyratrons were developed for operation at 200° C to 300° C, in a vacuum environment. The tubes were rated 15 amperes average current, 250 volts peak forward and inverse. A major effort consisted of reducing the recovery time from over 300 microseconds to less than 100 microseconds. The tubes were endurance tested over 3000 hours in an inverter circuit. Author

DIFFUSION LENGTHS IN SILICON OBTAINED BY AN X-RAY METHOD
John H. Lamneck, Jr. Washington Oct. 1969 9 p refs
(NASA-TM-X-1894) Avail: CFSTI CSCL 10B

The necessity for a rapid method of measuring diffusion lengths of silicon solar cells in radiation damage and subsequent annealing studies led to the development of a new procedure utilizing a standard X-ray machine. After the machine was calibrated with cells of known diffusion lengths, measurements on test cells could be made at the rate of one every 2 min with a standard deviation of less than 2 percent. EFFECT OF ELECTROTHERMAL INSTABILITIES ON BRAYTON- AND RANKINE-CYCLE MAGNETOHYDRODYNAMIC SPACE-POWER GENERATION SYSTEMS
Allan R. Bishop and Lester D. Nichols Washington Oct. 1969 18 p refs
(NASA-TN-D-5461) Avail: CFSTI CSCL 10B

Plane wave electrothermal instabilities are included in the analysis of idealized Brayton- and Rankine-cycle magnetohydrodynamic generators. It is shown that the instabilities cause an increase in Joule heating and a reduction in output power. An increase in the magnetic field can compensate for the reduction in output power. Author

ELECTRICAL CHARACTERISTICS OF A LARGE AREA THIN FILM CdS SOLAR CELL
Ernie W. Spisz and John R. Jack Washington Oct. 1969 25 p refs
(NASA-TM-X-1899) Avail: CFSTI CSCL 10B

The electrical characteristics of a large area (54.7 cm^2) thin film CdS solar cell were obtained over a range of temperatures and radiant intensity levels at atmospheric conditions and in an ultrahigh vacuum simulation facility. The electrical characteristics were obtained over the temperature range from 20° to 90°C at radiant intensity levels of 0.014, 0.070, 0.140, and 0.245 W/cm^2. By applying the conventional "lumped constants" photovoltaic equation to the data, the effect of temperature on the reverse saturation current of the diode and the effect of temperature and radiant intensity level on the series resistance were determined. PRELIMINARY INVESTIGATION OF A SINGLE-SHAFT BRAYTON ROTATING UNIT DESIGNED FOR A 2- TO 10-KILOWATT SPACE POWER GENERATION SYSTEM
Robert Y. Wong, Hugh A. Klassen, Robert C. Evans, and Charles H. Winzig Washington Oct. 1969 39 p refs
(NASA-TM-X-1869; E-5130) Avail: CFSTI CSCL 10B

A 525-hour hot test at design thermal conditions was made. The results indicated that the performance of the turbine, compressor, and alternator are close to design specifications; no evidence of major design flaws; that the gas bearings had no short term operational problems; and that alternator armature winding temperatures were higher than anticipated. COLD AIR INVESTIGATION OF A TURBINE WITH STATOR-BLADE TRAILING-EDGE COOLANT EJECTION. PART 1: OVERALL STATOR PERFORMANCE
Warren J. Whitney, Edward M. Szanca, and Frank P. Behning Washington Oct. 1969 21 p refs
(NASA-TM-X-1901; E-5182) Avail: CFSTI CSCL 01A

Overall stator performance was obtained with ratios of coolant to primary mass flow of 0, 0.02, 0.035, 0.05, and 0.07. The effects of coolant on the performance parameters, mass flow characteristic and outlet flow angle, were determined experimentally. These effects were also determined theoretically for the condition of design primary mass flow. Author

MOTOR-STARTING CHARACTERISTICS OF TWO INDUCTOR ALTERNATORS
Charles S. Corcoran, David S. Repas, and Martin E. Valgora Washington Oct. 1969 13 p refs
(NASA-TM-X-1912) Avail: CFSTI CSCL 10B

Two inductor alternators were started as induction motors. One machine had a 5.2-inch (13.2-cm) diameter rotor with amortisseur windings and laminated pole tips; the other had a 7.38-inch (18.7-cm) diameter rotor with solid poles. Armature current, field voltage, and rotational speed were measured as functions of time. Torque was computed and is presented as a function of speed. The machine starting performance is compared to the requirements of a typical Brayton cycle generating system. Author

CONCEPTUAL DESIGN AND STRUCTURAL MODEL OF A

560-WATT THIN-FILM SOLAR-CELL ARRAY

Francis J. Stenger Washington Oct. 1969 14 p refs
(NASA-TM-X-1913) Avail: CFSTI CSCL 10B

A structural model of a cadmium sulfide thin-film solar-cell array was constructed with a deployment structure weight of 0.12 lb/ sq ft (0.59 kg/m^2) of panel area and a projected power output of from 15.5 to 19.4 W/lb (34.2 to 42.7 W/kg) using available CdS solar cells. The rollout, nonretractable array used a 40-ft (12.2-m) long storable boom as the basic structural element. The boom stiffness was tested using two simple mechanical suspensions. Author

Meeting sponsored by COSPAR, the International Union of Biochemistry, the International Union of Biological Sciences, and the International Union of Physiological Sciences.
Edited by A. H. Brown and F. G. Favorite.
Amsterdam, North-Holland Publishing Co., 1968, p. 1-19. 7 refs.

The Mercury and Gemini space flights have provided approximately 2,000 manhours of weightless exposure which can be used in comparing flight results with the predicted effects of manned space flight. In general the environmental hazards and the effects upon man appear to be of less magnitude than originally anticipated. The effects noted on the various body systems are summarized. The principal physiologic changes noted were orthostatism for some 50 hr after the flight, reduced red cell mass, and reduced X-ray density in the os calcis and the small finger. Much was learned about man's ability to work in a pressurized suit in the extravehicular condition. All of these findings are of importance in relation to the planning for future long duration missions. (Author)

Amsterdam, North-Holland Publishing Co., 1968, p. 87-93.

Description of the results of the flight of fertilized frog eggs in the manned orbital flights Gemini 8 and Gemini 12. The experiment was designed to determine the effect of weightlessness or near weightlessness on the ability of the cell to divide normally and on subsequent differentiation and embryogenesis. Eggs were fixed periodically in flight so that recovered material could be carefully compared to simultaneous ground controls with respect to gross morphology and histology. Some embryos were recovered alive after 4 days in orbit. In general, no abnormalities were detected which were inconsistent with the controls. Death, shortly after recovery, of the embryos recovered alive in Gemini 12, remains unexplained. The protocol of the experiment and the experimental hardware are described. (Author)

SOME BIOLOGICAL PROBLEMS IN THE SEARCH FOR EXTRATERRESTRIAL LIFE.
Harold P. Klein (NASA, Ames Research Center, Moffett Field, Calif.).
(International Symposium on Bioastronautics and the Exploration of Space, 4th, San Antonio, Tex., June 27, 1968.)
IN: SPACE PROJECTIONS FROM THE ROCKY MOUNTAIN REGION; PROCEEDINGS OF THE SYMPOSIUM, DENVER, COLO., JULY 15, 16, 1968. VOLUME 3. [A69-11755 02-11]
Symposium sponsored by the American Astronautical Society and the American Institute of Aeronautics and Astronautics.
Tarzana, Calif., American Astronautical Society, 1968. 21 p. 44 refs.

General discussion of the possible existence of extraterrestrial life forms in the solar system. The various components of the Martian atmosphere are reviewed on the basis of data obtained from the Mariner 4 flyby of 1965. It is suggested that the factor most prohibitive to the existence of life on Mars would be the almost total lack of water vapor. The adaptation of terrestrial organisms to simulated Martian atmospheres is briefly discussed. Some problems in planning "life detection" experiments to be used on unmanned Mars probes are also treated. M.G.

CHARACTERIZATION OF RIBULOSE DIPHOSPHATE CARBOXYLASE AND PHOSPHORIBULOKINASE FROM THIOBACILLUS THIOPARUS AND THIOBACILLUS NEAPOLITANUS.
R. D. MacElroy, E. J. Johnson, and M. K. Johnson (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).
Archives of Biochemistry and Biophysics, vol. 127, Sept. 1968, p. 310-316. 24 refs.

Investigation of two enzymes involved in the fixation of CO_2 by the chemosynthetic autotrophs Thiobacillus thioparus and Thiobacillus neapolitanus. Both of these enzymes, ATP:D-ribulose-5-phosphate 1-*phosphotransferase* (phosphoribulokinase) and D-ribulose-1,5-diphosphate carboxylase (ribulose diphosphate carboxylase) appear to sediment at identical rates in sucrose density gradients and to have similar characteristics during gel filtration. In addition to the major peak of ribulose diphosphate carboxylase activity observed in sucrose density gradients, an additional lighter peak of activity, suggestive of a subunit, has been observed. The relationship of these enzymes to those found in Fraction I protein of plant tissue is discussed, and it is suggested that both enzymes from the chemoautotrophs may be part of the same moiety. M.M.

A69-12804 *
THE SEARCH FOR LIFE - PLANETARY EVOLUTION.
Richard S. Young (NASA, Washington, D.C.).
IN: SPACE PROJECTIONS FROM THE ROCKY MOUNTAIN REGION; PROCEEDINGS OF THE SYMPOSIUM, DENVER, COLO., JULY 15, 16, 1968. VOLUME 1. [A69-12801 02-30]
Symposium sponsored by the American Astronautical Society and the American Institute of Aeronautics and Astronautics.
Tarzana, Calif., American Astronautical Society, 1968. 19 p.

Discussion of the two primary objectives of the NASA Planetary Exploration Program - namely, to gain data concerning the origin of the solar system and the origin of life. These two objectives are actually so interwoven as to be essentially indistinguishable from each other. If present theories concerning the sequence of events which led to the origin of life on earth are correct, then it is clear that the very early environment of any given planet is critical to the ability of that planet to produce and sustain a living system. Thus the physics and chemistry of planetary formation and early evolution are of the utmost importance to an understanding of the origin of life. It is believed that the likelihood of life on the moon, Venus, and Jupiter is considerably less than for Mars, but that much can be learned about planetary evolution from each of them. P.v.T.

A69-13433 *
UPTAKE AND INCORPORATION OF EXOGENOUS LEUCINE IN BACTERIAL CELLS UNDER HIGH OXYGEN TENSION.
Ho Lee Young (NASA, Ames Research Center, Moffett Field, Calif.).
Nature, vol. 219, Sept. 7, 1968, p. 1068, 1069. 8 refs.

Investigation of the relationship between the transport and the incorporation of amino acids, and net synthesis of protein at high oxygen tension in cells of Pseudomonas saccharophila. The results indicate that the ratio of endogenous to exogenous leucine is greater in cells grown in oxygen than in cells grown in air during incubation, and not the reverse. The results also suggest that high oxygen tension has little direct effect on the incorporation of leucine into protein, but that it strongly inhibits the leucine uptake. M.M.

EFFECTS OF ACUTE EXPOSURE TO HIGH-ENERGY PROTONS ON PRIMATES.
S. Tom Taketa, Bruce L. Castle, Wayne H. Howard, Charles C. Conley, Webb Haymaker (NASA, Ames Research Center, Moffett Field, Calif.), and Charles A. Sondhaus (California, University, Lawrence Radiation Laboratory, Berkeley, Calif.).
(Workshop Conference on Space Radiation Biology, University of California, Berkeley, Calif., Sept. 7-10, 1965.)
Radiation Research Supplement, no. 7, 1967, p. 336-359. 45 refs.

Discussion of data from collaborative studies to determine the biological effectiveness of protons as compared with other types of radiation, specifically ^{60}Co gamma radiation. The study, which used 43 rhesus monkeys, demonstrated the phenomena of dose buildup from the action of high-energy protons to be independent of

the Bragg peak effect and to be related to the distance traversed by the primary protons. Data based on midpoint air dose, midpoint tissue dose, and average body dose were used for the evaluation. Protons appeared to be as effective or slightly more effective than gamma rays when the comparisons were based improperly on midpoint air dose, but less effective when based on absorbed tissue dose. Appearance, radiation syndrome symptoms, and pathological changes were essentially similar in both groups. Silver impregnation in the brains of 15 animals revealed glial activation in most of them and was considered a radiation effect. G.V.

EXTRATERRESTRIAL BIOLOGY - PROSPECTS AND PROBLEMS IN THE EARLY 1970'S.
Richard D. Johnson and Harold P. Klein (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Annual Meeting and Technical Display, 5th, Philadelphia, Pa., Oct. 21-24, 1968, Paper 68-1122. 7 p. 17 refs.
Members, $1.00; nonmembers, $1.50.

The scientific rationale and experimental strategy for the biological exploration of Mars are discussed in terms of the chemical and biological experiments planned for these missions in the early 1970's. The experimental concepts and hardware development are treated in conjunction with the various mission constraints. Specifically, the chemical experiments are discussed in terms of the specificity of the analysis as applied to extraterrestrial samples, the experimental complexity with respect to sample processing, and the various types of analysis with respect to the detectors. The biological experiments are discussed in terms of growth and reproduction, metabolism, enzyme activity, and microscope scanning. Problems associated with growth media, water availability, and interference from soil are treated in terms of the experiment design The evolution and integration of the various separate experiments into more complex instruments is discussed as a prospect for later missions. (Author)

CRITICAL TEMPERATURE FOR INTRACRANIAL SELF-STIMULATION IN WHITE RATS.
Pava Popovic, A. B. Silver, and V. P. Popovic (Emory University, Dept. of Physiology, Atlanta, Ga.).
American Journal of Physiology, vol. 214, Apr. 1968, p. 801-803. 12 refs.
Grant No. NGR-11-001-009.

Evaluation of experiments made with white rats in order to ascertain the critical temperature for self-stimulation. Bipolar stainless steel electrodes were chronically implanted in the hypothalamic supramammillary area ("pleasure center") of 18 white rats which were trained to press a lever for intracranial self-stimulation Each rat pressed the lever 40 to 60 times per minute whenever it was placed for 1 hr in the box. When the body temperature reached 22 to 23°C, the rats eventually stopped pressing the lever. This point represents the "critical body temperature" for intracranial self-stimulation. P.v.T.

A69-14692 *
DISPERSION AND ATTENUATION OF SMALL ARTIFICIAL PRESSURE WAVES IN THE CANINE AORTA.
Max Anliker, Eric Ogden (Stanford University, Dept. of Aeronautics and Astronautics, Stanford; NASA, Ames Research Center, Div. of Environmental Biology, Moffett Field, Calif.), and Michael B. Histand.
Circulation Research, vol. 23, Oct. 1968, p. 539-551. 36 refs.
Grant No. NGR-05-020-223.

Description of a method for determining the elastic behavior of large blood vessels in the canine aorta in terms of their transmission characteristics for small sinusoidal pressure signals. The method is new insofar as it uses transient signals of the form of finite trains of sine waves that are superimposed on the naturally occurring pressure fluctuations and are generated by an electrically driven impactor or by a pump. Its application to the thoracic aortas of 18 mature mongrel dogs anesthetized with pentobarbital has shown that dispersion and attenuation data for frequencies between 40 and 200 cps can be obtained without requiring either Fourier-transform computations or resolution of reflection interference. M.M.

A69-15332 *
MAGNITUDE ESTIMATES OF ROTATIONAL VELOCITY DURING AND FOLLOWING PROLONGED INCREASING, CONSTANT, AND ZERO ANGULAR ACCELERATION.
Brant Clark and John D. Stewart (NASA, Ames Research Center, Moffett Field, Calif.).
Journal of Experimental Psychology, vol. 78, no. 2, 1968, p. 329-339. 24 refs.

Description of an experiment in which velocity of rotation was observed by ten observers in a rotating simulator during and following accelerations about a vertical axis which varied between .5° to 1.5°/sec^2 and .006 to .030°/sec^3 and continued for 2 to 3 min. Trials with zero acceleration were also included. Magnitude estimates of velocity of rotation increased and then declined during the constant accelerations, while more complex effects occurred during increasing accelerations. Aftereffects and an autokinetic effect were also observed. The current theory of vestibular function is discussed in the light of these results. M.G.

CELLULAR LOCALIZATION OF ACETYL-COENZYME A SYNTHETASE IN YEAST.
Harold P. Klein and Linda Jahnke (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).
Journal of Bacteriology, vol. 96, Nov. 1968, p. 1632-1639. 23 refs.

Study of the subcellular sites of the enzyme acetyl-CoA synthetase which is involved in lipid synthesis in Saccharomyces cerevisiae. Direct assays are performed for the enzyme in the microsomal fraction of the cells of Saccharomyces cerevisiae. The data suggest that during aerobic, but not anaerobic, growth on glucose, the enzyme moves from the microsomal fraction into the mitochondrial fraction. It is further suggested that the enzyme leaves the mitochondria when the cells become older, but while they are still viable. M.G.

A69-15969 *
COMPARISON OF THREE METHODS TO DETERMINE THRESHOLDS FOR PERCEPTION OF ANGULAR ACCELERATION.
John D. Stewart (NASA, Ames Research Center, Moffett Field, Calif.) and Brant Clark.
American Journal of Psychology, vol. 81, June 1968, p. 207-216. 13 refs.

Comparative study of three psychophysical methods used to determine thresholds for the perception of angular acceleration in man. Sixteen men with normal vestibular function were studied using three random forced-choice procedures with a simulator rotating the subject about a vertical axis. The constant method, using a 10-sec constant acceleration, was found to be the most reliable, and there was a high correlation between thresholds determined by a forced-choice random double-staircase method and the constant method. The constantly increasing accelerations of the ramp method were found to produce unreliable, equivocal results. The thresholds determined by the constant and staircase methods for the 16 subjects varied between 0.07 and 1.19 deg/sec^2. G.V.

A69-15983 *
EFFECTS OF PROGRESSIVE HYPOHYDRATION ON MAXIMAL ISOMETRIC MUSCULAR STRENGTH.
J. S. Bosco, R. L. Terjung (San Jose State College, San Jose, Calif.), and J. E. Greenleaf (NASA, Ames Research Center, Moffett Field, Calif.).
Journal of Sports Medicine and Physical Fitness, vol. 8, June 1968,

p. 81-86. 15 refs.

Experimental investigation in which nine male college students between the ages of 20 and 29, who had previous athletic experience and were physically active, were hypohydrated for two one-week periods. During the third week of the diet, a general decrease was evident in all the isometric strength measures except knee extension, paralleled with a mean weight loss of 2.5%. In general, the maximal strengths exhibited decreasing trends but only elbow flexion was significantly decreased at up to 3.1% hypohydration. M.M.

A69-17105 *

IDENTITY BETWEEN THE GROWTH HORMONE DEGRADING ACTIVITY OF THE PITUITARY GLAND AND PLASMIN.

S. Ellis, J. M. Nuenke, and R. E. Grindeland (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

Endocrinology, vol. 83, Nov. 1968, p. 1029-1042. 63 refs.

Investigation confirming the identity between plasmin and the esterase contaminating the growth hormone. Degradation products have been found in highly purified preparations of growth hormone. The degradation of the growth hormone and its electrophoretic behavior is presumably caused by a trypsin-like peptidase present in pituitary extracts. The effect could be duplicated with human plasmin during the investigations. Several other tests were performed to establish the identity between plasmin and the esterase. G.R.

IN VIVO UTILIZATION OF ACETATE-1-C^{14} IN CENTRIFUGED RATS.

E. D. Neville and D. D. Feller (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

Aerospace Medicine, vol. 40, Feb. 1969, p. 164-167. 13 refs.

Fed and fasted male rats were centrifuged at 5 g for 1, 3, and 24 hr. After this exposure, the metabolism of the rat was followed for a 3-hr period by measuring plasma glucose, plasma FFA, expired $C^{14}O_2$ and CO_2 patterns, and recovery of C^{14} in plasma lipids from acetate-1-C^{14}. Centrifugation caused a significant rise in plasma glucose and FFA in both fasted and fed rats. Plasma glucose remained elevated during the 3-hr postcentrifugation period while plasma FFA returned to normal values. Lipid synthesis increased in the intact rat as measured by an increased plasma C^{14}-lipid content. The observed increase of acetate incorporation into plasma lipids of rats previously exposed to centrifugation stress supports the previous observation, on isolated tissues, that this stress enhances lipogenesis. The relative roles of plasma glucose and FFA in energy relations of stressed animals are discussed. (Author)

STUDIES OF THE ELECTRON TRANSPORT CHAIN OF EXTREMELY HALOPHILIC BACTERIA. I - SPECTROPHOTOMETRIC IDENTIFICATION OF THE CYTOCHROMES OF HALOBACTERIUM CUTIRUBRUM.

J. K. Lanyi (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).

Archives of Biochemistry and Biophysics, vol. 128, Dec. 1968, p. 716-724. 11 refs.

Room temperature and liquid nitrogen difference spectra of H. cutirubrum extracts show evidence of two b-type, two c-type, and one a-type cytochrome. A scheme for electron transport involving these components is suggested whereby, at pH 7.2, the electron flow proceeds through cytochrome b(559), cytochrome c(555), and cytochrome a(592). At pH 9.4, however, it appears that an alternate pathway through cytochrome b(563) and cytochrome c(550) is opened. DPNH and α-glycerophosphate reduce both b-type cytochromes, while succinate reduces only cytochrome b(559). After overnight incubation, cytochrome b(563) is inactivated and can no longer be reduced enzymically. (Author)

TRANSMISSION CHARACTERISTICS OF AXIAL WAVES IN BLOOD VESSELS.

M. Anliker, W. E. Moritz (Stanford University, Dept. of Aeronautics and Astronautics, Stanford, Calif.), and E. Ogden (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

(Society for Experimental Stress Analysis, Spring Meeting, Albany, N.Y., May 7-10, 1968, Paper 1350.)

Journal of Biomechanics, vol. 1, Dec. 1968, p. 235-246. 23 refs.

Grant No. NGR-05-020-223.

Determination of the phase velocities and damping of sinusoidal axial waves in the carotid artery of anesthetized dogs using an electrooptical tracking system. For frequencies between 25 and 150 Hz, the speed of the axial waves ranged between 20 and 40 m/sec and generally increased with frequency, while the natural pressure wave traveled at a speed of about 10 m/sec. It is noted, however, that on the basis of an isotropic wall model, the axial wave speed should be approximately 5 times higher than the pressure wave speed. This discrepancy can be interpreted as an indication of anisotropic behavior of the carotid wall. The carotid artery appears to be more elastic in the axial than in the circumferential direction. M.M.

ADRENAL EPINEPHRINE AND PHENYLETHANOLAMINE N-METHYL TRANSFERASE (PNMT) ACTIVITY IN THE RAT BEARING A TRANSPLANTABLE PITUITARY TUMOR.

Joan Vernikos-Danellis (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.), R. Ciaranello, and J. Barchas (NASA, Ames Research Center, Environmental Biology Div., Moffett Field; Stanford University, School of Medicine, Palo Alto, Calif.).

Endocrinology, vol. 83, Dec. 1968, p. 1357, 1358. 12 refs.

NIH Grants No. HD-02881; No. MH-13259; Grant No. NGR-05-020-168.

Determination of plasma corticosterone and adrenal phenylethanolamine N-methyl transferase (PNMT) in rats bearing a transplantable pituitary tumor for six weeks. Ten male Fischer rats were fed commercial rat chow and water and were maintained at a constant temperature of 24°C. Half the rats were implanted with tumor tissue suspended in saline and injected intramuscularly into the right hind leg. The rats were decapitated six weeks after tumor implantation. It was found that there was a 350% increase in adrenal PNMT and a 160% increase in adrenal epinephrine in the tumor-implanted animals as compared to the controls. G.R.

POTENTIAL EFFECTS OF RECENT FINDINGS ON SPACECRAFT STERILIZATION REQUIREMENTS.

S. Schalkowsky, R. C. Kline (Exotech, Inc., Washington, D.C.), and L. B. Hall (NASA, Washington, D.C.).

Space Life Sciences, vol. 1, Mar. 1969, p. 520-530. 6 refs.

Contracts No. NASw-1558; No. NASw-1666.

Discussion of an extended analytical model (accommodating information which has been developed in the past year or which is currently being evolved) for an assessment of spacecraft sterilization requirements. The probability of a release of viable organisms from the spacecraft is evaluated as a function of: (1) impact velocity magnitudes and the probability of their occurrence; (2) the degree of equipment fracturing at impact velocities; and (3) the number of viable organisms in spacecraft materials. It is concluded that the results of work now in progress on spacecraft material fracturing,

on the estimation of buried contamination loads, and on microbial resistance on mated surfaces, may lead to less severe dry-heat sterilization of planetary spacecraft than had been considered necessary in the past. G.R.

RAT BODY COMPOSITION - SENSOR IMPLANTATION AND LIGHTING EFFECTS.

Grover C. Pitts, T. Robert Bullard, John W. Tremor, Paul D. Sebesta, Franz Halberg, and Walter Nelson (Virginia, University, School of Medicine, Charlottesville, Va.; NASA, Ames Research Center, Moffett Field, Calif.; Minnesota, University, Medical School, Minneapolis, Minn.).

Aerospace Medicine, vol. 4, Apr. 1969, p. 417-420. 14 refs.
Contracts No. NAS 2-1554; No. NAS 2-2738.

The effects of transensor-implantation, sham-implantation, or no implantation and three lighting regimens (continuous light, or darkness, or 12 hr of each per day) on body composition of 54 adult female Sprague-Dawley rats were evaluated by analysis of variance with a factorial design. Body composition involved chemical fractionation into lipid, water, protein-nitrogen, and ash of eviscerated carcass and viscera treated separately. Statistically significant results included: (1) percent fat in eviscerated carcass reduced in presence of transensor, (2) percent fat in viscera reduced after sham operation, (3) percent water in fat-free viscera increased in presence of the transensor (probably edema evoked by transensor as an irritant), and (4) percent fat in eviscerated carcass increased with daily dark-fraction, probably reflecting effect of lighting regimen on feeding activity. CONTROL OF ATP-DEPENDENT CO_2 FIXATION IN EXTRACTS OF HYDROGENOMONAS FACILIS - NADH REGULATION OF PHOSPHORIBULOKINASE.

R. D. MacElroy (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.), E. J. Johnson, and M. K. Johnson (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.; Tulane University, Medical School, Dept. of Microbiology, New Orleans, La.).

Archives of Biochemistry and Biophysics, vol. 131, Apr. 1969, p. 272-275. 8 refs.
NSF Grant No. GB-7492.

The role of NADH in stimulating ATP-dependent CO_2 fixation has been examined in crude extracts of Hydrogenomonas facilis. It has been found that the stimulation cannot be attributed to reduction of the product, 3-phosphoglyceric acid, and consequent regeneration of substrate. Rather, NADH appears to specifically affect phosphoribulokinase, probably by causing an allosteric transition of this regulatory enzyme. The kinetics of the NADH effect on CO_2 fixation suggest cooperative binding of the effector. A similar cooperative response of the enzyme to ATP has been noted. It is suggested that the control of CO_2 fixation is mediated by allosteric regulation of phosphoribulokinase activity. (Author)

DIFFERENCES BETWEEN RADIATION-INDUCED LIFE SHORTENING AND NATURAL AGING IN DROSOPHILA MELANOGASTER.

Henri Atlan (NASA, Ames Research Center, Moffett Field, Calif.), Jaime Miquel, and Rosemarie Binnard.

Journal of Gerontology, vol. 24, Jan. 1969, p. 1-4. 7 refs.

Study of the mortality kinetics of Drosophila melanogaster showing essential differences between gamma radiation-induced life shortening and normal aging. Gamma irradiation of Drosophila melanogaster imagoes 1 to 20 days of age resulted in death at a constant time after exposure. Age at irradiation influenced survival time only when the flies were irradiated 30 to 90 days after eclosion. These results suggest that the life-shortening effects of gamma radiation on Drosophila are the result of a radiation syndrome which, at least for 1 to 20 day old flies, is unrelated to aging. P.v.T.

CHANGES IN GROWTH AND BODY COMPOSITION OF MICE EXPOSED TO CHRONIC CENTRIFUGATION.

Lanny C. Keil (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

Growth, vol. 33, 1969, p. 83-88. 14 refs.

Mature and weanling mice were centrifuged at 4.7 g for one and two months. After centrifugation, the animals were sacrificed, and their body composition was determined and compared to that of noncentrifuged controls. Centrifuged animals showed a significant reduction in body mass and body fat. Differences in water and protein content between the control and experimental animals may be due to a repression of growth imposed by centrifugation. Increases were seen in the total body calcium of the weanling males, while centrifuged females showed a reduction in calcium after two months of centrifugation. (Author)

EFFECT OF SALTS AND ORGANIC SOLVENTS ON THE ACTIVITY OF HALOBACTERIUM CUTIRUBRUM CATALASE.

Janos K. Lanyi and Joann Stevenson (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).

Journal of Bacteriology, vol. 98, May 1969, p. 611-616. 11 refs.

Observation that catalase in extracts of the extreme halophile Halobacterium cutirubrum exhibits up to threefold stimulation by 0.5 to 1.5 M monovalent salts and by 0.1 M divalent salts, while inhibition of enzyme activity occurs at higher concentrations. The inhibitory effect, and to some extent the stimulation, is salt-specific; the effectiveness of a salt in inhibiting enzyme activity depends on both cation and anion. Aqueous solutions of ethylene glycol, glycerol, and dimethyl sulfoxide containing no ions influence enzyme activity in the same manner as do salts. F.R.L.

CONVERSION OF ACETATE-2-^{14}C TO $^{14}CO_2$ AND ^{14}C-FATTY ACIDS IN THE PARTIALLY HEPATECTOMIZED RAT (33627).

E. D. Neville, K. S. Talarico, and D. D. Feller (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

Society for Experimental Biology and Medicine, Proceedings, vol. 130, 1969, p. 643-651. 17 refs.

Results of an experiment in which 67% of the liver of male rats was removed to determine the relationship of the changes occurring in the oxidation of acetate to changes in fatty acid synthesis. Control rats were exposed to sham surgery, in which the liver was removed, handled, and returned intact to the abdominal cavity. The liver weight and fatty acid content of the liver at various times after surgery are compared for the two groups. The results suggest that in addition to deposition via transport, the fatty acid content of the regenerating liver is increased by synthesis in situ, during the premitotic phase as well as the mitotic phase. B.H.

CHANGES IN PERCEIVED SIZE OF HIGH LUMINANCE TARGETS.

Richard F. Haines (NASA, Ames Research Center, Moffett Field, Calif.).

Aerospace Medicine, vol. 40, July 1969, p. 754-758. 24 refs.

Investigation of the relationship between target luminance, shape, and size and its apparent size. Various diffuse white targets were foveally fixated by three highly trained male observers. Target luminances ranged from 0 to 13,000 foot Lamberts, and target sizes ranged from 39 min of arc to 2 deg, 35 min of arc in width. An unilluminated (black) background was used. The observer moved a point source of light behind the target along each of four meridians until it just disappeared at the target's apparent edge. An apparent expansion of the target occurred between the unilluminated and the illuminated conditions which averaged over 5 min of arc. However, when a filter was used across the entire field of view to reduce the luminance of the point source and the target by the same amount, no regular relationship was found between target luminance or size and its apparent size. All observers remarked that the square target appeared enlarged and quite round under high luminance conditions. Possible explanations for and applications of these data are given. (Author)

CURRENT RESEARCH ON REGENERATIVE SYSTEMS.

Jacob Shapira, Adrian D. Mandel, Phillip D. Quattrone, and Nancie L. Bell (NASA, Ames Research Center, Biotechnology Div., Moffett Field, Calif.).

IN: LIFE SCIENCES AND SPACE RESEARCH VII; COSPAR, PLENARY MEETING, 11TH, OPEN MEETING OF WORKING GROUP V AND SYMPOSIUM ON BIOLOGICAL EFFECTS OF RADIATION IN SPACE, TOKYO, JAPAN, MAY 14-16, 1968 AND MAY 10, 1968, PROCEEDINGS. (A69-37612 20-04)

Meeting and symposium co-sponsored by the International Union of Biochemistry, the International Union of Biological Sciences, the International Union of Physiological Sciences, and the International Union of Pure and Applied Biophysics.

Edited by Wolf Vishniac and F. G. Favorite.

Amsterdam, North-Holland Publishing Co., 1969, p. 123-129. 11 refs.

Summary of multiple studies directed toward the development of a regenerative life support system, showing that easily synthesized organic compounds and microbiological materials are potentially capable of being used as foods for long-duration space missions. The organic compounds presently believed to offer the greatest potential are glycerol, simple glycerol derivatives such as triacetin, and formose sugars. Laboratory studies indicate that glycerol can be synthesized from formaldehyde, which in turn is obtained by the direct catalytic oxidation of methane, a by-product of the Sabatier reaction used in spacecraft atmosphere control systems. Formose sugars are derived from the self-condensation of formaldehyde. Mixtures of glycerol and triacetin have been shown to be suitable as a major component of diets fed to weanling rats for prolonged periods. These compounds do not exist as stereoisomers and therefore offer advantages over the formose sugars. An automated system for the continuous autotrophic production of Hydrogenomonas eutropha bacteria is in operation, and the nutritional requirements for growth in the system using urea as a nitrogen source, are being studied. Nutritional evaluation of Hydrogenomonas bacteria has shown that they are capable of supplying the total protein requirement of growing rats for prolonged periods. The potential and problems of these regenerative systems and the prospects for the accomplishment of a totally regenerative food system will be discussed. (Author)

SENSITIVITY OF THE ADRENAL CORTICOSTERONE RESPONSE TO ACTH AS A FUNCTION OF TIME AFTER HYPOPHYSECTOMY.

Joan Vernikos-Danellis (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

Endocrinology, vol. 84, June 1969, p. 1507, 1508. 5 refs.

Comparison of the sensitivity of the increase in adrenal corticosterone concentration in rats in response to ACTH at various time intervals after removal of the pituitary gland. The animals were most sensitive 2 and 4 hr after removal of the pituitary, and the sensitivity of this response decreased progressively at intervals of 12 hr or longer after hypophysectomy. (Author)

PRESSURE-DIAMETER RELATIONS OF CAPILLARIES AND SMALL BLOOD VESSELS IN FROG LUNG.

J. E. Maloney and B. L. Castle (NASA, Ames Research Center, Biotechnology Div., Moffett Field, Calif.).

Respiration Physiology, vol. 7, Aug. 1969, p. 150-162. 10 refs.

Static pressure-diameter measurements were made on the small pulmonary blood vessels of the frog lung, and the change in the septal area occupied by capillaries was investigated at intravascular pressures of 1 to 27 cm water. Over this pressure range, the smallest arteries (30 to 50 microns) increased their radius by 27 per cent, while the change for veins of the same size was 6 per cent. Medium size arteries and veins (50 to 150 microns) showed a similar pattern of increase in radius by 30 per cent, while the largest arteries (150 to 400 microns) increased their radius by 50 per cent, over the complete pressure range. Capillaries occupied 79 per cent of the alveolar septum at low intracapillary (1 cm water) pressures and less than 80.5 per cent at higher intracapillary pressures (27 cm water). These results indicate that the small arterial blood vessels of the lung are highly compliant and capable of large alterations in blood volume and resistance with changes in intravascular pressure. STUDIES OF THE ELECTRON TRANSPORT CHAIN OF EXTREMELY HALOPHILIC BACTERIA. III--MECHANISM OF THE EFFECT OF SALT ON MENADIONE REDUCTASE.

Janos K. Lanyi (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).

Journal of Biological Chemistry, vol. 244, Aug. 10, 1969, p. 4168-4173. 12 refs.

Description of the effects of monovalent and divalent cations and of polyamines on the menadione reductase activity for the purpose of exploring the mechanism of the salt dependence of this enzyme. There is no menadione reductase activity in the absence of

salt. This activity increases with salt concentration to a maximum at 2 mol or higher concentrations of sodium chloride. The enzyme activity lost at low salt concentrations can be restored by adding 2 mol NaCl. Z.W.

COMPENSATORY HYPERTROPHY AND PHENYLETHANOLAMINE N-METHYL TRANSFERASE (PNMT) ACTIVITY IN THE RAT ADRENAL.
Roland D. Ciaranello, Jack D. Barchas, and Joan Vernikos-Danellis (Stanford University, Dept. of Psychiatry, Stanford; NASA, Ames Research Center, Moffett Field, Calif.).
Life Sciences, vol. 8, Apr. 1, 1969, p. 401-407. 9 refs.
NIH Grant No. HD-02881; Contract No. NR-102-715; Grant No. NGR-05-020-168.

Investigation of the hypothesis that physiological as opposed to pharmacological conditions (exogenous adrenocorticotrophic hormone) might raise adrenal PNMT further in nonhypophysectomized rats. The data obtained show that enzyme activity increases 1.5 times over sham operated controls 40 days after surgery. It is noted that the possibility exists that chronic low levels of pituitary-adrenal stimulation might be more effective in increasing enzyme activity than acute, high levels. P.G.

VIRUSLIKE PARTICLES IN THE FAT BODY, OENOCYTES, AND CENTRAL NERVOUS TISSUE OF DROSOPHILA MELANOGASTER IMAGOES.
D. E. Philpott, J. Weibel, H. Atlan, and J. Miquel (NASA, Ames Research Center, Moffett Field, Calif.).
Journal of Invertebrate Pathology, vol. 14, July 1969, p. 31-38. 7 refs.

A viruslike particle has been found in the nucleus of fat-body cells and oenocytes of *Drosophila melanogaster* imagoes 15, 76, and 91 days old. The particle has also been observed in glial cells of the cephalic ganglionic center of 91-day-old flies and in glial cells of 29-day-old flies that were exposed to 50 kr of gamma radiation when they were one day old. IN: CIRCADIAN RHYTHMS IN NONHUMAN PRIMATES; INTERNATIONAL CONGRESS OF PRIMATOLOGY, 2ND, SYMPOSIUM, EMORY UNIVERSITY, ATLANTA, GA., JULY 2, 1968, PROCEEDINGS. (A69-42701 24-04)
Edited by F. H. Rohles.
Basel, Switzerland, S. Karger AG (Bibliotheca Primatologica, No. 9), 1969, p. 64-74. 12 refs.

Study of the phase relationships of circadian rhythms of heart rate, locomotor activity, and deep body temperature (DBT) in unrestrained *Cebus albifrons* and *Macaca nemestrina* in response to photoperiods of various lengths. The primates were maintained unrestrained for relatively long periods (as long as 18 months). For each experiment, the animals were placed in individual cages in a relatively constant environment. The circadian rhythm of DBT was determined by hermetically sealed miniature radio transmitters implanted retroperitoneally on the right side of the abdominal cavity. Although the results do not indicate which physiological mechanisms are responsible for the circadian rhythms of DBT, locomotor activity, and heart rate in the nonhuman primates, they do show that the relationships involved are nonlinear. G.R.

The Hague, Inter Scientias, 1969, p. 31-39, 41, 43 (7 ff.).

Description of a therapeutic application of centrifugation by which a 10 by 6 by 4 mm bullet fragment floating freely in the ventricular system of the human brain was moved to a fixed safe position where it was embedded in the posterolateral wall of the left lateral ventricle. The patient was briefly exposed to increased accelerations in a centrifuge with five degrees of freedom at the NASA Ames Research Center. He has remained symptom-free without an apparent neurological deficit over a period of six months following this procedure. V.Z.

EFFECTS OF HYPEROXIA AND HYPOXIA ON MITOSIS IN THE NORMAL AND REGENERATING RAT LIVER.

K. S. Talarico, D. D. Feller, and E. D. Neville (NASA, Ames Research Center, Environmental Biology Div., Moffett Field, Calif.).

Society for Experimental Biology and Medicine, Proceedings, vol. 131, 1969, p. 430-434. 9 refs.

Demonstration of the effects of hyperoxia and hypoxia on mitotic activity in the regenerating and normal rat liver by exposing partially hepatectomized and unoperated rats to hyperoxic and normobaric, hyperoxic and hypobaric, normoxic and hypobaric, and hypoxic and hypobaric environments. When exposed to 100 per cent oxygen at various pressures for various time periods up to 34 hr, no change was noted in the animals. When exposed to a hypoxic condition (air, 380 mm Hg) for the same time periods, the partially hepatectomized group showed a delay in the initiation of mitosis, while the unoperated group showed a reduction in mitotic activity due to the hypoxic environment. SYNTHESIS OF ACYCLIC ISOPRENOIDS BY THE γ-IRRADIATION OF ISOPRENE.
Colin Munday, Katherine Pering, and Cyril Ponnamperuma (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).
Nature, vol. 223, Aug. 23, 1969, p. 867, 868. 18 refs.

Discussion of experiments in which it was shown that branched chain acyclic polymers can be produced from isoprene under plausible geochemical conditions. Two series of experiments were conducted. In the first, isoprene was irradiated by cobalt 60 gamma rays in sealed tubes. In the second, isoprene was adsorbed onto the surface of vermiculite before irradiation. The products were then extracted from the vermiculite with 10 ml of freshly distilled isoprene. Excess solvent was removed under vacuum. A portion of the products of each series was hydrogenated in hexane at atmospheric pressure, using hydrogen with 5 per cent palladium as a catalyst. The products before and after hydrogenation were analyzed by gas chromatography and mass spectrometry. Parallel studies of the isoprene and the vermiculate before irradiation showed that they were free of the compounds sought. V.P.

A MICRO LAGOON TECHNIQUE FOR THE CULTURE AND OBSERVATION OF ISOLATED MAMMALIAN CELLS
Clarence D. Cone, Jr. and Kathryn M. Peddrew Washington Nov. 1968 26 p refs
(NASA-TN-D-4906) Avail: CFSTI CSCL 06A

A technique for physically partitioning a monolayer of cells into micro regions on a culturing surface is described. The method consists of forming a thin grease layer into a field of tiny ponds or lagoons in which small numbers of cells or other microbiological specimens can be confined for purposes of growth, manipulation, and microscopic observation. Special instruments and procedures which have been developed for lagoon-field formation are described in detail, as are the characteristics of various formation materials which have been evaluated. Factors and problems affecting various aspects of lagoon-field suitability for cytological purposes are discussed, and the details of special culturing vessels and lagoon-inoculation procedures which have been developed by the authors for particular types of experiments are presented. A number of cytological applications, particularly in the field of time-lapse cinephotography, in which the technique has proven to be exceptionally valuable are outlined. The basic micro lagooning techniques described have considerable flexibility for adaptation and should thus prove to be useful for a wide range of cytological applications where simple micro isolation is a prime requirement. NASA CONTRIBUTIONS TO BIOINSTRUMENTATION SYSTEMS—A SURVEY

Gershon Weltman, Moshe Klagsbrun, Donald Ukkestad, and Ben Ettelson 1968 101 p refs Prepared by Spacelabs, Inc.

(NASA-SP-5054) Avail: SOD $1.00; CFSTI CSLC 06B

Advances in bioinstrumentation devices and techniques achieved by the National Aeronautics and Space Administration are described to facilitate use of NASA contributions in medicine and the bioinstrumentation industry. Accordingly, the survey is directed largely toward two groups: those in medicine who plan, specify, and utilize advanced bioinstrumentation systems; and those in engineering who design, develop, and manufacture them. The objectives are to stress the correspondence between spaceflight and nonaerospace applications and to lay the groundwork for subsequent extrapolation of NASA's experiences by the reader. Five main areas of NASA bioinstrumentation system development are identified: (1) *Planning*—The techniques to establish information requirements and equipment specification for system development are outlined. (2) *Sensing and signal conditioning*—Detection of physiological signals under aerospace conditions and design of advanced electronic instrumentation to process and transmit these signals are discussed. (3) *Medical monitoring and data processing*—Significant NASA contributions to data processing, including acquisition techniques, computation of derived parameters, and methods of data display are included. (4) *Measurements in the field*—Solutions to some difficult problems of making laboratory-quality measurements in the field are treated. (5) *Manufacture*—NASA contributions to bioinstrumentation fabrication and quality assurance are presented. Author

MITOTIC SYNCHRONIZATION OF L-STRAIN FIBROBLASTS WITH 5-AMINOURACIL AS DETERMINED BY TIME-LAPSE CINEPHOTOGRAPHY

Clarence D. Cone, Jr. and Max Tongier, Jr. Washington Feb. 1969 28 p refs

(NASA-TN-D-5021) Avail: CFSTI CSCL 06A

A technique for producing mitotically synchronous cultures of L-strain fibroblasts by treatment with 5-aminouracil (an analog of thymine) is presented along with a detailed description of a procedure for determining the resulting degree of synchrony by use of time-lapse cinephotography. Several sets of representative experimental results illustrating the mitotic synchronization effectiveness of 5-aminouracil as determined by the time-lapse technique are presented and are interpreted on the basis of previous results for plant and animal cells. Basic effects on the validity of experimental results, caused by deviations of synchronized experimental cultures from ideal or perfect synchrony are also discussed, and a quantitative index for expressing the relative degree of synchrony attainable with various agents is defined. OSMOTICALLY INDUCED COALESCENCE OF SARCOMA CELLS THROUGH INTERCELLULAR BRIDGES IN VITRO

Clarence D. Cone, Jr., and Max Tongier, Jr. Washington Feb. 1969 24 p refs

(NASA-TN-D-5022) Avail: CFSTI CSCL 06R

A relatively detailed description is presented of a microtechnique by which cells possessing true intercellular bridges *in vitro* can be induced to coalesce into single mono- and multinucleate giant cells. The technique consists in the carefully controlled perfusion of a cell field with a hypotonic solution, which causes osmotic swelling and thereby induces connected cells to coalesce through expansion of the connecting bridge. Details of the perfusion system and methodology are discussed, along with the system of time lapse cinemicorgraphy used for recording the coalescence process. Principal features of an alternate coalescence technique utilizing a movable micropipet are also outlined. Representative photographic sequences reproduced from time lapse film recordings are presented to illustrate the basic nature of the coalescence phenomenon for the case of L-strain fibroblasts. An interpretation of the implications of coalescence in indicating cytoplasmic continuity of intercellular bridges, and other aspects of intercellular communication at the molecular level, is included.

Finally, a brief mention is made of several additional cytological applications of the osmotic swelling procedure. Author

COMBINATION EFFECTS OF TONE AND DURATION PARAMETERS ON PERCEIVED NOISINESS
Karl S. Pearsons Washington NASA Feb. 1969 49 p refs
(Contract NAS1-7461)
(NASA-CR-1283) Avail: CFSTI CSCL 06P

Three series of judgment tests were conducted to investigate the effects on perceived noisiness of tone content and duration parameters. Time patterns for the stimuli employed in the tests were triangular in shape to simulate aircraft flyover time histories. Stimuli for the first test included durations of 4, 12, and 32 seconds measured 10 dB below the maximum level of the stimulus. Tone-to-noise ratios in 1/3 octave bands for the stimuli at 2000 and 4000 Hz were varied to include 10 and 25 dB and no tone. In the second test stimuli included recordings of test stand turbofan engine noise using the same time history shape and durations mentioned above. The third test utilized pure-tone and broadband noise spectra like those used in the first Test, however, the duration of the tone differed from the duration of the noise, and the maximum level of the tone did not always occur at the same point in time as the maximum level of the noise. AN ANALYSIS OF THE OPERATION OF A MASS MEASURING SYSTEM IN AN ORBITING SPACECRAFT
Bruce A. Conway Washington Feb. 1969 29 p refs
(NASA-TN-D-5039) Avail: CFSTI CSCL 06B

An analysis of the operation of a mass measuring system, which is based on the oscillating spring mass principle, aboard a spacecraft is made. This analysis considers the dynamic effects of the oscillating device on an uncontrolled spacecraft by developing the equations of motion for the system. An approximate solution of these equations is then deduced, and a simple analytic expression for the maximum attitude error is found. Numerical integration of the equations of motion was performed on a digital computer for some typical measurement operations. Comparison between the approximate and exact solutions for these cases was very close. Results showed small (less than 0.02°) attitude errors arising from the operation of this device. Author

DYNAMICS OF THE VESTIBULAR SYSTEM AND THEIR RELATION TO MOTION PERCEPTION, SPATIAL DISORIENTATION, AND ILLUSIONS
Richard A. Peters Washington NASA Apr. 1969 249 p refs
(Contract NAS2-3650)
(NASA-CR-1309; TR-168-1) Avail: CFSTI CSCL 06P

In piloting tasks, visual observation of instrument indicators and of the visual field and sensations of motion, provide the sensible signals upon which the pilot bases his control of the aircraft. Variations of the gravitational-inertial force environment during the flight of an aircraft affect the pilot's motion sensors in his vestibular system and through them affect his control of the vehicle, his visual process, and his sense of orientation. A study is made of the basic physiology of the human vestibular system and its interconnection with the oculomotor system. The dynamic functions of the semicircular canals and utricles (otolith organs) and the relation between subjective perceptions of motion and the accelerations which produce them are studied. Mathematical models of the dynamic functions of the vestibular system are presented. The various illusions experienced by pilots of aircraft are related to the accelerations which produce them and to the dynamics of the vestibular sensors involved. Author

A PROCESS FOR IMPRINTING MICRO LAGOON FIELDS IN PLASTIC SURFACES FOR USE IN CELL AND TISSUE CULTURE

Clarence D. Cone, Jr. and Edward N. Fleenor, Jr. Washington Jun. 1969 33 p refs

(NASA-TN-D-5255) Avail: CFSTI CSCL 06C

The process involved the fabrication of a metal impression die possessing a raised image anvil of the micro lagoon field on its surface, and the impressment of the heated die into the surface of suitable plastic vessels. Details of the die fabrication process are given, including the techniques used for photo transference of the basic lagoon-field image to the metal die surface and the development of the anvil imprint image on the die surface by chemical etching. The process used for imprinting the lagoon-field image into the plastic culturing surfaces of various culture vessel types is also described. Photomicrographs of typical lagoon fields formed by the process are presented, along with an analysis of factors in the die-fabrication process which affect the dimensional accuracy of the resulting lagoons. Time-lapse studies of actual cell growth in lagoons produced by the impression process, using L-strain fibroblasts, indicate that the lagoons are of excellent optical quality and are very effective in preventing both the escape of cells from the lagoons and the intrusion of external cells into the lagoons. TOXICITY PROBLEMS IN PLASTIC HARDWARE DESIGNED FOR BIOLOGICAL SPACE-FLIGHT EXPERIMENTS

Richard Willoughby Washington Jun. 1969 7 p refs

(NASA-TM-X-1818) Avail: CFSTI CSCL 06C

In the development of hardware for biological space flight, various plastic materials were found to be toxic to sea urchin sperm and unfertilized eggs. Glass control chambers were not. Acrylic and polycarbonate plastics were tested as material for the hardware body, while fluorocarbon elastomer rubber, nitrile, three silicone rubbers, butyl rubber, and ethylene propylene were tested as O ring materials. Fertilized frog eggs were found to be compatible with ethylene propylene and acrylic plastic after careful treatment, principally outgassing by vacuum exposure, but no treatment was discovered which would sufficiently detoxify plastic hardware so that it would maintain sea urchin sperm and unfertilized eggs. COORDINATION OF THE VOLUNTARY MOVEMENTS OF MAN IN A ZERO GRAVITATIONAL FIELD (UNDER WEIGHTLESSNESS) [KOORDINATSIYA PROIZVOL'NYKH DVIZHENIY CHELOVEKA V NULEVOM GRAVITATSIONNOM POLE (V NEVESOMOSTI]

L. V. Chkhaidze Washington NASA Jul. 1969 34 p Transl. into ENGLISH of the book "Koordinatsiya Proizvol'nykh Dvizheniy Cheloveka v Usloviyakh Kosmicheskogo Poleta" Moscow, Nauka Press, 2d. ed., 1966

(Contract NASw-1692)

(NASA-TT-F-578) Avail: CFSTI CSCL 06S

The coordination of the voluntary movements of man in a zero gravitational field (weightlessness) is analyzed on the basis of observational data accumulated under conditions of temporary weightlessness and in flights of artificial manned satellites. The general biomechanical rules of movements performed under weightlessness conditions are derived from tests carried out according to cyclographic method. The discussions regarding coordination during weightlessness are supplemented by the personal reports of Soviet cosmonauts, as well as the American astronaut John Glenn. It is concluded that even prolonged weightlessness causes no serious or lasting disorders in an invididual's movement coordination if he has been properly and adequately trained. However, certain changes should be expected in the dimensionality of the dynamic components of the coordination structure of skills performed in an altered gravitational field, and the limits to the decrease of the elements of the movement structure can reach 50%. SECOND-ORDER WAVE STRUCTURE IN SUPERSONIC FLOWS

David A. Caughey Washington NASA Sep. 1969 87 p refs (Grant NGR-31-001-119)

(NASA-CR-1438) Avail: CFSTI CSCL 20D

Second-order effects upon the wave systems associated with bodies in uniform supersonic flight are considered. An appropriate scaling of the independent variables is introduced to take into account the locally small, but cumulative, nonlinearities which determine the validity of the classical perturbation theories at large distances from the body. Predicted shock angles for the flow over slender wedges (planar flow) and cones (Axisymmetric flow) are compared with exact inviscid calculations to show the improvement afforded by inclusion of second-order effects. Inclusion of the full second-order solution is required to achieve appreciable improvement over the first-order theory for the conical case. Author

CONCENTRATION OF MATTER AND ACTION OF ENZYMES IN COACERVATES

T. N. Yevreinova Oct. 1969 223 p refs Transl. into ENGLISH of the book "Kontsentrirovaniye Veshchestv i Deystviye Fermentov v Koatservatkh" Moscow, Nauka Press, 1966 p 3-186

(NASA-TT-F-525) Avail: CFSTI CSCL 06C

The book brings together published data and the author's own experimental findings on coacervate systems consisting of compounds formed biogenically: proteins, nucleic acids, enzymes, carbohydrates, and other biopolymers and low molecular compounds included in the composition of living organisms. Most attention is given to the main property of coacervation, i.e., the concentration of compounds in individua coacervate drops both during their formation and during their absorption of substances, including enzymes, from the surrounding solution. It is shown that coacervate drops constitute very suitable models which can be used to elucidate and reproduce many of the phenomena characteristic of protoplasm, and to approach the solution of the most important problem in biology, the artifical synthesis of living matter. BIOCHEMICAL AND METABOLIC EFFECTS OF A SIX-MONTH EXPOSURE OF SMALL ANIMALS TO A HELIUM-OXYGEN ATMOSPHERE

Robert W. Hamilton, Jr., Janis D. Cohen, Gerald F. Doebbler, Lorenzo F. Exposito, John M. King, et al Washington NASA Oct. 1969 90 p refs

(Contract NAS2-3900)

(NASA-CR-1372) Avail: CFSTI CSCL 04C

Selected biochemical analyses were made on the parent and two successive generations of mice. These included blood indices; electrophoretically separated tissue protein patterns from liver, skeletal muscle, and cardiac muscle; quantitative determinations of LDH, MDH, and G6PDH from the same tissues; serum insulin; and semi-quantitative histochemical estimates of liver glycogen. No cases of statistically significant difference or consistent trends were seen between the experimental environmental groups. Additional analyses of liver nucleotides and redox-coenzymes also failed to show a significant difference. The relative weights of liver, heart, kidney, and diaphragm (wet and dry) were the same in both groups. Histopathological examination of kidney and adrenal tissue produced unremarkable findings and none that were attributable to the nature of the gaseous environment. It must be concluded that prolonged exposure to helium-oxygen, relative to air, does not produce detectable changes in several key subcellular factors which might be altered by serious metabolic disturbances, and therefore the helium exposure is well tolerated. DYNAMIC RESPONSE OF THE HUMAN BODY TO VIBRATION WHEN COMBINED WITH VARIOUS MAGNITUDES OF LINEAR ACCELERATION.

Hubert C. Vykukal (NASA, Ames Research Center, Moffett Field, Calif.).

Aerospace Medicine, vol. 39, Nov. 1968, p. 1163-1166.

To determine the effects of vibration combined with higher linear accelerations on human body dynamics, a study was conducted whereby four subjects, in a semisupine position, were exposed to vibration (±0.4 g at 2-1/2 to 20 cps in 1/2 cps increments) combined with linear accelerations of 1, 2-1/2, and 4 g. The mechanical impedance of each subject was measured. A vibration device developed for use with various motion generators was utilized in the investigation. Results show significant changes in both impedance magnitude and body resonance. The effects of higher linear accelerations on the human body dynamics are increased stiffness, reduced damping of the whole body, and higher energy transmission to internal organs. Resonances at higher frequencies became more predominant in magnitude because of increased coupling of the body system when immersed in a high g environment. (Author)

A NEUTRAL BUOYANCY MICRO-ELECTRODE FOR PROLONGED RECORDING FROM SINGLE NERVE UNITS.

Torquato Gualtierotti and Pearl Bailey (NASA, Ames Research Center, Instrumentation Div., Neurobiology Branch, Moffett Field, Calif.).

Electroencephalography and Clinical Neurophysiology, vol. 25, 1968, p. 77-81. 7 refs.

Description of a new electrode which allows continuous recording from single neurones or nerve fibers for an extended period of time. It also allows recording during gross movement and high acceleration and vibration. The basic principle of such an electrode is that its density equals that of the surrounding tissue. Moreover, to avoid standing oscillations, the electrode is counterbalanced against torque momentum and is floating. A miniaturized voltage-follower to be used with the microelectrode is also described. M.M.

MEASUREMENT OF PILOT DESCRIBING FUNCTIONS FROM FLIGHT TEST DATA WITH AN EXAMPLE FROM GEMINI X.

Rodney C. Wingrove and Frederick G. Edwards (NASA, Ames Research Center, Moffett Field, Calif.).

(NASA, Annual University Conference on Manual Control Systems, 4th, University of Michigan, Ann Arbor, Mich., Mar. 25, 1968.)

IEEE Transactions on Man-Machine Systems, vol. MMS-9, Sept. 1968, p. 49-55. 11 refs.

Theoretical analysis of a technique for reducing the error in identifying the pilot-describing function from routine flight-test records due to the fact that the pilot's output noise is correlated with the input error signal. The error can be reduced in the computer processing by shifting the input signal by an amount equivalent to the pilot's time delay. This technique for reducing the identification error is analyzed with theory and is demonstrated with the identification of a simulated pilot model. The technique is applied to flight-test records obtained from the retrofire phase of the Gemini X mission. M.M.

INSTANT MODULAR 3-D MOCKUP FOR CONFIGURING CONTROL AND DISPLAY EQUIPMENT.

Charles C. Kubokawa (NASA, Ames Research Center, Moffett Field, Calif.).

IEEE Transactions on Man-Machine Systems, vol. MMS-9, Sept. 1968, p. 72-81. 18 refs.

A modular three-dimensional mockup technique was developed as a method for economizing and facilitating the design of control and display equipment. The integral parts of the mockup include modular easy-to-assemble console bays and panels, simulated magnetic backed three-dimensional controls and displays of actual size, various writing shelf configurations, fast assembly clamps, storage cabinet with casters, and a Polaroid camera. Human engineering constraints were designed into the mockup parts- i.e., optimum reach, height, view, and control limits - so that the designers could not deviate from human engineering inputs, facilitating optimum operating conditions. (Author)

THE EFFECT OF BREATHING 100% OXYGEN ON FOVEAL THRESHOLDS.

Mary M. Connors (NASA, Ames Research Center, Moffett Field, Calif.).

Human Factors, vol. 10, Aug. 1968, p. 377-384. 18 refs.

This study examined the effects of breathing 100% oxygen at sea level on the luminance thresholds necessary for perception of red (642 nm), green (521 nm), blue (468 nm), and yellow (584 nm), and the chromatic and absolute thresholds associated with these dominant wavelengths. Using two highly trained observers, thresholds were measured for one target size and exposure duration by the method of constant stimuli. For the foveal thresholds investigated, no differences were found between the condition of breathing 100% oxygen and breathing normal room air at sea level. There is at least some physiological basis for thinking that vision may improve in a high oxygen environment. At the other extreme, breathing high concentrations of oxygen under pressure is known to degrade vision. Evidence relating to the visual effects of high oxygen concentrations is evaluated and conclusions are drawn with reference to the findings of this and other studies. (Author)

PROTECTION AGAINST TOXIC ROCKET FUELS.

Wallace B. Frierson (SysteMed Corp.; NASA, Marshall Space Flight Center, Medical Center, Huntsville, Ala.).

American Industrial Hygiene Association Journal, vol. 29, Sept.-Oct. 1968, p. 456-460.

Description of a detailed treatment procedure for acute exposures to toxic rocket fuels or oxidizers. Other aspects of a preventive program are outlined. These cover construction of the facility, preparation and use of operating procedures, environmental health surveys, and inspections and monitoring of exposed employees. Among the toxic chemicals considered are UDMH, Aerozine 50, N_2O_4, fluorine derivatives, and the boranes. B.H.

ADVANCED DEVELOPMENTS IN HARD SPACE SUIT TECHNOLOGY.
H. C. Vykukal (NASA, Ames Research Center, Moffett Field, Calif.).
(AVIATION AND SPACE: PROGRESS AND PROSPECTS; PROCEEDINGS OF THE ANNUAL AVIATION AND SPACE CONFERENCE, BEVERLY HILLS, CALIF., JUNE 16-19, 1968, p. 86-92.)
ASME, Transactions, Series B - Journal of Engineering for Industry, vol. 90, Nov. 1968, p. 577-583.

Survey of oxygen generators for spacecraft based on water electrolysis. The water electrolysis cells surveyed are predominantly prototype units including both liquid and vapor feed cells. Cell design, operational performance, gas purity, and problems encountered during testing are discussed. Suggestions are given as to where future research might be concentrated in order to solve some of the more general problems associated with water electrolysis. (Author)

MICROBIOLOGICAL STUDIES ON A WATER MANAGEMENT SUBSYSTEM FOR MANNED SPACE FLIGHT.
Judd R. Wilkins and David C. Grana (NASA, Langley Research Center, Hampton, Va.).
Society of Automotive Engineers, Aeronautic and Space Engineering and Manufacturing Meeting, Los Angeles, Calif., Oct. 7-11, 1968, Paper 680718. 7 p.
Members, $0.75; nonmembers, $1.00.

Currently under investigation at the Langley Research Center in Hampton, Va., is a research test chamber to study and test life support subsystems for long-duration space missions. This system is designed to support four men for a period of one year in a near-earth circular orbit with resupply at a 90-day interval. Critical life support subsystems include the recovery of water from urine, waste management, and personal hygiene. Microbiological studies in support of the development and testing of a wick evaporator, water management subsystem are reported. The goal of this program is to produce water meeting the recommended standard of "essential sterility," that is, no more than a sum total of 10 microorganisms per ml. Modification of the wick evaporator system to permit the use of heat for sterilization will be described. Microbiological and chemical results obtained during research and development on a bench model and from two units inside the Integrated Life Support System (ILSS) test chamber are presented. The multidisciplinary approach used in this program and the background philosophy behind water standards for space missions are discussed. The laboratory techniques used for the microbiological examination of samples from the water management system are reviewed. (Author)

SPACE FLIGHT NUTRITION [NAHRUNG FÜR DEN WELTRAUMFLUG].
John R. Bannister (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Weltraumfahrt Raketentechnik, vol. 19, Nov.-Dec. 1968, p. 167-171. In German.

Discussion of biological, psychological, and technological requirements in the creation of nutrition programs for astronauts. Preservation and reconstitution techniques, such as dehydration and freeze-drying are examined, and the disposal of wastes is considered. It is concluded that, apart from technological considerations, the major requirement of future space flight diets will be to achieve as close an approximation to "normal" earth diets as possible, in terms of nutritional balance, appetite appeal, and psychological satisfaction. Space diets of the various flights are reviewed and evaluated from all these points of view. B.H.

THE IMPORTANCE OF STERILIZATION TECHNIQUES IN SPACE EXPLORATION.

Lawrence B. Hall (NASA, Washington, D.C.).

IN: STERILIZATION TECHNIQUES FOR INSTRUMENTS AND MATERIALS AS APPLIED TO SPACE RESEARCH; COSPAR, SYMPOSIUM, LONDON, ENGLAND, JULY 18-22, 1967, PROCEEDINGS (COSPAR Technique Manual Series. Number 4). [A69-15934 05-05]
Edited by P. H. A. Sneath.

Paris, COSPAR Secretariat, 1968, p. 3-18. 23 refs.

Summary of the present state of spacecraft sterilization to prevent viable terrestrial organisms from being transported to other planets. Mathematical models have been developed to define the scope and details of planetary quarantine. The COSPAR Resolution of 1964 provided a framework consisting essentially of three elements: a model of the principal parameters and their interrelation, agreements as to which parameters should serve as basic standards, and the selection of quantitative values for a chosen parameter. The possibility of contamination by nonlanding vehicles is considered. Microbial load estimation and control is discussed, as well as microbial survival and growth probabilities. G.R.

DETECTION TIME TO A POINT SOURCE OF LIGHT APPEARING ON A STAR FIELD BACKGROUND WITH AND WITHOUT A GLARE SOURCE PRESENT.

Richard F. Haines (Michigan State University, East Lansing, Mich.; NASA, Ames Research Center, Moffett Field, Calif.).

Human Factors, vol. 10, Oct. 1968, p. 523-529. 30 refs.

One hundred and twenty seven untrained observers were tested in a planetarium in order to determine how long it takes to detect the onset of a point source of light appearing at different locations within a star field with and without a veiling glare source present. Results indicated that detection time was shortest when test spots were flashed in a totally dark visual environment. Introduction of a simulated star field produced significantly longer detection times as did the introduction of a star field and glare source. These results are related to findings from previous investigations as well as to certain sighting situations performed in the aerospace environment. (Author)

THE EFFECTIVENESS OF WEIGHTLESS SIMULATORS FOR OBTAINING MAINTAINABILITY CRITERIA FOR SPACE SYSTEMS.
C. B. May (NASA, Marshall Space Flight Center, Huntsville, Ala.). IN: INTERNATIONAL ASTRONAUTICAL FEDERATION, INTERNATIONAL ASTRONAUTICAL CONGRESS, 18TH, BELGRADE, YUGOSLAVIA, SEPTEMBER 24-30, 1967, PROCEEDINGS. VOLUME 4 - LIFE IN SPACECRAFT. [A69-17642 06-05]
Edited by Michal Lunc.
Oxford, Pergamon Press, Ltd.; Warsaw, Państwowe Wydawnictwo Naukowe, 1968, p. 91-114.

Discussion of criteria relative to the operational problem, equipment design, man/machine interface, and interior and exterior layouts for weightlessness simulators. The nonparametric experimental design approach is used to obtain data relative to the performance of a representative removal and replacement task in the simulators. An air filled G4-c suit pressurized to 3.5 psi is used by three experienced subjects. The task utilized both power and hand tools in a one hand and a one hand plus knee attached mode. Scaling factors (considering the shirt-sleeve environment as the baseline) are presented for shirt-sleeve, pressurized 1-g, aircraft simulator, six-degree-of-freedom machines, and for underwater simulators.

APOLLO 4 AND 6 RADIATION ANALYSIS.
Timothy T. White and Alva C. Hardy (NASA, Manned Spacecraft Center, Space Physics Div., Houston, Tex.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-17. 7 p. 15 refs.
Members, $1.00; nonmembers, $1.50.

Analysis of radiation measurements inside the Apollo 4 and 6 command modules while passing through the most intense portions of the trapped radiation belts. Measurements of the integrated radiation dose behind shields of 0.015 and 0.9 in. of aluminum were made inside the command modules on both missions. Dose-rate measurements behind similar shielding were obtained in the Apollo 6 command module during the ascent to apogee. Dose calculations were made with Manned Spacecraft Center computer codes, using analytical shielding descriptions, models of the radiation environment, and radiation-transport data. The calculated mission doses were within a factor of 2.5 of the measured doses, with better agreement in the calculations for the more thinly shielded sensors. The differences between the calculated and measured doses were, for the most part, attributed to errors in the model environment. The analysis of the Apollo 4 and 6 data indicated that dose calculations for manned lunar missions which pass through the more intense portion of the trapped radiation belt are reliable and that the expected doses are well below the planning operational dose limits set by NASA. PRELIMINARY CLINICAL REPORT OF THE MEDICAL ASPECTS OF APOLLOS VII AND VIII.
Charles A. Berry (NASA, Manned Spacecraft Center, Houston, Tex.).
Aerospace Medicine, vol. 40, Mar. 1969, p. 245-254.

Preliminary clinical report of the significant medical data gathered on the missions of Apollo 7 and 8. Preventive medical activities in the preflight period and inflight treatment procedures are discussed. Cardiovascular findings and hematological and biochemical analyses conducted during both pre- and postflight examinations are reported. It is concluded that the Apollo spacecraft is capable of supporting man adequately in the space environment from a physiological point of view, and that radiation levels have not been proven to be significant in the flights thus far. MOTION CUES IN MAN-VEHICLE CONTROL.
Richard S. Shirley (NASA, Electronics Research Center, Office of Control Theory and Application, Cambridge, Mass.) and Laurence R. Young (Massachusetts Institute of Technology, Dept. of Aeronautics and Astronautics, Cambridge, Mass.).
IEEE Transactions on Man-Machine Systems, vol. MMS-9, Dec. 1968, p. 121-128. 5 refs.
Grant No. NsG-577.

Investigation of the human operator's use of roll-motion cues for man-vehicle control in a compensatory tracking task with a disturbance input. Extensive data for the human operator's describing function are taken for a wide range of vehicle dynamics under conditions of visual cues only, roll-motion cues only, and simultaneous visual and roll-motion cues. Addition of roll-motion cues to visual cues permits the human operator to increase his phase lead at frequencies above 3 rad/sec. This makes it possible for him to increase the system open-loop gain without a loss of system stability, and thus to reduce the system tracking error. Experimental results indicate that in a compensatory system with a disturbance input, any condition in which additional human operator lead at frequencies above 3 rad/sec would be useful is a condition in which roll-motion cues would aid. P.v.T.

HUMAN INFORMATION PROCESSING RATES DURING CERTAIN MULTIAXIS TRACKING TASKS WITH A CONCURRENT AUDITORY TASK.
Thomas E. Wempe and Daniel L. Baty (NASA, Ames Research Center, Moffett Field, Calif.).
IEEE Transactions on Man-Machine Systems, vol. MMS-9, Dec. 1968, p. 129-138. 7 refs.

Description of experiments conducted to determine the information processing rates of several subjects performing one- and two-axis compensatory tracking tasks with a secondary auditory task. The experimental variables were the order of controlled element dynamics, the forcing function, and the addition of a secondary task. Human information processing rates decreased slightly on each tracking channel with the addition of the second tracking channel or the secondary auditory task. Other than this effect, the information processing rates were additive until a limit in the total information processing rate was reached. This limit was related to the order of the controlled element. (Author)

AUDITORY TEMPORAL MASKING AND THE PERCEPTION OF ORDER.
J. L. Homick (NASA, Manned Spacecraft Center, Houston, Tex.), L. F. Elfner, and G. G. Bothe (Florida State University, Tallahassee, Fla.).
Acoustical Society of America, Journal, vol. 45, Mar. 1969, p. 712-718. 7 refs.
NSF-supported research.

An investigation of the effects of frequency, intensity, and time on the perception of temporal order and the amount of temporal masking produced under conditions of a short burst (12 msec) of tone separated temporally from a narrow-band noise indicates a similarity of function underlying the two phenomena. Temporal masking is greater and the perception of temporal order is more difficult when the signal is centered in the band of noise. Temporal masking is greater and the perception of temporal order is more difficult for a weak signal than for a more intense signal. The observed temporal masking can be interpreted in terms of a cochlear model. The relationship between temporal masking and the perception of temporal order is discussed in terms of a hierarchy of level of perception brought about by temporal cues. (Author)

AN ANALYTIC ELASTIC-VISCOELASTIC MODEL FOR THE SHAPE AND THE FORCES IN THE LEFT VENTRICLE.
Dhanjoo N. Ghista and Harold Sandler (NASA, Ames Research Center, Moffett Field, Calif.).
Journal of Biomechanics, vol. 2, Mar. 1969, p. 35-47. 7 refs.

An analytic model of the human left ventricle is presented, which incorporates the three-dimensional shape of the left ventricle and the effects of ventricular wall thickness. The model resembles a thick-walled ellipsoid of revolution, a shape chosen because its volume most closely approximates the volume of postmortem left ventricular chambers when compared with volumes estimated by other regular three-dimensional figures of equivalent dimensions. The shape and size parameters of the model are determined from ventricular dimensions obtained from single plane cineangiocardiography. The model is equilibrated by a uniform internal normal stress, corresponding to the measured pressure in the ventricle cavity, and zero stress on the outer surface. Elastic and quasi-static viscoelastic solutions (for stresses and strains) that provide for shear in the ventricular wall are obtained for uniform isotropic wall material. (Author)

EEG SENSING AND TRANSMITTING SYSTEM CONTAINED IN A FLIGHT HELMET.
Richard M. Westbrook and Joseph J. Zuccaro (NASA, Ames Research Center, Moffett Field, Calif.).
Aerospace Medicine, vol. 4, Apr. 1969, p. 392-396.

Taking EEG data from human subjects participating in aircraft or flight simulator programs is often impractical because the technique of applying the electrodes in slow and tedious and often abrasive to the subject's scalp. An EEG monitor helmet has been developed in which the electrodes can be applied quickly and easily because they require no special preparation of the subject's scalp. A pilot's flight helmet is used to hold the prepositioned electrodes. Electrical contact is made between scalp and electrodes by means of a paste electrolyte. All of the electronics, including the rf transmitter, are an integral part of the helmet's shell. This system has been tested in the laboratory and in flight. It provides excellent EEG data. DEVELOPMENT OF METEOROID PROTECTION FOR EXTRA-VEHICULAR-ACTIVITY SPACE SUITS.
William E. McAllum (NASA, Manned Spacecraft Center, Space Physics Div., Meteoroid Sciences Branch, Houston, Tex.).
American Institute of Aeronautics and Astronautics, Hypervelocity Impact Conference, Cincinnati, Ohio, Apr. 30-May 2, 1969, Paper 69-366. 10 p. 8 refs.
Members, $1.00; nonmembers, $1.50.

The space suit used during extravehicular activities requires meteoroid protection during the space exposure to prevent perforation of the pressure bladder. The development of protective cover-layers for the Gemini and lunar-surface EVA suits is described. The meteoroid mass, which must be absorbed in the coverlayer to satisfy the mission exposure time and the reliability requirements, was simulated by a hypervelocity glass projectile of equal penetrating energy. Textiles or "soft goods" that were compatible with suit fabrication techniques were impacted with the laboratory projectile to determine response to impact and resistance to penetration. An effective projectile breakup was achieved with nylon cloth; therefore, the bumper concept that was developed previously for metallic sheets was applied to the suit protection. Two configurations were developed, one of which used nylon felt and the other used neoprene as the primary energy absorber. (Author)

SPACECRAFT STERILIZATION BY DESTRUCTIVE HEATING.

Byron L. Swenson (NASA, Ames Research Center, Moffett Field, Calif.) and Lawrence B. Hall (NASA, Washington, D.C.).

COSPAR, Plenary Meeting, 12th, Prague, Czechoslovakia, May 11-24, 1969, Paper. 15 p.

Study of the problem of sterilization of spacecraft by destructive heating before entering a planet's atmosphere. It is concluded that a spacecraft can theoretically be sterilized in space by heating to destruction with thermite or similar agents, but heavy weight and design penalties must be accepted. A danger of contamination lies in microbes entrapped within plastic pieces surviving entry, since the low diffusivity of such materials protects them from experiencing high internal temperatures. LIFE DETECTION TECHNIQUES.

Richard S. Young (NASA, Washington, D.C.).

IN: EXOBIOLOGY: THE SEARCH FOR EXTRATERRESTRIAL LIFE; AMERICAN ASTRONAUTICAL SOCIETY AND AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, SYMPOSIUM, NEW YORK, N.Y., DECEMBER 30, 1967, PROCEEDINGS. [A69-32967 17-04]

Edited by M. M. Freundlich and B. M. Wagner. Tarzana, Calif., American Astronautical Society (AAS Science and Technology Series. Volume 19), 1969, p. 29-35.

Discussion of the rationale for life detection, including the reasons for the approaches that are taken. The problem of detecting life on an extraterrestrial body requires some degree of experimental sophistication. The single long-shot experiment is considered unlikely to produce unequivocable data, so that a multiple experiment approach is recommended. A discussion is presented of the types of experiments most likely to produce data interpretable as a function of life processes. These experiments include chemical analyses, identification of metabolic activity and evidence for growth and replication at the molecular and/or cellular level. All of these experiments are considered in the light of the realities of planetary mission capability. A discussion is offered concerning the problems of integrating such varied experiments into a single multipurpose laboratory concept. (Author)

EVALUATION OF LITHIUM PEROXIDE FOR OXYGEN SUPPLY AND CARBON DIOXIDE CONTROL.

R. Norman Prince (NASA, Manned Spacecraft Center, Crew Systems Div., Houston, Tex.) and Kenneth J. Dresser (United Aircraft Corp., Hamilton Standard Div., Windsor Locks, Conn.).

American Institute of Aeronautics and Astronautics, Thermophysics Conference, 4th, San Francisco, Calif., June 16-18, 1969, Paper 69-620. 12 p.

Members, $1.00; nonmembers, $1.50.

Contract No. NAS 9-8159.

Results of a series of 54 tests conducted to evaluate the feasibility of utilizing lithium peroxide for oxygen supply and carbon dioxide control in advanced extravehicular portable life support systems. The test data generated by these tests show a definite potential for significant weight and volume savings in portable life support systems and space vehicles supporting extravehicular excursions. For example, a lithium peroxide/oxygen system may be up to 11% smaller and 23% lighter than a comparable lithium hydroxide/oxygen system for a 4-hr 2000-Btu/hr (average) mission. This savings becomes even more significant for a vehicle that must support multiple excursions. The program objectives included the generation of system design data, as well as the evaluation of various chemical densities, chemical catalysts, bed temperature, and bed geometry. The most promising chemical form is a low-bulk density lithium peroxide catalyzed by 2% nickel sulfate. The most critical operating parameter was the temperature of the lithium peroxide bed which, under certain test conditions, exceeded 600°F. Although excessive bed temperatures reduce carbon dioxide removal, high temperatures enhance oxygen evolution due to thermal decomposition of the lithium peroxide. (Author)

VENTILATION-PERFUSION INEQUALITY AND OVERALL GAS EXCHANGE IN COMPUTER MODELS OF THE LUNG.

John B. West (NASA, Ames Research Center, Biotechnology Div., Moffett Field, Calif.).

***Respiration Physiology,* vol. 7, June 1969, p. 88-110. 23 refs.**

Study of the effects of increasing ventilation-perfusion inequality on overall gas exchange in digital computer models of the lung. Ventilation/unit volume and perfusion/unit volume were distributed log normally with respect to lung volume. Ventilation-perfusion inequality was found to affect the transfer of carbon dioxide nearly as much as oxygen. The reasons for the misconception that inequality does not interfere with carbon dioxide transfer are discussed. The effects of changing overall ventilation, blood flow, inspired oxygen, hemoglobin concentration, and the acid-base status of the blood were investigated when oxygen uptake and carbon dioxide output were held constant at normal values. In general, mismatch of ventilation and blood flow in a lung caused the arterial oxygen tension to fall and the carbon dioxide to rise. Increasing overall ventilation rapidly restored blood carbon dioxide tensions to normal but improved oxygen tensions little. M.M.

A REAL-TIME PROCESSING SYSTEM FOR DETERMINATION OF METABOLIC RATES OF A SUITED ASTRONAUT.
Russell J. Kelly (Boeing Co., Houston, Tex.), George F. Humbert, and David G. Billingsley (NASA, Manned Spacecraft Center, Houston, Tex.).
American Institute of Aeronautics and Astronautics, American Society for Testing and Materials, and Institute of Environmental Sciences, Space Simulation Conference, 4th, Los Angeles, Calif., Sept. 8-10, 1969, AIAA Paper 69-993. 7 p.
Members, $1.00; nonmembers, $1.50.

The metabolic rate and total energy expenditure of a suited astronaut were estimated during thermal-vacuum crew-training tests and extravehicular-mobility-unit lunar qualification tests. The crewman was configured in the Apollo space suit with a portable life-support system, and his metabolic rate was estimated by using the electrocardiogram and the portable-life-support-system oxygen-bottle pressure decay as received from telemetry. These parameters were processed by the Acceptance Checkout Equipment Spacecraft computer in real time, and the results were displayed on an alpha numeric CRT. An accurate method for determining the heart rate from the electrocardiogram under conditions of strenuous exercise is presented. Comparisons of heart rate and oxygen utilization methods for the calculation of total energy expenditure are made with posttest analysis of carbon dioxide production. Constraints and limitations of each method are discussed. (Author)

EFFECTS OF ANGULAR ACCELERATION ON MAN—THRESHOLDS FOR THE PERCEPTION OF ROTATION AND THE OCULOGYRAL ILLUSION.
Brant Clark (San Jose State College, San Jose, Calif.) and John D. Stewart (NASA, Ames Research Center, Moffett Field, Calif.).
Aerospace Medicine, vol. 40, Sept. 1969, p. 952-956. 32 refs.
Grant No. NGL-05-046-002.

Investigation of the sensitivity of normal human observers to angular acceleration about their yaw axis, using the perception of rotation and the oculogyral illusion as indicators. The data were obtained for 53 normal men, using a one-degree-of-freedom simulator that could produce angular accelerations with narrow limits of error. A forced-choice, random, double staircase method was used to present the 10-sec stimuli. Thresholds for the perception of rotation for these 53 men were found to vary from 0.05 to 2.20 deg per sec per sec with a mean of 0.41 deg per sec per sec. The thresholds for the oculogyral illusion for 32 men were significantly below these figures, the thresholds varying from 0.04 to 0.28 deg per sec per sec with a mean of 0.11 deg per sec per sec. These data show that normal men are extremely sensitive to angular acceleration about their yaw axis under optimum testing conditions. The results are discussed in relation to the psychophysiological mechanisms involved and to their implications for spatial orientation and the precision of control tasks in flight. (Author)

FLIGHT RESEARCH PROGRAM. XIV—LANDING PERFORMANCE IN JET AIRCRAFT AFTER THE LOSS OF BINOCULAR VISION.
Charles E. Lewis, Jr. and Gary E. Krier (NASA, Flight Research Center, Edwards, Calif.).
Aerospace Medicine, vol. 40, Sept. 1969, p. 957-963. 15 refs.

Thirteen pilots were studied in a T-33A jet trainer during a series of touch-and-go landings. Each flight included landing approaches with full binocular vision, followed by approaches with first the left and then the right eye covered. Both lateral and longitudinal miss-distance were photooptically measured from a specified touchdown point. Performance on final approach was analyzed with respect to airspeed control, sink rate, and the approach angle. Landing errors were clearly shown not to increase significantly during approaches made with one eye covered. The pilots were free to select any angle of descent during approach that they desired. Steeper approaches were consistently observed when vision was restricted to one eye than those flown with normal vision. One pilot was studied for three consecutive weeks during which his dominant eye was patched. Landing performance was analyzed during three flights (including thirty-five landings) and was compared with control data. Analysis of these data revealed no significant difference in landing performance with vision restricted to one eye over the entire period. (Author)

EFFECTS OF VARIOUS RESPIRATORY MANEUVERS ON THE PHYSIOLOGICAL RESPONSE TO ANGULAR ACCELERATION.
Jose G. Lipana (NASA, Flight Research Center, Lovelace Foundation Field Laboratory, Edwards, Calif.), John Fletcher (Systems Research Laboratories, Inc., San Antonio, Tex.), William Brown, and George Cohen (Systems Research Laboratories, Inc., San Antonio; USAF, School of Aerospace Medicine, Biodynamics Branch, Brooks AFB, Tex.).
(Aerospace Medical Association, Annual Scientific Meeting, San Francisco, Calif., May 5-8, 1969.)
Aerospace Medicine, vol. 40, Sept. 1969, p. 976-980. 8 refs.
Contract No. AF 41(609)-2897.

Study of the effects of breath holding, M1, Valsalva, and Mueller's maneuvers on healthy males during static condition at various postures and during pure axis rotations. The subject was seated inside a hollow spherical simulator. Rotation was at the rate of 6 rpm with the axis of rotation through the body. Heart rates, ECG, blood pressures, respiratory rates and voice were monitored by telemetry. The characteristics of the response pattern were dependent on the kind of maneuver, the instantaneous posture, and the time the maneuver was initiated. Early obliteration of the pulse pressures were notable with Mueller's and Valsalva maneuvers. On repeated performance, all of the maneuvers studied provoked nausea, vomiting, and syncopal symptoms of varying degrees. The onset of these symptoms limited the duration for which the subject can normally withstand prolonged rotation. Unlike the M1 maneuver, which had beneficial effect during linear positive acceleration, none of these maneuvers was protective against angular acceleration. On the contrary, performance of any of these maneuvers jeopardizes man's tolerance to this spectrum of acceleration. (Author)

PHYSICAL FITNESS AND TOLERANCES TO ENVIRONMENTAL EXTREMES.
K. E. Klein, H. M. Wegmann, H. Brüner, and L. Vogt (Deutsche Forschungs- und Versuchsanstalt für Luft- und Raumfahrt, Institut für Flugmedizin, Bad Godesberg, West Germany).
Aerospace Medicine, vol. 40, Sept. 1969, p. 998-1001. 33 refs.

During "submaximum" loading tests of 20-30 min duration at simulated altitude (312 mm Hg), during acceleration, and during exercise at sea level and at moderate simulated altitude (578 mm Hg), heart rates were significantly lower for highly trained athletes (20-25 per cent) than in nonathletes. In maximum tolerance tests, however, there was a significant difference between the two groups only for maximum oxygen uptake at physical exercise, but no indication was seen for a positive cross-adaption effect of physical exercise training on the other stressors. Statistical analysis of the correlation between heart rate responses to the different stressors and the corresponding tolerances proved negligible relationships only; whereas heart rates were always highly dependent on sea level maximum oxygen uptake. The results do not support the idea of an improvement of human tolerance to environmental extremes by physical exercise training. (Author)

PRESCRIPTION OF EXERCISE FOR THE HYPOKINETIC AIRLINE PILOT.
L. E. Morehouse (NASA, Manned Spacecraft Center, Dept. of Preventive Medicine, Houston, Tex.; California, University, Dept. of Physical Education, Human Performance Laboratory, Los Angeles, Calif.), W. L. Marxer, and E. D. Warren (NASA, Manned Spacecraft Center, Dept. of Preventive Medicine, Houston, Tex.; Federal Aviation Administration, Los Angeles, Calif.).
IN: AVIATION AND SPACE MEDICINE; PROCEEDINGS OF THE SEVENTEENTH INTERNATIONAL CONGRESS, OSLO, NORWAY, AUGUST 5-8, 1968. (A69-41783 23-05)
Edited by Birger Hannisdahl and C. W. Sem-Jacobsen.
Oslo, Universitetsforlaget, 1969, p. 146-153.

Discussion of the recent advances in exercise physiology and instrumentation which have made it possible to establish standards for evaluation of exercise tolerance, to define personal training loads, and to prescribe exercise for the hypokinetic airline pilots in accordance with their needs and interests. The signs of hypokinesis in airline pilots, due mostly to lack of physical exercise, the prescriptions of physical exercise in accurate doses, the pertinent predictive tests and their evaluation, are described. A number of methods and means of controlling the heart rate are reviewed. The procedures used in calibration tests to establish the current level of the pilot's most vigorous regular physical activity and the maximum work rate at which exercise is well tolerated, as well as the respective metered training regimens, are commented on in detail. O.H.

EVA MANEUVERING UNIT COMPARISON.
Allwin E. Wudell, William H. Tobey (Martin Marietta Corp., Space Operations Section, Research Dept., Denver, Colo.), and C. E. Whitsett, Jr. (NASA, Manned Spacecraft Center, Houston, Tex.).
American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-516. 46 p.
Contracts No. AF 33(615)-68-C-1175; No. NAS 9-9109.

Description of two studies on the comparison, through simulation, of three maneuvering units for space tasks. The maneuvering units considered are: (1) an unstabilized astronaut maneuvering unit (AMU), (2) a hand-held maneuvering unit (HHMU), and (3) an integrated maneuvering and life support system (IMLSS). The test subject was suspended in the gimbaled head of the six-degree-of-freedom servo-driven moving-base simulator. The simulation technique involves computation of the problem dynamics on a hybrid computer that then determines the commands for the moving base. Instrument maneuvering unit hand controller mockups are used by the test subject. Signals from the hand controller mockups are used in the hybrid program to introduce the thrust histories. The performance comparison data for the AMU and HHMU, as well as for four configurations of the IMLSS, are established. Z.W.

RECENT ADVANCES IN CLOSED LIFE SUPPORT SYSTEM CONCEPTS.
Jacob Shapira (NASA, Ames Research Center, Biotechnology Div., Moffett Field, Calif.).
American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-143. 12 p. 23 refs.

The logistics of long duration manned space missions demands that effective systems be developed for the recovery of useful materials from metabolic and other wastes. The order of priority is water, oxygen, and food. The current state of development is also in the same order. This work discusses those approaches to these problems which are currently under most intensive investigation in this country. Water is most conveniently recovered by a combination of vacuum distillation and multifiltration. Carbon dioxide is removed by absorption and is subsequently reduced to methane with hydrogen to produce additional water. Oxygen can be produced from water by electrolysis of recovered liquid water or directly from the vapor phase. Bioregenerative food systems may have utility, but physicochemical methods appear to offer many advantages. (Author)

A MULTIPURPOSE VENTRICULAR ACTUATING SYSTEM.
John A. Webb, Jr. and Vernon D. Gebben (NASA, Lewis Research

Center, Cleveland, Ohio).
International Federation for Medical and Biological Engineering, International Conference on Medical and Biological Engineering, 8th, and Annual Conference on Engineering in Medicine and Biology, 22nd, Chicago, Ill., July 19-25, 1969, Paper. 11 p.

Description of the design of a pneumatic driving system for heart assist or total heart replacement pumps. The system provides square pressure waveforms to drive the heart assist and uses feedback control to regulate a total heart replacement pump. A pneumatic square wave generator was developed to serve as a flexible tool for studying various cardiac assist techniques. This generator can be synchronized with the natural heart using the R-wave of the electrocardiogram as a trigger. The addition of feedback control to regulate a total heart replacement is discussed and data are given.

A LUNAR GRAVITY SIMULATOR, VOLUME 1
Washington NASA Nov. 1968 34 p
(Contract NAS1-7459)
(NASA-CR-1233-vol-1) Avail: CFSTI CSCL 14B

A prototype lunar gravity simulator using magnetic air bearing supports with constant force spring motors, and specially designed harness is described. The system is suspended from a steel ceiling. The subject, wearing a crash helmet and boots, rides in a three axis gimbaled harness. The harness system is suspended from the center of a spider ring which is supported by cables that wind and unwind by constant force spring motors. The system supports approximately 5/6 of the subject's weight, and permits freedom of movement. The simulator is designed to accommodate subjects weighing from 168 to 264 pounds. Testing results, precautions regarding operation, and details of the harness are presented.

VISUAL SENSING OF SPACECRAFT GUIDANCE INFORMATION. EARTH ORBIT RENDEZVOUS MANEUVERS
S. Seidenstein, W. K. Kincaid, Jr., G. L. Kreezer, and D. H. Utter Washington NASA Dec. 1968 257 p refs
(Contract NAS1-6801)
(NASA-CR-1214) Avail: CFSTI CSCL 06B

An analysis of each orbit rendezvous in terms of maneuver geometry served as a basis for establishing the requirements for visually sensed rendezvous guidance information. Analysis of the physical environment supported an evaluation of the sensory basis for visually deriving the desired information. Visual capabilities were then examined in terms of sensitivity, cross range motion perception, range, and range rate determinations. Estimates of sensitivity and variability are presented where available. Conclusions are drawn regarding the adequacy of available data, and recommendations are given for future areas of study. PRELIMINARY EVALUATION TEST OF THE LANGLEY CARDIOVASCULAR CONDITIONING SUIT CONCEPT
B. V. Blockley and S. L. Friedlander Washington NASA Dec. 1968 70 p refs
(Contract NAS1-6004)
(NASA-CR-1206) Avail: CFSTI CSCL 06K

Two experiments were conducted, each two weeks in duration, in which the same subject spent the major portion of each day immersed in water and the remainder of the time in bed. The man remained completely horizontal except when submerged. In the control experiment, a simple waterproof garment was worn over ordinary long underwear during water immersion; in the second experiment the man was dressed in a specially constructed pressure suit designed to prevent or retard the deconditioning of weightlessness (cardiovascular conditioning suit or CVCS). The cardiovascular conditioning suit successfully prevented the deterioration in orthostatic tolerance, impairment in tolerance for brief mild exercise, and reduction in maximum work capacity which had been observed in the control experiment. During the initial 5 days, when pressurization time in the suit was less than one hour per day, venous compliance increased roughly 2-fold, but had fallen again to the initial value by the morning of the 11th day. Venous compliance appears to be an excellent predictor of tilt-table response. In the experiment in which the CVCS was used there was essentially no difference in venous compliance between pre- and post-exposure, and the tilt responses were the same except for a slight elevation of diastolic pressures during the post-exposure tilt.

SKILL TRAINING FOR THE PRODUCTION OF A MEMORIZED MOVEMENT PATTERN
Margaret Robb and Richard W. Pew Washington NASA Dec. 1968 37 p refs
(Contract NASR-54(06))
(NASA-CR-1251) Avail: CFSTI CSCL 05H

Based on the assumption that man may be regarded as an information processing system, experiments were conducted to assess the efficacy of several kinds of feedback information. Five groups of subjects were trained under different feedback conditions in the execution of a distinctive movement pattern. In a subsequent test condition, all groups attempted to reproduce the movement pattern without the aid of any external concurrent feedback. The training conditions, reflecting different modes of feedback, were blanked, vision, vision–blanked, passive–active, and slow–standard. The main variables were the types of terminal and concurrent feedback administered to the subjects through internal and external modes. Performance was compared in terms of integrated absolute error scores and in terms of a more detailed performance criterion that attempted to separate out performance precision with respect to amplitude and timing accuracy. The results are graphically depicted and it is hypothesized that the stage during training at which augmented feedback is introduced may be important. M.G.J.

RAPID (EXPLOSIVE) DECOMPRESSION EMERGENCIES IN PRESSURE-SUITED SUBJECTS
Emanuel M. Roth Washington Nov. 1968 129 p
(Contract NASr-115)
(NASA-CR-1223) Avail: CFSTI CSCL 06S

A review is presented of the biomechanical factors determining lung damage following explosive decompression of space suits in vacuum test chambers. Critical variables, such as ratio of free volume of suit to area of orifice, pressure ratio, and pressure differential, are outlined. Calculations were made of orifices caused by catastrophic disruption of typical soft and hard space suits at seal sites, and predictions were made as to the likelihood of lung

damage, based on the location of the seal disruption and open/closed glottis conditions. It was concluded that all seal areas should be designed for slow propagation of disruptive processes, and that preparation of therapeutic devices and facilities for handling explosive decompression emergencies would be advisable. It was found that use of gases other than 3.7 psia O_2 in the suits alters the hazard; the higher the percentage of helium in the mixture, the less is the hazard. Also, since the maximum possible amplitude of transmural pressure is determined by the pressure difference, the higher the initial pressure in the suit, the more hazardous the exposure. The pathological physiology of explosive decompression was reviewed, followed by a summary of the most recent ideas in selection and testing of subjects to reduce the hazard and the treatment of individual syndromes and conditions. AN INVESTIGATION OF THE SUITABILITY OF WHITE RATS FOR SUB-ORBITAL STUDIES OF BEHAVIOR IN A GRAVITY FIELD
A. B. Broderson and K. O. Lange Washington NASA Dec. 1968 102 p refs
(Grant NsG-456)
(NASA-CR-1255) Avail: CFSTI CSCL 06C

Techniques were developed for evaluating the Spraque Dawley rat as a subject for the first of four in-flight gravity preference experiments to be launched into suborbital trajectories by Aerobee 150A rockets. Special configuration centrifuges were developed and used to experimentally determine the locomotion behavior of rats in fields of simulated gravity. Techniques were developed for investigating the effect of rocket launch stress on this behavior, and an environmental simulation system was developed and used to routinely prepare rats for the confinement, acceleration, spin, noise, and vibration of an Aerobee launch. The suitability of the subject and the effectiveness of the environmental simulation routine were verified by the satisfactory behavior demonstrated in the first flight experiment. Author

HUMAN VISUAL SAMPLING PROCESSES: A SIMULATION VALIDATION STUDY
John W. Senders, Jaime R. Carbonell, and Jane L. Ward Washington NASA Jan. 1969 110 p refs
(Contract NAS1-5059)
(NASA-CR-1258; BBN-1681) Avail: CFSTI CSCL 05H

The results obtained in some fundamental investigations strongly support the notion that the behavior of the pilot or controller/monitor is largely determined by, and calculable on, the basis of physical characteristics of the system. Based on the results a validation study more nearly approaching operational situations was undertaken. This study used an instrumented flight simulator, operational pilots, and complete measuring, recording, and analysis techniques to validate and improve the methods offered by the theory. The applied goal of the program was to make possible an a priori evaluation of the work load which any set of information sources to be monitored and controlled will place on the man. The following results were obtained: a measure of the goodness of prediction of the Nyquist models, and the development and a measure of goodness of prediction of a new queueing/cost-effectiveness model. SMALL PERTURBATION DYNAMICS OF THE NEUROMUSCULAR SYSTEM IN TRACKING TASKS
Raymond P. Magdaleno, Duane T. Mc Ruer, and George P. Moore Washington NASA Dec. 1968 133 p refs
(Contract NAS2-2824)
(NASA-CR-1212; TR-154-1) Avail: CFSTI CSCL 05H

Existing physiological data and human operator describing function data are synthesized by providing models which are compatible with the overall human operator's input/output characteristics, as well as with the individual components of the neuromuscular system in tracking situations. Of interest are recent anatomical and physiological data for the muscle spindle and input/output studies of the muscle which indicate that quasi-linear models can describe the basic behavior of these elements in tracking tasks. Two key developments are reported: 1) variation in muscle system parameters as a function of average muscle tension or operating point, and 2) the role of the muscle spindle both as an adaptive equalization element and in its effect on setting muscle tone or average tension. The pertinent whole human data include the covariation of high and low frequency describing function phase data and the variation of high frequency phase with set tension changes interpreted from force disturbance experiments. EFFECTS OF PRACTICE AND WORK LOAD ON THE PERFORMANCE OF A CODE TRANSFORMATION TASK (COTRAN)
Earl A. Alluisi and Ben B. Morgan, Jr. Washington NASA Dec. 1968 73 p refs
(Grant NGR-18-002-008)
(NASA-CR-1261) Avail: CFSTI CSCL 05H

Results are presented on the effects of practice and operator work load on the acquisition and performance of a code-transformation (COTRAN) task, which was developed to obtain performance measurements of that part of intellectual functioning which is typically called non verbal mediation; it follows the problem-solving paradigm. During the acquisition phase, 27 COTRAN problems were solved on each of four (Group-4, with four subjects), eight (Group-8, with twenty subjects), or twelve (Group-12, with four subjects) successive days. Performance reached asymptotic levels in four to six sessions, in general, and the differences in final levels of performance of the three groups (4, 8, and 12) were not statistically significant. During the transfer phase, each of the 28 subjects solved 27 COTRAN problems of each of five successive days while time-sharing the COTRAN task with different combinations of tasks selected from a multiple-task performance battery. The results indicated that skilled COTRAN performance is sensitive to at least two or three levels of work-load stress, and that different subjects may tend to adopt different strategies in time-sharing the COTRAN task with other tasks. PERIPHERAL VISION DISPLAYS, PHASE 2 REPORT
Leroy L. Vallerie Washington NASA Dec. 1968 49 p refs
(Contract NAS12-88)
(NASA-CR-1239; BSD-68-643) Avail: CFSTI CSCL 05H

Two commercially available display systems were investigated in conjunction with other concepts involving the use of flicker to

encode airspeed signals and differential brightness to enhance the discriminability of input signals. Tracking information was presented in three control dimensions: viz., pitch, roll and airspeed. An adaptive loop simulator was employed to evaluate operator performance. The results clearly indicated that effective control can be exercised using peripheral displays employing changes in motion as the primary encoding stimulus. A higher level of performance was achieved with one system which contained a single display for presenting integrated pitch and roll signals. The addition of airspeed was found to degrade performance in pitch and roll under all display conditions. Performance could not be enhanced by means of differential brightness. Further evidence was provided for the use of motion as a very effective means for encoding displays designed for viewing in the periphery. Author

PROPRIOCEPTIVE CUES AND THEIR INFLUENCE ON OPERATOR PERFORMANCE IN MANUAL CONTROL
James Herman Herzog Washington NASA Jan. 1969 178 p refs
(Contract NASr-54(06))
(NASA-CR-1248) Avail: CFSTI CSCL 05H

The neuromuscular control system of the human upper limb was investigated as an auxiliary source of sensory information. Analysis of a functional block diagram of the human operator indicated that a control system with interesting characteristics could be devised if the control stick were constructed to be a mechanical analog of the plant being controlled. This is called the matched manipulator control technique, in which the control force applied to the plant is a scalar multiple of the reaction force experienced by the operator. The operator is in a particularly advantageous position to formulate control strategies to emphasize either accurate control performance or minimum use of control effort. Experimentation with several human operators indicated that performance with the matched manipulator technique was consistently superior to control of the same plants with position type control sticks. This technique seems to offer an interesting and useful means of altering the interface between the human operator and his electro-mechanical surroundings in order to improve the system performance. A LUNAR GRAVITY SIMULATOR, VOLUME 2
Richard J. Morgen Washington NASA Dec. 1968 142 p refs
(Contract NAS1-7459)
(NASA-CR-1234) Avail: CFSTI CSCL 14B

The design of a vertical lunar gravity simulator is presented. The simulation technique involves negating the various limb segments separately using constant-force negator springs. Overhead support is provided by magnetic air pads which offer negligible resistance to horizontal movement. The torso harness that is used provides for six degrees of freedom over a wide range of movements. The dynamic behavior of the lunar gravity simulator is considered. Indications are that low fatigue-life negator coils mounted back-to-back will be suitable as constant-force, long-deflection springs. A conical drum, adjustable-force negator unit is optimized for minimum weight. A technique for determing the mass and center of mass of the various body segments is also presented. An analysis to determine the correct attachment points for negating the limbs and torso is presented. It is recommended that negator coils of the lowest rated fatigue life be used as constant-force, long-deflection spring elements. Author

MEASUREMENT OF PILOT DESCRIBING FUNCTIONS IN SINGLE-CONTROLLER MULTILOOP TASKS
Robert L. Stapleford, Samuel J. Craig, and Jean A. Tennant Washington NASA Jan. 1969 109 p refs
(Contract NAS2-3144)
(NASA-CR-1238; TR-167-1) Avail: CFSTI CSCL 05H

Problems of measuring pilot describing functions in multiloop tasks with one controller (i.e., where the pilot is controlling two, or more, response variables with a single manipulator are considered. Both direct and implicit measurement techniques were considered and tested experimentally. The experimental task used was attitude and altitude control with elevator of an aircraft in a simulated landing approach. Experimental results show that the measurement of multiloop describing functions is feasible, although the techniques are considerably more complex than those required for single-loop compensatory tasks. However, there are fundamental limitations on the accuracy of some of the results. These are discussed in detail. The experimental data also provide a spot check on the existing multiloop pilot model. The results support the current model and, in particular, show that the inner-loop (attitude) closure is quite similar to that for single-loop attitude tracking. Author

POTENTIAL PROBLEMS RELATED TO WEIGHTLESSNESS AND ARTIFICIAL GRAVITY
Ralph W. Stone, Jr. and William M. Piland Washington Jan. 1969 60 p refs
(NASA-TN-D-4980) Avail: CFSTI CSCL 06S

A study has been made of many publications to provide planners of future space missions with a summary of the pertinent problems associated with the weightless environment of space. Based on this study, a review is presented of the possible adverse effects of weightlessness on the astronaut's physiological processes and his performance in space. Techniques and devices which are potentially capable of counteracting the adverse effects of weightlessness are discussed. These counteractive measures include lower-body negative pressure devices, pressure cuffs, anti-g suits, the cardiovascular conditioning suit, exercise apparatus, and artificial gravity. The impact of additional weight and crew involvement in the inclusion of these devices on a particular mission is also discussed. The effects of these devices range from minor increases in launch weight and crew activity to significant vehicle-configuration complexity and astronaut involvement. Results are presented of research on the therapeutic value of the counteractive devices for weightlessness. Where an insufficient assessment of these devices exists, further research is recommended which could influence a decision on their use. Primarily, it is important to determine whether the effects of simulated weightlessness are progressive beyond that which has been experienced to date or whether the effects plateau at a specific level of physiological adaptation. A STUDY OF HUMAN OPERATOR PERFORMANCE USING REGRESSION ANALYSIS
August Llewellyn Burgett Washington NASA Jan. 1969 192 p refs
(Contract NASr-54(06))
(NASA-CR-1259) Avail: CFSTI CSCL 05I

The regression analysis technique is used to analyze the performance of human operators in low order compensatory manual control systems. This study is based on two experiments in which the subjects controlled single and double integrator dynamical systems with an input which was low frequency noise. In modeling the human operator system the crossover model is used. This model expresses the entire forward-loop of the compensatory control system as a series of operators: a gain K, a time-delay τ, and a single integration. The study takes the form of obtaining estimates of the parameters K and τ for twenty-five 20-second intervals for each day of testing. From an analysis of these parameter values, inferences are made about the performance of the human operators. Author

A FUNDAMENTAL STUDY OF PREDICTIVE DISPLAY SYSTEMS
John De Shon Warner Washington NASA Feb. 1969 200 p refs
(Contract NASr-54(06))
(NASA-CR-1274) Avail: CFSTI CSCL 05H

The particular predictive technique considered utilizes a repetitive, fast time, on-line computation scheme which provides a predicted response of the controlled element to the human operator based on certain assumptions about future control inputs and disturbances. An in depth discussion is provided on the various characteristics that are important in any predictive display application. The problem of performance measurement is discussed. An experimental investigation on the effects of the controlled element dynamics on performance with three display forms (exploratory prediction, on-line prediction, and no prediction) in a time vs. error format is reported. A minimum time terminal control task for a pure inertia system driven by a fixed three state relay controller was chosen for the study. The system is described by several independent parameters which are hypothesized as being important in a variety of manual control situations. These parameters are varied systematically to determine their effect on performance with the three display forms. Several new performance measures are developed for use in minimum-time terminal control tasks. Author

HUMAN TRANSFER CHARACTERISTICS IN FLIGHT AND GROUND SIMULATION FOR A ROLL TRACKING TASK
Fred D. Newell (Cornell Aeron. Lab., Inc.) and Harriet J. Smith
(NASA-TN-D-5007) Avail: CFSTI CSCL 05H

Pilot transfer characteristics for three pilots were measured in flight and in ground based simulators for a compensatory roll tracking task with small bank angle disturbances. The forcing function, in each case, consisted of the sum of ten sine waves with a bandwidth of 1.5 radians per second. A variable stability T-33 airplane was used to obtain the flight measurements. Ground based simulator measurements were obtained with both the T-33 airplane and a general purpose simulator which used a contact analog color display. Three different controlled elements were used, two of which were simple single degree of freedom controlled elements that were studied previously. The third was a multiple degree of freedom element representative of an airplane with good handling qualities and was considered and controlled as a single degree of freedom configuration in roll. The results of the simple controlled element experiments agreed reasonably well with previous results. For the multiple degree of freedom controlled element experiment, a noticeable effect of display was found. For this experiment, which was restricted to a small disturbance bank angle tracking task with good controlled element dynamics, nonvisual motion cues appeared to be of less importance than visual cues. CORRELATION STUDY OF THE SIMULATION OF GEMINI EXTRAVEHICULAR ACTIVITY WITH FLIGHT RESULTS
Harry L. Loats, Jr., G. Samuel Mattingly, and G. M. Hay Washington NASA Feb. 1969 199 p refs
(Contract NAS1-7142)
(NASA-CR-1146; ERA-67-7) Avail: CFSTI CSCL 22A

The water immersion simulation of the Gemini EVA utilized full-scale mockups of the Gemini vehicle including portions of the Agena target vehicle with valid replicas of ancillary EVA equipment such as tools, astronaut maneuvering unit, etc. All important items were maintained in a neutrally bouyant condition. Bio-instrumentation was incorporated into the Gemini flight suits and continuous voice and film records were obtained. The water immersion simulation of the Gemini extravehicular activity provided a valid training time line for performance of complex extravehicular tasks and provided adequate measures of the level of work entailed. A second capability evidenced as a result of the program was the method for evaluating various competitive hardware concepts such as tools and motion restraints. The technique used in the preflight evaluation and training was to perform the simulation run with ERA subjects prior to actual performance of the training run by the astronaut. This technique permitted pre-evaluation of hardware in a repetitive manner and served to assess the validity of the water simulation mode. Factors such as drag-damping and orientational stability were compensated by variation of the mockup orientation and configuration. Author

SIMULATION OF PACKAGE TRANSFER CONCEPTS FOR SATURN 1 ORBITAL WORKSHOP
Charles B. Nelson Washington Mar. 1969 15 p
(NASA-TN-D-5111) Avail: CFSTI CSCL 06B

Investigated was the problem of manual transferring massive packages in a zero-g environment from the Saturn docking adapter into the crew quarter areas of the Saturn stage. Only a single handrail was to be used to assist the astronaut during package manipulation. Preliminary transfer simulation studies with a six degree of freedom simulator established the efficiency of the pole and the basic man/package transfer technique. Analysis and correlation of data from the simulations indicated that a combination of package parameter size and mass (moment of inertia) effected package maneuverability; a package with a moment of inertia 3.4 to 4.0 N–m-sec^2 (300 to 350 in.–lbf–sec^2) appeared to be the upper limit for one man to transfer within a reasonable time frame. G.G.

PERFORMANCE AND CAVITATION DAMAGE OF AN AXIAL-FLOW PUMP IN 1500° F (1089 K) LIQUID SODIUM
Dean C. Reemsnyder, Walter S. Cunnan, and Carl Weigel Washington Apr. 1969 25 p refs
(NASA-TN-D-5138) Avail: CFSTI CSCL 13L

A low headrise axial flow pump was operated in liquid sodium at temperatures to 1500° F for 558 hr to investigate pump performance and blade cavitation damage in alkali metals. The research rotor had nine insertable blades of three different materials, a blade tip diffusion factor of 0.40, and a hub tip radius ratio of 0.77. Overall performance was obtained, and a 200 hr cavitation endurance test was conducted in 1500° F sodium at 3450 rpm. Post-test blade inspection indicated that there was slight cavitation damage and that the Ni–Cr-base superalloy (René 41) was more cavitation damage resistant to high temperature sodium than either 316 or 318 stainless steel. SYSTEMS APPROACH TO EVALUATING HYDROGENOMONAS CULTURES
John F. Foster and John H. Litchfield Washington NASA Apr. 1969 48 p refs
(Contract NAS2-4270)
(NASA-CR-1296) Avail: CFSTI CSCL 06M

Cultures of *Hydrogenomonas eutropha* are confirmed as a stable process operating at room temperature for waste conversion, to consume the metabolic wastes carbon dioxide and urea; and the hydrogen by-product from water electrolysis. Environmental measurements with feedback controls can balance consumption of these wastes by individual makeups at the same rates as consumption. In this manner, a stable culture with constant conversión rates can be maintained in steady state growth for long periods and is suitable for consideration as a continuous waste conversion process. The growth rate indicated by careful experimental measurements is a fractional increase of 0.33 per hour of the weight of bacterial cells in the culture, which is harvested continuously from a cellular culture maintained at a constant concentration of 6.1 g (dry weight) per liter of liquid culture. These values can be used for calculating the maximum production rate of cellular material in evaluating potential practical applications. Author

THE RELATIONSHIP BETWEEN OPTICAL DISTORTION AND BINOCULAR DEPTH PERCEPTION
L. R. Loper and R. C. Stout Washington Apr. 1969 10 p refs
(NASA-TN-D-5162) Avail: CFSTI CSCL 06B

Binocular depth perception, a vital function during spacecraft docking and lunar landing, could be degraded by any spacecraft system optical transparency. A study of the relationship between binocular depth perception and optical distortion in the Apollo pressure suit helmets and visors was made to aid in setting optical distortion limits for the helmets and visors. Data obtained from the study indicated that all the helmets and visors which were tested degraded binocular depth perception. As measured by the Howard–Dolman apparatus, there is evidently a systematic effect of optical distortion in the Apollo helmets and visors on binocular stereoscopic depth perception. A program for studying this problem in greater depth is outlined. Author

A TECHNIQUE FOR IDENTIFYING PILOT DESCRIBING FUNCTIONS FROM ROUTINE FLIGHT-TEST RECORDS
Rodney C. Wingrove and Frederick G. Edwards Washington May 1969 33 p refs
(NASA-TN-D-5127) Avail: CFSTI CSCL 06B

The problem of identifying the input-output relationship of the pilot by use of measured data from routine flight operations in which the pilot provides feedback control is considered. The problem in using the measured input and output data directly is that any extraneous output noise by the pilot causes an error in identification. This problem is solved by the development of a computer processing technique that, under certain conditions, yields an estimate relatively free from identification error. A theoretical analysis to show that this technique will reduce the identification error is presented. The simulation and identification of several known system elements are included to compare with the theory and to illustrate the use of this technique. Also, results obtained from the retrofire phase of the Gemini X mission are presented to demonstrate the application of this technique to routine flight-test records. Author

THE EQUIPOTENTIAL SPACE SUIT DESIGN CONCEPT AND ITS APPLICATION TO A SPACE SUIT ELBOWJOINT
Donald E. Barthlome Washington May 1969 43 p ref
(NASA-TN-D-5221) Avail: CFSTI CSCL 06K

Space-suit design studies indicate that a high operational feasibility exists for a concept involving a nonconstant-volume space-suit elbow joint, a joint-assist mechanism, and a space-suit pressure stabilizer. The space-suit pressure stabilizer serves to limit pressure changes within the joint to ± 0.05 psi (0.035 N/cm^2). The joint-assist mechanism, or joint assist, is a modified constant-force spring mounted on a soft space-suit joint. The cross section of the spring has been altered so that most of the energy required to bend the joint is provided by the joint assist. The joint and stabilizer, both of which exhibit relatively high degrees of elasticity, store most of this energy and return it to the joint assist as the joint and stabilizer return to their initial configurations. Therefore, if friction is neglected, the joint, joint assist, and stabilizer constitute a system with a total potential energy that remains constant (regardless of the angle of bend) and equal to the initial potential energy given to the assist during installation on the joint. Test results show that the maximum bending moment required by the joint was reduced from 1.40 lbf-ft (1.90 N-m) without the assist to 0.10 lbf-ft (0.14 N-m) with the assist, a reduction of 14 to 1. PERCEPTION OF SPACE AND TIME IN OUTER SPACE
A. A. Leonov et al Washington NASA May 1969 111 p refs Transl. into ENGLISH of the book "Vospriyatiye Prostranstva i Vremeni v Kosmose" Moscow, Nauka Press, 1968 p 1–115
(Contract NASw-1692)
(NASA-TT-F-545) Avail: CFSTI CSCL 06S

The characteristic dynamics of spacecraft flight are explained as well as the role of astronauts in the "man-spacecraft" system. The authors describe how the conditions of existence and the psychophysiological mechanisms of perception of space and time outside the earth change during a flight in outer space. The effect of weightlessness, prolonged isolation in a small area, emotional tension, and other factors of space flight on human perception of time are explained. Author

A STUDY OF ASTRONAUTS' EXTRAVEHICULAR WORK CAPABILITIES IN WEIGHTLESS CONDITIONS
E. C. Wortz, W. Schreck, W. Robertson, G. Lamb, and L. Browne Washington NASA May 1969 247 p
(Contract NAS1-7571)
(NASA-CR-1334) Avail: CFSTI CSCL 05E

Exploratory experiments were conducted on methods of erection and assembly of large modules, transportation of cargo modules, and crew rescue during weightless simulation by neutral buoyancy techniques. A formal experiment was conducted on four typical restraint systems during the performance of various tasks with varying work envelopes. Data were collected on energy expenditures, reactive loads, and performance times. Conclusions are drawn about various aspects of extravehicular activity work and the efficacy of restraint systems. SIMULATION OF GEMINI EXTRAVEHICULAR TASKS BY NEUTRAL-BUOYANCY TECHNIQUES
Otto F. Trout, Jr., Gary P. Beasley, and Donald L. Jacobs (NASA Manned Spacecraft Center) Washington Jun. 1969 92 p refs
(NASA-TN-D-5235) Avail: CFSTI CSCL 05E

Neutral-buoyancy simulation techniques were applied to investigate experimentally the astronaut's extravehicular tasks in the Gemini flight program. The preflight hardware, procedures, modes of performance, and data developed during the neutral-buoyancy tests are described and compared with those pertaining to the extravehicular activities in the Gemini flights. Continuing development of the simulation during this investigation showed that the techniques are useful in assessing procedures and supporting hardware, obtaining a reasonable estimate of the subject's energy expenditure, and developing realistic time lines in training the astronaut for the extravehicular tasks in space. EXPERIMENTS AND A MODEL FOR PILOT DYNAMICS WITH VISUAL AND MOTION INPUTS
Robert L. Stapleford, Richard A. Peters, and Fred R. Alex Washington NASA May 1969 126 p refs
(Contract NAS2-3650)
(NASA-CR-1325; TR-168-2) Avail: CFSTI CSCL 05H

This report describes the results of a simulator program to investigate the effects of motion cues on a manual-control tracking task. The experimental variables were controlled-elements dynamics, linear motion characteristics, and angular motion characteristics. The data obtained include: pilot describing functions, both overall (combined visual and motion feed-backs) and separate (independent visual and motion pathways); remnant characteristics; and tracking performance. These data are also compared with previous experimental results. A multimodality pilot model for both visual and motion feedbacks is derived. The dynamics of the two (angular and linear) motion feedback paths and the integration of visual and motion feedbacks are discussed. The implications of the experimental data and the multimodality pilot model on the design requirements for moving-base simulators are also reviewed. Author

SOLID ELECTROLYTE SYSTEM FOR OXYGEN REGENERATION
L. Elikan and J. P. Morris Washington NASA Jun. 1969 180 p refs
(Contract NAS1-7306)
(NASA-CR-1359) Avail: CFSTI CSCL 05E

High efficiency multi-cell batteries employing $(ZrO_2)_{0.9}(Y_2O_3)_{0.1}$ electrolyte were constructed and operated for periods exceeding 100 days. Three five-cell batteries were life-tested; their lives were 152, 112, and 77 days. A continuous carbon deposition reactor in which the CO in the $CO–CO_2–H2–H_2O$ mixture produced by electrolysis was decomposed to form solid C and CO_2, was operated for 100 days without interruption and without decline in catalyst activity. Over 60% conversion was obtained throughout the test. The carbon produced was dry, free flowing, and non-clogging. Palladium foils were found to be an effective means of removing H_2 from a CO, CO_2, $H_2.H_2O$ mixture. Operated 800°C and above, no carbon deposition was observed on the foil. Based on the performance of the multi-cell electrolysis battery, carbon deposition reactor, and palladium foils tested, it is estimated that a solid electrolyte oxygen system can be built for a 4-man, 100-day mission which will weigh 121 pounds and require 1160 watts of power. PREDICTING HUMAN PERFORMANCE IN SPACE ENVIRONMENTS
Warren H. Teichner and Diane Olson Washington NASA Jun. 1969 186 p refs
(Grant NGR-22-007-070)
(NASA-CR-1370) Avail: CFSTI CSCL 06L

An attempt is made to provide a systematic framework which can be used for predicting the effects of the physical environment on human performance. The nature of the approach was: (1) to develop a general classification scheme for the description of tasks; (2) to develop postulates from the basic literature of psychology so as to formulate a quantitative model of wide scope representing fundamental behavioral processes assumed to underlie performance at the tasks; (3) to develop relationships between environmental conditions and major physiological effects known or thought to result from them; (4) to postulate relationships between selected ones of the underlying behavioral processes and the physiological effects, and then to use these relationships along with the performance model to predict the effects of the environment on performance; and (5) to develop a general criterion for determining the environmental conditions which should be considered limiting. EFFECTS OF DIFFERING AMOUNTS OF TRAINING AND OF MONOCHROMATIC TARGETS ON SEXTANT SIGHTING PERFORMANCE
Emmett C. Lampkin and Robert J. Randle Washington Aug. 1969 10 p refs
(NASA-TN-D-5190) Avail: CFSTI CSCL 05I

Sighting performance using a standard marine, gimbal mounted sextant with a special telescope substituted for the eyepiece was studied in combinations of simulated monochromatic stars. The stars were simulated by projecting a point source of light onto a parabolic mirror. The point source was provided by placing a lamp behind a 0.0005-inch-diameter aperture and positioning it at the focal point of the parabolic mirror. The collimated image of the aperture being projected was perceived as a star at infinity. The combinations of stars studied were: red-red, white-white, and red-green. It is concluded that five days of training are sufficient for achieving a performance asymptote; and monochromatic stars may be used for sextant sightings, with performance being more consistant from the red end of the spectrum. A discussion of the results is presented. F.O.S.

REQUIREMENTS STUDY FOR A BIOTECHNOLOGY LABORATORY FOR MANNED EARTH ORBITING MISSIONS. VOLUME 1: RESULTS, RECOMMENDATIONS AND REQUIREMENTS
L. T. Kail Washington NASA Aug. 1969 169 p
(Contract NAS7-518)
(NASA-CR-1408; DAC-58155) Avail: CFSTI CSCL 06S

The objective of the study presented here was to expand and incorporate the results of past studies, into an all-encompassing life science research program (gap-filling as required) to identify manned Earth-orbital life science laboratory equipment requirements for the 1970's. Another objective of the study was to identify and integrate requirements that are common to the four life science research fields of biomedicine and human research, behavior, bioscience, and life support systems. An elementary sketch of a concept for a biotechnology laboratory as part of a multipurpose space station is shown. The individual equipment items required in the "laboratory area" are described. The centrifuge shown relates to requirements of experiments considered in this report and represents another program currently under study by NASA for life sciences research. This study has addressed itself to the total research activities and equipment encompassed by such a laboratory. The results of the study provide a basis for further definition of a facility. Author

MAN'S CAPABILITY FOR SELF-LOCOMOTION ON THE MOON. VOLUME 2: SUMMARY REPORT
E. C. Wortz, W. G. Robertson, L. E. Browne, and W. G. Sanborn Washington NASA Sep. 1969 85 p refs Revised
(Contract NAS1-7053)
(NASA-CR-1043; Rept-68-4262-Vol-2-Rev-1) Avail: CFSTI CSCL 06S

A comprehensive study of man's self-locomotive capabilities in simulated lunar gravity is presented. An inclined-plane and a gimbal-vertical simulator equipped with treadmills were used to simulate lunar gravity. Man's locomotive characteristics and the metabolic costs of walking, running, and loping at velocities from 2 to 12.8 km/hr were determined for subjects in pressurized Gemini-4C suits. The results showed that the energy cost of locomotion in simulated lunar gravity is considerably less than that in earth gravity. Ascending grades caused large increases in metabolic cost over that of level walking where the magnitude of the cost depends on the simulation technique used. Increasing the load carried from 75 to 400 earth pounds had a small and inconsistent effect on metabolic costs. Changing the smooth, hard walking surface to sandy soil caused a large increase in the metabolic cost at the higher locomotion rates. Author

DIFFERENTIAL THRESHOLDS FOR MOTIONS IN THE PERIPHERY
James M. Link and Leroy L. Vallerie Washington NASA Sep. 1969 22 p refs
(Contract NAS12-88)
(NASA-CR-1439; BSD-69-701) Avail: CFSTI CSCL 06N

A study was conducted to determine the differential thresholds for rotary and linear motion in the periphery. Isograms were developed based on threshold estimates obtained from ten subjects using the psychophysical method of limits. The results of this study indicated that differential thresholds for rotary and linear motion

were found to increase as a linear function of eccentricity angle. Threshold isograms for both types of motion are elliptical in shape with the horizontal axis approximately twice as long as the vertical axis. Based on statistical analysis, there appears to be no real difference between rotary and linear motion. Subjects, however, reported a preference for rotary motion. Thresholds decreased logarithmically as a function of changing speed. Age of the subject appears to be a highly significant factor which influences the perception of motion. At high display velocities, subjects reported the occurrence of interference factors such as blur, fusion, strobing and flicker. These factors were particularly noticeable with the linear display. REMOVAL OF ACID GASES AND OXIDES OF NITROGEN FROM SPACECABIN ATMOSPHERES
A. J. Gully, R. M. Bethea, R. R. Graham, and M. C. Meador Washington NASA Jul. 1969 148 p
(Contract NAS1-7584)
(NASA-CR-1388) Avail: CFSTI CSCL 06K

The methods of removal of oxides of nitrogen and of the acid gases sulfur dioxide, hydrogen chloride, hydrogen fluoride, and chlorine in low concentrations from air as part of the effort to develop an effective atmospheric purification subsystem for long-term manned space missions were studied. Methods investigated were: (1) reaction with basic solid materials, (2) adsorption, and (3) for oxides of nitrogen, catalytic reduction of nontoxic to less toxic gases. Adsorption at ambient temperature of both chlorine and nitrogen dioxide on activated carbon was found to be rapid with sulfur dioxide being adsorbed to a lesser extent. In exploratory work, nickel oxide and copper oxide were found to exhibit appreciable activity in the catalytic decomposition of nitrogen dioxide. Maximum decomposition of nitrogen dioxide observed (nickel oxide catalyst at 482°C) was 53%. Nitric oxide was the major decomposition product. Solid-gas reaction was found to be the most generally effective method of contaminant removal. The solid reactants tested included sodium carbonate, sodium bicarbonate, barium carbonate, calcium carbonate, lithium carbonate, and manganese dioxide. Author

Investigations performed to develop techniques for control of temperature in extravehicular space suits have provided technological knowledge of general applicability to temperature control systems. This report summarizes this knowledge. Other reports, referenced in this report, deal with the specific application to space suits and the related materials research performed. A heat pipe thermal switching device is described, and test results presented. Techniques for bonding of capillary structures to solid substrates are discussed. Recommendations for suitable bonding techniques are provided. Heat pipes of flexible materials are described, and data resulting from experimentation with flexible heat pipes presented. Concepts for preventing freezing or for restart of frozen heat pipes are discussed and experiments, demonstrating feasibility of one of these concepts, are described and data presented. Author

APPLICATION OF HUMAN TRANSFER FUNCTIONS TO SYSTEM ANALYSIS
James J. Adams and Maxwell W. Goode Washington Oct. 1969 32 p refs
(NASA-TN-D-5478; L-6382) Avail: CFSTI CSCL 05E

An analytical study was made of a full-scale, manually controlled lunar landing simulator by using analytical transfer functions for the pilot control response along with the analytical representation for the mechanisms. The results of this study show that some of the dynamic characteristics of the simulator were in a range to influence the response of the manually controlled systems that were to be tested. Tests were made in which the dynamic response of the simulator was varied over a limited range of characteristics. The results confirm the conclusion of the analytical study in that the change did influence the piloted response. Author

ROTATING SPACE STATION STABILIZATION CRITERIA FOR ARTIFICIAL GRAVITY

Carl A. Larson Washington Oct. 1969 46 p refs

(NASA-TN-D-5426) Avail: CFSTI CSCL 06S

An understanding of man's dependency on a gravity field is an area where research has yielded limited results, thereby, prompting space station designers to include provisions for providing an artificial gravity field capability. A rotogravic environment, though satisfying certain of man's physiological requirements, can introduce other complicated requirements. Therefore, this investigation was devoted to obtaining, for space station designers, insight into how man's physiological tolerances and range of adaptability can be used to define operational and configurational design criteria. CHARACTERISTICS OF THE TACTILE INFORMATION CHANNEL

J. C. Bliss, J. W. Hill, and B. M. Wilber Washington NASA Oct. 1969 181 p refs

(Contract NAS2-4582)

(NASA-CR-1389) Avail: CFSTI CSCL 06S

Experiments with multiple-point tactile and visual stimulus fields are described. A number of the experiments involved a brief presentation of between 2- and 12-point stimuli randomly distributed in a 3 by 8 matrix. The subject's task was to specify the location of each point stimulated in the entire matrix (whole report) or in the subset of the matrix indicated by a marker (partial report). In some of these latter experiments all stimulators were activated after the point stimuli, forming an erasure field which interfered with the perception of the stimuli. Analogous visual and tactile experiments were performed. The experiments with the erasure post-field indicated that information is transferred in parallel, rather than sequentially, to higher centers. A model for both visual and tactile information processing is proposed. In another series of experiments the point stimuli were presented sequentially rather than simultaneously. The results indicated a strong dependence of the number of positions perceived in the correct spatial location with a minimum occurring in the range of 50 to 100 ms. Author

CALCULATION OF COMPLEX CHEMICAL EQUILIBRIA.

Frank J. Zeleznik and Sanford Gordon (NASA, Lewis Research Center, Cleveland, Ohio).

I & EC - Industrial and Engineering Chemistry, vol. 60, June 1968, p. 27-57. 93 refs.

Review of the calculation of complex chemical equilibria, with equal emphasis on both thermodynamic fundamentals and numerical analysis. Considerable attention is given to multipurpose schemes used to obtain solutions of the system of simultaneous equations describing chemical equilibrium, and special purpose schemes are treated in outline. The literature is surveyed, and some of the advantages and disadvantages of the various equilibrium computation schemes proposed are indicated. The application of equilibrium computations to typical problems is discussed. The two alternate, but equivalent, formulations of the conditions of chemical equilibrium are contrasted: first as a minimization of the Gibbs free energy and second as a set of equilibrium constant relations. I.P.

Irving Warshawsky (NASA, Lewis Research Center, Cleveland, Ohio).

Electrochemical Society, Journal, vol. 115, Oct. 1968, p. 1045, 1046. 8 refs.

Study of the reaction rate and the mechanism for the reaction between lithium hydride and liquid ammonia at -78°C. It is suggested that, once the reaction is underway, its continuation necessitates a chemisorption process in which ammonia dissociates at the lithium amide/liquid ammonia interface into a proton and an amide ion. M.G.

RELIABILITY IN THE ELIMINATION OF MULTIVALUEDNESS IN PHASE MEASUREMENTS [O NADEZHNOSTI USTRANENIIA MNOGOZNACHNOSTI FAZOVYKH IZMERENII].

G. I. Skrypnik, A. A. Serova, and D. I. Ataev.

Radiotekhnika i Elektronika, vol. 13, Oct. 1968, p. 1753-1761. 6 refs. In Russian.

Description of an algorithm for resolving the ambiguity arising in the two-scale method of phase measurements. The method of the greatest probability for white Gaussian noise interference is used to formulate the algorithm. A relationship is established between the reliability of eliminating the multivaluedness and the basic characteristics of the system in the presence of a parasitical shift between the scales. The results are extended to the case of multiscale measurements. I.P.

TRANSIENT ELECTRO-OSMOSIS IN CAPILLARY TUBES.

W. T. Hanna (Carnegie-Mellon University, Pittsburgh, Pa.; NASA, Lewis Research Center, Cleveland, Ohio) and J. F. Osterle (Carnegie-Mellon University, Pittsburgh, Pa.).

Journal of Chemical Physics, vol. 49, Nov. 1, 1968, p. 4062-4068. 10 refs.

Transient electroosmosis of water in glass capillary tubes is treated analytically. The usual selective ion adsorption mechanism is assumed. The analysis is restricted to tube radii greater than about 3×10^{-5} m for which the effects of fluid compressibility and electrical capacitance and inductance are negligible. The problem considered is the transient response of the system to a step change in either pressure or voltage under various external loading conditions. The resulting time histories of the induced force (voltage or pressure) and the fluid flow and electrical current are solved for. A Laplace transform technique is employed. Coupling coefficients are established in the Laplace domain relating the electrical current and fluid flow rate to the electric field and pressure gradient. The cross-coupling coefficients are shown to obey the reciprocal relations for nonsteady-state irreversible processes. (Author)

SYNTHESIS OF FLUORINATED POLYURETHANES.
R. Gosnell and J. Hollander (Whittaker Corp., Narmco Research and Development Div., San Diego, Calif.).
IN: CRYOGENIC PROPERTIES OF POLYMERS; PROCEEDINGS OF THE NASA-CASE CONFERENCE ON THE PROPERTIES OF POLYMERS AT CRYOGENIC TEMPERATURES, NASA LEWIS RESEARCH CENTER AND CASE-WESTERN-RESERVE UNIVERSITY, CLEVELAND, OHIO, APRIL 25-27, 1967. [A69-16485 05-18]
Edited by T. T. Serafini and J. L. Koenig.
New York, Marcel Dekker, Inc., 1968, p. 279-298.
NASA-sponsored research.

The purpose of the investigation described was to develop LOX-compatible adhesive systems which have structural utility at cryogenic temperatures. Work was concentrated on the preparation of fluorinated polyurethanes. Initial efforts were directed at highly fluorinated aliphatic and aromatic diamines. Several diamines were prepared and all were studied in their reaction with phosgene to prepare the corresponding diisocyanates. A unique chlorocarbonylation technique was developed for the synthesis of these fluorinated diisocyanates resulting in higher yields and less byproducts than conventional phosgenation. Using a conventional approach to polyurethanes, highly fluorinated hydroxyl-terminated polyester and polyether oligomers were sought for reaction with the several isocyanates. Simple polymers were prepared and tested in LOX, three of which were shown to be LOX-compatible. Efforts were made to determine structural effects on LOX-compatibility. (Author)

HIGH TEMPERATURE DECOMPOSITION OF AMMONIUM PERCHLORATE USING CO_2 LASER-MASS SPECTROMETRY.
G. L. Pellett and W. R. Cofer, III (NASA, Langley Research Center, Hampton, Va.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-143. 15 p. 15 refs.
Members, $1.00; nonmembers, $1.50.

Description of a CO_2 laser pyrolysis/mass spectrometry technique wherein ammonium perchlorate (AP) was rapidly pyrolyzed at heating rates up to 222 cal/cm^2-sec within the low-pressure ion-source chamber of a mass spectrometer. By using single square-wave heating pulses, and cinephotography of oscilloscope-displayed mass spectra, time-correlated analyses of pyrolysis products and their evolution rates were obtained during consecutive periods of transient heatup and growth, quasi-steady decomposition, and transient cooldown. Laser pyrolyses of doped-AP samples exhibited widely variable relative species contributions due to condensed-phase (CP) decomposition. Mechanistic features of CP decomposition are discussed, and their possible relevance to solid-propellant combustion is considered. M.M.

ELECTRON MICROPROBE ANALYSIS OF VANADIUM IN THE PRESENCE OF TITANIUM.
Kenneth G. Snetsinger, T. E. Bunch, and Klaus Keil (NASA, Ames Research Center, Space Sciences Div., Moffett Field, Calif.).
American Mineralogist, vol. 53, Sept.-Oct. 1968, p. 1770-1773. 8 refs.

Description of a special method of electron microprobe analysis of vanadium in the presence of titanium by compositional studies of chromite in chondritic meteorites. This procedure involves the determination of the ratio of the intensity of $TiK_{\alpha 1,\,2}$ to that of $TiK_{\beta 1,\,3}$, the latter value being measured at the wavelength of $VK_{\alpha 1,\,2}$, pure rutile (TiO_2) being used for this determination. Then titanium and vanadium are measured on a standard chromite and on the unknown chromite, the $TiK_{\alpha 1,\,2}/TiK_{\beta 1,\,3}$ ratio obtained from rutile being used to correct the $VK_{\alpha 1,\,2}$ intensity for interference from $TiK_{\beta 1,\,3}$ in the standard and the unknown. Z. W.

SOME PARAMETERS AFFECTING AUGER AND PHOTOELECTRON SPECTROSCOPY AS AN ANALYTICAL TECHNIQUE.
L. I. Yin, I. Adler, and R. Lamothe (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Applied Spectroscopy, vol. 23, Jan.-Feb. 1969, p. 41-50. 28 refs.

Various possibilities of Auger and photoelectron spectroscopy as an analytical technique are discussed. In some applications, simple electrostatic analyzers with coarse resolution may suffice and even be preferable. Typical spectra obtained with a hemispherical electrostatic analyzer of 0.6% energy resolution are presented and discussed. Such factors as sample thickness, sample potential, surface contamination, and incident angle of the exciting X rays have been found to affect the quality and character of the observed spectra. These results characterize some of the features, problems, and capabilities of applied Auger and photoelectron spectroscopy. (Author)

THE GROWTH OF SINGLE CRYSTALS BY CONTROLLED DIFFUSION IN SILICA GEL.
Bernard Rubin (NASA, Electronics Research Center, Cambridge, Mass.).
AIChE Journal, vol. 15, Mar. 1969, p. 206-208. 9 refs.

Single crystals of calcium tartrate tetrahydrate, neodymium-doped calcium tartrate tetrahydrate, and cuprous chloride have been grown by controlled diffusion in silica gel using both metathetical and decomplexation reactions. Conditions for the optimum growth of the crystals are given, and it is shown how the pH of the gel, the temperature of its formation, the concentration of the reactants which make up the gel, and the concentration of the reactants which result in the crystal are important in attaining good single-crystal products. Crystals have been grown up to 11 mm on edge in three to four weeks, and in many cases take on a form which seems to have been cut and polished. (Author)

VACUUM-ULTRAVIOLET PHOTOCHEMISTRY. IX - PRIMARY AND CHAIN PROCESSES IN THE PHOTOLYSIS OF HYDROGEN PEROXIDE.
L. J. Stief (Melpar, Inc., Research Div., Falls Church, Va.; NASA, Goddard Space Flight Center, Greenbelt, Md.) and V. J. DeCarlo (Melpar, Inc., Research Div., Falls Church, Va.).
Journal of Chemical Physics, vol. 50, Feb. 1, 1969, p. 1234-1240. 32 refs.
Contract No. NASw-1417.

Evidence is presented for the occurrence of primary processes leading to the formation of both atomic and molecular hydrogen in the photolysis of H_2O_2 at 1236 Å. Formation of OH in a primary process probably occurs as well. The latter is apparently the sole process required to explain the results at 1470 and 2537 Å. Processes leading to the formation of $O(^1D)$ account for less than 1% of the photochemical decomposition. Chain processes leading to the formation of O_2 but not H_2 occur at 1236 Å. The possibilities considered are a free radial chain and an energy chain. It is shown that the results are more consistent with the occurrence of an energy chain involving atomic hydrogen and vibrationally excited OH radicals. Emission of OH $A\ ^2\Sigma^+ \rightarrow X\ ^2\Pi$ (0, 0) band at 3064 Å was observed during photolysis of H_2O_2 at 1236 and 1470 Å. (Author)

CHEMICAL REACTIONS OF DUCTILE METALS DURING COMMINUTION.
Alan Arias (NASA, Lewis Research Center, Cleveland, Ohio).
Metallurgical Society of AIME, Transactions, vol. 245, Apr. 1969, p. 685-695. 15 refs.

Investigation of the behavior of metal powders during ball milling either in pure water or in oxygenated water in order to gain an insight into the grinding mechanism. It is found that zirconium, tantalum, iron, and stainless-steel powders ground in pure water were extensively comminuted and simultaneously oxidized with hydrogen release, whereas nickel, copper, and silver powders did not react with water and their particle sizes increased. On grinding nickel, copper, and silver in water pressurized with oxygen, nickel and copper became extensively comminuted and were oxidized, whereas silver did not react with oxygen and its particle size increased. From these results and other considerations, it is hypothesized that for extensive comminution of ductile metals and alloys to occur on grinding they must react with the grinding media. Z.W.

THE EFFECT OF TIME OF HEATING ON THE THERMAL POLYMERIZATION OF L-LYSINE.
Milton R. Heinrich, Duane L. Rohlfing, and Ester Bugna (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).
Archives of Biochemistry and Biophysics, vol. 130, Mar. 1969, p. 441-448. 28 refs.

Investigation of several parameters of the thermal polymerization of L-lysine free base at 195°C over the time period from 15 min to 4 hr. Free lysine disappeared within 1 hr. The concentration of α-aminocaprolactam and of oligomers of several sizes reached a maximum after 30 to 45 min, and subsequently decreased. Molecular size, as judged by biuret color intensity and by gel filtration, increased rapidly and, in part, ultimately exceeded 100,000. Racemization was extensive and paralleled the disappearance of free lysine. Catalytic activity for the decarboxylation of oxaloacetic acid increased rapidly and reached a maximum after 2 hr. Dinitrophenylation and subsequent hydrolysis indicated that the polymers were branched, and that the linear portions contained more ε- than α-peptide bonds. A partial understanding of the method of chain growth can thus be inferred. M.G.

TEMPERATURE DEPENDENCE OF THE RATE CONSTANTS FOR THE REACTIONS $O^+ + O_2 \rightarrow O_2^+ + O$ AND $O^+ + N_2 \rightarrow NO^+ + N$.
Peter Stubbe (NASA, Goddard Space Flight Center, Laboratory for

Space Sciences, Greenbelt, Md.).
Planetary and Space Science, vol. 17, June 1969, p. 1221-1231. 23 refs.

The dependence of the rate constant k_r for the reactions $O^+ + O_2 \rightarrow O_2^+ + O$ (k_1) and $O^+ + N_2 \rightarrow NO^+ + N$ (k_2) on the gas temperature T, the vibrational temperature T_v of the molecular reactant, and the relative flow velocity v_s between the gases, is studied theoretically by means of a collision theory approach. The resulting expression for k_r contains the two unknown parameters A (activation energy) and P_0 (scaling factor) which have to be determined empirically. $k_1(T)$ is found to have a minimum at about 650°K and a nearly linear increase for temperatures above 750°K. For the second reaction, the rate constant is presented as a function of T and A, since uncertainties in the experimental results do not allow a reliable determination of A. The increase rate of k_2 with $T_v(N_2)$, the vibrational temperature of N_2, falls off strongly with increasing gas temperature. (Author

STUDIES OF THE ELECTRON TRANSPORT CHAIN OF EXTREMELY HALOPHILIC BACTERIA. II—SALT DEPENDENCE OF REDUCED DIPHOSPHOPYRIDINE NUCLEOTIDE OXIDASE.
Janos K. Lanyi (NASA, Ames Research Center, Exobiology Div., Moffett Field, Calif.).
Journal of Biological Chemistry, vol. 244, June 10, 1969, p. 2864-2869. 16 refs.

Characterization of the electron transport chain of Halobacterium cutirubrum, and examination of the role of b-type cytochromes in the oxidation of DPNH. The results suggest a main branch of electron transport which includes a flavoprotein, reduced by DPNH, and a subsidiary branch consisting of flavoproteins and cytochrome b(559), reduced by DPNH and succinate. The branches join at the c-type cytochromes. The relation of DPNH oxidase activity to NaCl concentration, and the irreversible inactivation of the enzyme in the absence of salt reflect the behavior of a single component of the system, DPNH dehydrogenase. The place of the b-type cytochromes in a proposed electron transport system based on these findings is confirmed through the determination of salt dependence curves. B.H.

OBSERVATIONS ON PERMEATION OF POLYTETRAFLUOROETHYLENE BY COMPOUNDS OF RHENIUM, MOLYBDENUM, AND TUNGSTEN

Harold Leibecki Washington Nov. 1968 16 p refs

(NASA-TN-D-4886) Avail: CFSTI CSCL 07B

Observations of diffusion of rhenium, molybdenum, and tungsten hexafluorides into polytetrafluorethylene and hydrolysis of the resultant material are reported. Exposure of *polytetrafluoroethylene to rhenium or molybdenum hexafluoride*, followed by hydrolysis, results in impregnation of the plastic with a metal compound. Tungsten hexafluoride was observed to grow a fibrous product (composition unresolved) on the surface of the plastic during ambient air hydrolysis. Rhenium hexafluoride hydrolysis yielded a mixture of rhenium oxides. The polytetrafluoroethylene sample was investigated for electrical conduction and was found to be substantially more conductive than the pure plastic. The hydrolysis product of molybdenum hexafluoride impregnation was postulated to be a mixture of molybdenum oxides. The electrical conduction properties of the product were not investigated. Author

EVALUATION OF THE RESULTS OF A ROUND ROBIN ANALYSIS FOR OXYGEN fN POTASSIUM AND SODIUM

Glenn R. Zellars and Charles A. Barrett Washington Dec. 1968 39 p refs

(NASA-TN-D-4971) Avail: CFSTI CSCL 07D

Analysts from 17 laboratories analyzed tube samples of *high-purity potassium and sodium for oxygen*. Most oxygen analyses were determined by the mercury amalgamation method and several by vacuum distillation; one value of oxygen in potassium was obtained by neutron activation analysis. Analytical results submitted by the participating laboratories gave a mean value for oxygen in potassium of 14.7 ppm with a standard deviation of 5.08 ppm. For dodium, the mean value was 10.7 ppm with a standard deviation of 4.70. The oxygen results for each alkali metal showed variations significantly in excess of the experimental error. Statistical techniques were applied to the oxygen data to identify the most likely sources of variability. Author

SOLVENT PURIFICATION PROCEDURES USED IN ORGANIC GEOCHEMISTRY LABORATORIES

Keith A. Kvenvolden and J. M. Hayes Washington Feb. 1969 15 p refs

(NASA-TM-X-1746) Avail: CFSTI CSCL 07D

As organic and inorganic solvents are often a source of contamination in organic geochemistry, questionnaires were sent to *organic chemical laboratories on the use and purification of solvents*. An analysis of the replies shows: (1) Analytical reagent grade solvents generally are unacceptable for organic geochemical use unless they are purified by some kind of column chromatography or distillation. (2) In some applications, spectroscopic grade and pesticide or nanograde quality solvents were used successfully as received from the manufacturers. (3) Pretreatment of solvents before distillation is not a common practice. (4) Laboratories reporting successful distillation techniques use simple distillation setups with good fractionating columns operated under high reflux ratios. (5) In a few instances, the level of residue contamination in solvents used for analyses was reported and varied from 10^{-7} to 10^{-9} gm/ml. (6) Techniques of fractional crystallization and zone melting seem to provide higher purity solvents than can be prepared by distillation. Author

THE DISSOCIATION ENERGY OF GASEOUS TITANIUM MONONITRIDE

Carl A. Stearns and Fred J. Kohl Washington Feb. 1969 20 p refs

(NASA-TN-D-5027) Avail: CFSTI CSCL 07D

The titanium nitride molecule has been identified in the vapor phase over solid $TiN_{0.78}$ at temperatures above 2250°K. *The Knudsen effusion method was used in conjunction with a* double-focusing mass spectrometer. The high resolution of the spectrometer made possible the identification of the TiN molecule. From experimentally determined partial pressures, the enthalpy for the reaction $TiN(g) = Ti(g) + 0.5\ N_2(g)$ has been calculated as $\Delta H^o_{298} = -1.8 \pm 7$ kcal/mole (-7.5 ± 29 kJ/mole). This reaction enthalpy yields thermodynamic properties for gaseous TiN when combined with published thermodynamic data: (1) $TiN(g) = Ti(g) + N(g)$, $D^o_{298} = 111.2 \pm 8$ kcal/mole (465.3 ± 33 kJ/mole); (2) TiN(s) = TiN(g), $\Delta H^o_{s,298} = 195.5 \pm 9$ kcal/mole (818.0 ± 38 kJ/mole); and (3) $Ti(s) + 0.5\ N_2(g) = TiN(g)$, $\Delta H^o_{f,298} = 114.8 \pm 8$ kcal/mole (480.3 ± 33 kJ/mole). EFFECTS OF LITHIUM AND OXYGEN LOSSES ON THE MAGNETIC AND CRYSTALLOGRAPHIC PROPERTIES OF SPINEL LITHIUM FERRITE

D. H. Ridgley, H. Lessoff, and J. D. Childress Washington Mar. 1969 31 p refs

(NASA-TR-R-305) Avail: CFSTI CSCL 07B

A study of the effects of sintering temperatures and cooling rates on the magnetic and crystallographic properties of spinel *lithium ferrite shows that both the magnetic moment and lattice* parameter increase with sintering temperature. Either annealing at lower temperatures or slow cooling under oxygen causes reoxidation of the Fe^{+2} formed at higher temperatures with attendent decreases in moment and lattice parameter and gradual precipitation of α–Fe_2O_3 as a second phase. The various products formed were shown to be equivalent to solid solutions of spinel lithium ferrite with Fe_3O_4 on rapid cooling and to solid solution of lithium ferrite and γ–Fe_2O_3 with precipitation of α–Fe_2O_3 on slow cooling. Lithium losses and α–Fe_2O_3 precipitate amounts are calculated. The magnetic moment and lattice parameter of stoichiometric lithium ferrite were determined: magnetic moment at 25°C = 3736±20G; lattice parameter at 28°C = 8.3293±0.0005Å. Author

A COMPARISON OF TWO SPECTROPHOTOMETRIC METHODS FOR THE DETERMINATION OF PALLADIUM IN TITANIUM-BASE ALLOYS

Warren F. Davis Washington Mar. 1969 28 p refs

(NASA-TM-X-1767) Avail: CFSTI CSCL 07D

This report compares extraction procedures using 1–nitroso 2–naphthol and dimethylglyoxime for the spectrophotometric determination of palladium in titanium-base alloys. Dimethylglyoxime has greater selectivity but lower sensitivity, similar precision (about 25 ppm at the 0.2 percent level), is faster, and covers a wider range of palladium contents than does 1–nitroso 2–naphthol. The dimethylglyoxime procedure has no interferences by any of the common or potential alloying elements, for example, cobalt, niobium, and tantalum; thus it is well suited to the determination of 0.1 *to 1.0 percent palladium in titanium-base alloys*. Selectivity is improved by the presence of nitrate. Author

PRELIMINARY DEVELOPMENT OF SPECTROCHEMICAL ANALYSIS OF SUPERALLOYS WITH THE LIQUID-LAYER SOLID-SAMPLE SPARK TECHNIQUE
Ramon M. Barnes Washington Mar. 1969 23 p refs
(NASA-TM-X-1753) Avail: CFSTI CSCL 07D

A comparison study is made, for the spectrochemical analysis of cobalt-base superalloys, between the liquid-layer solid-sample spark technique and the conventional point-to-plane spark analysis in air. The changes of analytical concentration curves are indicated for alloying constituents of two developmental cobalt-base alloys, and correlation of the changes to preliminary microscopic, metallographic, and spectroscopic phenomena are hypothesized. ANALYSIS OF LIGHT-SCATTERING DATA FROM POLYMER SOLUTIONS
James A. Ryan Washington Apr. 1969 18 p refs
(NASA-TN-D-5177) Avail: CFSTI CSCL 07D

An analysis was made of various factors affecting the analytical fitting of curves to a Zimm plot of light scattering data from dilute polymer solutions. The use of a computer to completely fit the data analytically was not feasible. However, a procedure was developed whereby the computer calculates the points on the limiting tangent. This tangent is then extrapolated graphically to zero concentration. A computer program was written which incorporates this method. Author

THE SYNTHESIS OF A NOVEL POLYIMIDE PRECURSOR
Peter Delvigs, Li-Chen Hsu, and Tito T. Serafini Washington Apr. 1969 16 p refs
(NASA-TN-D-5184) Avail: CFSTI CSCL 07C

A novel blocked polymide precursor was synthesized by using diethylamine as the blocking reagent. The structure of the blocked precursor is the bis(n,N-diethylamide) of the polyamic acid derived from pyromellitic dianhydride and 4,4'-diaminodiphenyl ether. The blocked precursor was more resistant to thermal imidization than the corresponding polyamic acid. The weight average, molecular weight of the blocked precursor could be increased by solid-state polymerization. However, the molecular weight of the polyamic acid could not be changed from its initial value. Furthermore, the blocked precursor was still completely soluble after solid-state polymerization. The solvolytic stability of the blocked precursor in anhydrous N,N-dimethylacetamide was superior to that of the polyamic acid. Author

DETERMINATION OF OXYGEN IN LITHIUM BY THE VACUUM DISTILLATION METHOD
Randall F. Gahn Washington May 1969 13 p refs
(NASA-TN-D-5197) Avail: CFSTI CSCL 07B

The vacuum distillation method for determining oxygen in alkali metals was applied to lithium. In this method the nonvolatile impurities, assumed to be lithium monoxide, are separated from the volatile lithium by heating the lithium sample in high vacuum. The alkalinity or the lithium content of the impurities is then converted to an oxygen concentration. Method reproducibility was determined at the 30 and 80 ppm oxygen levels. Method accuracy was evaluated through quantitative oxygen additions and recoveries, estimation of the method blank, and characterization of the distillation residue from the lithium-oxygen system. RADIATION INDUCED REDUCTION OF AMMONIACAL NICKEL (2) SULFATE TO METALLIC NICKEL
Warren H. Philipp and Stanley J. Marsik Washington May 1969 14 p refs
(NASA-TN-D-5213) Avail: CFSTI CSCL 07C

Aqueous ammoniacal nickel (II) sulfate solutions containing a variety of soluble organic compounds were irradiated with 2MeV electrons. When this organic additive was either a primary alcohol, secondary alcohol, or cyclic ether, the divalent nickel was reduced to elemental nickel powder. The reaction mechanism involves the decomposition of water by the ionizing radiation into hydrogen atoms and hydroxyl radicals. The organic additive scavenges the hydroxyl radicals by reducing them, and the remaining hydrogen atoms then reduce the divalent nickel to the free metal powder. Author

STUDY OF FERROMAGNETIC LIQUID
Robert Kaiser and Ronald E. Rosensweig Washington NASA Aug. 1969 100 p refs
(Contract NASw-1581)
(NASA-CR-1407) Avail: CFSTI CSCL 07D

It is possible to induce substantial magnetic forces in ferrofluids. These are stable micro-dispersions formed by grinding a ferromagnetic powder in the presence of a surfactant solution. Novel hydrocarbon base ferrofluids with increased magnetization and improved thermal stability have been prepared. Water, fluorocarbon and nonvolatile ester base ferrofluids have also been synthesized. Physical properties of numerous magnetite base ferrofluids were measured. For these systems the particle size is less than 150 Å. Magnetic properties can be accounted for by superparamagnetic theory and particle concentration. The maximum attainable concentration of particles varies as a function of the ratio of the stabilizing layer thickness to the particle diameter. A minimum value of 30 Å was observed. Ferrofluid viscosity increases as a function of carrier liquid viscosity, particle concentration, and the stabilization ratio. Author

PROPERTIES OF NONAQUEOUS ELECTROLYTES
Rudolf Keller, James N. Foster, Douglas C. Hanson, John F. Hon, and James S. Muirhead Washington NASA Aug. 1969 253 p refs
(Contract NAS3-8521)
(NASA-CR-1425; R-7703) Avail: CFSTI CSCL 07D

Aprotic electrolytes with and without dissolved cupric fluoride and cupric chloride were studied. The electrolytes were based on four solvents: propylene carbonate, dimethyl formamide, acetonitrile, and methyl formate. Characterized components were used to prepare the solutions. Structural studies were performed utilizing nuclear magnetic resonance and electron paramagnetic resonance techniques. Various physical properties were determined including solubility, heat of solution, vapor pressure, viscosity, density, sonic velocity, conductance, diffusion coefficient, and dielectric constant. ELECTROCHEMICAL BEHAVIOR OF THE ALUMINUM ELECTRODE IN MOLTEN SALT ELECTROLYTES
Betty S. DelDuca Washington Oct. 1969 30 p refs
(NASA-TN-D-5503) Avail: CFSTI CSCL 07D

The kinetics for dissolution and deposition of solid aluminum in molten $AlCl_3$-NaCl and $AlCl_3$-$(LiCl\text{-}KCl)_{eut}$ electrolytes were studied by means of galvanostatic and potentio-static techniques over a temperature range of 175° to 313°C (448 to 586 K). The apparent exchange currents varied from 1 to 56 mA/cm^2. Surface diffusion was found to be the rate-determining step at low overpotentials, and charge transfer the rate-determining step at high

overpotentials. The most probable anodic rate-determining step was found to be $Al \rightarrow Al^{+} + e^{-}$; the most probable cathodic rate-determining step was $Al^{+++} + e^{-} \rightarrow Al^{++}$ in $AlCl_3$-$(LiCl\text{-}KCl)_{eut}$ electrolyte and $Al^{++} + e^{-} \rightarrow Al^{+}$ in $AlCl_3 \cdot NaCl$ electrolyte. Current efficiencies for dissolution were close to 100 percent. Author

RADIATION MODELS USING DISCRETE RADIATOR ENSEMBLES. S. Karp (NASA, Electronics Research Center, Cambridge, Mass.), Robert M. Gagliardi, and Irving S. Reed (Southern California, University, Dept. of Electrical Engineering, Los Angeles, Calif.). IEEE, Proceedings, vol. 56, Oct. 1968, p. 1704-1711. 14 refs. Grant No. AF AFOSR 496-67.

In recent literature, radiation emitted or reflected from a body or surface has been modeled as equivalent radiation from a collection of individual discrete radiators. This model has application to the analysis of forward and backscatter from rough surfaces, clutter and chaff models for radar, and cavity emissions at optical frequencies. The present work investigates radiation using a generalization of the above radiator ensemble. Some degree of coupling is assumed to exist between individual radiators, and each radiator emits random energy bursts as a Poisson process. Analysis is confined to power spectral densities and first-order statistics of the resulting scalar radiation field. The results indicate that the pulsed radiator model can account for many properties of radiation. A by-product of the analysis is a filter model for dispersive channels, applicable to radar design problems. (Author)

RADAR ATTITUDE SENSING SYSTEM.
Eugene Burcher (NASA, Washington, D.C.) and Edward Rupp (Bell Aerospace Corp., Bell Aerosystems Co., Buffalo, N.Y.).
IN: EASCON '68; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ELECTRONICS AND AEROSPACE SYSTEMS CONVENTION, WASHINGTON, D.C., SEPTEMBER 9-11, 1968, RECORD. [A69-13176 03-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 60-63.

A radar attitude sensing system for use in earth orbital and lunar orbital vehicles is described. This is a multipurpose flight control instrument which employs radar data to obtain vehicle roll, pitch, yaw, altitude, and velocity. It uses a lightweight radar with an electronically steered antenna to provide an all solid-state sensor with no moving parts. The system employs a monopulse antenna configuration whose sum beam illuminates the terrain about the vehicle nadir. The radar return on the sum beam and two pairs of difference beams provides all of the measurement information. Operation is described at the block-diagram level. Theoretical performance is determined and is compared with results from an aircraft flight test program. These results are extrapolated to orbital altitudes and velocities. (Author)

RADIO FREQUENCY INTERFERENCE EXPERIMENT DESIGN FOR THE APPLICATIONS TECHNOLOGY SATELLITE.
Varice F. Henry (NASA, Goddard Space Flight Center, Greenbelt, Md.) and John J. Kelleher (NASA, Washington, D.C.).
IN: EASCON '68; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ELECTRONICS AND AEROSPACE SYSTEMS CONVENTION, WASHINGTON, D.C., SEPTEMBER 9-11, 1968, RECORD. [A69-13176 03-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 514-520. 6 refs.

Description of the design of experiments to provide data on mutual rf interference between satellite and terrestrial telecommunications systems. The proposed experiment is designed to measure and evaluate the amount of mutual interference between communication satellite and terrestrial microwave relay systems at the shared common-carrier frequency bands of 6 and 4 GHz. It is proposed to measure terrestrial-to-satellite interference at 6 GHz and satellite-to-terrestrial interference at 4 GHz. To implement the technical requirements of this experiment, it is necessary to use a satellite of the type planned for the ATS F and G programs. These spacecraft, each carrying a 30-ft parabola as the prime antenna, will be capable of 0.1^{o} pointing accuracy and full earth-scanning coverage. It is postulated that measurements will be made of several parameters relevant to a fuller understanding of existing conditions with respect to such interference. M.M.

MILLIMETER WAVELENGTHS FOR SPACE COMMUNICATIONS?
John J. Kelleher (NASA, Washington, D.C.) and William O. Binkley (NASA, Goddard Space Flight Center, Systems Div., Extra High Frequency Technology Section, Greenbelt, Md.).
Microwave Journal, vol. 11, Nov. 1968, p. 30, 32, 34, 36.

Discussion of new short-wave bands to meet the growing needs of proliferating space services. Migration to bands above 10 GHz, where the spectrum is not so crowded, is suggested. Their utilization will depend on technical feasibility and adequate hardware. It is considered to be reasonably certain that millimeter wavelengths can be used for earth/space communications, provided that systems are designed to compensate for propagation anomalies and that frequency bands are made available. CHARACTERISTICS OF LOW-LATITUDE VLF EMISSIONS.
Tadanori Ondoh (NASA, Goddard Space Flight Center, Greenbelt, Md.) and Susumu Isozaki.
Radio Research Laboratories, Journal, vol. 15, May 1968, p. 133-146. 13 refs.

Study of vlf emissions at 2, 5, and 21 kHz, which were observed since March 1966, August 1964, and December 1966, respectively, at Hiraiso (geomagnetic latitude 26.2° N), located well below the latitude of peak occurrence of vlf emissions. The diurnal variation of the 2-kHz emission is similar to those at mid-latitudes and high latitudes. However, the diurnal variation of the 5-kHz emission at Hiraiso is different from those at high latitudes. As for simultaneous occurrence of vlf emissions at 2 and 5 kHz, power fluxes observed at Hiraiso are always larger at 2 than at 5 kHz. This characteristic is similar to the broadband vlf emissions observed in the auroral zone. The rate occurrence of 21-kHz vlf emissions at low latitudes suggests that 21-kHz vlf emissions may be generated relatively near the ionosphere on geomagnetic lines of force starting from the auroral zone. A MATHEMATICAL TECHNIQUE FOR PROGRAMMING AUTOMATIC PICTURE TRANSMISSION TRACKING ANGLES.
David E. Pitts (NASA, Manned Spacecraft Center, Houston, Tex.).
Journal of Applied Meteorology, vol. 7, Dec. 1968, p. 1036-1038.

A computer can be used to calculate look angles for automatic picture transmission (APT) receiving stations. This method eliminates the laborious use of the plotting board and overlays, and enables the APT operator to have all possible orbit types preprogrammed and available a very short time after a new APT satellite is placed in orbit. The necessary coordinate transformations are presented in a form that makes them adaptable for use with very small computers. (Author)

CONDUCTIVE EMI - RESPONSIBILITY AND CONTROL.
Gary Harris (NASA, Goddard Space Flight Center, Solar Physics Branch, Greenbelt, Md.).
Frequency Technology, vol. 7, Feb. 1969, p. 22-25.

Discussion of electromagnetic interference (EMI) problems created by the coupling of noise from one subassembly to another by means of conductive paths. The discussion is primarily aimed at spacecraft but the information is equally appropriate when applied to ship-board installations, aircraft, and other environments. It is suggested that the overall responsibility for the control of an EMI program should rest with some central authority within the systems management organization. G.R.

Conference sponsored by the International Foundation for Telemetering.

Tarzana, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 4), 1968, p. 430-439.

The paper describes three potentially practical methods for estimating the SNR in a PCM signal. One method, referred to as the "spectral null" method, uses spectral characteristics of PCM signals to estimate the SNR; the other two use statistical properties of the signal - i.e., its mean value and variance. These two methods are known as "variance estimation" and "null zone." The implementation of each method is discussed. The spectral null method takes the least amount of equipment, but is more difficult to calibrate and operate over a wide range of bit rates than the other two systems. All three approaches, however, are uncomplicated enough to be included in almost any existing PCM data-handling system. Performance characteristics of each system are analyzed. It is shown that the variance estimation method is the most versatile. It can reliably estimate the SNR to within 1.5 dB over a range of SNRs from 0 to +10 dB. (The SNR is defined as the ratio of signal energy per bit/noise power density.) Under certain conditions all three methods can provide estimates to within 1 dB, especially over a SNR range from +3 to +10 dB. (Author)

Description of the communications for the Apollo Applications Program (AAP), which will consist of a series of extended-duration manned missions in low earth orbit. The initial missions are based upon equipment and techniques proved in previous space flight missions. This is especially true of the communications systems, which rely on the Gemini, Saturn, and Apollo communications hardware operating with the manned space flight network. Following AAP missions may include new spacecraft developments involving television, teleprinters, satellite relays, and spacecraft data management systems. These developments are described briefly, but many of them are concepts only in early development stages. Z.W.

Tarzana, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 4), 1968, p. 544-559. 6 refs.

The waveform distortion resulting from adjacent channel crosstalk and from amplitude and phase nonlinearity in channel filters limits the minimum channel spacing and, hence, the bandwidth utilization efficiency of a double sideband/suppressed carrier (DSB/SC) telemetry link. The paper presents results of an analysis defining the minimum achievable mean-square error when Butterworth filters are used in the DSB demodulator/demultiplexer. With data inputs consisting of band-limited random signals, solutions are given for various combinations of data order, filter order, channel spacing, and filter cutoff. The tradeoff between waveform distortion and channel spacing is illustrated, and optimum locations for the filter cutoff are defined. The irremovable error based on Weiner optimum filter theory is presented as an interesting basis for comparison. (Author)

CONJUGATE ECHOES IN ALOUETTE-2 TOPSIDE-SOUNDER DATA.
Jayaram Ramasastry, Edward J. Walsh (NASA, Electronics Research Center, Cambridge, Mass.), and John R. Herman (Lowell Technological Institute, Research Foundation, Lowell, Mass.).
IEEE Transactions on Antennas and Propagation, vol. AP-16, Nov. 1968, p. 771-774.

Three types of ionograms containing symmetric conjugate echo traces which appear frequently in the Alouette 2 satellite topside-sounder data are presented and explained in terms of multiple reflections between conjugate points of the field line passing through the satellite. Such symmetric traces have not been previously reported in the literature. The high intensity of these traces gives credence to the existence of magnetospheric waveguides along which signals can propagate with very little attenuation. (Author)

FM/AM TELEMETRY TO MEASURE IMPACT ACCELERATIONS.
Dean R. Harrison (NASA, Ames Research Center, Moffett Field, Calif.).
IN: INSTRUMENTATION IN THE AEROSPACE INDUSTRY. VOLUME 14 - INSTRUMENT SOCIETY OF AMERICA, INTERNATIONAL AEROSPACE INSTRUMENTATION SYMPOSIUM, 14TH, BOSTON, MASS., JUNE 3-5, 1968, PROCEEDINGS. [A69-23245 10-11]
Edited by John Leak.
Pittsburgh, Instrument Society of America, 1968, p. 221-224. 8 refs.

An FM/AM telemetry system has been designed which provides three-axis acceleration measurements during impact tests of models of soft-landing structures. The system was designed to employ a three-axis piezoelectric accelerometer working into three separate FM/AM telemetry circuits. Each carrier was received and detected by a separate receiver at the ground station. The subcarrier output of the receiver was recorded directly on magnetic tape. The frequency of the subcarrier was preset to the center frequency of the tape recorder FM electronics to facilitate demodulation of the recorded subcarrier during playback of the tape. During calibration, drop-test acceleration wave forms were recorded by both telemetry and direct wire techniques. Wave-form comparisons showed close correlation for each axis tested. (Author)

ANALYSIS OF APERTURE RADIATION FROM AN AXIALLY SLOTTED CIRCULAR CONDUCTING CYLINDER USING GEOMETRICAL THEORY OF DIFFRACTION.
C. A. Balanis (NASA, Langley Research Center, Hampton, Va.) and L. Peters, Jr. (Ohio State University, Dept. of Electrical Engineering, Columbus, Ohio).
IEEE Transactions on Antennas and Propagation, vol. AP-17, Jan. 1969, p. 93-97. 8 refs.

The wedge-diffraction theory in combination with the creeping-wave theory is used to compute the radiation pattern of an axial slot on a circular conducting cylinder. The slot is excited by a parallel-plate waveguide operating in the TEM mode. The total field in the "lit" region is obtained by the superposition of the wedge-diffracted and creeping-wave fields. The total field in the "shadow" region is obtained solely from the creeping-wave contribution. (Author)

DATA RELAY SATELLITES FOR SUPPORT OF NASA R&D MISSIONS.

Paul F. Barritt (NASA, Office of Tracking and Data Acquisition, Washington, D.C.).

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL REGION III CONVENTION, 7TH, COCOA BEACH, FLA., NOVEMBER 18-20, 1968, RECORD. [A69-25288 11-07]

New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. S3-4pl to S3-4p5.

For the past three years, NASA has been studying the potential use of satellites in synchronous orbit for direct communication between other, low-altitude spacecraft and the mission control centers. Requirements for tracking and data acquisition service which could be provided by a data relay satellite system (DRSS) range from voice and low data for the operation of a manned earth orbital mission up to several megahertz of video data from an Earth Resources Technology Satellite. The range of requirements results in conflicts in technological approaches - for example, in the choice of operating frequency. For one set of requirements, a low frequency should be selected, while another set of requirements suggests a very high frequency. NASA is continuing its study efforts toward defining a DRSS which will meet the Agency's requirements in hopes of getting a development program underway in the near future. In the meantime, work is proceeding on the development of technology that has potential application to a DRSS. (Author)

COMMUNICATIONS FOR SPACE RESEARCH.

Gerald Truszynski (NASA, Washington, D.C.).

Signal, vol. 23, Apr. 1969, p. 19-22.

Review of developments in tracking and communications networks which are essential for a successful space mission. To support the broad spectrum of requirements stemming from the variety of missions, NASA has developed three functionally oriented tracking and data acquisition networks, together with a worldwide communications system which ties the networks and the control centers together to form an integrated entity for support of any specific mission. Data processing capacity is studied, and results obtained from the new 210-ft antenna currently in use at Goldstone are discussed. Attention is given to the Unified S-band System, which is the heart of the Manned Space Flight Net. It is basically the same communications system developed initially by the Jet Propulsion Laboratory for the Deep Space Net. It is considered that a high state of perfection has been achieved in communications systems. The possibilities of a Data Relay Satellite System are being studied. F.R.L.

THE APPLICATION OF THE IMAGE ORTHICON TELEVISION SYSTEM TO ROCKET TRAJECTORY DETERMINATION.

J. D. Stolarik, K. Burrows (NASA, Goddard Space Flight Center, Greenbelt, Md.), and M. Miller (NASA, Goddard Space Flight Center, Greenbelt, Md.; Vitro Corporation of America, New York, N.Y.).

Planetary and Space Science, vol. 17, Mar. 1969, p. 579-584. 7 refs.

During darkness or twilight, the high optical sensitivity of the image orthicon TV camera tube can be used to track a light source carried on board a rocket and hence, by relating the position of the light to a star background, the rocket's trajectory can be determined. The technique is considerably simpler and potentially more accurate than standard radar and Doppler methods currently in use. A method of computing trajectory from one TV site, in conjunction with very limited radar data is described. (Author)

Mailloux (NASA, Electronics Research Center, Cambridge, Mass.), M. E. Louapre (Aerojet-General Corp., El Monte, Calif.), and D. H. Steinbrecher (Massachusetts Institute of Technology, Cambridge, Mass.).

IN: SYMPOSIUM ON REMOTE SENSING OF ENVIRONMENT, 5TH, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICH., APRIL 16-18, 1968, PROCEEDINGS. [A69-26974 12-14]

Symposium sponsored by the U.S. Navy, the U.S. Air Force, the U.S. Army, the U.S. Geological Survey, and the Department of Agriculture.

Ann Arbor, Michigan, University, Willow Run Laboratories, 1968, p. 9-58. 121 refs.

Grant No. NGR-22-009-163.

Discussion of the principles of operation and present capabilities of microwave radiometric sensors. Antennas and radiometric receivers are treated at length as the two major functional subsystems of the sensor. Scanning antennas are useful where rapid successive measurements are to be made, as in mapping applications. For airborne application, power and weight requirements allow schemes such as Sperry Rand's AN/AAR-33, which consists of three parabolic dishes rotating continually about an axis along the length of the aircraft. Each antenna is connected for $\pm 55^{\circ}$ of angular scan. The prime function of the receiver in a microwave radiometric sensor is to measure the antenna temperature. The method by which this is achieved is described. Projected capabilities offered by near-future solid-state component advances are discussed. P.v.T.

SYNTHESIS TECHNIQUES FOR A CLASS OF SSB-AM-PM SIGNALS.
John H. Painter (NASA, Langley Research Center, Hampton, Va.).
IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, May 1969, p. 450-456.

This paper develops synthesis techniques for a particular type of single-sideband sinusoidal carrier which is phase modulated by a subcarrier. Mathematical expressions for signal efficiency, sensitivity of design to parameter variation, and ratio of peak to average power are derived and incorporated in a computer program. Given the desired power ratios for modulated signal components, the program solves for the corresponding modulation parameters and evaluates signal efficiency, design sensitivity, and peak to average power ratio. A sample signal design is presented for clarity. (Author)

ENHANCEMENT OF PHOTON-BUNCHING EFFECTS.
Melvin D. Aldridge (NASA, Langley Research Center, Hampton, Va.).
Journal of Applied Physics, vol. 40, Mar. 15, 1969, p. 1720-1727. 16 refs.

Analysis showing that photon-bunching effects in a spatially coherent noise field can be enhanced by the superposition of a monochromatic coherent "signal" and/or by shaping the spectrum of the incident noise. For a Lorentz spectral shape, the addition of "signal" to noise is shown to increase bunching effects by a factor no greater than 4. By changing the noise spectrum from a Lorentz to a rectangular shape, bunching effects are shown to increase by a factor of 2 despite the fact that total incident noise power decreases. In all cases, the ratio of bunching noise to shot noise is proportional to the average number of detected noise photons per cycle of noise bandwidth. For the specific problem analyzed, the maximum value of the ratio of bunching noise to shot noise is determined. In the absence of "signal," the results are found to agree with the exact distribution of Bèdard (1966). (Author)

TRACKING AND DATA ACQUISITION FOR SPACE EXPLORATION.
Robert J. Coates (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Space Science Reviews, vol. 9, May 1969, p. 361-418. 75 refs.

The tracking and data acquisition systems provide the key link between the remote spacecraft and the scientific experimenter on the ground. The operation of the space experiment takes place through the links of command, telemetry, and tracking. The evolution from the early very simple spacecraft missions toward more complex and sophisticated missions has been paralleled by a similar evolution in the tracking and data acquisition systems. The early Minitrack interferometer tracking system still carries the major tracking workload for space missions; however, greater tracking accuracy requirements for more recent missions, such as OGO and the Apollo mission, have brought about the development of unified tracking and data acquisition systems which utilize hybrid pseudo-random code/sidetone ranging techniques. The data acquisition has evolved from analog telemetry systems to the present-day heavy use of PCM digital telemetry. Likewise the command systems have evolved from early simple "on/off" command systems into PCM digital command data systems. The trend is toward greater real time control of more complex functions on board the spacecraft. Newer spacecraft are incorporating computer-type systems in the spacecraft which require programming and memory load through the ground command link. The most attractive concept for the next generation network for tracking and data acquisition is a network consisting of synchronous-orbit Tracking and Data Relay Satellites for covering launches and low-orbit earth satellites plus a few selected ground stations for supporting spacecraft in high earth orbit and lunar orbit. (Author)

RADIO PROPAGATION EXPERIMENTS WITH INTERPLANETARY SPACECRAFT.
Glenn A. Reiff (NASA, Office of Space Science and Applications, Washington, D.C.).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N.Y., Jan. 22-24, 1968, Paper 68-35.)
Journal of Spacecraft and Rockets, vol. 6, May 1969, p. 551-557. 18 refs.

Results of the Mariner 5 development and flight near Venus in 1967 are highlighted in this summary of the scientific findings provided by spacecraft radio propagation experiments. Description of the work required to adapt these experiments for the exploration of Venus provides a good example of the unexpected, subtle interactions that can arise when developing a specific spacecraft mission. In conducting radio propagation investigations, effects of the transmission medium on frequency, phase, and amplitude of electromagnetic waves are used to measure properties of the medium. The scientific data obtained from the Pioneers and Mariners have been the source of new information concerning the environments of the sun, Mars, and Venus. Dual-frequency propagation experiments and S-band occultation experiments are described. (Author)

FLIGHT AND LABORATORY TESTS OF AN "L-BAND" TELEMETRY RF SYSTEM.
R. Bruce Richardson and Robert W. Borek (NASA, Flight Research Center, Edwards AFB, Calif.).
Telemetry Journal, vol. 4, June-July 1969, p. 21-24.

Discussion of laboratory and flight test results for an airborne solid-state uhf telemetry transmitter. Worst-case conditions showed the minimum rf output power to be 5 W, with a dc-to-rf power conversion efficiency of 7.8%. The transmitter met all other specified requirements with the exception of the vibration tests. A brief flight-test program to verify operational characteristics was satisfactorily completed. Continuous telemetry data acquisition was accomplished to an average distance equal to 95% of the theoretical horizon range. G.R.

STADAN PCM DATA HANDLING SYSTEMS.
Henry J. Franks, Jr. (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: NTC 69; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, NATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., APRIL 22-24, 1969, RECORD. (A69-36237 19-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 31-33.

Description of the capabilities of the PCM data handling system used in the NASA Space Tracking and Data Acquisition Network (STADAN). As there is a considerable number of scientific satellites that must be decommutated by STADAN, the output capabilities of these systems are explained rather than the group synchronizer capabilities. The work shows how one user, the BIOSAT project, utilizes these systems to aid in the mission. (Author)

BACKFIRE ANTENNAS FOR TELEMETRY AND TRACKING APPLICATIONS.
Louis R. Dod (NASA, Goddard Space Flight Center, Advanced Development Div., Greenbelt, Md.).
IN: NTC 69; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, NATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., APRIL 22-24, 1969, RECORD. (A69-36237 19-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 77-84. 15 refs.

Results of tests of four backfire antennas with lengths of 0.5, 1.0, 1.5, and 2.0 wavelengths at the 1500-MHz test frequency for radiation characteristics as a function of the physical dimensions. Gains of 3 to 4.5 dB over conventional endfires have been measured. Based upon the design data, a five-element array has been modeled and tested. The results of the array measurements and the application of the antennas to tracking and telemetry are discussed.(Author)

A PERFORMANCE EVALUATION OF A TWO-ELEMENT LARGE APERTURE ANTENNA ARRAY.
Leonard F. Deerkoski (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: NTC 69; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, NATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., APRIL 22-24, 1969, RECORD. (A69-36237 19-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 97-103. 5 refs.

Description of a two-element adaptively phased array with element gains of 18 dB assembled and evaluated at 136 MHz. The gain improvement of the system over that of a single element was measured while tracking ATS-C. The measured gain improvement fell within 0.5 dB of the theoretical maximum 90 per cent of the time, corresponding to a normalized improvement of 2.5 dB for the two-element array. The relative phase between array elements was measured while tracking Relay 2 and ESSA spacecraft, and analysis of the data from several array baselines showed the phase noise to be essentially independent for element separations greater than 400 ft. DATA HANDLING EQUIPMENT REQUIREMENTS FOR CONVOLUTIONAL PCM TELEMETRY.
John Y. Sos (NASA, Goddard Space Flight Center, Information

Processing Div., Greenbelt, Md.).
IN: NTC 69; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, NATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., APRIL 22-24, 1969, RECORD. (A69-36237 19-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 191-194.

Description of the characteristics of ground data handling equipment for convolutional telemetry in the 100 to 3200 bits per second range; i.e., the bit rate of most Explorer satellites. The performance of commercially-available, bit and frame synchronizers and magnetic tape recorders is considered. It is shown that for rate one-half codes, such equipment can be specified. For lower rate codes, however, special development will be required. The performance of sequential decoders is also discussed. It is shown that for a 16-time processing speed-up of the 1.6 kHz bit rate, a special-purpose hardware sequential decoder is required. The IMP-1 spacecraft's convolutional PCM telemetry system is used as an example throughout the paper. (Author)

COMPARISONS BETWEEN TOPSIDE AND GROUND-BASED SOUNDINGS.
John E. Jackson (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IEEE, Proceedings, vol. 57, June 1969, p. 976-985. 20 refs.

Review of past observations which show that electron density profiles derived from topside ionograms have a tendency to be slightly too low. This problem is then examined in the light of more recent and better controlled experiments in which vertical electron density profiles were obtained essentially simultaneously by topside and ground-based soundings. These new measurements confirmed past observations and indicated that the error had a tendency to increase with satellite altitude. From a study of the ground echoes, which are often seen on topside ionograms, it is shown that the above discrepancies can be partially attributed to systematic errors (0 to 30 km) in the topside ionogram height markers. Horizontal electron density gradients can also contribute to this discrepancy. The errors found in the N(h) profile (although systematic) are usually too small to detract significantly from the general usefulness of topside ionograms. Also, the portion of the error due to incorrect height markers can often be calculated from a ground trace analysis, and the ionogram data can be corrected accordingly. (Author)

FREQUENCY SHIFTS OBSERVED IN THE ALOUETTE II CYCLOTRON HARMONIC PLASMA RESONANCES.
Robert F. Benson (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
IEEE, Proceedings, vol. 57, June 1969, p. 1139-1142. 8 refs.

Investigation of the cyclotron harmonic plasma resonances observed by Alouette 2 using a technique that yielded frequency measurements with an accuracy of the order of 1 kHz. A comparison of earlier Alouette 1 results with the present Alouette 2 results indicates that the bulk of the original excitation volume associated with the higher cyclotron harmonic resonances is confined to a region considerably less than one antenna length in radius from the antenna, that the size of this region decreases with increasing harmonic number, and that it increases significantly as the radiating antenna becomes parallel to the direction of the earth's magnetic field. M.M.

ON FILTERING PRIOR TO LIMITING DIGITAL SIGNALS IN STRONG NOISE.
John H. Painter (NASA, Langley Research Center, Hampton, Va.).
IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL SOUTHWESTERN CONFERENCE AND EXHIBITION, 21ST, SAN ANTONIO, TEX., APRIL 23-25, 1969, RECORD. (A69-39437 21-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 8 C 1-8 C 8.

Examination of the problem of optimizing the filter prior to limiting a digital signal in strong noise. In particular, the case for choosing the noise bandwidth of a single-pole low-pass filter is treated in detail. The optimization criterion adopted is that of maximizing the expected gain of a simple feedback system which tracks the limited digital signal. A closed-form mathematical model, applicable to the strong-noise case, is solved by use of a digital computer to obtain the "optimum" bandwidth. A comparison of results is made for the case of a periodic square-wave signal and for the case of a weakly periodic (pseudorandom) digital signal. (Author)

TRANSMISSION CHARACTERISTICS OF SPLIT-PHASE PCM CODES.
B. H. Batson (NASA, Manned Spacecraft Center, Houston, Tex.), N. M. Shehadeh, and R. Van Cleave (Houston, University, Houston, Tex.).
IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL SOUTHWESTERN CONFERENCE AND EXHIBITION, 21ST, SAN ANTONIO, TEX., APRIL 23-25, 1969, RECORD. (A69-39437 21-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 8 F 1-8 F 8.

Determination of certain transmission characteristics of a carrier which is amplitude-shift-keyed (ASK), phase-shift keyed (PSK), or frequency-shift-keyed (FSK) by a split-phase PCM code. The ensemble-average autocorrelation function and the power spectral density (Fourier transform of the ensemble-average autocorrelation function) are determined for each modulation scheme. All the calculations assume a random bit pattern with equally likely ones and zeros. It is also assumed that the modulation is noncoherent—i.e., that the phase of the PCM modulating sequence is not related to the phase of the carrier. B.H.

EQUATORIAL PLANE PATTERN OF AN AXIAL-TEM SLOT ON A FINITE SIZE GROUND PLANE.
C. A. Balanis (NASA, Langley Research Center, Hampton, Va.) and L. Peters, Jr. (Ohio State University, Dept. of Electrical Engineering, Columbus, Ohio).
IEEE Transactions on Antennas and Propagation, vol. AP-17, May 1969, p. 351-353. 5 refs.

Discussion of the edge diffraction effects in a TEM-mode axially slotted ground plane of finite width and length in an analysis of the scattered and radiated wave fields in waveguides of different geometries. The diffractions from the edges of the ground plane and their contributions to the overall radiation pattern are calculated. A diffraction superimposition procedure is applied to radiation pattern calculations. V.Z.

COSMIC RAY EXPERIMENTS SOURCE-ENCODING IN THE IMP-I SPACECRAFT.

Ciro A. Cancro and Paul J. Janniche, Jr. (NASA, Goddard Space Flight Center, Spacecraft Technology Div., Greenbelt, Md.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 49-71.

Description of the design and operation of three separate detectors for covering a wide range of cosmic-ray events on the IMP-I spacecraft. These devices are the medium-energy detector (MED), the low-energy detector (LED), and the very low energy detector (VLED). A cross section of each detector is presented, and the events analyzed in each particular detector are outlined. The source encoding associated with each detector receives output pulse signals from its detector, identifies and analyzes events of interest, monitors event rates, selects results to be telemetered, and feeds these results to accumulators and then to storage registers in the spacecraft central encoder. Since there are many other experiments on the spacecraft, the central encoder transfers the data from the registers to the telemetry at the appropriate times in accordance with the PCM format. Z.W.

CODING—AN ENGINEERING TOOL FOR THE DIGITAL TELEMETRY LINK.

Ronald M. Muller (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 123-135. 7 refs.

Discussion of various digital coding techniques from an engineer's and user's points of view. Each technique is displayed in a uniform way which measures performance against the best possible (Schannon) channel. Encoding-decoding complexity and other system merits and drawbacks of each technique are discussed. The reader is introduced to coding by drawing analogies with an everyday and familiar coded communication channel-spoken English. Bit, word, and block error detection and correction techniques are then presented. A concatenated block code scheme which combines these techniques is developed. Z.W.

A 17:1 DUAL BAND CIRCULARLY POLARIZED FOCUSED TWO-CHANNEL MONOPULSE TRACKING SYSTEM.

Paul A. Lantz (NASA, Goddard Space Flight Center, Greenbelt, Md.), George G. Chadwick, Roderic W. Hurlburt, and Roger R. Yaminy (Radiation Systems, Inc., McLean, Va.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 203-217. 8 refs.

Description of a dual circularly polarized feed system for operation in incremental bands over the frequency range from 136 to 2300 MHz. The characteristics of a 60-ft parabola excited by the feed system are discussed. Tracking data for this system have also been obtained using a helicopter, the Apollo 8 vehicle, and Cassiopeia A. It is shown that the two-channel monopulse technique allows the use of antenna feeds which, in turn, provide sidelobes of greater than -20 dB relative to the main lobe peak for all frequencies. This sidelobe performance reflects the fact that the feed is approximately focused at all frequencies. The characteristics of a similar feed used in the Apollo Range Instrumented Aircraft are also described. P.G.

TRACKING AND DATA RELAY SATELLITE SYSTEM.

P. F. Barritt and A. M. G. Andrus (NASA, Washington, D.C.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 248, 249, 251 (4 ff).

Discussion of the Tracking and Data Relay Satellite System (TDRSS), using satellites in synchronous orbit to relay data between a low-altitude earth orbital spacecraft (both manned and automated) and the various mission control centers. It is shown that such a system would improve mission reliability, contribute immeasurably to the safety and morale of the crews of manned spacecraft, enable experimenters to monitor their experiments in real time, and relieve constraints on mission planning and operations that are imposed by the short duration of ground-based tracking and data acquisition facilities. The benefits outlined are realizable upon the implementation of an operational TDRSS consisting of three satellites and their supporting ground stations. P.G.

RFI CHARACTERISTICS OF A DELAY RELAY SATELLITE SYSTEM.

John W. Bryan (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 287-294.

Determination of the effect of RFI caused by earth-based emitters on the operation of geosynchronous satellites for relay of data from near-earth orbiting satellites. The information presented is based upon known frequency assignments and known equipment

capabilities. All data and analyses given are for the continental U.S. only. A survey of the space command band from 148 to 155 MHz discovered over 15,000 potential RFI sources. While most of these sources do not emit at the NASA command frequencies, their combined spectral density is sufficiently great to cause concern over adjacent channel interference. Z.W.

10.6-MICROMETER LASER COMMUNICATION SYSTEM EXPERIMENT FOR ATS-F AND ATS-G.

J. H. McElroy, H. L. Richards, N. McAvoy, T. E. McGunigal, W. E. Richards, and H. Yagelowich (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 296-305. 7 refs.

Description of the first intersatellite laser communication experiment using a laser communication system weighing 30 lb and consuming 30 W on board the ATS-F and ATS-G satellites. A 6-in. aperture optical antenna, with a 92 dB antenna gain, and a 500 mW carrier provide a minimum 23 dB carrier-to-noise ratio for a 5-MHz bandwidth system. This experiment will permit analysis of laser communication systems as a base line for future operational system designs. O.H.

THE S-BAND TELEMETRY, TRACKING, AND COMMAND EXPERIMENT.

R. H. Pickard, P. E. Schmid, and P. J. Heffernan (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)

Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 306-323. 14 refs.

The ATS-F S-band Telemetry, Tracking and Command Experiment is designed to develop and demonstrate critical aspects of the technology necessary for an operational tracking and data relay satellite (TDRS) system within the framework of existing applications flight programs. The experiment involves the implementation and operation of a two-way radio link between a synchronous satellite (ATS-F) and a near-earth orbiting satellite (Nimbus E). The link will be used for precision range and range-rate tracking of Nimbus E from ATS-F, relay of Nimbus E telemetry to the ground via ATS-F, and command of Nimbus E from the ground through ATS-F. The basic purpose of the experiment is to gain experience in the implementation and operation of real time telemetry, tracking, and command links using a synchronous satellite relay. A specific major program goal is to establish the extent to which it is possible to determine the orbit of a near-earth orbiting spacecraft using tracking data obtained from a synchronous satellite. AN ANALYSIS OF THE TELECOMMUNICATIONS PERFORMANCE OF A LUNAR RELAY SATELLITE SYSTEM.

G. D. Arndt, B. H. Batson, and S. W. Novosad (NASA, Manned Spacecraft Center, Information Systems Div., Houston, Tex.).

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INTERNATIONAL CONFERENCE ON COMMUNICATIONS, BOULDER, COLO., JUNE 9-11, 1969, CONFERENCE RECORD. (A69-42500 23-07)

New York, Institute of Electrical and Electronics Engineers, Inc. (IEEE ICC Conference Publications. Volume 5), 1969, p. 7-21 to 7-27. 6 refs.

Investigation of the performance characteristics of two lunar relay satellite system (LRSS) configurations proposed recently for providing a communications capability between the earth and a lunar orbiter situated behind the moon. The expected communications capabilities are determined for operations with the present Apollo communications system and with a conceptual modified Apollo communications system. Positive circuit margins are expected with both LRSS configurations for the full-downlink phase-modulated mode when using the present and the modified Apollo spacecraft high-gain antennas. Both LRSS configurations also provide a satisfactory performance for wideband downlink modes and all uplink modes when using the spacecraft high-gain antennas of the modified Apollo system. Recommendations for obtaining maximum use of the LRSS configurations are outlined. V.Z.

TEST AND PRELIMINARY FLIGHT RESULTS ON THE SEQUENTIAL DECODING OF CONVOLUTIONAL ENCODED DATA FROM PIONEER IX.

Dale R. Lumb (NASA, Ames Research Center, Moffett Field, Calif.).

IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INTERNATIONAL CONFERENCE ON COMMUNICATIONS, BOULDER, COLO., JUNE 9-11, 1969, CONFERENCE RECORD. (A69-42500 23-07)

New York, Institute of Electrical and Electronics Engineers, Inc. (IEEE ICC Conference Publications. Volume 5), 1969, p. 39-1 to 39-8.

Discussion of tests and preliminary flight results of the Pioneer 9 deep space probe with a telemetry link operated for about a month in the coded mode with sequential decoding of a rate-½, 25-bit constraint-length convolutional code. A comparison of the decoding-computation for the subcarrier channel and rf channel levels of testing with computer-simulation data revealed that the Pioneer demodulator/bit synchronizer was responsible for the principal disagreement between the system and simulation test results for the three highest Pioneer data rates. Close agreement is obtained between the preliminary Pioneer flight data and the test results. V.Z.

RADIOFREQUENCY TRANSMISSION CHARACTERISTICS OF SEVERAL ABLATION MATERIALS

Melvin C. Gilreath, William F. Croswell, and Stark L. Castellow, Jr. Washington Nov. 1968 41 p refs

(NASA-TN-D-4879) Avail: CFSTI CSCL 20N

An experimental investigation was conducted to determine the transmission loss, and effects upon the radiation patterns and impedance of typical antennas, produced by thermally degraded ablation materials. A cone-shaped model was used, which consisted of a truncated aluminum substructure with flush-mounted antennas over which a thermal-protection test material was bonded. Measurements of transmission loss through several thermal protection materials were made at 2.66 GHz and 9.60 GHz. The dielectric properties of all virgin materials were measured at room temperature. In addition, antenna radiation patterns, voltage standing wave ratios (VSWR), and gain were determined before and after the materials were subjected to the thermal test. It was concluded that, in general, materials which form and retain continuous conductive char layers during thermal exposure produce very high transmission losses. Also, it is shown that antennas which are

covered with such high-loss materials may exhibit extreme perturbations in the radiation patterns that are not present when the antenna is covered with the virgin material. The antennas used for this test program experienced an increase in VSWR when covered with the high-loss materials; however, the loss attributable to this mismatch was less than 2 dB. Author

RELATIONSHIP BETWEEN COMPLEX- AND ENVELOPE-COVARIANCE FOR RICIAN FADING COMMUNICATION CHANNELS
Erwin Mondre Washington Nov. 1968 33 p refs
(NASA-TN-D-4825) Avail: CFSTI CSCL 09D

In practice, the measurement of the covariance function (which characterizes a time and frequency selective fading communication channel) involves envelope detecting the received signals before correlating. Envelope covariance is insufficient for an accurate evaluation of system performance and rather a complex covariance is needed. This paper presents a study of these two covariances for Rician statistics. The general properties of the Rician distribution are discussed. The relationship between complex covariance and covariance of the envelopes of a complex Rician fading communication channel is derived. It includes the well known case of Rayleigh fading. For the assumption of symmetric spectrum of the narrow band random process there exists a monotonic relationship which allows the evaluation of the complex covariance once the envelope covariance is measured. An extension to unsymmetric spectrum is given. The results obtained show that the envelope covariance represents a lower bound of the magnitude of the complex covariance. Author

RADIOFREQUENCY TRANSMISSION CHARACTERISTICS OF CANDIDATE ABLATION MATERIALS FOR PLANETARY-ENTRY-VEHICLE HEAT SHIELDS
Melvin C. Gilreath, Andreq J. Chapman, and Douglas M. Hatcher Washington Dec. 1968 62 p refs
(NASA-TN-D-4920) Avail: CFSTI CSCL 22B

An experimental investigation was conducted to determine the radiofrequency properties of several candidate ablation materials for planetary-entry-vehicle heat shields. The radiofrequency transmissibility of each ablative material was determined by the real-time measurement of the attenuation of a 35 GHz signal while each sample was exposed to a simulated planetary entry environment. The simulated planetary environment was produced by providing a heating rate, pressure, and free-stream Mach number in an arc-heated supersonic wind tunnel. Recordings of the transmission loss obtained through each material during the arc-tunnel test and photographs of all test specimens before and after thermal exposure are presented. In addition to the transmission loss measurements, the dielectric properties of most virgin materials were measured at room temperature and are also presented. Author

LUNAR SURFACE TRANSMISSION LOSS FOR THE APOLLO ASTRONAUT
Jefferson F. Lindsey, III Washington Dec. 1968 28 p refs
(NASA-TN-D-4915) Avail: CFSTI CSCL 17B

Radio-wave propagation theory is reviewed with emphasis on point-to-point communications on the lunar surface. The geometric optics solutions for both a plane surface and a spherical surface are presented. The transmission loss is found to slope at 40 dB/decade of distance at the longer distances for which the path difference between the direct and the reflected wave is less than one-half wavelength. The Bremmer series for radio-wave diffraction solution is presented for calculation of the transmission loss near the line of sight when the geometric optics solution does not apply. In addition to smooth-surface effects, the roughness effects of knife-edge diffraction and of small hills are used to obtain a combined-effects transmission loss plot. Finally, measured data are presented which confirm that the maximum astronaut-to-lunar-module range will be at least 8200 feet and that the maximum astronaut-to-astronaut range will be at least 6000 feet. ERROR ANALYSIS OF INPUT-NOISE-TEMPERATURE MEASUREMENTS OF LOW-NOISE AMPLIFIERS
Hans-Juergen C. Blume Washington Jan. 1969 41 p refs
(NASA-TN-D-4997) Avail: CFSTI CSCL 09C

The method presented provides means of determining all effects which significantly influence measurement of the output-noise-power ratio (Y-factor) of a typical low-noise-amplifier test setup. The error analysis of the Y-factor method illustrates the error propagation which occurs in the derivations of the input noise temperature and gives an estimate of the maximum error. The general concepts used in determining these influences and the error propagation are applied to reflection-type amplifiers. Numerical examples demonstrate the value in considering all elements which (1) affect the calibrated noise power along the transfer path from the noise source to the amplifier under test, and (2) add noise power along the path from the amplifier to the noise indicator. The error analysis applied to the examples revealed that for minimization of the input-noise-temperature error, accurate knowledge of the losses and temperatures is more important than obtaining extremely

high ratios of the hot- to cold-noise source temperatures. A comparison between the input noise temperature determined by considering all influencing effects and the input noise temperature determined without considering these effects for a typical low-noise measuring system for reflection-type amplifiers revealed a considerable difference. A COMPARSION OF SEQUENTIAL DECODING METRICS BY COMPUTER SIMULATION

Thomas V. Saliga (M.S. Thesis—Md. Univ., College Park, 1968) Washington Jan. 1969 56 p refs

(NASA-TR-R-294) Avail: CFSTI CSCL 17B

This paper determines a sequential decoder's performance and metric sensitivity by means of a computer simulation using two metrics: (1) A log-a-posteriori probability metric, and (2) A cross-correlation metric. Both metrics are defined, derived, and tabulated for the memoryless gaussian channel. Simulations of a rate 1/2, constraint-length 32 coded data system are made using 16 level quantized metrics. When good metric and decoder parameters have been found, the decoder's computational load, overflow probabilities, and error probability are found as a function of channel signal-to-noise ratio, using at least 500 simulated telemetry frames per data point. It is shown that the correlation metric is inferior to the probability metric by at least 1.5 decibels and suffers a higher error rate. In addition, the correlation metric decoder degrades intolerably with 0.5 decibel signal-amplitude fluctuations, whereas the probability metric decoder is negligibly affected. Author

THE ADMITTANCE OF A PARALLEL-PLATE APERTURE ILLUMINATING A DISPLACED DIELECTRIC–DIELECTRIC BOUNDARY

J. Earl Jones Washington Feb. 1969 60 p refs

(NASA-TN-D-5038) Avail: CFSTI CSCL 09F

The variational method is used to determine the admittance of a transverse-electromagnetic-mode excited, parallel-plate aperture having an infinite flange and illuminating a displaced dielectric–dielectric boundary. The results are applied to provide insight into two problems of interest: (a) the effect of an air gap on the admittance of dielectric coated aperture antennas and (b) the admittance of an aperture antenna coated with an underdense plasma slab. Numerical computations for the air gap problem are verified experimentally. For either problem, the most significant changes in the admittance occur for displacements less than 0.25 wavelength. (The wavelength referred to is the free space wavelength divided by the square root of the relative permittivity of the medium between the boundary and the aperture.) For the dielectric coated slot antenna, changes in the admittance due to an air gap are enhanced if either the slot width is reduced or the permittivity is increased. For a slot antenna coated with a thin underdense plasma slab, the admittance becomes more sensitive to changes in the layer thickness as the plasma becomes more dense. As observed theoretically for both the air gap problem and the underdense-plasma problem, the admittance is not influenced by the presence of surface waves. Experimental verification of this result is given for the air gap problem. Author

RADIOMETRIC TECHNIQUES APPLICABLE TO THE MEASUREMENT OF SOLAR ACTIVITY AND ATMOSPHERIC ATTENUATION AT MILLIMETER WAVELENGTHS

George G. Haroules Washington Apr. 1969 21 p refs

(NASA-TR-R-306) Avail: CFSTI CSCL 17B

The available dynamic range for measurements of this type is determined by the brightness temperature of the sun and the sky noise fluctuation level at the frequency of observation. During the period of measurement, it is assumed that the solar flux intensity is constant and that all apparent variations in solar intensity are associated with atmospheric effects. Similar radiometric measurement instruments are used for the determination of solar radiation characteristics at millimeter wavelengths. Useful data are limited to those periods when the weather conditions are relatively mild. Here, the assumption is made that all apparent variations in solar intensity are associated with the radiation characteristics of the sun itself. The most useful data concerning solar radiation characteristics are obtained under clear weather conditions; that concerning atmospheric attenuation is obtained under adverse weather conditions. THE LOG-A-POSTERIORI PROBABILITY METRIC FOR USE IN SEQUENTIAL DECODING

T. V. Saliga Washington Apr. 1969 25 p refs

(861-51-75-01-51)

(NASA-TN-D-4930) Avail: CFSTI CSCL 17B

Convolutional encoding with sequential decoding is one of the best coded communications systems available for spacecraft telemetry. When implementing a sequential decoder, a decoding confidence measure based upon the received signal probabilities is used. The best known measure is the log-a-posteriori probability metric. Tabulations of the metric for various telemetry system parameters are given. Both a continuous and a quantized metric are treated for various symbol signal-to-noise ratios on a Gaussian channel. Quantized symbol metrics are tabulated for 2, 4, 8, and 16 levels, and it is shown that the quantized LAP metric is an approximation of the ideal continuous metric. Author

SOLAR EFFECTS ON VHF COMMUNICATIONS BETWEEN A SYNCHRONOUS SATELLITE RELAY AND EARTH GROUND STATIONS

Sheldon Wishna and James R. Greaves (Allied Res. Associates, Inc., Concord, Mass.) Washington Apr. 1969 11 p

(NASA-TN-D-5100) Avail: CFSTI CSCL 17B

An investigation has been performed to correlate VHF interference, as reported by participating ground stations, with the occurrence of certain solar phenomena. The participating ground stations were taking part in the Weather Facsimile (WEFAX) experiment, which utilizes the Applications Technology Satellite

(ATS)-1 to relay processed meteorological data from a central weather station to the ground stations. The VHF communication system, located on board the satellite, is an active frequency translator with an uplink receive frequency of 149.22 MHz and a downlink transmit frequency of 135.6 MHz. The data were transmitted to the satellite from the ATS ground station located at Mojave, California. The ATS-1 satellite is at an altitude of 19,300 nautical miles and is located over the equator at 151° West longitude. Approximately 50 ground stations located in an area extending from the east coast of the United States to Australia and Japan participated in the program. The analysis was conducted over an 8-month period beginning on January 2, 1967 and continuing through August of the same year. Author

PARAMETRIC ANALYSIS OF MICROWAVE AND LASER SYSTEMS FOR COMMUNICATION AND TRACKING: A SUMMARY

F. Kalil Washington Apr. 1969 97 p refs

(NASA-TR-R-309) Avail: CFSTI CSCL 17B

A comparative analysis was made of laser and microwave telecommunication systems for space applications. Parametric families of curves are presented that give the weights and telecommunications capabilities of spaceborne communication systems. These curves permit the mission planner and designer to compare various sytems and select the one that best meets their requirements. A sample case demonstrates the use of these curves. The sample calculation and concluding remarks point out the advantages of a computerized method that uses the calculus of maxima and minima for selecting the optimum spaceborne communication system configuration that can provide the specified information rate for the least spaceborne weight penalty and/or cost. PERFORMANCE CHARACTERISTICS OF THE APOLLO ASTRONAUT BACKPACK ANTENNA

Jefferson F. Lindsey, III Washington May 1969 22 p refs

(NASA-TN-D-5081) Avail: CFSTI CSCL 09E

Antenna patterns and voltage-standing-wave ratio measurements were made, including both surface reflection effects and free space data. The antenna pattern data were taken at frequencies of 259.7, 279.0, and 296.8 megahertz, with surface reflection effects included. The voltage standing wave ratio in this range were under 2.0:1, and the gains with surface reflection effects and the astronaut standing ranged from the worst case null of −5 decibels at 259.7 megahertz to +2 decibels at 279.0 megahertz. In the bending over and lying down positions, the gains range from −28 to +1 decibels. As a result, no height gain correction factor in the transmission loss is required in the circuit margin calculations for the bending over and lying down positions. Author

RADIO FREQUENCY INTERFERENCE EXPERIMENT DESIGN FOR THE APPLICATIONS TECHNOLOGY SATELLITE

Varice F. Henry and John J. Kelleher Washington May 1969 15 p refs

(NASA-TN-D-5041) Avail: CFSTI CSCL 17B

The proposed experiment described herein is designed to measure and evaluate the amount of mutual interference between communications-satellite and terrestrial microwave relay systems at the shared common carrier frequency bands of 6 and 4 GHz. It is proposed to measure terrestrial-to-satellite interference at 6 GHz and satellite-to-terrestrial interference at 4 GHz. To meet the technical requirements of this experiment, it is necessary to utilize a satellite of the type planned for the ATS F and G program. These spacecraft, each carrying a 30-foot parabola as the prime antenna, will be capable of 0.1-degree pointing accuracy and full earth-scanning coverage. Measurements will be made of several parameters to obtain a fuller understanding of existing conditions related to such interference. Parametric measurements will include transmitted and received power levels, propagation-path loss and variations as a function of range, elevation angle, RF polarization, and geographical location of interference sources. SLOPE DIFFRACTION ANALYSIS OF TEM PARALLEL-PLATE GUIDE PATTERNS

D. C. F. Wu and R. C. Rudduck Washington NASA May 1969 52 p refs

(Grant NGR-36-008-005)

(NASA-CR-1326; TR-1691-29) Avail: CFSTI CSCL 09E

The radiation pattern of a TEM mode parallel plate waveguide is analyzed by wedge diffraction theory in conjunction with a slope correction term. This slope correction term is the diffraction by a conducting wedge due to an incident wave with sinusoidal amplitude variation over the wave front. Such a wave is referred to as a slope wave. The slope diffraction takes into account the nonuniform wave in calculating second order diffractions for the open ended guide. The slope correction term provides an improvement in the accuracy of the pattern in the region near the plane of the aperture as compared to the previous wedge diffraction calculations. Author

THEORETICAL FLOW FIELD CALCULATIONS FOR PROJECT RAM

H. Webb, Jr., H. Dresser, K. Korkan, and R. Raparelli Washington NASA May 1969 153 p refs

(Contract NAS1-8172; Proj. RAM)

(NASA-CR-1308) Avail: CFSTI CSCL 17B

Theoretical flow fields for seven flight conditions for the RAM-C blunted cone configuration are presented. Both viscous and inviscid flow regions are considered in an analysis leading to predictions of nonequilibrium chemical effects within the entire flow field. Special emphasis is placed on the presence of free electron

concentrations which are responsible for the phenomena of radio attenuation. The flight investigation of these effects is the purpose of the RAM Project. Nonequilibrium flow is predicted by using a one-dimensional analysis along streamlines both in the boundary layer region and in the inviscid flow region. For two of the flight conditions, calculations were performed to evaluate the influence of a larger nose radius on the flow field. This change in geometry occurs when the beryllium nosecap is ejected. Very small plottable differences were found on outer streamlines for the lower speed flight condition when comparisons were made on similarly located normals. Author

ANALYTIC FUNCTION MODELS OF NOISE AND MODULATION

John H. Painter, Someshwar C. Gupta, (Southern Methodist Univ.), and Jon W. Bayless (Southern Methodist Univ.) Washington Jun. 1969 32 p refs

(NASA-TR-R-314) Avail: CFSTI CSCL 17B

The theory of complex analytic time functions are applied to a representation of stochastic and deterministic time processes. By using analytic notation, noise and modulated signals are represented in the same manner. A mathematically rigorous method of transition from real to analytic processes is given. By use of the theory of distributions, the rotating vector, or phasor, method is generalized to arbitrary functions and stochastic processes. The advantages of analytic time function notation are exploited to derive correlation and spectral functions for both signal and noise processes. The polar and quadrature forms for band pass processes are derived. Author

WEATHER SATELLITE PICTURE RECEIVING STATIONS: INEXPENSIVE CONSTRUCTION OF AUTOMATIC PICTURE TRANSMISSION GROUND EQUIPMENT

Charles H. Vermillion 1969 107 p refs

(NASA-SP-5080) Avail: CFSTI CSCL 17B

A description is given of how one can procure or build the antenna, FM receivers, and other components for the automatic picture transmission (APT) ground station. A facsimile video enchancement device is also described, along with the direct readout infrared (DRIR) adapter unit which can convert the APT system to receive nighttime as well as daytime cloudcover data. The DRIR system takes advantage of the NIMBUS 3 high resolution infrared radiometer (HRIR) which transmits pictures over the same frequencies used by the APT system in the daytime. Detailed drawings and parts lists are included for each system. Installation, alignment, and operation of the complete APT ground station are also described. The APT ground stations are inexpensive and reliable. They can be built from surplus parts for under $500 or procured for as low as $5000. With them, scientists, local weather stations, amateurs, and others can receive satellite-taken photographs of the earth as APT-equipped satellites pass overhead. Author

VAPORIZATION AND DECOMPOSITION KINETICS OF CANDIDATE RE-ENTRY BLACKOUT SUPPRESSANTS IN LOW-PRESSURE FLAMES

Shelby C. Kurzius and Fredrik H. Raab Aug. 1969 65 p refs

(Contract NAS1-7169)

(NASA-CR-1330; TP-181) Avail: CFSTI CSCL 17B

This study provides the first experimental measurements of thermal accommodation coefficients between liquids and high-temperature gas. Beams of uniformly sized droplets were sent across 5 and 10 torr $H_2/CO/O_2$/air flames and their evaporation rates were photographically determined. Droplet sizes were on the order of the mean free path in the flames. From the observed evaporation rates, the following translational thermal accommodation coefficients were obtained for combustion gases at about 2500 K: water, 0.76 ± 0.14; perfluoro–octane, 0.17 ± 0.04; Freon E–8, 0.22 ± 0.10. Apparently, only translational energy is effectively transferred from the gas to the liquid; the measured accommodation coefficients are in agreement with predictions based on Baule's classical theory, in which the surface of the condensed phase is regarded essentially as a super-dense gas. Additionally, measurements of the decomposition kinetics of sulfur hexafluoride and perfluoro–octane vapors in 10, 20, 40, and 100 torr $H_2/CO/O_2$/air flames are reported. Author

APPLICATIONS OF ANALYTIC FUNCTION THEORY TO ANALYSIS OF SINGLE-SIDEBAND ANGLE-MODULATED SYSTEMS

John H. Painter Washington Sep. 1969 42 p refs

(NASA-TN-D-5446) Avail: CFSTI CSCL 17B

The theory and notation of complex analytic time functions and stochastic processes are applied to the investigation of the single-sideband angle-modulation process. Low-deviation modulation and linear product detection in the presence of noise are carefully examined for the case of sinusoidal modulation. Modulation by an arbitrary number of sinusoids or by modulated subcarriers is considered. Also treated is a method for increasing modulation efficiency. An examination of the asymptotic (low-noise) performance of nonlinear detection of a single-sideband carrier which is heavily frequency modulated by a Gaussian process is discussed. Author

COMMUNICATION SYSTEM DESIGN

Louis A. Frasco Washington Oct. 1969 32 p refs

(NASA-TN-D-5472) Avail: CFSTI CSCL 17B

A general system design philosophy palatable to both analog and digital communication engineers is presented. The method of presentation is novel and some new results and calculations are presented. An attempt is made to establish the relevance of the more theoretical aspects of communication system design (i.e., statistical communication theory, information theory and coding, etc.) to the work of the practicing system design engineer in evaluating real systems. Consideration of the fidelity of the overall system, from source characterization to user requirements, is of prime importance. The use of the computer in system management of hybrid analog/digital systems is also discussed. In addition, optimum bounds on performance are calculated for the space channel and compared with the performance of some existing systems. Author

(NASA-TR-R-320; C-78) Avail: CFSTI CSCL 17B

This report presents a method for evaluating the theoretical performance of quantum communication systems based on the communication efficiency parameter, $\beta = P/N_0R$. For Gaussian systems, β represents the minimum average amount of energy required to decipher a bit of information, with zero error, in the presence of white noise of spectral density N_0. For certain quantum systems, the Gaussian result is directly applicable with N_0 replaced by $h\nu$. In general, β is recognized to be the minimum number of average (photon) events required to decipher a bit of information with zero error. To make comparisons with Gaussian systems, the parameter κ is introduced with $h\nu/\kappa$ becomes the effective Gaussian spectral density of the quantum system. Several systems are considered in addition to the capacity bound for the narrow-band quantum channel introduced by Gordon. Unlike the Gaussian channel, there is no lower bound on β as the bandwidth-to-data-rate ratio, α, is increased. Thus β can be continually decreased at the

expense of average data rate. For large values of α, PPM direct detection asymptotically approaches the lower bound for β. Author

A STUDY OF 2 GHz ELECTROMAGNETIC WAVE PROPAGATION OVER OPTICAL PATHS IN THREE GEOGRAPHICAL REGIONS OF THE UNITED STATES

J. O. Hebert, Jr., F. M. Ingels, D. F. Fitzgerald, E. E. Gross, and S. Y. Lee Washington NASA Oct. 1969 135 p refs Revised (Grant NGR-25-001-007)

(NASA-CR-1442) Avail: CFSTI CSCL 17B

Statistical signal level distributions are used to derive an empirical relationship between electromagnetic wave propagation *reliability, fade margin, path length, and geographical location*. This procedure allows the microwave systems designer to calculate the fade margin required for a particular optical path and a given reliability for operating frequencies in the 2 GHz region. Cross correlations of microwave signal fading over selected paths and the fading obtained over a high elevation angle path are included. G.G.

PULSE-RESPONSE CURVES OF CONVENTIONAL LOW-PASS FILTERS

William D. Stanley (Old Dominion Univ.) and Doris M. Higgins Washington Oct. 1969 116 p refs

(NASA-TN-D-5494) Avail: CFSTI CSCL 17B

A catalog of 100 different pulse responses of conventional low-pass filters is presented. The pulse responses were obtained by a computer simulation of a general digital filter whose characteristics could be varied to correspond very closely with the various analog filter functions. The standard Butterworth, the Chebyshev (with various ripples), and the Bessel filter functions are considered. Filter orders from 1 to 5 are included. For each filter type and order, responses corresponding to four different products of bandwidth and pulse width are considered. Author

THE SDP-3 - A COMPUTER FOR USE ON BOARD SMALL SCIENTIFIC SPACECRAFT.

R. A. Cliff (NASA, Goddard Space Flight Center, Spacecraft Technology Div., Flight Data Systems Branch, Greenbelt, Md.).

IN: EASCON '68; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ELECTRONICS AND AEROSPACE SYSTEMS CONVENTION, WASHINGTON, D.C., SEPTEMBER 9-11, 1968, RECORD. [A69-13176 03-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 521-527.

The SDP-3 is a general-purpose stored-program computer which has been designed for use as the core of the data system of a small scientific spacecraft. It is a serial, two's complement, 16-bit-word machine. It has one level of indirect addressing and one hardware index register. To facilitate time-sharing operation there is a 16-level priority interrupt system and a real-time clock. The 4K memory is divided into 16 pages of 256 words each. There is a user and a monitor mode. Interpage access is prohibited in user mode. (Author)

AN ALGORITHM FOR DERIVING THE EQUATIONS OF MATHEMATICAL PHYSICS BY SYMBOLIC MANIPULATION.

James C. Howard and Howard Tashjian (NASA, Ames Research Center, Moffett Field, Calif.).

ACM, Communications, vol. 11, Dec. 1968, p. 814-818, 826. 6 refs.

A method is described whereby a digital computer can be used to derive the equations of mathematical physics in any curvilinear coordinate system requested by the user. The effectiveness of the technique is demonstrated by using it to derive the Navier-Stokes equations of fluid motion and the continuity equation. To derive these equations by this method, the user need know only the coordinate transformation equations relating the curvilinear coordinates of interest to an orthogonal Cartesian triad. When this program is used and the coordinate transformation equations are supplied as input, the computer will derive the Navier-Stokes equations and the continuity equation. The equations obtained will be relative to the curvilinear coordinate system specified by the transformation equations used as input. In the paper, the emphasis is on theoretical considerations and methodology rather than on programming details. (Author)

THE SDP-1 STORED-PROGRAM COMPUTER.

Rodger A. Cliff (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-4, Nov. 1968, p. 864-870.

A stored-program computer could be used to advantage on small scientific spacecraft because of its flexibility. The paper describes the design and programming of a stored-program computer specifically adapted to this particular application. In order to be suitable for use in a small scientific spacecraft, a computer must have the following characteristics: reliability, low power drain, light weight, small size, problem-solving power, and flexibility. To meet these requirements, a computer was designed that has 1024 words of program memory and 512 words of data memory. The words are 12 bits in length and both memories are randomly accessed. In order to protect the program, the program memory is of the nondestructive read-out type. The data memory is the conventional read/write variety. The computer is organized such that the power drain is small and less hardware is required by restricting parallel gating of information, number of registers, and number and complexity of instructions. Considerable effort has been devoted to programming the computer. Analysis shows that it takes on the order of 2 msec to perform one of the floating-point operations. These limitations should be acceptable; the computer is not expected to be required to perform extremely complex or lengthy computations. (Author)

COHORT-II - A MONTE CARLO GENERAL PURPOSE SHIELDING COMPUTER CODE.

Leonard Soffer and Lester C. Clemons, Jr. (NASA, Lewis Research Center, Cleveland, Ohio).

American Nuclear Society, Conference on the Effective Use of Computers in the Nuclear Industry, Knoxville, Tenn., Apr. 21-23, 1969, Paper. 17 p. 10 refs.

COHORT II integration into a single package with more flexible geometry and biasing. Written completely in FORTRAN-IV for the IBM-7094 computer, it represents a major revision and modernization of the original COHORT code. The code method is the conventional one in which "particles" are generated, tracked and analyzed. The allowed shielding geometry is flexible, with space divided into homogeneous regions bounded by surfaces describable by a general quadratic equation. Spherical, cylindrical, and rectangular parallelepipeds are allowed for the source regions. Biasing options include selection of source particles from preferred locations, energies and directions. The exponential transform can also be used during particle tracking, and secondary gammas can be generated and placed on tape during a neutron problem to be tracked during a subsequent computer run. Output includes number fluxes in energy bins at arbitrarily located point detectors and average over regions. Energy-integrated quantities such as dose rates are also obtainable. Checkout calculations are performed for point isotropic neutron and gamma sources in polyethylene and aluminum, and for two duct problems. B.H.

A DEVICE FOR PRINTING ALPHANUMERIC LISTINGS AND DIGITAL DATA PLOTS.

John W. Oglesbee (NASA, Lewis Research Center, Cleveland, Ohio).

Instrument Society of America, National Aerospace Instrumentation Symposium, 15th, Las Vegas, Nev., May 5-7, 1969, Paper. 16 p.

A commercially available high-speed printer has been modified to perform x-y plotting of digital data. The resulting device performs the dual function of printing and plotting at relatively low cost. The basic printing mechanism and its modification to a plotting device are described. A small digital computer is required as a control device, and the special software developed for this application is discussed. In the plotting mode, the device is capable of producing a typical (7" square) plot in less than 25 sec. Any number of points can be plotted in this time, with a resolution of 1 part in 500. Several variables can be plotted simultaneously using a different symbol for each variable. The plotter generates any one

of a number of different grid patterns, complete with titles, axes labels, and numerical scales. When not plotting, the device can be used as a 300 character per second printer. (Author)

STUDY OF A GLOBAL SEARCH ALGORITHM FOR OPTIMAL CONTROL.
Elwood C. Stewart, William P. Kavanaugh, and David H. Brocker (NASA, Ames Research Center, Moffett Field, Calif.).
International Association for Analog Computation, Meeting, 5th, Lausanne, Switzerland, Aug. 28-Sept. 2, 1967, Paper. 25 p.; Discussion, O. W. Kolbe (Stuttgart, Technische Universität, Stuttgart, West Germany), p. 24. 8 refs.

Feasible method of implementing the maximum principle, based on an adaptive random search algorithm which utilizes direct measurements of the boundary cost-function hypersurfaces. No restrictions are placed on the continuity of the surfaces or the number of valleys. The adaption enhances convergence by varying the mean and variance of a probability distribution as a function of past performance. The algorithm has both local and global search properties so that "hanging up" in local valleys is avoided. A hybrid computer implementation of the algorithm is discussed. The usefulness of the algorithm is investigated experimentally for a fifth-order nonlinear minimum-fuel orbit-transfer problem. Convergence is generally obtained within several thousand iterations (1 to 2 min). Details are given on the manner in which the system iterates, typical solutions obtained for a wide range of situations, and the convergence properties of several variations of the basic algorithm. Cross sections through the boundary hypersurfaces reveal the striking irregularities which high-order systems can have and, hence, demonstrate the effectiveness of the adaptive random search approach in coping with them. THE IMPACT OF SPEECH COMMUNICATION WITH COMPUTER.
Wayne A. Lea (NASA, Electronics Research Center, Man-Computer Systems Branch, Cambridge, Mass.).
IN: SPACE, TECHNOLOGY, AND SOCIETY; CANAVERAL COUNCIL OF TECHNICAL SOCIETIES, SPACE CONGRESS, 6TH, COCOA BEACH, FLA., MARCH 17-19, 1969, PROCEEDINGS. VOLUME 1. [A69-35070 18-34]
Edited by L. E. Jones, III.
Cape Canaveral, Fla., Canaveral Council of Technical Societies, 1969, p. 15-19 to 15-31. 47 refs.

Discussion of the possibilities of speech communication with computers with regard to studies in a number of related fields such as acoustics, phonetics, linguistics, language learning, speech and hearing physiology, psychology, bionics, communication theory, human engineering, and computer science. It is noted that, among the several possible modalities of man-computer communication, speech is particularly promising, especially for manned space flight. The many specific advantages of speech justify a comprehensive program in automatic speech recognition and synthesis, segmentation and production of natural-flowing continuous speech, and development of relevant physiological and linguistic models. It is noted that mechanisms for aiding the deaf, blind, and other physically handicapped may result from efforts to mechanically analyze or synthesize speech. P. G.

THE IMP-I COMPUTER EXPERIMENT.
Rodger A. Cliff and Stephen Paull (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: NTC 69; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, NATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., APRIL 22-24, 1969, RECORD. (A69-36237 19-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 176-183.

The SDP-3 computer was designed to serve as the core of the data system of a small unmanned spacecraft. It is a 16-bit serial machine with 4096 words of memory. The computer will be flown as an engineering experiment on IMP 1. In this application, it will handle control and data compression for four scientific experiments. Interface between the computer and the experiments is accomplished by experiment interface packages which are located within the experiment package. These experiment packages are supplied to the experiment builder by the computer builder. The experiment interface packages are constructed from a line of standard interface modules, which in turn are built of the same ICs used in the SDP-3. An adaptive format consisting of data tagged with identification and word count is used for data transmission. (Author)

Paris, Centre National d'Etudes Spatiales, 1969, p. 109-118. 5 refs.

Description of the basic design and principles of operation of an onboard spacecraft computer. Structured around a dual bussing system, the computer has a variable memory size up to a maximum of 65K words in 4096 word increments. It has a provision for the incorporation of standby redundant central processing units and input/output devices as needed for enhanced reliability during a long mission. A dynamic memory protection feature is implemented to ensure that writing occurs only in desired memory areas. Program control over interrupt priority is provided. The location of the binary point may also be specified in the program, and scaling is automatic. This provides some of the features of floating point without the hardware and memory penalties. V.P.M.

Discussion of some design implications of an interactive experimenter computer system both from software and hardware standpoints. Three major design areas are considered. In one approach, the astronaut/experimenter and the machine/experimenter play interchangeable roles of question answering. In another, the astronaut/experimenter and the machine/experimenter converse in terms of shared-inference that tend to make the experimental environment more transparent. In the third approach, the astronaut/experimenter and the machine/experimenter share an experimental context and mutual language of context that will enhance the selectivity of experiment design. Evaluation of traditional assignment of computer functions to logic and memory on the basis of trends in their cost and mission characteristics. The higher information content of a higher-level language is exploited for the savings of memory. An instruction set was selected from the directly executable statements of FORTRAN, and the remaining statements were identified for compilation. Programs written in this language occupied 75 per cent less memory than those obtained by compilation. A computer for the execution of the selected FORTRAN statements was functionally designed in order to estimate the corresponding logic hardware effort. The tradeoff between costs saved through memory reduction and expenditures for the additional logic hardware considered development, manufacturing, power, and weight costs. The proposed concept shows a cost advantage for missions with a high weight penalty and large memory requirements. Another advantage is the higher execution speed inherent in this organization. Contract No. NAS 5-10022.

Description of a disk-oriented programming system designed to support all attitude-dependent portions of the Radio Astronomy

Explorer-A (RAE-A) mission. RAE-A is a gravity-gradient stabilized spacecraft characterized by four 750-ft long experimental booms. Functions performed by the attitude support system, during both spin and despin mission phases, include: reduction and calibration of telemetry data; determination, prediction, and command of spacecraft attitude; simulation of data for test purposes; and system maintenance. Design constraints imposed by mission requirements, spacecraft sensors, and existing ground support equipment (computers and tracking stations) are discussed. Summary descriptions of major program modules are given, including descriptions of use and typical mission support performance. All significant attitude-related events that occurred during support of the RAE-A mission, including apogee motor ignition and real-time observation of total spacecraft attitude during boom deployment maneuvers, are discussed. Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 14-22. 5 refs.

Description of the design of a stored program computer for spacecraft use and its application on the fourth Orbiting Astronomical Observatory (OAO-C). The computer is a medium scale, parallel machine and has a memory capacity of 16,384 words of 18 bits each. It possesses a comprehensive instruction repertoire and operates on 45 W of power (including the dc to dc converter). The machine operates at a 667 KHz rate and executes an add instruction in 7.5 microseconds. The primary functions of this computer include auxiliary command storage, spacecraft monitoring and malfunction reporting, data compression and status summary, and emergency corrective action for certain anomalous situations. RECENT IMPROVEMENTS IN THE SDP-3 COMPUTER.
R. A. Cliff (NASA, Goddard Space Flight Center, Spacecraft Technology Div., Greenbelt, Md.).
IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 16-17, 1969, PROCEEDINGS. (A69-41734 23-07)
Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 23-48. 5 refs.

Description of the SDP-3, a small serial computer which will be flown as an engineering experiment on the IMP-I spacecraft. In this application it will handle data acquisition for four of the scientific experiments. Modifications to the SDP-3 which improve its operation with little change in hardware complexity include: (1) permitting full-word indirect addressing in user mode for all instructions which do not modify the contents of memory, (2) extending output channel capability to cover all of memory, (3) a new subroutine linkage instruction, (4) a conditional skip on memory zero instruction, (5) byte-oriented instructions, and (6) improved index register manipulation instructions. The use of 8-bit MSI shift registers produces a significant hardware and power saving at the expense of deleting all left-shifting instructions. Further hardware savings are realized with a special multiplication instruction which allows the MQ (multiplier quotient) register to be deleted. As a result of these and other modifications the power dissipation of the SDP-3 has been decreased by 2/3 W and the number of ICs by 260, while in most respects operation has either been unchanged or improved. Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 72-77.

Description of an on-board data handling system for a 1970 earth orbiting spacecraft, using medium scale integration, complementary MOS arrays. The organization can be divided into several distinct parts: a 512-word by 16-bit memory, a logarithmic data compressor, five rate counter/registers, an address switcher, and a control block. The system contains random access 64-bit memory arrays, 8-bit preset counters, and 8-bit parallel load shift registers. The smallest of these arrays contains over 200 active devices. The rest of the scheme is composed of multiinput NAND and NOR arrays, D type flip-flops, and seven-stage binary ripple counters. Z.W.

WHY DATA SYSTEM STANDARDS?
W. B. Poland, Jr., R. T. Fitzgerald, and R. J. Coates (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: INTERNATIONAL FOUNDATION FOR TELEMETERING, INTERNATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., SEPTEMBER 15-17, 1969, PROCEEDINGS. (A69-41734 23-07)
Woodland Hills, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 5), 1969, p. 461-469.

Discussion of some ideas about data system standards which have been developed at the Goddard Space Flight Center (GSFC) of NASA over a period of about nine years, mainly as the result of experience gained in using the Space Tracking and Data Acquisition Network (STADAN), a collection of tracking, command, and telemetry stations for ground support of scientific satellites. As the purposes and uses of data system standards are often misunderstood, a description is given of the growth and current implementation of the working approach to standards at GSFC. This approach is conditioned by the operating environment and by a number of administrative decisions, which are discussed. The areas included in the existing GSFC standards and some of those planned for future coverage are described, and some considerations bearing on the feasibility of combining GSFC and other data systems are examined. O.H.

ALGORITHMS FOR TEST PATTERNS IN MULTITERMINAL DEVICES WITH SYMMETRY CONSTRAINTS.

W. W. Happ and A. S. Weitzenfeld (NASA, Electronics Research Center, Cambridge, Mass.).
IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, INTERNATIONAL CONFERENCE ON COMMUNICATIONS, BOULDER, COLO., JUNE 9-11, 1969, CONFERENCE RECORD. (A69-42500 23-07)
New York, Institute of Electrical and Electronics Engineers, Inc. (IEEE ICC Conference Publications. Volume 5), 1969, p. 41-13 to 41-18. 14 refs.

Description of procedures developed to identify unique test patterns for multiterminal devices with specified symmetry. Combinatorial concepts and coding procedures are defined by examining in detail an illustrative example: the unique three-terminal two-ports which result from a four-terminal passive network with symmetry. Algorithms are developed to derive nonredundant one-ports from an N-terminal parent network with specified symmetry. Applications are examined in (1) failure diagnostics of microcircuits, (2) generation of useful network functions for multiterminal thin-film devices, (3) partitioning of large systems into smaller subsystems, and (4) modelling with preassigned accuracy. (Author)

CENTRAL DATA SYSTEM CONCEPTS FOR SPACECRAFT DATA MANAGEMENT.
Richard O. Fimmell (NASA, Ames Research Center, Data Systems Branch, Moffett Field, Calif.), Alexander Egger, and Louis M. Bello (TRW Systems Group, Electronic Data Systems Laboratory, Data Systems Electronics Dept., Redondo Beach, Calif.).
Telemetry Journal, vol. 4, Aug.-Sept. 1969, p. 63-72.

Discussion of the design concepts of a central data system (CDS) for more efficient, flexible data management, and description of its application in an advanced deep space solar probe. The design features high data sampling rates, programmable data processing, bulk data storage capability (for data sampled during periods of noncommunication), and standard experiment package/CDS interfaces. The basic system concept is based upon sampling each data point at a high rate in a fixed sequence and allowing a central processor to select, process, and format sampled data into a highly efficient format for transmission. The CDS is programmable so that data formulating and processing may be programmed via the command link to optimize data transmission for unexpected conditions. Preliminary design efforts have indicated that a CDS to process data from seven particle and fields experiments can be designed, using present state-of-the-art components, to weigh 16.5 lb and consume 5.4 W from the dc/dc converter. COMPUTE—A TIME-SHARING DESK CALCULATOR PROGRAM
Paul Swigert Washington Nov. 1968 24 p
(NASA-TN-D-4917) Avail: CFSTI CSCL 09B

Introductory details are presented on the COMPUTE program, written primarily in FORTRAN 4, which operates under the IBM 360/67 Time-Sharing System (TSS). The program allows the TSS user to perform various numerical calculations without writing FORTRAN programs. The user may thus solve various numerical problems while at the TSS terminal by simply communicating with COMPUTE. It is anticipated that the user will obtain from this introduction the information necessary to begin using COMPUTE. More specific information about the capabilities of COMPUTE can be derived from the actual use of the program. This is possible because of numerous error, warning, and information messages generated by COMPUTE and printed at the terminal. Author

ADAPTIVE SIMULATION USING MODE IDENTIFICATION
Rob Roy, C. H. Schley, and A. R. Axelrod Washington NASA Nov. 1968 70 p refs
(Grant NGR-33-018-014)
(NASA-CR-1179) Avail: CFSTI CSCL 12B

An input-output process model is formulated using only the process operating record: the processes considered have a finite settling time. As the structure of the process is not known, nonlinear and linear processes fall within the class of processes studied. Since the process parameters are not monitored, the overall cause-effect relationship of the model must change, based only on the on-line operating record of the process. The problems of process identification and pattern recognition are examined in relation to the procedures for assigning a given input pattern to a particular category. Methods for adaptive modal construction are described, and some results are presented on the application of the modal learning technique to both linear and nonlinear systems. Adaptive simulation by the method of potential functions is described, along with the method of realizing the algorithm. Aizerman's proof of the convergence of the algorithm for the two-category case is extended to R categories. M.G.J.

HUMAN INTELLECT AUGMENTATION TECHNIQUES Final Report
D. C. Engelbart Washington NASA 1969 78 p refs
(Contract NAS1-5904)
(NASA-CR-1270) Avail: CFSTI CSCL 09B

A multiproject program that is exploring the value of computer aids to augmenting human intellectual capability is discussed. Outlined briefly are the background and the "bootstrapping" nature of the program (e.g., the report was produced with the experimental computer aids) and its status at the start of this project. Advances during the project were in the programming system (CRT on-line debugging, etc.),in both off-line and on-line computer-aided text-manipulation systems implemented on a CDC 3100, and in specifications, designs, and nearly completed implementation of a time-shared system on the SDS 940, which will be committed to serving 12 on-line CRT consoles for this program. Special features of the design included commercial-TV display consoles, special equipment to reduce CPU overhead to a few percent for servicing I/O, a new machine-oriented, systems programmer compiler language,

a compiler-compiler, and a Control Metalanguage Translator for compiling the interactive part of the on-line system from a special Control Metalanguage description. Author

HAND-PRINTED INPUT FOR ON-LINE SYSTEMS
M. I. Bernstein and H. L. Howell Washington NASA Mar. 1969 114 p refs
(Contract NAS12-526)
(NASA-CR-1284) Avail: CFSTI CSCL 09B

This document describes a program for recognizing hand-printed information in real time, which provides on-line computer users with a means of inputting two-dimensional information as simply as writing with pen and paper. The program operates under the time-sharing system and uses a RAND Tablet for input and a CRT display for output. Each user of the program builds a unique character dictionary, based on samples of his own input characters. For each user, the program currently recognizes about 100 different characters, which are chosen from a larger alphabet by the individual user. This document describes how the recognition program interfaces with the time-sharing system; what functions the program performs in recognizing hand-drawn input; and how the character dictionary is constructed and tested. COMPUTER PROGRAM FOR DIMENSIONAL ANALYSIS
A. D. Sloan and W. W. Happ Washington Apr. 1969 31 p refs
(NASA-TN-D-5165) Avail: CFSTI CSCL 09B

In order to scale models of devices (ships, space capsules, integrated circuits, etc.) and phenomena (nuclear detonations, space-charge widening, sloshing in fuel tanks, etc.), it is necessary to determine nondimensional groupings of variables. A computer program establishes sets of invariant or nondimensional sets of variables and searches for an optimum set under specified optimization criteria. This Fortran IV program is based on algorithms of integer programming. Typical running times are 2 minutes for 10^4 sets of equations. Author

A SPACECRAFT ANALOG-TO-DIGITAL CONVERSION SYSTEM EMPLOYING MOSFETS
Donald C. Lokerson Washington Jul 1969 29 p refs
(NASA-TN-D-5228) Avail: CFSTI CSCL 09B

The analog-to-digital conversion systems used in past Interplanetary Monitoring Platform spacecraft are reviewed to indicate why a new voltage-controlled oscillator is required and what characteristics are desirable for the new oscillator. Since the system developed employs metal oxide semiconductor field effect transistors (MOSFETS), this type of transistor is described. Analysis, design, and developmental innovations are described in detail for the system, which is composed of an analog commutator, a voltage-to-frequency oscillator, an internal voltage regulator, and a digital storage register. The system performance using special calibration equipment is described in detail for the operation over a nominal 0 to +5 volt input with a 5-millisecond sample time. The linearity is within ±0.5 percent of the 6-kHz to 46-kHz frequency range. Tests indicate long-term stability is about ±0.2 percent over a three-month period, whereas short-term stability is ±0.5 percent after warmup. The system described can be adapted to permit measurements at hundreds of megohms impedance. The time constants can be changed to allow a wide range of frequencies and sample times. Author

A SIMPLE TECHNIQUE FOR AUTOMATIC COMPUTER EDITING OF BIODATA
Ram Swaroop, (Computing and Software, Inc., Greenbelt, Md.) Kenneth A. West, (Computing and Software, Inc., Greenbelt, Md.), and Charles E. Lewis, Jr. Washington Jul. 1969 20 p refs
(NASA-TN-D-5275) Avail: CFSTI CSCL 09B

Before any data are statistically analyzed, it is always necessary to edit the data to some extent. Furthermore, when large quantities of data are collected, the editing must be performed by automatic means. One common task in the editing process is the identification of observations which deviate markedly from the rest of the sample, commonly known as outliers. A simple statistical technique for identifying the outliers and the necessary computer program is presented. The program requires as input only the data set, sample size, and preselected levels of significance at which outliers are to be identified. It is assumed that the data set is a random sample of size larger than two from a normal population. Two examples are presented to illustrate applications of the described technique. Author

A COMPILATION OF CURRENT COMPUTER PROGRAMS FOR LOW-THRUST TRAJECTORY ANALYSIS
Alfred C. Mascy Washington Jul. 1969 68 p
(NASA-TM-X-1824) Avail: CFSTI CSCL 09B

A catalog of brief descriptions of current low-thrust trajectory and mass computation programs is presented. All known sources were contacted, and questionnaires were sent to those who indicated that they possessed such codes. A total of 59 descriptions of computer programs pertinent to this discipline are compiled. They are capable of generating flyby and rendezvous trajectories with their associated mass computation. Included in the codes are those capable of variable thrust trajectory as well as constant thrust with coast trajectory calculations. No attempt is made to evaluate any computer code or in any way compare programs; rather, the descriptions of existing codes are presented. Further details concerning a particular program may be obtained from the organization shown on each description. Author

AN EXPERIMENTAL AND THEORETICAL INVESTIGATION OF STRIATIONS IN A He-Ne LASER
T. B. Carlson, F. M. Shofner, and C. W. Bray Washington NASA Jul. 1969 60 p refs
(Grants NGR-43-001-056; NSF GK-1638)
(NASA-CR-1387) Avail: CFSTI CSCL 20E

This investigation shows that striation oscillations in the He–Ne discharge occur over significant ranges of pressure and current with respect to the optimum values for maximum laser power. This instability, which is of the order of 500 KHz in frequency, effectively modulates the coherent light output of the He–Ne laser as well as the discharge tube voltage and current. A theoretical analysis has been modified to predict the striation frequency pressure and radius dependences for the single constituent gas. The experimental results for the He–Ne laser show good correlation with the functional dependence predicted. One practical design consideration is that striation effects can be minimized by using small diameter tubes which have characteristically higher striation frequencies and modulate the coherent output less effectively. FORTRAN PROGRAM FOR MACHINE COMPUTATION OF GROUP TABLES OF FINITE GROUPS
Gabriel Allen, David D. Evans, and Paul Swigert Washington Sep. 1969 43 p refs
(NASA-TN-D-5402) Avail: CFSTI CSCL 09B

A FORTRAN program has been written for machine computation of group tables for finite groups. The use of the method depends on the fact that every finite group of order n is isomorphic to some subgroup of the symmetric group S_n. The procedure for using the program is as follows: After the proper isomorphism has been established, the appropriate elements of S_n are entered into the program as input data. The program computes and prints out the group table for these elements of S_n. Then the translation is made from the elements back to the original group elements. Two examples are shown. Author

COMPUTER-AIDED FILTER DESIGN MANUAL
Sidney Gussow and Glenn Weathers Washington NASA 1969 106 p refs
(Contract NAS8-20055)

(NASA-SP-3049) Avail: CFSTI CSCL 09B

A computerized filter design procedure to provide a simplified and accurate method of design and synthesis for engineers having minimum experience in this area is described. It may also be utilized by experienced personnel to perform laborious and complex calculations. The procedure consists of selection, analysis and synthesis of electric wave filters for telemetry applications. Filter selection includes the use of charts to assist in rapid choice of a suitable configuration. Passive synthesis programs calculate the component circuit values required for the specific filter; use realization techniques for singly and doubly loaded networks, and assist the designer in tuning. Active synthesis is accomplished through active quadratic networks which are connected in cascade, and it is reported that the active design is not satisfactorily accurate for narrow bandwidth requirements or for a frequency much beyond 500 kHz. The analysis programs calculate filter response characteristics, including amplitude, phase, time delay, and group delay responses. A.C.R.

A STEPPING MOTOR DRIVE CIRCUIT USING MAGNETIC CORE LOGIC.

Joseph C. Thornwall (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-4, Sept. 1968, p. 672-679.

Description of a new magnetic core circuit used to supply power in the proper phase and time sequence to a bidirectional stepping motor. This circuit will power a standard voltage stepping motor from a nonstandard voltage power supply and includes a means for maintaining a constant energy pulse excitation over a wide range of dc power supply input voltage, a means for supplying power to the winding of the motor on pairs of isolated conductors, and a means for conductively isolating the low-level logic circuits from the high-level power circuits. THE ADMITTANCE OF A PARALLEL-PLATE WAVEGUIDE APERTURE ILLUMINATING A METAL SHEET.

J. Earl Jones, C. T. Swift (NASA, Langley Research Center, Hampton, Va.), L. L. Tsai, R. C. Rudduck, and W. D. Burnside (Ohio State University, ElectroScience Laboratory, Columbus, Ohio).

IEEE Transactions on Antennas and Propagation, vol. AP-16, Sept. 1968, p. 528-535. 20 refs.

Research sponsored by Ohio State University; Grants No. NsG-448; No. NGR-36-008-048.

The admittance of a parallel-plate waveguide aperture having an infinite flange and illuminating a metal sheet is determined by two separate methods: (1) wedge diffraction theory; and (2) an integral transform solution. Numerical computations obtained by either method are in excellent agreement and are verified experimentally. A Smith chart is employed to show that, for a given aperture width, the admittance locus coalesces about the half-space value as the metal sheet recedes to infinity. A strong interaction between the aperture and the metal sheet occurs for distances in the vicinity of integral multiples of one half-wavelength. The interaction becomes much more localized with respect to distance as the distance to the sheet is increased; however, the admittance is always infinite at these distances. (Author)

EFFECTS OF ELECTRIC FIELDS ON ANNEALING OF RADIATION DAMAGE IN MOSFET'S.

Vitaly Danchenko, Upendra D. Desai, Joseph M. Killiany (NASA, Goddard Space Flight Center, Greenbelt, Md.), and Sidney S. Brashears (Electro-Mechanical Research, Inc., College Park, Md.).

IEEE Transactions on Electron Devices, vol. ED-15, Oct. 1968, p. 751-756. 16 refs.

Radiation damage in p-channel MOS devices by 1.5 MeV electrons has been studied by thermal annealing in conjunction with electric fields between the metallic gate and the substrate. Both positive and negative gate biases retard the process of annealing. Annealing with negative gate bias reveals: (1) that during thermal annealing the majority of the electrons that recombine with the positive charge in the oxide originate from the conduction band of the silicon, and (2) that during irradiation a great number of ionized electrons that remain in the oxide do not recombine with the holes, but are trapped in weakly bound states. The effect of positive bias on annealing of radiation damage is obscured by the positive charge induced due to positive bias-temperature treatment alone. No effect of drain-to-source potential on annealing has been observed. (Author)

AUTOMATIC DISTORTIONLESS CONTROL OF MAGNETIC FIELD MODULATION.

Russell J. Jirberg (NASA, Lewis Research Center, Cleveland, Ohio).

Review of Scientific Instruments, vol. 40, Jan. 1969, p. 173, 174.

Description of a design for maintaining magnetic field modulation at a desired level. A closed-loop mode of control is used. The system utilizes a light-sensitive resistor as one leg of an attenuator which adjusts the driving signal fed to the modulation amplifier. With appropriate control of the illumination incident upon the photocell, changes in core magnetization with field can be automatically compensated for. G.R.

REFLECTIONS OF ELECTRON BEAMS IN THERMIONIC DIODES.

James F. Morris (NASA, Lewis Research Center, Cleveland, Ohio)

Journal of Applied Physics, vol. 39, Dec. 1968, p. 6099, 6100. 9 refs.

Discussion of plasma collisional effects on positive-ion sheaths at emitters and on net currents in cesium diodes. To represent possible current reductions by collisions, the discussion relies on a kinetic reflection coefficient (due to Baksht et al., 1967) for electron beams. Results of the study indicate that kinetic reflections appear to affect sheath structures and transport only trivially in cesium diodes. Hence calculations for positive-ion sheaths in thermionic converters require no corrections for plasma scattering of emitted electron beams back to the emitters. M.G.

PERFORMANCE CHARACTERISTICS AND SPECIFICATION OF PCM BIT SYNCHRONIZER/SIGNAL CONDITIONERS.
B. Peavey (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: INTERNATIONAL TELEMETERING CONFERENCE, LOS ANGELES, CALIF., OCTOBER 8-11, 1968, PROCEEDINGS. [A69-19092 07-07]
Conference sponsored by the International Foundation for Telemetering.
Tarzana, Calif., International Foundation for Telemetering (ITC Proceedings. Volume 4), 1968, p. 407-419. 5 refs.

Discussion of the test data obtained on synchronizers used at the Goddard Space Flight Center and its satellite tracking and data acquisition network stations. The test data indicate that there is no single synchronizer excelling in all respects. It is shown that bit error rate alone does not wholly characterize the synchronizers, particularly when operating with low (less than 7 dB) SNRs plus jitter. Definitions of performance parameters which would uniformly and unambiguously describe and specify synchronizers are suggested and discussed. Z.W.

X-RAY FLUORESCENCE AND ELECTRON MICROPROBE TECHNIQUES FOR DETERMINATION OF THIN-FILM THICKNESSES.
James E. Cline (NASA, Electronics Research Center, Cambridge, Mass.).
IN: PHYSICAL MEASUREMENT AND ANALYSIS OF THIN FILMS.
Edited by F. M. Murt and W. G. Guldner.
London, Plenum Press (Progress in Analytical Chemistry. Volume 2), 1969, p. 83-92. 5 refs.

Discussion of two methods for determining the thickness of thin films: X-ray fluorescence and electron microprobe techniques. For X-ray fluorescence, a linear relationship is obtained between the function $-\log(1 - I_t/I_0)$ and the mass thickness of the thin film, where I_t is the intensity of the characteristic X-rays from the thin film and I_0 is the limiting intensity from thick layers. For electron-microprobe techniques, a more complex relationship is found due to the variation of the effective electron excitation function, which reaches a maximum at a penetration depth depending on the electron-beam voltage of the characteristic X-rays emitted. A method is described for the simultaneous determination of both gold and molybdenum thicknesses in a laminated metallization system used for integrated circuits. (Author)

SMALL-SIGNAL AND SATURATION CHARACTERISTICS OF AN X-BAND CYCLOTRON-RESONANCE OSCILLATOR.

B. Kulke and R. W. Wilmarth (NASA, Electronics Research Center, Microwave Circuits Branch, Cambridge, Mass.).

IEEE, Proceedings, vol. 57, Feb. 1969, p. 219, 220.

Design information and operating characteristics are given for an experimental X-band cyclotron-resonance oscillator. Saturated power levels near 3 W, at 0.8% efficiency, are reported. Qualitative agreement with theory has been observed under small-signal, zero-space-charge conditions. (Author)

A SiC BACKWARD DIODE.

Richard Farrell (NASA, Electronics Research Center, Cambridge, Mass.).

IEEE, Proceedings, vol. 57, Feb. 1969, p. 221, 222.

SiC backward diodes which operate between 77 and 1000 K have been developed. Figures of merit ($\gamma\sqrt{R}$) of 19, 300, 3960, and 15 at 12.5 MHz, 50 MHz, and 8.8 GHz, respectively, have been measured with detector area on the order of 10^{-5} cm^2. These results are compatible with a prior analysis which predicted an upper frequency limit of between 0.1 and 1.0 GHz for SiC backward diodes. (Author)

Contract No. NAS 12-565.

Description of a thermal control system built to provide cooling for a traveling wave tube (TWT) mounted in a spacecraft. The system was designed to demonstrate the capability of heat pipes to provide high thermal conductance paths for 750 W (dissipated at the TWT collector) to flow to a flat plate radiator where the heat can be radiated to space. The evaporators of four heat pipes and the TWT collector are attached to a block located at the center of the radiator. The heat pipe condensers, placed along the diagonals of the square radiator plate, maintain the diagonals very nearly isothermal, thus keeping the fin effectiveness high. Test results are included, showing the system thermal performance in several modes of operation for varying power dissipations. The results of failure of one, two, three, or all four pipes are presented. Also included is an analytical investigation of the weight and area requirements of both passive and heat-pipe space radiators. This analysis serves as a general guide in judging the effect of temperature limits and power dissipation on the thermal control system. (Author)

New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 191-195.

Contract No. NAS 12-565.

Description of a vacuum tube which has been constructed to obtain more efficient utilization of heat than is provided by thermoelectric or thermionic devices. The vacuum tube is such that its cathode is directly heated by a radioisotope source external to the tube. The tube design incorporates a heat pipe to provide almost isothermal transfer of heat from the external source to the cathode. Test results demonstrate operation with an external electrical heater and a radioisotope heat source. M.M.

RADIATION AND NEAR-FIELD COUPLING BETWEEN TWO COLLINEAR OPEN-ENDED WAVEGUIDES.

Robert J. Mailloux (NASA, Electronics Research Center, Cambridge, Mass.).

IEEE Transactions on Antennas and Propagation, vol. AP-17, Jan. 1969, p. 49-55. 22 refs.

Description of an experimental and theoretical study of closely spaced collinear coupled waveguides radiating through a common perfectly conducting ground plane. The problem is formulated as a set of simultaneous integral equations and is solved approximately by expanding the aperture field in a Fourier series. The special case of a single isolated waveguide is treated first, and the results are compared with experiment as well as with the approximate results of Lewin (1951). Attention is given to the edge singularities. The more general case of two collinear coupled waveguide slots is solved by the same numerical method using the symmetrical properties of the geometry. Phase and amplitude of the mutual coupling are evaluated and compared with experiment. Agreement is excellent. (Author)

THE INFLUENCE OF AIR-GAP TOLERANCES ON THE ADMITTANCE OF A DIELECTRIC-COATED SLOT ANTENNA.

J. Earl Jones (NASA, Langley Research Center, Hampton, Va.). (Institute of Electrical and Electronics Engineers, International Antenna and Propagation Symposium, Boston, Mass., Sept. 9-11, 1968.)

IEEE Transactions on Antennas and Propagation, vol. AP-17, Jan. 1969, p. 63-68. 9 refs.

The admittance of a TEM mode-excited parallel-plate aperture having an infinite flange and illuminating a displaced dielectric

boundary is determined by the variational method. The results are applied to provide insight into the following two problems of interest: (1) the effect of an air gap on the admittance of dielectric-coated aperture antennas, and (2) the admittance of an aperture antenna coated with an underdense plasma slab. Numerical computations for the air-gap problem are verified experimentally. (Author)

IN: ANNUAL NATIONAL RELAY CONFERENCE, 17TH, OKLAHOMA STATE UNIVERSITY, STILLWATER, OKLA., APRIL 22, 23, 1969, PROCEEDINGS. [A69-28042 13-09]
Conference sponsored by the National Association of Relay Manufacturers and Oklahoma State University.
Scottsdale, Ariz., National Association of Relay Manufacturers, 1969, p. 11-1 to 11-12. 6 refs.

Outline of the background required by the relay user and designer alike for a better understanding of the requirements of spacecraft with magnetic field constraints. The fields of various relay types are compared. Spacecraft instruments and stabilization systems are described, as well as techniques for minimizing the effects of operational and permanent fields and methods for measuring these fields. The overall problem of spacecraft magnetic cleanliness and the effect of a relay on this problem is briefly touched upon.

IN: ANNUAL NATIONAL RELAY CONFERENCE, 17TH, OKLAHOMA STATE UNIVERSITY, STILLWATER, OKLA., APRIL 22, 23, 1969, PROCEEDINGS. [A69-28042 13-09]
Conference sponsored by the National Association of Relay Manufacturers and Oklahoma State University.
Scottsdale, Ariz., National Association of Relay Manufacturers, 1969, p. 13-1 to 13-23. 18 refs.

Study of the problem of the increase in the temperature rise of relay coils when air is removed from the ambience outside and inside the relay case. The space environment and relay applications are described. The normal thermal considerations for relays are discussed and the data obtained are evaluated. The conclusions drawn from this study are: (1) the temperature rise of a sealed or unsealed relay increases substantially and continuously as pressures are varied from sea level to the range equivalent to 250, 000 to 350, 000 ft; (2) for altitudes over 50, 000 to 100, 000 ft, these increases cannot be deduced from published convection derating curves; gaseous conduction is an important phenomenon at these levels; (3) at pressures equivalent to orbiting altitudes, maximum average coil temperatures of sealed relays are generally around 150°C, while those of unsealed relays frequently exceed 200°C; (4) radiation is an important factor in relay cooling at altitudes above 200, 000 ft and is the principal factor at 500, 000 ft; and (5) black- or gray-painting the relay cans will substantially increase emissivity, resulting in much lower coil temperatures at high altitudes. P.v.T.

THERMAL INSTABILITIES LIMITING POWER DISSIPATION IN TRANSISTORS.
S. M. Spitzer (NASA, Electronics Research Center, Cambridge, Mass.).
Solid-State Electronics, vol. 12, May 1969, p. 433-437. 8 refs.

Explanation of the development of second breakdown and other thermal instabilities using solutions to the heat flow equation. Stability criteria in cases where the multiplication factor can be assumed to be unity are presented in terms of α_T, the thermal coefficient of the emitter-base junction. It is found that simple Ebers-Moll theory does not contain information about base resistance and its stabilizing effects on device operation. An experimental parameter, α_T', contains this base resistance information, and yields stability criteria predicting reduced power dissipation capability for the transistor at low current levels. The calculation of α_T' is developed, and the application of this calculation is discussed. (Author)

HOW RELIABLE ARE MOS IC's? AS GOOD AS BIPOLARS, SAYS NASA.
Leon C. Hamiter, Jr. (NASA, Huntsville, Ala.).
Electronics, vol. 42, June 23, 1969, p. 106-110.

Results of an MOS IC reliability study conducted by NASA, including a discussion of the causes of device degradation and failure. Thousands of MOS ICs from a single manufacturer were tested at 25°C operating life, 85°C operating life, 125°C reverse bias, 125°C storage, and 150°C storage. Some 4, 339, 000 circuit hours were accumulated in this group of tests alone, with only three failures - a failure rate of 0.095% per 1000 hours at maximum stress. This test experience is comparable to NASA's experience with operational systems using MOS ICs. It was found that MOS and bipolar ICs of equal complexity offer approximately the same failure rates. A complex MOS circuit offers a lower total failure rate than discrete parts or less complex ICs that must be assembled on printed-circuit boards and interconnected to perform the equivalent function.

THE EFFECTS OF DIELECTRIC OVERCOATING ON ELECTROMIGRATION IN ALUMINUM INTERCONNECTIONS.
Stuart M. Spitzer and Seymour Schwartz (NASA, Electronics Research Center, Cambridge, Mass.).
(Institute of Electrical and Electronics Engineers, Annual Reliability of Physics Symposium, 7th, Washington, D.C., Dec. 2-4, 1968.)
IEEE Transactions on Electron Devices, vol. ED-16, Apr. 1969, p. 348-350. 12 refs.

Study of the effects of dielectric overcoating as a function of aluminum thickness. It is seen that surface treatment is effective for aluminum less than 5000 Å thick. It is pointed out that for aluminum thickness greater than 6000 Å, surface passivation will have no effect with respect to electromigration. It is shown that the type of aluminum deposition technique and deposition and post-deposition heat treatment is critical in obtaining the maximum bulk component of the activation energy. The dielectric overcoating, in combination with optimal bulk properties, increases the mean time between failure of the aluminum stripes by one to two orders of magnitude, at high current densities and elevated ambients, over that found in many conventional integrated circuits. M. M.

THERMAL EFFECTS ON THE INTEGRITY OF ALUMINUM TO SILICON CONTACTS IN SILICON INTEGRATED CIRCUITS.

Robert J. Anstead and Samuel R. Floyd (NASA, Goddard Space Flight Center, Greenbelt, Md.).

(Institute of Electrical and Electronics Engineers, Annual Reliability of Physics Symposium, 7th, Washington, D. C., Dec. 2-4, 1968.) IEEE Transactions on Electron Devices, vol. ED-16, Apr. 1969, p. 381-386.

Observations of serious discontinuities in aluminum interconnections at contact windows of integrated circuits, by means of the scanning electron microscope. In some instances the discontinuities have produced catastrophic failure. Two types of discontinuities have been observed, and simulation of one type has been possible through exposure to temperatures 25 to 50°C below the aluminum-silicon eutectic of 577°C. A preliminary electron probe analysis has revealed the presence of silicon in the interconnection regions overlying the silicon dioxide steps bordering the contact windows. M. M.

REFLECTION COEFFICIENT OF A TEM MODE SYMMETRIC PARALLEL-PLATE WAVEGUIDE ILLUMINATING A DIELECTRIC LAYER.

W. D. Burnside, R. C. Rudduck, L. L. Tsai (Ohio State University, ElectroScience Laboratory, Columbus, Ohio), and J. E. Jones (NASA, Langley Research Center, Hampton, Va.).

Radio Science, vol. 4, June 1969, p. 545-556. 18 refs.

Grant No. NGR-36-008-005.

The reflection coefficient of a symmetric parallel-plate waveguide operating in the TEM mode and illuminating a lossless dielectric layer is analyzed by wedge-diffraction and geometrical-optics techniques. The interactions between the waveguide and the dielectric layer are treated in terms of iterative bounce waves. The *reflection from the dielectric layer and the scattering from the* waveguide for cylindrical wave incidence are both represented by resultant component cylindrical waves. Thus each interacting bounce wave between the guide and the dielectric layer becomes the superposition of a finite number of cylindrical wave components. The reflection coefficient of the guide is then obtained by adding the various bounce wave contributions to the guide's free-space reflection coefficient. For the two geometries considered (the thin-walled guide and the ground-plane guide) calculated results are in excellent agreement with those measured. (Author)

LINEAR OPERATION OF A P-N-P-N TETRODE.

Nicholas C. Voulgaris (NASA, Electronics Research Center, Cambridge, Mass.) and Edward S. Yang (Columbia University, Dept. of Electrical Engineering, New York, N. Y.).

IEEE Transactions on Electron Devices, vol. ED-16, May 1969, p. 468-478. 15 refs.

NSF Grant No. GK-1550; Grant No. NGR-33-008-090.

Model of a four-terminal p-n-p-n device operating as a semiconductor tetrode amplifier. The equations characterizing this *model are based on the physical structure of a commercially* available silicon planar p-n-p-n tetrode; they are use (1) to derive the device terminal characteristics; (2) to synthesize small-signal equivalent circuits suitable for lf operation (h-parameter circuit) and for hf operation (bridged hybrid-π circuit); (3) to study the dependence of short-circuit gains of the tetrode on the dc biasing currents and frequency; and (4) to obtain a stability condition which must be satisfied to ensure that the operation of the device is restricted in its OFF state where it can function as a small-signal linear amplifier. The theoretical results are in close agreement with experimental values. (Author)

DESIGN OF A LONG-LIFE RELIABLE NUCLEAR EXPERIMENT FOR SPACE FLIGHT.

James H. Trainor and Donald J. Williams (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IEEE Transactions on Geoscience Electronics, vol. GE-7, Apr. 1969, p. 74-77. 9 refs.

Description of an experiment which has been developed for flight on OGO-F in polar orbit. Measurements will be made of the electron flux and spectra above 30 keV, both for precipitating and locally mirroring electrons as well as atmospheric backscatter. The scientific purposes, detector and electronic systems, packaging, thermal design, internal calibration, and test philosophy are discussed. This work emphasizes the design features and philosophy used in the development, fabrication, and testing of the experiment in order to ensure a long, useful lifetime in space. (Author)

AN OMNIDIRECTIONAL MICROWAVE ANTENNA FOR USE ON SPACECRAFT.
William F. Croswell and Capers R. Cockrell (NASA, Langley Research Center, Hampton, Va.).
IEEE Transactions on Antennas and Propagation, vol. AP-17, July 1969, p. 459-466. 17 refs.

Description of the qualitative theory, design, and development of a parallel-plate waveguide-fed antenna, suitable for flush-mounted broad-band spacecraft applications. The antenna makes use of wedge-like metal posts placed uniformly about the periphery of the feed plates to provide both structural strength and practical interconnection routes for cables without disrupting the antenna impedance and patterns. Measurements taken on the antenna, which is mounted on spheroids up to 50 wavelengths in circumference, are presented. Equatorial patterns are omnidirectional within plus or minus 0.25 dB, and polar patterns have beam widths similar to a half-wave dipole. (Author)

RADIATION CHARACTERISTICS OF A CAVITY-BACKED CYLINDRICAL GAP ANTENNA.
Calvin T. Swift, Thomas G. Campbell (NASA, Langley Research Center, Hampton, Va.), and Henri Hodara (Tetra Tech, Inc., Pasadena, Calif.).
(Institute of Electrical and Electronics Engineers, Plasma Sheath Symposium, 3rd, Boston, Mass., Sept. 21-23, 1965.)
IEEE Transactions on Antennas and Propagation, vol. AP-17, July 1969, p. 467-477. 6 refs.
Contract No. NAS 1-4623.

The input impedance and the equatorial radiation patterns of a vhf cavity-backed cylindrical gap antenna are derived and compared with experiments. The experiments generally support the computations, provided that the gap dimension is neither larger than about one hundreth of a wavelength, nor so thin that mechanical tolerances in the feed design become important. The results show that the tuning, impedance bandwidth, and the radiation patterns of this antenna can be controlled very accurately by adjusting the internal radius and height of the cavity. Salient points of this antenna are its wide-band characteristics (10-per cent bandwidth), its pattern circularity, and particularly the fact that it can be made an integral part of a space vehicle. (Author)

A69-40703 *
APERTURE RADIATION FROM AN AXIALLY SLOTTED ELLIPTICAL CONDUCTING CYLINDER USING GEOMETRICAL THEORY OF DIFFRACTION.
Constantine A. Balanis (NASA, Langley Research Center, Hampton, Va.) and Leon Peters, Jr. (Ohio State University, Dept. of Electrical Engineering, Columbus, Ohio).
IEEE Transactions on Antennas and Propagation, vol. AP-17, July 1969, p. 507-513. 18 refs.

Computation of the equatorial radiation pattern of a parallel-plate TEM mode axial slot on an infinite cylinder of elliptical cross section, using wedge-diffraction and creeping-wave theory. The wedge-diffracted fields are obtained by the diffraction interaction from a set of infinite wedges approximating the parallel-plate-cylinder geometry. Surface-wave propagation on curved bodies, commonly used in scattering, is employed for the creeping-wave contribution. The total field in the lit region is approximated using superposition of wedge-diffracted and creeping-wave fields and in the shadow region solely by creeping-wave fields. The computed patterns are compared with experimental results since boundary-value solutions are not readily available. Good agreement between theory and experiment is indicated. (Author)

OPTIMUM DESIGN OF GERMANIUM MICROWAVE BACKWARD DIODES.
John B. Hopkins (NASA, Electronics Research Center, Cambridge, Mass.).
IEEE, Proceedings, vol. 57, Aug. 1969, p. 1458-1460. 7 refs.

Computer calculation to obtain data to serve as guidelines in the fabrication of optimum germanium backward diode microwave detectors. Curves are presented indicating obtainable performance for varying junction diameter, impedance level (determined by the size and impurity concentration), and operating frequency. Z.W.

A69-41228 * #
APPLICATION OF A VARIABLE RESISTANCE TO ARREST OSCILLATIONS IN A PULSED CAPACITOR DISCHARGE CIRCUIT.
Dah Yu Cheng (NASA, Ames Research Center, Moffett Field, Calif.).
Review of Scientific Instruments, vol. 40, Sept. 1969, p. 1153-1157. 5 refs.

Kirchhoff's equation for the current flow from a capacitor connected in series with an inductance and a resistance (that varies with current) is solved by an iterative integration scheme. The resistance of the circuit is assumed to increase during the discharge due to Joule heating. The conditions for over-, under-, and critical damping are derived and used to design a circuit that has a short risetime and a long decay time without current oscillation. The realistic nature of the circuit is verified experimentally. (Author)

A69-41589 *
ADMITTANCE OF A WAVEGUIDE-FED APERTURE LOADED WITH A DIELECTRIC PLUG.
Calvin T. Swift (NASA, Langley Research Center, Hampton, Va.).
IEEE Transactions on Antennas and Propagation, vol. AP-17, May 1969, p. 356-359.

The admittance of a rectangular aperture antenna, loaded with a dielectric plug, was previously formulated as a boundary-value problem and the results are summarized. Calculations and supporting measurements show that a TE_{03} mode can be strongly excited in the plug, resulting in a resonant perturbation of the admittance. (Author)

A 60-GHz MULTIFREQUENCY RADIOMETRIC SENSOR FOR DETECTING CLEAR AIR TURBULENCE IN THE TROPOSPHERE.
George G. Haroules and Wilfred E. Brown (NASA, Electronics Research Center, Microwave Laboratory, Cambridge, Mass.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, Sept. 1969, p. 712-723. 14 refs.

The temperature profile in a horizontal path forward of an aircraft can be sensed with a multichannel 5-mm passive radiometric receiving system. The characteristic signature of the multichannel radiometric output as a function of time would provide a measure of the range to the region of temperature discontinuity forward of the aircraft. Applicability to clear air turbulence (CAT) detection is predicated on the assumption that temperature discontinuities, at least in some cases, are associated with regions of such turbulence. It is therefore concluded that such a device has potential application as a CAT detector. Preliminary calculations indicate that the presence of a CAT region could be detected approximately 5 to 6 min before penetration, assuming an aircraft speed of 600 mph. A description is given of the design and construction of a two-frequency instrument which will be used to support the measurement program for determining the correlation between the meteorological parameters that are associated with the phenomenon called CAT. A multifrequency multibeam system is also described as the detector system for future supersonic aircraft. (Author)

THE EFFECTS OF REACTOR RADIATION ON 22-VOLT SILICON VOLTAGE REGULATOR DIODES

Suzanne T. Weinstein Washington Nov. 1968 24 p refs

(NASA-TN-D-4923) Avail: CFSTI CSCL 09A

Twenty-five silicon voltage regulator (Zener) diodes (S1N2985B) were exposed to reactor radiation to a total fast neutron fluence of 8.2×10^{13} neutrons per square centimeter and a gamma dose of 6.3×10^{7} rads carbon. The Zener voltage remained essentially constant and the breakdown knee was somewhat softened. The forward and reverse-leakage currents increased, and the forward voltage drop at high forward currents increased. The junction capacitance remained unchanged. Author

RESEARCH AND DEVELOPMENT OF A SINGLE GUN COLOR CRT, PHASE 1 Final Report

Thomas E. Sisneros, Paul A. Faeth, and Joseph A. Davis Washington NASA Dec. 1968 72 p refs

(Contract NAS12-534)

(NASA-CR-1228) Avail: CFSTI CSCL 09A

The feasibility of producing cathode-ray tubes which have a current density-dependent color variation at constant accelerating voltage has been demonstrated. The screens for these tubes were prepared by combining superlinear phosphors with linear or sublinear phosphors. The preparation of phosphors having a superlinear intensity versus current density behavior was studied. Phosphors having superlinear behavior in the current density range normally used for CRT operation were prepared by partially poisoning (ZnCd)S:Ag with a few ppm of Ni. A number of experimental screens and tubes were prepared utilizing various combinations of experimental phosphors. Color shifts from reddish-orange to yellow and from yellowish-green to yellow to orange have been obtained. Author

E-TYPE PHOTODEMODULATORS FOR COHERENT LIGHT SIGNALS Final Technical Report

John L. Mason Aug. 1968 47 p refs

(Contract DA-ARO-D-31-124-G634)

(AD-677374; REPT-07094-1-F) Avail: CFSTI CSCL 9/1

The theoretical studies are summarized and an experimental investigation is reported for an E-type traveling-wave phototube. The principal feature of such a device is the centrifugal electrostatic focusing of the electron beam. The theoretical study yields a small-signal power theorem, the types of waves propagating along a thin E-type beam, and a small-signal analysis of the traveling-wave phototube. An expression for the equivalent resistance of the device is derived, with numerical results given for the case of zero circuit loss, zero space charge, and synchronous beam velocity. For comparison, equivalent resistance values are given for O-type phototubes. The experimental investigation involved a phototube designed to operate at S-band. Design considerations and measurement techniques are discussed. Experimental curves for the equivalent resistance are presented and compared with the theoretical results. Author (TAB)

EVALUATION OF VACUUM UV DETECTOR-SPECTROSCOPY SYSTEMS FOR CAPSULE REENTRY MEASUREMENTS

Ronald L. Ohlhaber, Mark W. P. Cann and Harold V. Watts Washington NASA Feb. 1969 167 p refs

(Contract NAS1-7481)

(NASA-CR-1268; IITRI-V6045) Avail: CFSTI CSCL 20F

Various vacuum ultraviolet detector-spectroscopy systems that could be employed for spectroscopic measurement of the shock wave created ahead of a capsule experiencing hypervelocity reentry conditions were analyzed and evaluated. A generalized set of measurement requirements and environmental conditions was established for a 50,000 ft/sec entry velocity. These conditions are then used to evaluate such detector-spectroscopy systems as ion chambers, proportional counters, Geiger-Mueller tubes, photoelectric tubes, wavelength shifters, photoconductive cells, photovoltaic cells, reverse biased diodes, miniature photodiode arrays, and photoelectric cathode with retardation grid analyzers. The most favorable system appears to be a wavelength dispersing device (grating) followed by an electronically scanned miniature detector array. The array elements could be chosen from either photodiodes, phototransistors, or photoconductors, whichever shows the best vacuum ultraviolet response. Author

PARAMETERS AFFECTING FIRING TIME OF SIMULTANEOUSLY TRIGGERED TRIGATRON SPARK GAP SWITCHES

Michael D. Williams Washington Mar. 1969 31 p refs

(NASA-TN-D-5077) Avail: CFSTI CSCL 09E

The investigation was conducted primarily to determine how the variation of each of several spark gap parameters affects the firing-time differences (switch jitter) of simultaneously triggered trigatron spark gap switches. These parameters were switch voltage (15 to 20 kV), peak trigger voltage (14 to 20 kV), and the curvature of the edge of the trigger electrode hole. The firing times were measured by using the light emitted from the switches. The more significant conclusions are (1) By inference, the physical differences in the members of a switch group create firing-time differences like a component of true switch jitter and only higher switch voltages (of the parameters investigated) significantly diminish their magnitude; (2) true switch jitter is more sensitive to changes in switch voltage than to changes in peak trigger voltage; (3) increased peak trigger voltage is not very effective in reducing switch jitter; (4) the curvature of electrode hole edges does not significantly affect switch jitter in the fast mode of switch operation; and (5) the curves of the firing distributions are not Gaussian integrals as previously believed. RELIABILITY HANDBOOK FOR SILICON MONOLITHIC MICROCIRCUITS. VOLUME 2: FAILURE MECHANISMS OF MONOLITHIC MICROCIRCUITS
William O. Shurtleff Washington NASA Apr. 1969 35 p refs
(Contract NAS8-20639)
(NASA-CR-1347; Rept-03-67-04-Vol-2) Avail: CFSTI CSCL 09A

Defects are enumerated that are introduced into monolithic microcircuits during the various processes of manufacture; the impact of these defects on microcircuit failure rates and the techniques that are used to correct or remove the defects from the processes are considered. The techniques of processing that are used in the manufacture of monolithic microcircuits are sophisticated, numerous, and complex. There is a finite probability that defects are introduced at each step of the manufacturing process. These defects are of concern to both the manufacturer and the user of monolithic microcircuits in two major respects: (1) Defects reduce the effective yield of the manufacturer, thereby increasing the cost of each microcircuit bought by the user, and (2) Defects may cause microcircuit reliability problems which adversely affect the user's end product and the reputation of the microcircuit manufacturer. DEVELOPMENT OF AN EXPERIMENTAL SILICON CARBIDE BACKWARD DIODE OPERABLE TO 1000°K
Richard Farrell Washington Apr. 1969 7 p refs
(NASA-TN-D-5183) Avail: CFSTI CSCL 09A

Silicon carbide backward diodes which operate between 77°K and 1000°K were developed. Figures of merit ($\gamma \sqrt{R}$) of 19,300, 3,960, and 15 at 12.5 MHz, 50 MHz, and 8.8 GHz, respectively, were measured with detector areas on the order of 10^{-5} cm^2. These results are compatible with a prior analysis which predicts an upper frequency limit of between 0.1 and 1.0 GHz for SiC backward diodes. Author

CAVITATION PERFORMANCE OF 80.6° HELICAL INDUCER IN LIQUID HYDROGEN
Phillip R. Meng and Royce D. Moore Washington Jun. 1969 14 p refs
(NASA-TM-X-1808) Avail: CFSTI CSCL 09E

The cavitating and noncavitating performance of an 80.6° helical inducer was evaluated in liquid hydrogen over a temperature range from 31.0° to 40.2° R (17.2 to 22.3 K). The inducer was operated at 30 000 rpm at flow coefficients from 0.08 to 0.12. The net positive suction head requirements decreased with increasing liquid temperature; at constant temperature, these requirements increased rapidly with flow coefficient. At the lower values of flow coefficient and the higher liquid temperatures, the inducer produced a useful head rise even with vapor at the inducer inlet. Author

FABRICATION AND CHARACTERISTICS OF MICROWAVE BACKWARD DIODES IN INDIUM ARSENIDE
John B. Hopkins Washington Sep. 1968 25 p refs
(NASA-TN-D-5401) Avail: CFSTI CSCL 09A

The many advantages of backward diodes for microwave mixing and detecting – zero bias, low local oscillator power, low $1/f$ noise, and environmental insensitivity – are significantly offset by the high capacitance associated with a narrow tunneling junction. This either severely limits high-frequency operation or requires small-area junctions which are fragile and susceptible to burnout at low power levels. This limitation can be reduced considerably by selection of a semiconductor with small band-gap and low carrier effective mass, with consequent high tunneling probability and reduced capacitance per unit area. Thus, a device of given size permits higher frequency operation, or equivalent electrical performance with larger area, leading to improved ruggedness and resistance to burnout. Computer-aided studies of the characteristics of tunneling junctions have confirmed the initial estimate that, among elemental and III-V semiconductors, InAs offers optimum improvement of detector performance. TRANSISTOR PERFORMANCE IN INTENSE MAGNETIC FIELDS
Wayne R. Hudson, Erwin H. Meyn, and Clarence W. Schultz (Conn. Univ.) Washington Sep. 1969 14 p refs
(NASA-TN-D-5428) Avail: CFSTI CSCL 09A

The forward current transfer ratio ($h_{FE} = (\Delta I_{collector}/\Delta I_{base})$) of a germanium junction transistor operating in the common emitter mode is reduced by the application of a magnetic field. This reduction is greatest when the magnetic field vector is perpendicular to the direction of minority carrier motion through the base region. The base thickness is also an important variable. Transistors with smaller base (planar diffused) regions are less affected by magnetic fields. Author

LEAK DETECTION IN HERMETICALLY SEALED DEVICES
I. Litant Washington Oct. 1969 13 p refs
(NASA-TN-D-5457) Avail: CFSTI CSCL 09A

A method for detecting leaks in a hermetically sealed device was developed. The method comprises the introduction of a low-boiling halogenated liquid into the device through the leaks, and detecting the vaporizing liquid as it escapes from the leaks by the use of a halogen detector. The leaks may thus be pinpointed, and the leak rate determined. Author

A TRANSFORMER OF CLOSELY SPACED PULSED WAVEFORMS HAVING A NONZERO AVERAGE VALUE

Janis M. Niedra Washington Oct. 1969 27 p refs

(NASA-TN-D-5473; E-5185) Avail: CFSTI CSCL 09E

With the use of diodes, transistors, and magnetic cores, a passive circuit was constructed that transformed the voltage, either up or down, of repeated positive or negative pulses. This circuit combined a pulse transformer with switching devices to effect a resonant flux reset. It could transform various pulsed waveforms that had a nonzero average value and were relatively closely spaced in time. The circuit provided direct current isolation between multiple loads and between a load and the source, similar to a conventional transformer. Several experimental circuits were tested. Author

APPLICATION OF PRESSURIZED LIQUID NITROGEN INSIDE PARAMETRIC-AMPLIFIER STRUCTURES FOR INPUT-NOISE-TEMPERATURE IMPROVEMENT

Hans-Juergen C. Blume Washington Oct. 1969 31 p refs

(NASA-TN-D-5509) Avail: CFSTI CSCL 09E

The temperature rise caused by power dissipation in lossy capacitance diodes in cooled parametric amplifiers, especially in monostatic high-power radar systems, diminished the noise-reduction effect of the coolant. To obtain good heat conduction from the diode so that it would remain at ambient temperature, liquid nitrogen helium gas under pressure was employed as dielectric material surrounding the lossy diode. All adjustments for optimum performance of a 400-MHz amplifier were accomplished at room temperature before immersion into liquid nitrogen by using calculated and measured values from curves that showed resonant frequency variation of each circuit due to the change of the relative dielectri c constant from 1 to 1.435, the slight change of the physical dimension caused by thermal contraction, and the change of the operating frequency at high gain. Author

ENERGY DISTRIBUTION OF A SPIRALING ELECTRON BEAM

Bernhard Kulke Washington Nov. 1969 25 p refs

(NASA-TN-D-5490) Avail: CFSTI CSCL 09A

A retarding-field analyzer was used to investigate the energy conversion and the energy spread of a spiraling electron beam, where the trajectory is generated from a magnetic corkscrew-magnetic ramp combination. It was found that in the absence of space-charge effects, a relatively narrow, near rectangular energy distribution will be generated by the corkscrew when the axial magnetic field is tuned to cyclotron resonance. The normalized width of this distribution is approximately independent of the degree of energy conversion, in agreement with the theory, and the mean transverse energy varies as the square of the corkscrew current. The magnetic ramp amplifies both the mean transverse energy and the energy spread linearly. Both these quantities also can be estimated by using the mirroring effect of the magnetic ramp, in conjunction with variable corkscrew current. Author

OPTIMAL STOCHASTIC CONTROL.

W. M. Wonham (NASA, Electronics Research Center, Cambridge, Mass.).

IN: STOCHASTIC PROBLEMS IN CONTROL; AMERICAN AUTOMATIC CONTROL COUNCIL, JOINT AUTOMATIC CONTROL CONFERENCE, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICH., JUNE 26, 1968, PROCEEDINGS. [A69-14693 04-10]

New York, American Society of Mechanical Engineers, 1968, p. 107-120.

Brief survey of results obtained from investigations of stochastic control, which has evolved largely within the framework of dynamic programming. Only system models where stochastic elements are featured explicitly are considered. The survey is restricted to small dynamic systems described by random differential equations, the "large" systems of operations research being ignored. The solvable stochastic version of the well-known linear-quadratic regulator problem is presented. The so-called separation theorem is presented and discussed. A system designed to operate partly open-loop, as is the case with some guidance systems, and where corrections are applied only at certain preassigned points along the trajectory is also examined. M. G.

L_2-STABILITY OF TIME-VARYING SYSTEMS - CONSTRUCTION OF MULTIPLIERS WITH PRESCRIBED PHASE CHARACTERISTICS.

M. I. Freedman (NASA, Electronics Research Center, Cambridge, Mass.).

SIAM Journal on Control, vol. 6, Nov. 1968, p. 559-578. 6 refs.

Investigation of a system consisting of a linear element G(s) and a time-varying gain n(·). It is shown that the system is stable for all n(·) in a sector [0, k) if it is assumed that the system is stable for all constant gains in that sector. The proof employs a "multiplier" operator. However, a method is used to eliminate any "multiplier" dependence from the final results, so that these results are explicit and geometric. The techniques developed are believed to show promise of eliminating the multiplier dependence from many recent stability results. G. R.

ON A MATRIX RICCATI EQUATION OF STOCHASTIC CONTROL.

W. M. Wonham (NASA, Electronics Research Center, Cambridge, Mass.).

SIAM Journal on Control, vol. 6, Nov. 1968, p. 681-697. 7 refs.

NSF Grant No. GK-967; Grant No. AF AFOSR 693-67.

Discussion of a generalized version of the matrix Riccati and matrix quadratic equations which arise in problems of stochastic control and filtering. The generalization consists in the addition of a linear positive operator to the linear terms of the standard Riccati equation and, in certain cases, a weakening of the usual hypothesis of complete observability to observability of unstable modes. The proofs given are simple applications of Bellman's principle of quasi-linearization and of a known monotone convergence property of symmetric matrices. Applications to control and filtering are indicated. G. R.

(AMERICAN AUTOMATIC CONTROL COUNCIL, JOINT AUTOMATIC CONTROL CONFERENCE, 9TH, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICH., JUNE 26-28, 1968, *PROCEEDINGS*, p. 364-382.)

IEEE Transactions on Automatic Control, vol. AC-13, Oct. 1968, p. 504-514. 28 refs.

Research supported by the Massachusetts Institute of Technology and ARPA; Grant No. NGR-22-009-124.

Derivation of the dynamical equations of a "second-order" filter which estimates the states of a nonlinear plant on the basis of discrete noisy measurements. The filter equations contain terms involving the second-order partial derivatives of the plant and output equations. Simulation results are presented which yield a comparison of the performance of the first- versus the second-order filter. It is demonstrated that the use of second-order terms in the Taylor series expansion to correct bias errors can improve the performance of a filter which is to estimate the state variables of a nonlinear plant. ON THE STABILIZATION OF CONTROLLABLE SYSTEMS.

William A. Wolovich (NASA, Electronics Research Center, Office of Control Theory and Application, Cambridge, Mass.).

IEEE Transactions on Automatic Control, vol. AC-13, Oct. 1968, p. 569-572. 12 refs.

Conditions are obtained for the asymptotic stabilization of linear dynamical systems through the use of linear state-variable feedback. The procedures developed rely on uniform controllability of the given systems, and yield explicit expressions for the transition matrices of the stabilized systems. As a consequence of the treatment, explicit expressions are obtained for Liapunov transformations which reduce the stabilized systems to canonical (phase-variable) form. Results are given for time-varying multivariable (multiinput) systems. (Author)

ANALYSIS OF COMMUTATED NETWORKS EMPLOYING FEEDBACK CIRCUITS.

Michael T. Borelli (NASA, Marshall Space Flight Center, Huntsville, Ala.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, Jan. 1969, p. 39-45. 5 refs.

A method of analysis has been developed for feedback systems employing commutated networks in the forward loop and linear transfer functions in the feedback loop. The method handles single-phase and polyphase commutated networks as well as coupled and uncoupled networks. Although commutated networks are linear from the superposition theory viewpoint, linear feedback theory is shown to be not applicable because of the harmonics present in the feedback. Techniques for simplifying the analysis of commutated networks by the use of equivalent block diagrams provide additional insights into commutated network operation. (Author)

DOMAIN ANALYSIS AND MEASUREMENT TECHNIQUES FOR DISTRIBUTED RC STRUCTURES. I - ANALYSIS IN THE RECIPROCAL TIME DOMAIN.

W. W. Happ (NASA, Electronics Research Center, Cambridge, Mass.) and S. C. Gupta (Southern Methodist University, Dallas, Tex.).

Journal of Applied Physics, vol. 40, Jan. 1969, p. 109-117. 18 refs.

The impulse response in distributed-parameter systems results in a spectrum of delta functions in the time domain for LC structures. It is shown that for RC structures the impulse response results in a spectrum of Poisson-derived functions in the reciprocal time domain. This isomorphism is exploited for the analysis of RC devices to establish a calculus of Poisson-derived functions and a transform technique which is essentially the Laplace transform. Applications of this technique to thin-film devices and minority-carrier devices are examined and lead to the determination of the transient response for one-ports and two-ports that are subject to a wide range of terminations. Illustrative examples of excitations include the impulse, the step, and the ramp, as well as signals generated by the distributed parameter devices themselves. Significant advantages accrue from a spectral description of RC devices in the reciprocal time domain. (Author)

STABILITY OF SYSTEMS WITH SECTOR NONLINEARITIES - A COMPARISON OF VARIOUS INEQUALITIES.

G. Zames (NASA, Electronics Research Center, Cambridge, Mass.).

IEEE Transactions on Automatic Control, vol. AC-13, Dec. 1968, p. 709-711.

Discussion of a common method of deriving stability conditions of the multiplier-type. This method involves two steps: (1) the feedback equation is transformed into a new equation containing a pair of positive operators; and (2) an appropriate multiplier is introduced. Depending on which of these steps is performed first, two different results are obtained, and it has not been clear in the past whether either result is preferable to the other. It is shown that, under suitable hypotheses, it is preferable to perform step (1) first - i.e., a better stability condition is obtained if the transformation into positive operators is performed before the multiplier is introduced. M. M.

A COMPUTATIONAL APPROACH TO OPTIMAL CONTROL OF STOCHASTIC SATURATING SYSTEMS.

W. M. Wonham and W. F. Cashman (NASA, Electronics Research Center, Cambridge, Mass.).

International Journal of Control, First Series, vol. 10, July 1969, p. 77-98. 20 refs.

Digital computation of a suboptimal nonlinear feedback control for a time-variant linear system subject to additive white noise. The cost functional is the expectation, under stochastically stationary conditions, of a quadratic function of state and control variables. The design of an eighth-order attitude control and of a second-order tracking system are given as examples. For the latter system, the elliptical differential equation of dynamic programming is solved by finite differences to yield the true optimal control, and results are compared with those for the suboptimal control. The procedure can be modified if the observations of the state include additive noise. B. H.

DIGITAL SIMULATION STABILITY CRITERION.

Carl F. Lorenzo and Leslie L. Scalzott (NASA, Lewis Research Center, Cleveland, Ohio).

Instruments and Control Systems, vol. 42, Apr. 1969, p. 113-117. 6 refs.

Discussion of a criterion for computer stability analysis. A digital stability scheme is presented which is premised on the use of only perturbed transient responses. The stability analysis block in the program should be capable of handling any time function (continuous or discontinuous, oscillatory or nonoscillatory, periodic or aperiodic) and any system, linear or nonlinear. The criterion developed is essentially an approximation to asymptotic stability (which requires ultimate state boundedness of the output). G.R.

Conference sponsored by the U.S. Naval Postgraduate School and the University of Santa Clara.

New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 197-201.

Study showing that the use of multiloop feedback provides a considerable reduction in sensitivity and in the gain-sensitivity product in active distributed RC networks as compared to single-loop circuits. Design equations are presented allowing various optimizations depending on the specific requirements. It is concluded that the use of a single RC line provides zero Q sensitivity to passive element variation and allows tuning, for example, by varying the dc bias on a depletion-layer capacity in a monolithic distributed RC structure without any effect on the resonant Q. New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 207-214.

Contracts No. NAS 12-639; No. NASw-1729.

Study of the ability of a phase-lock loop (PLL) demodulator to acquire and remain locked on a desired signal in the presence of receiver noise and pulse interference such as that generated by radar equipments. Measurements were conducted over a wide range of PLL operating conditions for a typical space instrumentation receiver. The PLL and interference signal parameters varied during the test included the desired signal-to-noise ratio, the signal-to-interference ratio, the offset of the pulse carrier frequency from the desired signal, the pulse width and pulse repetition rate of the interference signal, and the receiver tracking bandwidth. ANALYSIS OF COMMUTATED NETWORKS EMPLOYING FEEDBACK CIRCUITS

Michael T. Borelli Washington Nov. 1968 93 p refs

(NASA-TN-D-4893) Avail: CFSTI CSCL 09E

The development of advanced automatic control systems often requires new and unusual circuits, components, techniques, and other such items, to provide the necessary control to accomplish a specific mission. An adaptive automatic flight control system for large space booster vehicles has been developed that uses tracking-notch filters composed of commutated networks (CN's) From this successful application and others cited in the literature, it appears that these networks are particularly well suited for use in tracking filters. In this investigation of CN's and in most practical cases, the reactive elements are capacitors. The commutation action in a resistor–capacitor CN can transform the frequency response characteristics of a low pass filter into that of a highly selective band pass filter. Effective low-frequency band pass or band elimination filters can be realized without the use of magnetic elements. These and other transformations of a network's basic characteristics provide very interesting properties that are useful for some special applications. The methods of analysis are those employing full-wave balanced commutation and include: (1) classical method; (2) difference equations; (3) modulation equivalents; and (4) Laplace transforms. Author

ANALYSIS AND DESIGN OF INDUCTORS FOR PROTECTING POWER TRANSISTORS AGAINST CURRENT SURGES IN INVERTER BRIDGE CIRCUITS

Francis Gourash Washington Jan. 1969 46 p refs

(NASA-TN-D-4995) Avail: CFSTI CSCL 09A

An analysis of transistor inverter and converter bridge circuits shows that surge currents exist during the switching time interval. These currents result from transistor unequal turnon and turnoff switching characteristics. The surge currents are limited only by the resistance of the power source and the saturated resistance of the transistors. They can reach peak values which exceed the transistor's maximum current rating by an order of magnitude. Inductors avoid transistor failure by limiting the current surges to safe levels. They also substantially reduce the circuit power loss due to the surge currents. A technique for the design of inductors with the proper inductance is presented. Author

INVERTER-CONVERTER AUTOMATIC PARALLELING AND PROTECTION

C. L. Doughman, B. A. Marino, and N. D. Lenhart Washington NASA Feb. 1969 164 p refs

(Contract NAS3-2792)

(NASA-CR-1225) Avail: CFSTI CSCL 09E

Electrical control and protection circuits are developed for a multi-channel, paralleled ac system and for a multi-channeled, paralleled dc system. Electrical control for each of the two systems consists of automatic paralleling circuits and electrical contactor control circuits. Protection circuits for the ac system include overvoltage, undervoltage, overfrequency, underfrequency, frequency reference protection, overcurrent, load division and differential current. Protection circuits for the dc system are the same as for the ac system except that no frequency protection circuits are included. Test results verify and demonstrate the developed technology. A SUBOPTIMAL APPROXIMATION TO THE KALMAN FILTER

Leon Bess Washington Mar. 1969 28 p refs

(NASA-TN-D-5082) Avail: CFSTI CSCL 09C

A suboptimal estimation scheme similar to the Kalman filter is described which makes use of scalar weighting factors instead of matrix factors. It is shown that the accuracy degradation of the suboptimal estimator is not too great for most cases of practical interest. Moreover, it readily lends itself to physical interpretation. Author

NOISE IN AXISYMMETRIC CONVERGENT ELECTRON BEAMS

H. G. Kosmahl and L. U. Albers Washington May 1969 62 p refs

(NASA-TN-D-5212) Avail: CFSTI CSCL 09E

The noise along axisymmetric convergent electron beams used in O-type high power microwave tubes was investigated analytically as a function of several tube design parameters. The computations and investigations were carried out for magnetically fully confined flow, Brouillon flow, and electrostatically focused flow for power levels near 1 kW and perveances from 0.1×10^{-6} to 1.0×10^{-6}. The computed minimum noise figures ranged between 20 and 60 db depending on voltage, perveance, area convergence, and gun design. Author

DESIGN CONSIDERATIONS FOR CYCLOTRON RESONANCE OSCILLATORS

Bernhard Kulke Washington Jun. 1969 38 p refs

10 ELECTRONICS

(NASA-TN-D-5237) Avail: CFSTI CSCL 09E

From the linearized kinetic theory of stimulated cyclotron radiation, and from related physical arguments, some design criteria are deduced for spiraling-beam cyclotron-resonance oscillators for possible use at millimeter-wave frequencies. While an optimum choice of the geometry of the interaction region is important, the most essential design problem is the control and minimization of the axial velocity spread on the spiraling beam. FLIGHT TEST EVALUATION OF A SMALL ONE-MAN LUNAR FLYING DEVICE.
Maxwell W. Goode (NASA, *Langley Research Center, Space* Mechanics Div., Hampton, Va.) and Lee H. Person, Jr. (NASA, Langley Research Center, Flight Mechanics and Technology Div., Hampton, Va.).
(American Institute of Aeronautics and Astronautics, Flight Test, Simulation and Support Conference, 2nd, Los Angeles, Calif., Mar. 25-27, 1968, Paper 68-240.)
Journal of Spacecraft and Rockets, vol. 5, Dec. 1968, p. 1468-1472.

Initial test evaluation of a small one-man flying device referred to as "POGO," and discussion of the feasibility of the vehicle control concept, the piloting differences between earth and lunar gravity, and the impact of pressure suits on vehicle handling qualities. The concept of direct manual control of a thrust vector (proportional acceleration command system) appears to be feasible. Pitch and roll control sensitivities were too high - resulting in a disharmony between attitude and translational capabilities. The test results have indicated that the effects of the pressure suits on the handling qualities of the vehicle did not present any major problems. The piloting differences between earth and lunar gravity operations are sufficient to warrant training of astronauts in simulated lunar gravity.

AUTOMATIC CONTROLS FOR FACILITIES AND MERCURY ION THRUSTERS IN DURABILITY TESTING.
C. R. Nichols (NASA, Lewis Research Center, Research Facilities Section, Cleveland, Ohio) and S. J. Obloy (NASA, Lewis Research Center, Electronics Section, Cleveland, Ohio).
(American Institute of Aeronautics and Astronautics, Propulsion Joint Specialist Conference, 4th, Cleveland, Ohio, June 10-14, 1968, Paper 68-576.)
Journal of Spacecraft and Rockets, vol. 5, Dec. 1968, p. 1484-1486. 7 refs.

Description of design alterations in several vacuum chamber systems of Lewis Research Center, carried out as a result of three-year durability tests, to provide for automatic shutdown during unattended operation. These alterations and the use of thruster-control circuits permitted a vacuum-chamber operation with reduced support manpower. The 8.5 to 850-m^3 chambers use normal roughing, oil-diffusion, and cryopumping systems. Chamber pressure, with thrusters operating, is typically in the 10^{-7}-torr range. Also described are thruster controls allowing continuous testing of ion thrusters for almost three months with only one man per shift.

WEFAX - WEATHER DATA RELAY COMMUNICATIONS EXPERIMENT.
Sheldon Wishna (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: EASCON '68; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ELECTRONICS AND AEROSPACE SYSTEMS CONVENTION, WASHINGTON, D.C., SEPTEMBER 9-11, 1968, RECORD. [A69-13176 03-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 496-500.

Description of WEFAX (abbreviation for Weather Facsimile), an experiment designed to explore the operational feasibility of direct transmission, via a satellite relay, of meteorological data from a central weather station source to widely scattered remote weather stations or receiving units. The transmission media used for the experiment are the vhf communication facilities of the ATS-1 (Applications Technology Satellite), while the receiving stations cooperating in this program are the network of APT (Automatic Picture Transmission) ground stations. The WEFAX experiment has been highly successful in demonstrating the feasibility of transmitting weather data via a synchronous satellite. Usable receptions can be assured nearly 95% of the time. M.M.

FACTORS INFLUENCING THE CHOICE OF FACILITIES AND TECHNIQUES FOR AERONAUTICAL DEVELOPMENT.
Richard E. Kuhn (NASA, Langley Research Center, Hampton, Va.).
(New York Academy of Sciences, International Congress on Subsonic Aeronautics, New York, N.Y., Apr. 3-6, 1967.)
New York Academy of Sciences, Annals, vol. 154, Nov. 22, 1968, p. 1036-1054. 25 refs.

Examination of factors in the development of aeronautical tools such as wind tunnels, tow-test rigs, etc. As an example of how the nature of the system to be tested can affect the nature of the test itself, it is noted that the large deflections of the air flow that V/STOLs produce have required that oversized wind-tunnels and specialized towed rigs be used. The introduction of variable sweep required a reevaluation of the entire longitudinal-stability area. Work with the jumbo jets highlighted another problem area: the gap between the Reynolds number capability of existing tunnels and the actual flight Reynolds numbers. A number of specialized facilities have been developed for the determination of aerodynamic derivatives necessary in the study of the dynamic motions of aircraft. Operational considerations as noise and IFR traffic control are also discussed. G.R.

WIND-TUNNEL WALL EFFECTS AT EXTREME FORCE COEFFICIENTS.
Harry H. Heyson (NASA, Langley Research Center, Hampton, Va.).
(New York Academy of Sciences, International Congress on Subsonic Aeronautics, New York, N.Y., Apr. 3-6, 1967.)
New York Academy of Sciences, Annals, vol. 154, Nov. 22, 1968, p. 1074-1093. 37 refs.

Study of wall constraints at extreme force coefficients, the magnitude of which in V/STOL testing has been shown experimentally to be large and to differ from the effects noted in conventional testing. A progress report on theoretical work now being conducted by NASA, the University of Washington, and the Boeing Company is presented. Some of the real effects encountered in wind-tunnel testing are also discussed. These include the requirements for moving belts in ground-effect testing, and the recirculation limits on minimum speed which have been discovered in tests at the University of Washington. F.R.L.

A69-15575 *
A REVIEW OF FACILITIES AND TEST TECHNIQUES USED IN LOW-SPEED FLIGHT.
Seth B. Anderson and Laurel G. Schroers (NASA, Ames Research Center, Moffett Field, Calif.).
(New York Academy of Sciences, International Congress on Subsonic Aeronautics, New York, N.Y., Apr. 3-6, 1967.)
New York Academy of Sciences, Annals, vol. 154, Nov. 22, 1968, p. 1094-1114. 11 refs.

Discussion of the means by which new facilities, developed to support flight-test programs, and new flight techniques, devised to help explore problem areas, have been applied. The relative merits and limitations of each facility and technique are pointed out, and future needs are discussed. Principal attention is given to the facilities and test techniques for studying low-speed problems of handling qualities, stability and control, and performance. A typical problem has been chosen to illustrate the relationship between facilities. F.R.L.

UNIFORMITY OF PROTON BEAMS AVAILABLE AT THE NASA SYNCHROCYCLOTRON (SREL).
Gerald F. Hill, William C. Honaker, and K. H. Kim (NASA, Langley Research Center, Hampton, Va.).
(Radiological Society of North America, Scientific Assembly and Annual Meeting, Chicago, Ill., Nov. 26-Dec. 1, 1967.)
Radiology, vol. 91, Sept. 1968, p. 562-567. 6 refs.

Summary of approximately 30 beam configurations which are available with a 600 MeV proton synchrocyclotron used in space-radiation research. Attention is given to such parameters as proton beam energy, energy spread, intensity, intensity profile, repeatability, and area. The results are primarily related to large-area beams, which are of interest to experimenters studying the radiation effects of protons on animals. Uniformity of several large-area beams is discussed in terms of dose-rate (rads/min) in muscle. B.H.

CHARACTERISTICS OF COMPOSITE CARBON RESISTORS USED FOR MEASURING ACCELERATOR TERMINAL VOLTAGES.
F. R. Stevenson and D. J. Gauntner (NASA, Lewis Research Center, Cleveland, Ohio).
Review of Scientific Instruments, vol. 40, Jan. 1969, p. 140-144. 16 refs.

Investigation of a voltage divider board composed of 1152, 22 MΩ composite carbon resistors used to measure the terminal voltage of a 3 MeV Dynamitron. The board was calibrated in situ using the ^{9}Be and D photoneutron threshold reactions and a magnetic analyzer. The present calibration of the divider board, which was made after over 5 years of extensive accelerator usage, agrees within 2% with the original factory calibration. The linear temperature coefficient of resistance was measured to be $+(0.85 \pm 0.10) \times 10^{-3}/^{\circ}C$ in the range 25 to 35°C. The divider board resistance decreased linearly with voltage ($-1.1 \times 10^{-5}\%/V$) up to 2 MeV which corresponds to 1750 V on each resistor. The results show that composite carbon resistors and the techniques described can be applied with confidence to the measurement of high voltage. (Author)

IN SITU VACUUM TESTING - A MUST FOR CERTAIN ELASTOMERIC MATERIALS.
John P. Mugler, Jr. (NASA, Langley Research Center, Space Environment Branch, Hampton, Va.), Lawrence R. Greenwood, William S. Lassiter (NASA, Langley Research Center, Hampton, Va.), and Robert A. Comparin (Virginia Polytechnic Institute, Blacksburg, Va.).
(SPACE SIMULATION CONFERENCE, 3RD, SEATTLE, WASH., SEPTEMBER 16-18, 1968, PROCEEDINGS, p. 85-89.)
Journal of Spacecraft and Rockets, vol. 6, Feb. 1969, p. 219-221.

An experimental program has been conducted to measure the vacuum-induced changes in the mechanical and thermal properties of several filled elastomers wherein both in-situ and before-and-after tests were conducted. The results from the in-situ tests showed that vacuum exposure caused substantial increases in maximum stress and modulus of solid rocket fuel and decreases in thermal conductivity of heat-shield material even though the vacuum weight loss was small. A comparison of the results from the in-situ and before-and-after tests showed that in-situ vacuum testing was necessary to obtain valid measurements of the vacuum-induced changes because reexposure of the materials to the atmosphere caused the properties to substantially or fully revert to their preexposure values. (Author)

A PYROTECHNIC-ACTIVATED CALORIMETER FOR FLIGHT RESEARCH AT LUNAR RETURN VELOCITY.
Don D. Davis, Jr. and Clotaire Wood (NASA, Langley Research Center, Hampton, Va.).
IN: USE OF PYROTECHNIC AND EXPLOSIVE ELEMENTS IN SPACE SYSTEMS; CENTRE NATIONAL D'ETUDES SPATIALES, INTERNATIONAL CONFERENCE, TARBES, HAUTES-PYRENEES, FRANCE, JULY 9-12, 1968, PROCEEDINGS [UTILISATION DES ELEMENTS PYROTECHNIQUES ET EXPLOSIFS DANS LES SYSTEMES SPATIAUX; CENTRE NATIONAL D'ETUDES SPATIALES, COLLOQUE INTERNATIONAL, TARBES, HAUTES-PYRENEES, FRANCE, JULY 9-12, 1968, PROCEEDINGS]. [A69-23003 10-27]
Paris, Dunod Editeur, 1969, p. 369-378.

Discussion of a rather unique application of a pyrotechnic device to solve a problem that was encountered in the design of the reentry package for Project Fire. Project Fire was undertaken by NASA to investigate the heating environment of vehicles entering the earth's atmosphere at velocities slightly greater than lunar return velocities. The primary object was to obtain onboard measurements that would define the hot-gas radiance and the total heating on a blunt-nosed body of fairly large scale. These results, on a firmly established basis, were needed to test various theoretical and empirical heat-transfer prediction techniques that had been proposed by individual research scientists, as well as others that would be proposed in the future. P.v.T.

MICROELECTRONIC DATA AND CONTROL TRANSMISSION SYSTEM FOR DYNAMIC WIND-TUNNEL TESTING.
James H. Schrader and C. D. Nichols (NASA, Langley Research Center, Hampton, Va.).
IN: INSTRUMENTATION IN THE AEROSPACE INDUSTRY. VOLUME 14 - INSTRUMENT SOCIETY OF AMERICA, INTERNATIONAL AEROSPACE INSTRUMENTATION SYMPOSIUM, 14TH, BOSTON, MASS., JUNE 3-5, 1968, PROCEEDINGS. [A69-23245 10-11]
Edited by John Leak.
Pittsburgh, Instrument Society of America, 1968, p. 252-256.
Description of a microelectronic data and control transmission system designed for use in a wind tunnel where access to the test model is not practical during a relatively long period of time covering a series of test conditions. It provides for remote control of various electromechanical transducers in the model, and ensures complete remote setup capability on the data system. The overall system is capable of transmitting up to 20 high-response data signals from the model and up to 54 auxiliary control functions to the model over a single 1/16-in. diameter cable. (Author)

APOLLO MISSION SIMULATION WITH VISUAL PRESENTATION.
Riley David McCafferty (NASA, Manned Spacecraft Center, Kennedy Space Center, Fla.) and Lawrence W. Lockwood (General Electric Co., Apollo Systems Dept., Houston, Tex.).
Society of Motion Picture and Television Engineers, Technical Conference, 105th, Miami Beach, Fla., Apr. 20-25, 1969, Paper 105-74. 16 p.
$0.50.
Description of the command module simulator for the Apollo Program, and delineation of the onboard computer system and the dynamically controlled visual presentation. All simulated systems functions are originated in computer software packages, which functionally tie the onboard computer, and the guidance, navigation, and orbital mechanics together with a dynamic visual presentation via an infinity-optics display to supply composite training capability. Realistic visual simulation of the views which would be seen from the spacecraft at any portion of the mission is provided to the astronauts in the simulator trainer. M.M.

FOUR-GIMBAL SYSTEMS FOR SIMULATION DISPLAY.
John W. Wilson (NASA, Langley Research Center, Hampton, Va.).
Simulation, vol. 12, Mar. 1969, p. 115-120. 8 refs.
Discussion of a driving law for the fourth angle for two different four-gimbal systems. The first system has advantages in design and implementation for platform isolation. The second is specifically designed to minimize occlusion in visual display systems. In each system, the fourth-angle driving law is a direct consequence of maximizing the angle between the two axes causing the singularity. Thus, a necessary differential constraint is found to maintain a nonsingular solution. A sufficiency condition for a nonsingular solution is also found. The second four-gimbal system that minimizes occlusion has the interesting result that the maximum angle between the singularity-forming axes is not always 90°. G.R.

A SOLUTION TO TRITIUM PUMP CONTAMINATION FOR SMALL ACCELERATORS.
Robert Steinberg and Donald L. Alger (NASA, Lewis Research Center, Cleveland, Ohio).
American Nuclear Society, Conference on Small Accelerators, New York, N.Y., Apr. 8, 9, 1969, Paper. 9 p.

Description of a method for reducing tritium contamination in a small 200-kV, 15-mA positive ion accelerator designed primarily for the production of neutrons. The vacuum system associated with the small accelerator is designed for reducing problems arising because: (1) the diffusion pump exhausts tritium to the surrounding area through the roughing pump, and (2) after prolonged pumping of tritium, the getter-ion pump becomes unstable, necessitating the changing or cleaning of its elements accompanied by a release of tritium. A solution to these problems is suggested which involves the separation of the static (beam) and dynamic (beam on) pumping functions and the incorporation of a titanium bulk sublimator into the vacuum system. The system permanently buries tritium in the pump chamber walls, thus reducing the problem of uncontrolled tritium release. Separation of the pumping functions has the advantage that the sublimator provides considerable pumping speed in the 1×10^{-4} to 2×10^{-3} torr range where start-up can be difficult for a getter-ion pump alone. LIGHTWEIGHT, HIGH-THERMAL-CAPACITY FORCE MODELS FOR USE IN ARC TUNNELS.
James G. Fowke and James N. Mueller (NASA, Langley Research Center, Hampton, Va.).
Journal of Spacecraft and Rockets, vol. 6, Mar. 1969, p. 326, 327.

Discussion of lightweight, high-heat-capacity uncooled models for satisfying model-balance compatibility during force tests in high-enthalpy hypersonic arc tunnels at high simulated altitudes. The models discussed are made of copper or beryllium coated with pure cobalt. G.R.

A69-27906 *
THE LUNAR COLONY.
R. W. Johnson (NASA, Advanced Manned Missions Program Office, Washington, D.C.).
Science Journal, vol. 5, May 1969, p. 82-88.

Description of the various stages of development of a lunar colony. The stages described comprise the use of the Lunar Module for the first scientific studies, the establishment of semipermanent bases, and finally a permanent colony. The construction of large permanent lunar bases is discussed in detail, taking account of the solution of special problems connected with the supply of oxygen, food, water, power, and transportation. Convincing reasons why such a colony should be established to support a lunar scientific observatory are cited. G.R.

A PROGRAM PLAN FOR EARTH ORBITAL SPACE ASTRONOMY.
Jean R. Olivier (NASA, Marshall Space Flight Center, Huntsville, Ala.) and Harry L. Wolbers (McDonnell Douglas Corp., McDonnell Douglas Astronautics Co., Huntington Beach, Calif.).
IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, Mar. 1969, p. 242-252.

Manned space flight offers the opportunity to couple the astronaut/scientist's ability to select and process data and to calibrate, modify, and repair instruments with the vantage point for astronomical observations provided by a platform located above the earth's atmosphere. The role which manned space flight may play in the 1970-1990 time period in meeting astronomical research needs is examined. The instruments and facilities that appear feasible for that period are described. (Author)

APPLICATIONS OF A TUBE WIND TUNNEL IN SUPERSONIC TESTING.
William J. Sheeran, Kenneth C. Hendershot (Cornell Aeronautical Laboratory, Inc., Hypersonic Facilities Dept., Buffalo, N.Y.), and Homer B. Wilson, Jr. (NASA, Marshall Space Flight Center, Thermal Environment Branch, Huntsville, Ala.).
American Institute of Aeronautics and Astronautics, Aerodynamic Testing Conference, 4th, Cincinnati, Ohio, Apr. 28-30, 1969, Paper 69-335. 16 p. 17 refs.
Members, $1.00; nonmembers, $1.50.

Discussion of the operation and applications of the short-duration tube wind tunnel at the Cornell Aeronautical Laboratory. This facility has been in operation for a number of years and is capable of providing supersonic test environments at freestream Reynolds numbers of up to 4×10^7 ft^{-1}. The facility is a modification of the Ludwieg pressure-tube type of wind tunnel and has a steady flow duration of approximately 40 msec when using room-temperature air as the test gas. This test period is more than adequate to establish the model flowfields and to make the desired measurements. Base-heating tests involving a Saturn S-IC model are described, as well as base-burning investigations conducted with a scale-model solid propellant rocket. The use of this facility in basic investigations of rocket plumes and the evaluation of blast-wave effects is also discussed. (Author)

THE AMES COMBINED HEATING FACILITY.
Forrest E. Gowen and Frank H. Nichols (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerodynamic Testing Conference, 4th, Cincinnati, Ohio, Apr. 28-30, 1969, Paper 69-342. 7 p. 10 refs.
Members, $1.00; nonmembers, $1.50.

The paper describes a facility that can be used for testing ablative heat-shield material models with diameters as large as 10 cm, in a combined convective and radiative heating environment with constant or transient heating conditions. With this size model, convective heating rates as large as 1000 W/cm^2 coupled with radiative heating rates up to about 900 W/cm^2 are available. Data from initial tests conducted in the facility are presented. They include results from calibrations of the convective and radiative heating systems as well as results from the first transient heating tests, with heating cycles which simulate realistic manned entry heating environments. MANNED AEROSPACE SIMULATION.
Donald C. Dust, Ronald D. Denison, and Robert E. Coate (NASA, Ames Research Center, Moffett Field, Calif.).
American Society of Mechanical Engineers, Design Engineering Conference and Show, New York, N.Y., May 5-8, 1969, Paper 69-DE-27. 7 p.
Members, $0.75; nonmembers, $1.50.

Description of the techniques and equipment used at NASA-Ames for manned aerospace simulation to produce research results applicable to the design and development of aerospace vehicles. How these same techniques and equipment can be applied to research applicable to other types of manned vehicles is discussed. Why and how simulators are useful in research are explained. The equipment required to provide a useful simulation system is divided into four main areas which include the computing, motion, visual, and audio systems. The requirements and specifications of these various systems and how they add to the realism of the simulator and the validity of the research results are shown. (Author)

EXPLORATORY INVESTIGATION ON THE MEASUREMENT OF SKIN FRICTION BY MEANS OF LIQUID CRYSTALS.
E. J. Klein and A. P. Margozzi (NASA, Ames Research Center, Moffett Field, Calif.).
(Israel Journal of Technology, vol. 7, no. 1-2, 1969, p. 173-180.)
IN: ISRAEL ANNUAL CONFERENCE ON AVIATION AND ASTRONAUTICS, 11TH, TEL-AVIV AND HAIFA, ISRAEL, MARCH 5, 6, 1969, PROCEEDINGS. [A69-29011 14-12]
Jerusalem, Weizmann Science Press of Israel, 1969, p. 173-180.
5 refs.

New method proposed for the direct measurement of local skin

friction in aerodynamic testing makes use of thin coatings of cholesteric liquid crystal mixtures which respond to shearing forces by changes in their wavelength of maximum light scattering. A calibration of shear versus wavelength was obtained for a sample substance; a static calibration was made to measure the effects of temperature, pressure, and angle of viewing; and the behavior of the substance was observed in a pipe-flow experiment. Preliminary results showed that the method appears feasible. However, for such a method to become widely applicable in wind-tunnel testing, further research will be needed - i.e., to obtain liquid crystal mixtures sensitive over appropriate ranges on the shear scale, to prevent the occurrence of roughness on the surface of liquid crystal coating subjected to aerodynamic shear forces, and to develop a suitable optical measuring technique for data acquisition. IN: MAN IN HIS ENVIRONMENT; INSTITUTE OF ENVIRONMENTAL SCIENCES, ANNUAL TECHNICAL MEETING AND EQUIPMENT EXPOSITION, 15TH, ANAHEIM, CALIF., APRIL 20-24, 1969, PROCEEDINGS. [A69-30356 15-11]

Mt. Prospect, Ill., Institute of Environmental Sciences, 1969, p. 347-353.

Contract No. NAS 2-3921.

Description of a versatile high-intensity solar radiation simulator currently being used for both high- and low-intensity testing. Designed for thermal balance tests, power conversion studies, and material degradation experiments, it uses a 20-kw xenon lamp and a 5-kw krypton lamp as sources and may be run in three basic optical modes: (1) a 4-5/8-in.-diam target plane with radiant intensities from 10 to 40 solar constants; (2) a 12-in. target plane with intensities up to 8 solar constants; and (3) a 30-in. target plane with intensities up to 2 solar constants. In addition, operation with the krypton source only provides solar intensities as low as 1/25 of a solar constant without any modification of the optical system. The maximum variations in uniformity throughout the target planes for the three modes are approximately ±2.5%, ±3.0%, and ±3.5%, respectively. The optical, mechanical, and electrical design of the system is described in detail. System performance for the first 450 hr of operation is presented. F.R.L.

PROBLEMS OF FLOW SIMULATION IN WIND TUNNELS.

J. Lloyd Jones (NASA, Ames Research Center, Aeronautics Div., Moffett Field, Calif.).

American Institute of Aeronautics and Astronautics, Fluid and Plasma Dynamics Conference, San Francisco, Calif., June 16-18, 1969, Paper 69-660. 9 p. 18 refs.

Members, $1.00; nonmembers, $1.50.

Illustration of flow-simulation problems that are generated or amplified as a result of recent trends in aircraft design that require more detailed attention to local flow conditions on models in wind-tunnel tests to assure that the test results can be used to predict adequately the aerodynamic characteristics of the aircraft. Because the effects of viscosity are fundamental in the proper modeling of local flows in wind-tunnel tests, the boundary layer and its coupling with the external flow are key features in the examples cited. These examples include problems of providing known boundary-layer-flow characteristics and problems resulting from flow separation and shock-boundary-layer interactions. Test techniques to resolve some of these simulation problems are discussed, and limitations of existing wind-tunnel facilities are examined in relation to these problems. (Author)

THE FLOW THROUGHOUT A WIND TUNNEL CONTAINING A ROTOR WITH A SHARPLY DEFLECTED WAKE.

Harry H. Heyson (NASA, Langley Research Center, Hampton, Va.).

IN: AERODYNAMICS OF ROTARY WING AND V/STOL AIRCRAFT; CORNELL AERONAUTICAL LABORATORY AND U.S. ARMY AVIATION MATERIEL LABORATORIES, SYMPOSIUM, 3RD, BUFFALO, N.Y., JUNE 18-20, 1969, PROCEEDINGS. VOLUME 2 - WIND TUNNEL TESTING, NEW CONCEPTS IN ROTOR CONTROL. [A69-35226 18-01]

Buffalo, N.Y., Cornell Aeronautical Laboratory, Inc., 1969. 45 p. 42 refs.

Examination of the flowfield throughout a wind tunnel of a rotor with sharply deflected blades, using modified NASA TR R-124 and TR R-302 computer programs. The general nature of the computed flowfield is verified by flow studies. The predominant effect at low speed is a region of reversed flow in front of the wake near the floor. This region initiates large-scale vortices in the flow which are the apparent cause of the minimum-speed V/STOL testing limits. V.P.M.

FLASH X-RAY TECHNIQUE FOR RECESSION MEASUREMENTS IN ABLATING MODELS.
P. C. Kassel, Jr. (NASA, Langley Research Center, Hampton, Va.).
IN: ICIASF '69; INTERNATIONAL CONGRESS ON INSTRUMENTATION IN AEROSPACE SIMULATION FACILITIES, 3RD, POLYTECHNIC INSTITUTE OF BROOKLYN, FARMINGDALE, N.Y., MAY 5-8, 1969, RECORD. (A69-35714 19-11)
New York, Institute of Electrical and Electronics Engineers, Inc. (IEEE Publication 69 C 19-AES), 1969, p. 63-67.

A commercial flash X-ray unit, in conjunction with one of two special film transport devices, has been used to obtain sequenced dynamic radiographs of ablating models during reentry simulation tests at an arc jet facility. A technique is described for obtaining, from these radiographs, the location of the surface and the char-virgin material interface of the model as a function of time. (Author)

ELECTRON BEAM FLOW VISUALIZATION IN HYPERSONIC HELIUM FLOW.
Leonard M. Weinstein, Richard D. Wagner, Jr., Arthur Henderson, Jr., and Stewart L. Ocheltree (NASA, Langley Research Center, Hampton, Va.).
IN: ICIASF '69; INTERNATIONAL CONGRESS ON INSTRUMENTATION IN AEROSPACE SIMULATION FACILITIES, 3RD, POLYTECHNIC INSTITUTE OF BROOKLYN, FARMINGDALE, N.Y., MAY 5-8, 1969, RECORD. (A69-35714 19-11)
New York, Institute of Electrical and Electronics Engineers, Inc. (IEEE Publication 69 C 19-AES), 1969, p. 72-78. 18 refs.

An electron-beam fluorescence probe and the afterglow associated with it have been investigated for visualizing hypersonic helium flowfields. Although densities were generally too high for quantitative measurements with the electron beam, the qualitative visualization allows flow structure to be observed. The value and versatility of the method is demonstrated by the results obtained during several research projects in which the fluorescence probe and afterglow were used. (Author)

A 500,000 SAMPLE PER SECOND DIGITAL RECORDER FOR THE AMES ELECTRIC ARC SHOCK TUNNEL.
H. Lee Seegmiller and Louis Mazer (NASA, Ames Research Center, Moffett Field, Calif.).
IN: ICIASF '69; INTERNATIONAL CONGRESS ON INSTRUMENTATION IN AEROSPACE SIMULATION FACILITIES, 3RD, POLYTECHNIC INSTITUTE OF BROOKLYN, FARMINGDALE, N.Y., MAY 5-8, 1969, RECORD. (A69-35714 19-11)
New York, Institute of Electrical and Electronics Engineers, Inc., (IEEE Publication 69 C 19-AES), 1969, p. 243-247.

Description of a 500,000 sample per second digital data acquisition system for the Ames electric arc shock tunnel. As many as 24 analog input signals can be accepted, and full-scale output may be obtained from input voltages in 10 ranges between 0.5 and 500 mV. Bipolar 8-bit information is stored in four parallel magnetostrictive delay lines during a 10 msec period and is recirculated for nondestructive interrogation. Examples of model pressure and heat-transfer data obtained in the expanding nozzle flow of the shock tunnel are presented. The shielding and grounding arrangement are also described. (Author)

THE IMPACT OF FAILURE DATA ON MANAGEMENT OF A LAUNCH OPERATIONS RELIABILITY PROGRAM.
Robert E. Cato, Jr. (NASA, Kennedy Space Center, Cocoa Beach, Fla.) and Wallace C. Wheadon (General Electric Co., Cocoa Beach, Fla.).
IN: ANNALS OF ASSURANCE SCIENCES; PROCEEDINGS OF THE EIGHTH RELIABILITY AND MAINTAINABILITY CONFERENCE, DENVER, COLO., JULY 7-9, 1969. (A69-35999 19-15)
Conference sponsored by the American Institute of Aeronautics and Astronautics, the Society of Automotive Engineers, and the American Society of Mechanical Engineers.
New York, Gordon and Breach, Science Publishers, Inc., 1969, p. 238-243.

Discussion of efforts which have been made to conduct a responsible launch-operations reliability program with existing failure data. The basic reliability organization and requirements are discussed, and the corrective action program which is one potential source of field-failure data is reviewed. Reliability problems which occured as a result of poor data are discussed. Recovery plans to obtain acceptable field-failure data and the manner in which such data could be used to upgrade the existing program are treated. M.M.

ANALYSIS OF A MULTIPLICATIVE FEED SYSTEM FOR MONOPULSE TRACKING APPLICATIONS.

Hugh P. Taylor (Ewen Knight Corp., East Natick, Mass.), George G. Haroules, and Wilfred E. Brown (NASA, Electronics Research Center, Cambridge, Mass.).
IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, July 1969, p. 581-588.

In angle tracking antenna applications, the angle sensing boresight accuracy capabilities are important. The ability of an antenna to precisely determine the bearing angle to a point source is determined by the slope of the control function pattern at boresight. In the presence of extraneous interference, the magnitudes of the sidelobe and backlobe responses are important. Control pattern slope (angular sensitivity) is primarily a function of aperture illumination. It can be described by a current distribution in intensity and phase at every point. Once distribution is defined, lobe structure is defined by the associated transform. When more than one feed is used, the distribution will be a vector sum of the individual feed distributions. The resulting secondary pattern can be defined in terms of the amplitude distribution and the phase center locations of the contributing feeds. With a four-horn monopulse configuration, the feed phase centers are displaced from the boresight axis. Placing the phase centers on the boresight axis by rotating the feeds through 45 deg results in a different set of intensity and phase values. A quite different secondary pattern results. The control function obtained by the subtraction of the powers from a paired set of on-axis feeds results in a lower sidelobe level than that obtained with a conventional monopulse combiner for a given feed taper. Castle (Textron, Inc., Spectrolab Div., Sylmar, Calif.), Robert Fink (Hughes Aircraft Co., Culver City, Calif.), J. S. Griffith (California Institute of Technology, Jet Propulsion Laboratory, Pasadena, Calif.), Peter Lenn (U.S. Army, Materiel Command, Washington, D.C.), Malcolm Lillywhite (Martin Marietta Corp., Friendship International Airport, Md.), L. A. Nelson (McDonnell Douglas Corp., St. Louis, Mo.), A. F. Matel (Hughes Aircraft Co., Culver City, Calif.), and C. W. Quillin (Textron, Inc., Spectrolab Div., Sylmar, Calif.).
Mt. Prospect, Ill., Institute of Environmental Sciences, 1968. 165 p. 107 refs.
Members, $5.00; nonmembers, $9.00.

This handbook is a compilation of the most useful information on solar simulation for simulator operators, designers of facilities, spacecraft thermal designers, and others connected with space simulation testing. A further purpose is to aid in communication between workers in the field; hence there are sections on nomenclature, test requirements, system parameters, and other subjects. The space environment is described, with emphasis on the thermally important properties of space. The handbook emphasizes solar simulators used for thermal vacuum testing. Since system integration tests require essentially the same environment as thermal balance testing, and the tests frequently are run concurrently, the handbook in practice covers the facility requirements of this type of testing as well. Brief attention is given to other types of space simulation testing and their individual requirements. The tentative standard for space and solar simulation, MIL-STD-810B, Test Method 517, which proposes a somewhat idealized requirement, is discussed. A scale of requirements with various degrees of simulation accuracy is provided. Solar simulators themselves are discussed with reference to systems, sources, and components. Parameters of good solar simulators and components are given, with numerous examples. Solar simulator effects on thermal control coatings are considered. Solar instrumentation and current methods of measuring spectral irradiance are described, as well as the necessary cold shroud and vacuum requirements. Suggestions on operation and maintenance are provided. F.R.L.

PHYSICAL, CHEMICAL, AND BIOLOGICAL ACTIVITIES AT THE LUNAR RECEIVING LABORATORY.
W. W. Kemmerer, Jr., J. A. Mason, and B. C. Wooley (NASA, Manned Spacecraft Center, Lunar Receiving Laboratory, Houston, Tex.).
BioScience, vol. 19, Aug. 1969, p. 712-715.

Description of the quarantine and release policies for crew and lunar samples followed in the NASA Lunar Receiving Laboratory. The activities of the three functional areas of the laboratory—namely, the sample operations area, the crew reception area, and the administration and support area—are described. The first two areas are confined within the unit-biological-barrier system and assume the following major tasks: (1) physico-chemical testing of lunar samples, (2) time-critical and scientific investigations that must be completed within the proposed quarantine examination of lunar samples, (3) biological examination of the astronauts, (4) permanent storage under vacuum of a portion of the samples, and (5) sample distribution to the scientific community. The physico-chemical test laboratory provides detailed microscopic, limited petrographic, and compositional data on selected lunar samples. Microbiological, zoological, and botanical testing is discussed in detail, and the radiation counting laboratory is described. B.H.

DESCRIPTION OF A REAL-TIME DIGITAL FULL-SCALE CMG CONTROL SYSTEM SIMULATION FOR MANNED SPACECRAFT.
Robert G. Kyle and Claude R. Keckler (NASA, Langley Research Center, Hampton, Va.).
American Institute of Aeronautics and Astronautics, Aerospace Computer Systems Conference, Los Angeles, Calif., Sept. 8-10, 1969, Paper 69-940. 12 p.
Members, $1.00; nonmembers, $1.50.

Description of a real-time digital computer-hardware simulation of the Apollo Telescope Mount (ATM) mission. The simulation has been developed and employed to evaluate full-scale control moment gyro (CMG) system performance in providing stabilization and control for the ATM cluster configuration. The full-scale CMG system is linked to a digital computer program representing the ATM spacecraft, and the simulation operates in a real-time mode. System-stability and gimbal-rate limit cycling problems were encountered during initial simulation operations. These problems and solutions are discussed, and typical simulation data of spacecraft and CMG system response are presented. Future computer system hardware simulations to be employed in CMG technology development are outlined and include use of a control flight test bed to reproduce the spacecraft motion and examine CMG system-spacecraft interactions. APPLICATION OF THE LINE-SOURCE TECHNIQUE FOR VACUUM THERMAL CONDUCTIVITY MEASUREMENTS.
Lawrence R. Greenwood (NASA, Langley Research Center, Hampton, Va.) and Robert A. Comparin (Virginia Polytechnic Institute, Blacksburg, Va.).
American Institute of Aeronautics and Astronautics, American Society for Testing and Materials, and Institute of Environmental Sciences, Space Simulation Conference, 4th, Los Angeles, Calif., Sept. 8-10, 1969, AIAA Paper 69-1013. 5 p. 5 refs.
Members, $1.00; nonmembers, $1.50.

Experimental study of the accuracy of the line-source technique for measuring the thermal conductivity of an ablative heat-shield material. The technique was then used to determine the thermal conductivity of the material in a vacuum. The thermal conductivity of the same samples was measured first by using the guarded hot-plate technique, and then by using the line-source technique. The results showed that the average thermal conductivity measured by the line-source technique was within 2 per cent of the other value with a maximum deviation for any one sample of less than 7 per cent. Vacuum measurements using the line-source technique showed a 15-per cent decrease in thermal conductivity after exposure to the vacuum for 24 hours. After reexposure to the atmosphere, the thermal conductivity returned to its original value. (Author)

EFFECTS OF MISSION ENVIRONMENTS ON THE MECHANICAL PROPERTIES OF DACRON PARACHUTE MATERIAL.
David C. Spence (NASA, Langley Research Center, Hampton, Va.).
American Institute of Aeronautics and Astronautics, American Society for Testing and Materials, and Institute of Environmental Sciences, Space Simulation Conference, 4th, Los Angeles, Calif., Sept. 8-10, 1969, AIAA Paper 69-1018. 6 p. 10 refs.
Members, $1.00; nonmembers, $1.50.

Study of the effects of mission environments on the mechanical properties of two groups of tensile samples of Dacron-55 parachute material. The first group was exposed to the mission environments of ethylene oxide decontamination, dry heat sterilization, vacuum, and a simulated Martian atmosphere, and was tensile tested in situ. The second group was a control group and was stored and tested at a temperature of 75 deg F and 45 per cent relative humidity. The results indicate that the sequential exposure of Dacron parachute material to these mission environments will induce changes in the mechanical properties of this material, not to exceed minus 7.7 per cent in maximum stress, minus 18.0 per cent in elongation, minus 17.4 per cent in total energy, minus 9.9 per cent for initial modulus, and plus 4.5 per cent for final modulus. (Author)

AN IN SITU FACILITY FOR THE DETERMINATION OF THE EFFECTS OF A SPACE ENVIRONMENT ON THE SOLAR ABSORPTANCE OF MATERIALS.
M. S. Cridlin, C. A. Nicoletta, and J. D. Mann (NASA, Goddard Space Flight Center, Greenbelt, Md.).
American Institute of Aeronautics and Astronautics, American Society for Testing and Materials, and Institute of Environmental Sciences, Space Simulation Conference, 4th, Los Angeles, Calif., Sept. 8-10, 1969, AIAA Paper 69-1021. 6 p. 9 refs.
Members, $1.00; nonmembers, $1.50.

Description of a laboratory facility for measuring total solar absorptance in the space environment. The use of a vacuum

integrating sphere allowing for an absolute absorptance value eliminates the difficulties encountered in optical measurements through a window. Four samples can be mounted in the facility at the same time but irradiated individually. The space environment consists of ultrahigh vacuum, low energy protons and electrons, from 1 to 30 kev, and solar electromagnetic radiation. All radiation doses are measured at the sample position. Sample temperatures are controlled and recorded during preirradiation, irradiation, and optical measurement phases. The facility should prove an accurate and dependable tool for determining the qualifications of thermal control coatings when exposed to a space environment. M.M.

EFFECTS OF SIMULATED MARS DUST EROSION ENVIRONMENT ON THERMAL CONTROL COATINGS.
G. L. Adlon, E. L. Rusert (McDonnell Douglas Corp., St. Louis, Mo.), and W. S. Slemp (NASA, Langley Research Center, Applied Materials and Physics Div., Hampton, Va.).
American Institute of Aeronautics and Astronautics, American Society for Testing and Materials, and Institute of Environmental Sciences, Space Simulation Conference, 4th, Los Angeles, Calif., Sept. 8-10, 1969, AIAA Paper 69-1023. 11 p. 7 refs.
Members, $1.00; nonmembers, $1.50.

Evaluation of thermal control coatings, windows, and mirrors for application on the proposed 1973 Mars Viking Lander vehicles, under simulated Martian surface conditions. Such parameters as weight and thickness losses, solar absorptance, IR emittance, reflectance, and transmission changes were measured. Ten thermal control materials, two mirrors, and two window materials were exposed to different dust densities at 45 and 90 degree angles and exposure times of 2 to 4 hours. Large increases in solar absorptance were measured for the majority of the coatings exposed to the simulated environment. The hard materials (flame sprayed coatings and glass reference slides) and the soft aluminum-silicate pigmented glass resin coating lost the most coating weight. After 10 minutes of exposure, the fused silica and the alumino-silicate window materials were rendered unusable from a transmittance standpoint. (Author)

PRESSURE MEASUREMENTS AND GAS-FLOW ANALYSIS IN CHAMBERS A AND B DURING THERMAL VACUUM TESTS OF SPACECRAFT 2TV-1 AND LTA-8.
H. K. F. Ehlers (NASA, Manned Spacecraft Center, Space Environment Effects Section, Houston, Tex.).
American Institute of Aeronautics and Astronautics, American Society for Testing and Materials, and Institute of Environmental Sciences, Space Simulation Conference, 4th, Los Angeles, Calif., Sept. 8-10, 1969, AIAA Paper 69-1033. 8 p.
Members, $1.00; nonmembers, $1.50.

During several thermal-vacuum tests of two manned spacecraft, pressures and gas flows in various locations and in various directions in two large vacuum chambers were studied to determine whether the vacuum of space was simulated sufficiently to meet the test objectives. An attempt was made to identify and locate gas sources inside the vacuum chambers and to determine the effect of the gases on the simulation. The study consisted of a theoretical analysis based on a simple mathematical model, and an experimental analysis based on measurements taken with several regular tubulated ion gauges in fixed positions. The results show that the vacuum of space was adequately simulated, even in the presence of numerous gas leaks. The effects and the detection of several gas leaks are described.

WHAT'S IMPORTANT IN SIMULATION?
John P. Reeder (NASA, Langley Research Center, Flight Mechanics and Technology Div., Hampton, Va.).
IN: FLIGHT SAFETY FOUNDATION, ANNUAL INTERNATIONAL AIR SAFETY SEMINAR, 21ST, ANAHEIM, CALIF., OCTOBER 8-11, 1968, TECHNICAL SUMMARY. (A69-41127 22-02)
Arlington, Va., Flight Safety Foundation, Inc., 1968, p. 98-116. 10 refs.

Discussion of simulation requirements to reduce aircraft flight time for training to a minimum. It is noted that fixed-base piloted flight simulators have proved very useful in advanced vehicle research, in navigation and traffic control studies, and in procedural training. However, a high degree of interpretation by trained pilots is often required to predict the suitability of aircraft behavior or actual aircraft controllability from fixed-base simulation. Consequently, the interpretation of fixed-base simulation may often be wrong. The various problems of flight simulation, such as the need for motion, characteristics of the control system and instrumentation, visual simulation, and motion in critical maneuvers are considered. Factors which are missing in simulation (such as the "pucker factor") are discussed, and it is shown how these factors alter the emphasis in piloting performance in an aircraft. It is concluded that simulation cannot wholly replace flight training in the aircraft concerned, but that it may markedly reduce the amount of flight training required.

THE SIMULATOR TO MATCH THE TRANSPORTS TO COME.
Maurice D. White and John C. Dusterberry (NASA, Ames Research Center, Moffett Field, Calif.).
Astronautics and Aeronautics, vol. 7, Sept. 1969, p. 54-60.

Description of a new flight simulator for advanced transport aircraft. The large lateral motion of the simulator is emphasized. It is stated that the simulator developed is expected to extend simulation capabilities significantly beyond those of existing aircraft research simulators. The equipment is provided with motions large enough so that by systematically limiting them it can be learned what motions training simulators need. Factors contributing to the pilot's confidence in his evaluation are considered. Problems arising from the length of the fuselage of large aircraft are discussed. It is noted that asymmetric loss of engine thrust at supersonic speeds on a supersonic transport could whip the cockpit through quite large and confusing movements and that a simulator should reproduce the accelerations expected during these maneuvers with reasonable fidelity. BLAST SHIELDS TESTING
Walter V. Medenica Washington Nov. 1968 68 p refs
(NASA-TN-D-4894) Avail: CFSTI CSCL 20K

Several types of protective steel shields were exposed to explosive blasts of RP-1 and liquid oxygen (LOX) or liquid hydrogen (LH_2) and LOX combinations, as a ride-along project of the Pyro Project. They included: solid arched plates, angle deflectors, wire screen No. 1 (65.3% open area), wire screen No. 2 (48% open area), solid flat plates, and wire screen No. 3 (27% open area). The first four of the above shields were instrumented with strain gauges and pressure transducers. Author

ANALYSIS OF NUMERICAL INTEGRATION TECHNIQUES FOR REAL-TIME DIGITAL FLIGHT SIMULATION
John W. Wilson and George G. Steinmetz Nov. 1968 98 p refs
(NASA-TN-D-4900) Avail: CFSTI CSCL 22A

Low order numerical integration techniques are analyzed and established as adequate for digital simulation of man in the loop nonaerodynamic rigid body problems. In addition to low order integration techniques, a Green's function approach is presented for the solution of the gyroscope equations. This approach yields an exact solution to the gyroscope output for the simulated forcing function with virtually no limitation on the integration interval size. Effects of roundoff error are shown to be marginal for the translational dynamics with solution rates on the order of 32 solutions per second on a floating point machine with a 27-bit fractional part. Two example problems were solved by using the techniques established. A Gemini–Agena eleven degree of freedom problem was programed in FORTRAN and then modified to a Gemini–Agena elastically coupled system. Primary concern was given to minimizing the time required of the arithmetic unit. The results of these problems indicate the utility of the IBM 7094 class of computers for this type of problem since only a small fraction of the memory and arithmetic processing time was used (10 to 15 percent each). This study strongly supports the desirability of multiprograming to alleviate inefficiency on a more sophisticated machine. Author

ACCEPTANCE TESTING LUNAR AND PLANETARY VEHICLES (A CONCEPT)
Fritz Kramer Washington Dec. 1968 24 p
(NASA-TN-D-4924) Avail: CFSTI CSCL 22D

This report presents the least known of the two concepts which allow us to study the effects of lunar or planetary gravitation on the full-size prototype vehicle with respect to vehicle dynamics and driving characteristics, and to familiarize the astronauts with the behavior of surface vehicles under different gravitations. The concept is explained and illustrated for lunar application because the moon exhibits relative to Earth the smallest gravitational attraction, and causes, therefore, the greatest deviation of the vehicle's behavior from its behavior on Earth. However, the principle and its implementation are applicable without restriction or degradation to any other magnitude of gravitational acceleration. Author

ANALYSIS OF NONEQUILIBRIUM AIR STREAMS IN THE AMES 1-FOOT SHOCK TUNNEL

Robert S. Hiers, Jr. and John O. Reller, Jr. Washington Jan. 1969 27 p refs

(NASA-TN-D-4985) Avail: CFSTI CSCL 14B

An analysis and the results of a preliminary calibration of nonequilibrium test streams in the Ames 1-foot shock tunnel are presented. The facility is combustion driven and is normally operated in the tailored-interface mode to provide a nominal reservoir enthalpy of 9,100 J/gm and pressure of 275 atm. In addition, the shock tunnel is operated in the equilibrium-interface mode to provide enthalpies between 6,000 J/gm and 15,000 J/gm at a nominal reservoir pressure of 275 atm. Results are presented for three typical operating conditions. Static pressure, pitot pressure, velocity, mass flow, and stagnation point heat transfer were measured in the test stream. These data are compared with numerically integrated and sudden-freeze models for air undergoing both chemical and vibrational relaxation. It is shown that the sudden-freeze model is satisfactory for calibrating the test stream if certian frozen-flow parameters are determined using experimental data. An added advantage of this approach is that flow properties in the test stream may be obtained without specifying the relaxation rates. Author

A RENDEZVOUS AND STATION-KEEPING SIMULATOR WITH FLY AROUND CAPABILITY AND VIRTUAL IMAGE VIEWING

William M. Kahlbaum, Richard E. Bardusch, and John J. Stumpf Washington Apr. 1969 40 p refs

(NASA-TN-D-5123) Avail: CFSTI CSCL 14B

A screen-type-refractive-virtual-image rendezvous simulator has been designed and built at the Langley Research Center. In this simulator, the test subject views combined images of a celestial background, a featureless earth horizon, and a rendezvous target vehicle through a circular window with a 30° field of view. The virtual images of the horizon and stars appear to be at infinity, while the target-vehicle image appears to be at some closer distance. The three elements of the display are rear projected on screens by means of separate gimbaled projectors. The horizon and star images are generated optically, while the target-vehicle image is generated by a closed-circuit television system. The observed size of the target-vehicle image varies as a function of problem range. Range changes within 160 meters of the observer are simulated by moving the television camera along a range bed. Range changes beyond 160 meters with satisfactory television line resolution are simulated by continuously shrinking the raster on the television projection tube. Since the problem requires three degrees of continous rotational freedom for the observer, a central computer program generates attitude information (by means of quaternion rate equations) and presents this information to the simulator in the form of direction cosine matrices. EXPLODING WIRE INITIATION AND ELECTRICAL OPERATION OF A 40-kV SYSTEM FOR ARC-HEATED DRIVERS UP TO 10 FEET LONG

Robert E. Dannenberg and Anthony F. Silva Washington Apr. 1969 41 p refs

(NASA-TN-D-5126) Avail: CFSTI CSCL 14B

This report describes an energy storage and electric arc driver system for shock driven facilities. Energy for the arc is supplied from a capacitor bank rated at 1 MJ at an operating voltage of 40 kV. Results are presented for arc discharge lengths of 54 and 116 inches with peak currents of 600 kA. The entire arc strike sequence of exploding wire initiation, dwell period, and subsequent bank discharge is discussed. The effect of different wire types on arc initiation is also discussed. The composition of the driver gas is shown to be a factor limits the discharge of stored energy from the capacitor bank. Author

VISUAL SIMULATION IMAGE GENERATION USING A FLYING-SPOT SCANNER

Charles A. Wagner Washington Apr. 1969 58 p refs

(NASA-TN-D-5151) Avail: CFSTI CSCL 14B

The flying-spot scanner television camera used as a video signal generator for visual flight simulation is analyzed. A description of the technique is included as well as a detailed theoretical analysis of the quality of the video that can be produced. A commercially available flying-spot scanner designed for flight simulation was tested, and its capabilities are presented. Discussion is limited to the television camera; display devices such as monitors are not included. The flying-spot scanner was found to be a low-cost device which can simulate all motions of an aircraft except roll. Large excursions at high rates are easily achieved. It is limited to a relatively small field of view, a fixed forward visibility, and simulation of flat terrain. The quality of the video is adequate over a moderate range of altitudes; very high and very low altitudes result in poor performance. Possible approaches to increasing the useful altitude range are discussed. Author

MAGNETIC FIELD PROPERTIES RELATED TO THE DESIGN OF A ONE-COMPONENT MAGNETIC SUPPORT-AND-BALANCE SYSTEM

K. R. Sivier Washington NASA May 1969 50 p refs

(Grant NGR-23-005-003)

(NASA-CR-1352) Avail: CFSTI CSCL 14B

Calculations have been made of the magnetic performance characteristics of air-cored solenoids applied to a one-component magnetic support-and-balance system. These characteristics include field strength, field gradients, static stability derivatives for a ferromagnetic body in the solenoid field, and the solenoid power required to produce given field strengths and to levitate a magnetic body. These characteristics were calculated only in the vicinity of the solenoid axis and are shown to be related simply to four fundamental, shape dependent, dimensionless parameters (and to several ratios of these parameters). Author

ONE COMPONENT, MAGNETIC, SUPPORT AND BALANCE SYSTEM FOR WIND TUNNEL MODELS

K. R. Sivier and M. Henderson Washington NASA May 1969 83 p refs

(Grant NGR-23-005-003)

(NASA-CR-1353) Avail: CFSTI CSCL 20D

Sphere drag at subsonic Mach numbers and Reynolds numbers from about 25 to 4000 was measured by the instrumentation. The

system was used with a vertical wind tunnel and incorporated a simple error-rate type of feedback control system to hold the model vertically. The natural radial stability of the system was used to hold the model on or near the axes of the solenoids and the wind tunnel. The system performed well, especially at Reynolds numbers where unsteady lateral aerodynamic forces were absent or very small. Author

EXPERIMENTAL EVALUATION OF A SUBSONIC EXPANSION TUBE
Philip C. Malte and Kenneth R. Sivier Washington NASA Jun. 1969 88 p refs
(Grant NGR-23-005-003)
(NASA-CR-1354) Avail: CFSTI CSCL 01A

An experimental study of a subsonic expansion tube was carried out to determine its utility as a test facility for studying the drag of small spherical particles at subsonic Mach numbers and Reynolds numbers below 1000. Of particular interest were the length of steady flow achieved, the steadiness of this flow, the tube geometry needed to optimize the flow quality, and the growth of the unsteady boundary layer on the tube walls. It was found that a 15 ft long tube was capable of providing useful flows for at least 15 msec for Mach numbers up to about 0.7. Author

SPECTRAL AND OPERATIONAL CHARACTERISTICS OF A HIGH-INTENSITY CARBON ARC SOLAR SIMULATOR
Ernie W. Spisz and John R. Jack Washington Jul. 1969 18 p refs
(NASA-TM-X-1825) Avail: CFSTI CSCL 14B

A commercially avialable high intensity carbon arc solar simulator was evaluated to determine its suitability as a finely controlled radiant source for experimentally determining the solar absorptance of various materials. The spectral distribution of the radiant intensity is determined over the wavelength range from 0.36 to 2.1 μm, and the stability and uniformity of the radiant beam are evaluated. A control system which provides both a constant radiant intensity and a slowly varying sinusoidal perturbation of the radiant intensity is also discussed. Author

DESCRIPTION OF THE HIGH-ENTHALPY ARC TUNNEL AT THE LANGLEY RESEARCH CENTER INCLUDING TEST STREAM CONDITIONS AT SELECTED OPERATING POINTS
William L. Wells Washington Jul. 1969 52 p refs
(NASA-TN-D-5295) Avail: CFSTI CSCL 14B

The high-enthalpy arc tunnel consists of a 4-megawatt direct current power supply, a 75,000-foot^3 pump-down vacuum system, a commercial long-axial-arc gas heater, a free jet test section, and necessary high-pressure cooling water and test gas systems. Three supersonic conical nozzle lengths are used to provide a wide range of test stream parameters. The nozzle exit radii are 1.00 inch, 2.30 inches, and 3.82 inches. The arc gas heater was operated at chamber pressures from 1.2 to 3.3 atm with corresponding air mas-flow rates from about 0.02 to 0.08 lb/sec. Stagnation pressures behind the normal shock measured at the stream center line cover a range from about 0.03 to 0.72 atm and cold-wall heating rates range from about 200 to 903 Btu/ft^2-sec on a 1-inch diameter flat-faced probe. Calculated enthalpies based on these measurements range from about 10,000 to 13,000 Btu/lb. In all three nozzles, measurements were made of pressure and heating-rate distributions on a specific probe shape. Graphical comparisons show reasonably good agreement between the measured heating-rate distributions and theory and between the measured pressure distributions and data from a tunnel where the flow is known to be smooth and uniform. USE OF A SIX-DEGREES-OF-FREEDOM MOTION SIMULATOR FOR VTOL HOVERING TASKS
Emmett B. Fry, Richard K. Greif, and Ronald M. Gerdes Washington Aug. 1969 26 p refs
(NASA-TN-D-5383) Avail: CFSTI CSCL 14B

A piloted, six degrees of freedom motion simulator has been evaluted with regard to its ability to simulate VTOL visual hovering tasks. Characteristics of the variable stability jet lift Bell X-14A aircraft were simulated, and results for the roll and pitch axes were compared with flight data. The roll axis data were also compared with data from two and single degree of freedom simulators. Control power and damping requirements for the roll and pitch axes compared very well with flight data. The simulator's motion quality was considered outstanding for VTOL hovering flight. Its travel limits were large enough to simulate hover/maneuver tasks on a one to one scale. Roll lateral motions (two degrees of freedom motions) gave essentially the same results as six degrees operation for evaluation of roll axis maneuvers. Author

EXPERIMENTAL VERIFICATION OF SURFACE VEHICLE DYNAMICS
B. D. Van Deusen, J. M. Sneyd, C. H. Hoppe, and R. F. Hughes Washington NASA Sep. 1969 139 p refs
(Contract NASw-1607)
(NASA-CR-1399) Avail: CFSTI CSCL 13F

Techniques were developed to allow prediction of the dynamic response of vehicles traversing yielding and nonyielding rough surfaces. Virgin terrestrial and extraterrestrial surfaces were classified according to their frequencies and amplitude distribution. An attempt to verify these conditions was undertaken. A four wheeled truck and a specially designed single wheel trailer were instrumented and driven (pulled) across both yielding and nonyielding surfaces. The surface profile was measured on both surfaces and soil parameters were measured on the yielding surface. With this input information the theoretical prediction was compared with the physical measurements in a statistical fashion. The analog computer simulation was converted to a digital computer simulation to allow a more useful and versatile prediction technique. Author

INTERACTION OF LINEAR WAVES WITH OBLIQUE SHOCK WAVES
J. F. McKenzie (California, University, Dept. of Applied Electrophysics, La Jolla, Calif.) and K. O. Westphal (NASA, Ames Research Center, Moffett Field, Calif.).
Physics of Fluids, vol. 11, Nov. 1968, p. 2350-2362. 19 refs.

Derivation of formulas for the amplitudes of waves that diverge from a shock as a result of any given incident disturbance. It is shown that in an ideal gas (where the Mach number M is large), that the pressure amplitude and the component of the energy flux normal to the shock of a transmitted sound wave are of O (M^2) greater than those in the incident sound wave. Furthermore, if the impinging sound wave is incident near the critical angle, the ratio of the pressure amplitude of the transmitted sound wave to that of the incident one is of O (M^3). It is also shown that incident entropy-vorticity waves can generate intense sound waves behind a strong shock. The dependence of the transmission, reflection, and generation coefficients for sound waves on the Mach number and the angle of incidence is depicted in a series of graphs. The results are applied to the amplification of small disturbances in the solar wind on passage through the bow shock of the earth. M. G.

IONIZING SHOCK STRUCTURE IN A MONATOMIC GAS.
Donald L. Chubb (Columbia University, New York, N. Y.; NASA, Lewis Research Center, Cleveland, Ohio).
Physics of Fluids, vol. 11, Nov. 1968, p. 2363-2376. 27 refs.
Contract No. AF 49(638)-1634.

The structure of an ionizing shock front in a monatomic gas is described. Both atom-atom and electron-atom collisional ionization are considered. The ionization rates for either of these processes are assumed to be controlled by the rate of excitation from the ground state to the first excited level. In the front part of the shock, called the atom-atom shock, atom collisional dissipative mechanisms (viscosity and thermal conductivity) determine the shock structure. A bimodal Mott-Smith velocity distribution function is assumed for the atoms in this region, which has a thickness of the order of the atom-atom viscosity mean free path. In the rear part of the shock front, called the relaxation zone, the collisional ionization processes determine the structure. For this region, which has a thickness proportional to the electron-atom ionization mean free path, Maxwellian velocity distributions are assumed for the electrons, ions, and atoms. It is found that for Mach numbers of 30 or more the atom-atom shock is of comparable thickness to the relaxation zone, and the degree of ionization behind the atom-atom shock is of the order of 10^{-1}. (Author)

A NUMERICAL SOLUTION OF UNSTEADY FLOW IN A TWO-DIMENSIONAL SQUARE CAVITY.
L. F. Donovan (NASA, Lewis Research Center, Cleveland, Ohio).
American Institute of Chemical Engineers, Annual Meeting, 61st, Symposium on Fundamental Research in Fluid Mechanics, Part I, Los Angeles, Calif., Dec. 1-5, 1968, Paper 25 C. 18 p. 13 refs.
$0.50.

Numerical solution of the continuity equation and unsteady Navier-Stokes equations for two-dimensional flow in a square cavity. The fluid is initially at rest, and the upper surface of the cavity moves with constant velocity throughout the calculations such that the Reynolds number is 100, based on the length and velocity of the moving surface and the viscosity of the fluid. Good agreement is shown between the calculated position of the vortex center at large times and both the position of an experimentally determined vortex center and the position of the vortex center calculated from an extant solution of the steady Navier-Stokes equations. Velocity profiles at large times are in excellent agreement with those calculated from an extant solution of the steady Navier-Stokes equations. Another method of presenting the results of the calculations is also used to illustrate the results more clearly. M. M.

Members, $1.00; nonmembers, $1.50.

Study of the effect of including the streamwise history or nonsimilar terms in the usual transformed laminar boundary-layer equations at three locations on a typical, blunted, compression surface. The locations represent regions of mildly positive pressure gradient, mildly negative pressure gradient, and strongly negative pressure gradient. Theoretical boundary-layer solutions were obtained at the three stations by numerically solving the laminar boundary-layer equations both with and without the streamwise history terms included. Both solutions are compared with experimental boundary-layer data. The results indicate that in the presence of a strong negative pressure gradient the solutions exhibit a significant difference when the streamwise history terms are considered. The largest differences appear in velocity profile and displacement thickness, with the data confirming the validity of the fully nonsimilar solution. (Author)

HYPOTHESIS FOR THE ORIGIN OF CROSS-HATCHING.
Murray Tobak (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N. Y., Jan. 20-22, 1969, Paper 69-11. 8 p. 21 refs.
Members, $1.00; nonmembers, $1.50.

Cross-hatching is hypothesized to be caused by spatially periodic fluctuations in surface pressure, the origin of which is the presence in the boundary layer of an array of regularly spaced counterrotating longitudinal vortices. The vortices originate from surface irregularities near the leading edge; the probability of their appearance

is enhanced by the presence of a local region of concave curvature in the boundary-layer streamlines. Surface ablation is not a necessary condition for the presence of the pressure fluctuations that lead to cross-hatching, but may be the mechanism causing the streamline curvature. For cross-hatching to appear, the boundary layer aft of the concavity must be turbulent and the local flow must be supersonic. (Author)

INTEGRATION OF THE EQUATIONS GOVERNING THE ONE-DIMENSIONAL FLOW OF A CHEMICALLY REACTIVE GAS.
H. E. Bailey (NASA, Ames Research Center, Moffett Field, Calif.).
Combustion Institute and University of California, Specialists' Session on Chemical Kinetics Calculations, University of California, Berkeley, Calif., Oct. 30, 1968, WSCI Paper 68-46. 35 p. 11 refs.

Introduction of the concept of parasitic eigenvalues in the numerical solution of sets of ordinary differential equations. The use of an implicit method is proposed for the solution of differential equations containing such parasitic eigenvalues. These ideas are then applied to the integration of the equations which govern the one-dimensional flow of a chemically reactive gas. In particular, results are given for the flow downstream of a normal shock wave and for the flow in a converging-diverging nozzle. The conditions under which the more complicated computations required by the implicit method appear justified are delineated. M. M.

THE EFFECT OF ACCELERATION ON HEAT TRANSFER IN A TURBULENT BOUNDARY LAYER.
Robert W. Graham (NASA, Lewis Research Center, Cleveland, Ohio).
University of Minnesota, Heat Transfer Seminar, University of Minnesota, Minneapolis, Minn., Feb. 18, 1969, Paper. 17 p. 5 refs.

Review of some recent research concerning acceleration effects on forced convection in a turbulent boundary layer. The results obtained show that for accelerated turbulent flow, the heat-transfer levels are generally below the unaccelerated values. The following conclusions are made: (1) conventional turbulent-flow heat-transfer correlations overpredict at the throat; (2) momentum boundary-layer history is relatively unimportant, while thermal boundary-layer history is very important; (3) for subsonic and sonic conditions the energy thickness integral approach is useful in predicting local heat-transfer rates; and (4) little information exists concerning the nature of the turbulence structure in accelerating flow. Much has to be learned about production and dissipation of turbulence. M. M.

MEASUREMENT OF MEAN DROP SIZES FOR SPRAYS FROM SUPERHEATED WATERJETS.
Paul B. Gooderum and Dennis M. Bushnell (NASA, Langley Research Center, Aero-Physics Div., Hampton, Va.).
Journal of Spacecraft and Rockets, vol. 6, Feb. 1969, p. 197, 198. 11 refs.

Investigation of the mean drop size generated in the lowest ambient pressure mode of dispersion, usually referred to as the vapor pressure breakup regime. The results obtained indicate that for vapor pressure breakup of liquid water jets under low Weber number conditions the final resultant mean drop size depends only on the temperature of the injected water and the orifice diameter. M. M.

DIRECTION OF MAXIMUM TURBULENT VORTICITY IN A SHEAR FLOW.
R. G. Deissler (NASA, Lewis Research Center, Cleveland, Ohio).
Physics of Fluids, vol. 12, Feb. 1969, p. 426, 427. 7 refs.

Derivation of an equation for the direction of maximum turbulent vorticity in a turbulent shear flow. For a weak homogeneous turbulent field with a uniform transverse velocity gradient, that direction is found to be reasonably close to (but different from) the direction of maximum mean strain rate for a range of velocity gradients. The degree of alignment of the turbulent vortices is also determined. (Author)

APPROXIMATE EQUATIONS OF MOTION FOR GASES AND LIQUIDS.
John A. Dutton (Pennsylvania State University, Dept. of Meteorology, University Park, Pa.) and George H. Fichtl (NASA, Marshall Space Flight Center, Huntsville, Ala.).
Journal of the Atmospheric Sciences, vol. 26, Mar. 1969, p. 241-254. 14 refs.
NSF Grant No. GA-1595X.

Development of a set of conditions which justify the application of the Boussinesq approximation to compressible fluids. Two cases are found and compared. In the first, in which the vertical scale of the motion can be of the same order of magnitude as the scale height of the medium, the perturbation momentum must be nondivergent and the effects of perturbations of pressure appear in several places. In the other case, where the vertical scale of the motion is much less than the scale height, the perturbation velocities are nondivergent and the perturbation pressure appears only in the pressure gradient force. The approximate equations lead to linearized equations controlling the stability of wave motion which are formally equivalent to those for the same problem in the flow of a stratified medium which is incompressible in the sense that the flow is solenoidal. Various properties of the approximate equations are investigated, and it is shown that acoustic modes are not permitted. M. G.

UNDEREXPANDED JET NOISE REDUCTION USING RADIAL FLOW IMPINGEMENT.
Darshan S. Dosanjh (Syracuse University, Syracuse, N. Y.) and Francis J. Montegani (NASA, Lewis Research Center, Cleveland, Ohio).
(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 6th, New York, N. Y., Jan. 22-24, 1968, Paper 68-81.)
AIAA Journal, vol. 7, Mar. 1969, p. 458-464. 14 refs.
Grant No. NsG-431.

Noise from high-speed jet flows was investigated using the impingement of a radial annular jet flow on the first shock-cell region of a moderately underexpanded axisymmetric converging main jet flow. Acoustical data and the spark shadowgraphs of the interacting jet flows were recorded in an anechoic chamber. Different nozzle arrangements were used, and the operating main jet total pressure, the percent impingement, and the impingement location were varied. Under all operating conditions, a characteristic variation of the total acoustic power level with percent impingement was observed. Moreover, under selected operating conditions the total acoustic power emitted by the interacted jet flows was lower than that emitted by the main jet flow alone. A maximum sound pressure level reduction of 3-1/2 db was achieved. As a result of interaction of two impinging jet flows, the strong shock pattern in the main underexpanded jet flow is modified, and the emergence of new repetitive shock structure interposed between the original repetitive shock pattern of the main jet flow is observed in the interacted jet flows. The shadowgraphs of the interacting jet flows also reveal almost spherical acoustic emissions originating from individual sources located near each oblique shock tip. An acoustic model based on a finite number of wideband acoustic monopole sources distributed on a line is proposed. The results of the analysis agreed qualitatively with those obtained experimentally. (Author)

USE OF PRESTON TUBES FOR MEASURING HYPERSONIC TURBULENT SKIN FRICTION.
Earl R. Keener and Edward J. Hopkins (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerodynamic Testing Conference, 4th, Cincinnati, Ohio, Apr. 28-30, 1969,

Paper 69-345. 11 p. 27 refs.
Members, $1.00; nonmembers, $1.50.

A brief review is made of supersonic Preston-tube correlations which account for the effects of Mach number and Reynolds number for adiabatic surfaces. Experimental results are presented which show that two of these correlations are applicable to nonadiabatic surfaces in an airstream at M = 7. Direct measurements with a skin-friction balance were used for the calibrations. The Reynolds number ranged from 4 to 14 million, and the ratio of wall-to-adiabatic-wall temperature ranged from 0.3 to 0.5. The major conclusion is that the correlation can be simplified and made independent of the boundary-layer-edge condition, by basing the correlation factors on only three measurements, namely wall temperature, wall pressure, and Preston-tube pressure. NASA-Army-supported research.

The boundary layer equations for incompressible two-dimensional turbulent flows with arbitrary pressure distributions are solved by the method of weighted residuals. The method is capable of predicting skin friction, boundary layer integral parameters, and velocity profiles. The analytical technique contains a theoretical convergence criterion, and enables computations to be made to any desired accuracy (subject to the accuracy of the selected turbulence model). To obtain solutions, a mixing length model for the turbulent shear description is used in conjunction with initial profile data modified by orthogonal functions. Analytical results are compared with three experimental cases: (1) the Schubauer and Klebanoff flow over an airfoil-like body which includes favorable and adverse pressure gradients and leads to separation, (2) the equilibrium flow with an adverse pressure gradient of Bradshaw, and (3) the favorable pressure gradient equilibrium flow of Herring and Norbury. In all three cases excellent agreement is obtained. The method is sufficiently rapid to permit its use as a subprogram in analyses of broader extent. (Author)

In seeking a rational approach to the variety of transitional behavior, the author conjectures that many instability paths to turbulence are admissible and that their effectiveness hinges on whether the given mechanism supplies the proper scales, intensity level, and three-dimensional phase relations needed for self-regeneration. Conceptual lessons are drawn from a recently completed critical survey of the literature on transition to turbulence, and a number of unifying conjectures are advanced for subsonic speeds. The roles of linear amplification, nonlinear limiting, and secondary instability inducted by unsteady nonlinear effects are illustrated for a number of transitional flows, including those in presence of roughness and streamwise vorticity. A clarification is advanced for the question of fast vs slow transition. An overall model of the linear and nonlinear processes leading to transition is proposed. (Author)

Experiments on the effect of trip geometry, size, and location on the position of transition at local Mach numbers up to 8.5. The pressure drag of the trip is investigated at local Mach numbers of 4.7 and 5.5. Based on test results, a flow model was constructed which includes trip-produced multiple vortex filaments similar to those found at supersonic speeds that are assumed to be responsible for introducing the disturbances that lead to transition. The Reynolds number based on the distance from the leading edge to the roughness position as well as Mach number and wall-to-total temperature ratio should be considered in choosing the smallest effective trip size. The effect of trip shape on the position of transition at hypersonic speeds is small; however, certain shapes exhibit the advantageous characteristic of having drag coefficients which were relatively independent of roughness height over a restricted range of the variables tested. Recent results of turbulence measurements in very effective drag-reducing fluids. Effects of the polymer on turbulence intensity are found not to be directly related to friction reduction. Turbulence intensity is found to be a function of Reynolds number, polymer concentration, and location in the flowfield and may be locally higher or lower than for Newtonian flow. Turbulence spectral measurements show moderate effects in both macroscale and microscale for polymer

solutions, suggesting a possible elasticity effect which is not related to the drag-reduction phenomenon. Friction factors for flow of a very effective drag-reducing dilute polymer solution in uniformly rough pipes are presented. The onset of "fully rough" effects is found to occur at higher Reynolds numbers in the polymer solution than in water, in accordance with predictions based on the sublayer thickening effect of the polymer. The friction factors are found to be less for the polymer than for water in the roughness transition regime, but there is an indication that in the fully rough regime no drag reduction will be realized. The data are analyzed in terms of a roughness function based on the effects of the polymer and the roughness on the law of the wall velocity profile. (Author)

Effects of concentration, flow rate, and tube diameter on drag reduction in nonpolar soap solutions. Aluminum dioleate in toluene solutions were used in pressure drop measurements at concentrations of 0.2, 0.5, 0.75, and 1.0%. Pressure drop measurements were made in tube diameters ranging from 0.01 to 2.0 in. A few such measurements were also made with an aluminum palmitate soap in toluene. The results of these measurements differed from those observed in aqueous systems. Higher concentrations (0.75%) were required before drag reduction occurred. No critical upper shear stress was observed. While little mechanical degradation was observed after an initial holding period, the solutions degraded on aging. Thus, while aqueous soap systems have appeared to be at equilibrium and have shown reversible shear effects, the changes in viscosity with time for these nonpolar systems indicate that they were not at equilibrium. It is believed that the differences in the nature of the soap structure in solution for the two types of systems cause the observed differences in the turbulent flow behavior. (Author)

Evaluation of the mass flux requirements for drag reduction by uniform injection of a high molecular weight polymer solution into a turbulent boundary layer on a flat plate or slender body of revolution. This evaluation is necessary in order to determine the feasibility of using polymer solutions to reduce skin friction drag on marine vehicles. Uniform injection is chosen for analysis since it raises the additive concentration to the drag reducing level in the wall region only, where recent experiments have shown that it is needed. Calculations of skin friction reduction and mass flux required are plotted for conditions of interest for marine vehicles. Distributed injection is compared with slot injection and is found to require between 40 and 140 times less additive solution than does slot injection to maintain equivalent drag reduction. A "specific additive consumption" is defined and compared with specific fuel consumption of several underwater propulsion units. The comparison shows slot injection of a 1000 ppm solution to be of marginal value, while porous wall injection would give more performance increase than adding an equal amount of fuel. It is noted that there is considerably more performance advantage to be gained from a continuous ablating additive coating than from additional fuel, if it could be made to ablate at the optimum rate. (Author)

Incompressible turbulent boundary layer analysis based on a two-region characterization for eddy viscosity. The eddy viscosity for the inner region is described with Spalding's generalized function, whereas the outer region, characterized by large eddy scales, is treated through an application of Prandtl's eddy viscosity model for free shear flows. A similarity solution for the outer region is obtained for a linearized motion equation and suitably joined to the inner solution by requiring continuity of shear stress and eddy viscosity. The present matching criteria for the two regions result in the preservation of the velocity profile shape in the defect plane, while simultaneously yielding the correct longitudinal development of all layer parameters such as momentum thickness and wall shear stress. The present model is extended to the low Reynolds number regime where the wake strength is greatly diminished. It is suggested that interfacial conditions are, collectively, the particular feature of incompressible flow which may serve as the point of reference for variable density transformations. (Author)

New York, Plenum Press, 1969, p. 463-474. 18 refs.
Grant No. NGR-40-002-009.

Demonstration that some viscoelastic fluid theories show an increased "resistance" to nonviscometric (or nonshearing) deformations due to "normal-stress effects," but no upper limit on stretch rate is discernible. Using this fact on a one-dimensional Burgers-type model of "weak turbulence," drag reduction is predicted. Some observations on transition in solutions of polyethylene-oxide (Polyox) were made using a water table. It was found that (1) the rate of spread of turbulent "spots" is reduced; (2) a fine-grained wavy structure covered the surface and waviness increased with concentration; and (3) turbulent spot generation at sharp edges was reduced. (Author)

New York, Plenum Press, 1969, p. 475-493. 15 refs.
Navy-NASA-sponsored research.

In developing the constitutive equation for an arbitrary fluid on a purely phenomenological basis, it has been shown that the stress tensor can be represented as a generalized functional depending on a Finger rate of strain tensor. If only the first derivative with respect to time and only a single quadratic term are retained in the general equation, then the second-order fluid results. From the phenomenological point of view, there is no a priori reason why the coefficients in the second-order fluid should be related to each other. However, it has been found experimentally that, for the second-order fluid, the two second-order coefficients can, to a good approximation, be expressed in terms of one of them. This has been shown to lead to equations which differ from the Navier-Stokes equation by a term which depends only on the Weissenberg number. The theory of viscosity of polymeric solutions (Kirkwood, 1948, 1954), or theories closely related to it, have been able to explain

the linear viscoelastic properties of polymeric solutions quite well. It is shown that it is possible to develop a constitutive equation which includes nonlinear as well as viscoelastic terms from these same assumptions. The coefficients of the acceleration tensors are found to depend only on the concentration and intrinsic viscosity for a wide variety of polymers. It suggests, as does the Weissenberg conjecture, that in dilute polymer solutions, nonlinearity and viscoelasticity are always present together. Their relative importance will depend on the nature of the flow. (Author)

A NEW MOMENTUM-INTEGRAL METHOD FOR TREATING MHD AND SIMPLE HYDRODYNAMIC ENTRANCE FLOWS.
Richard E. Schwirian (NASA, Lewis Research Center, Cleveland, Ohio).

New momentum integral method for describing the incompressible flow of a conducting fluid in the entrance of an MHD channel. The method is distinctive in that an "edge" stress is permitted to exist at the boundary layer-free stream interface. The edge stress exerts a drag force on the free stream and mathematically accounts for the development of viscous stresses in the free-stream flow as the fluid enters the channel. By a prudent choice of the edge stress variation, the governing differential equation is forced to yield an asymptotic solution with the correct wall stress. The edge stress method allows accurate analytical solutions for the friction factor and pressure variation in laminar entrance flows to be obtained for all Hartmann numbers. This accuracy exists at all points in the flow, both near the entrance and arbitrarily far downstream. Nonmagnetic turbulent flow is described. (Author)

Investigation of the effect of vortex motion on jet penetration and spreading. Experiments were conducted in a Mach 2 airstream. Two injector configurations were used. The first was a half-delta wing with a 30° semiapex and a 12° angle of attack. Helium was injected from the upper surface in line with the mean position of the vortex. The second injector was a flat plate at the same angle of attack and equal projected frontal area. Measurements of the helium concentration profiles at various downstream distances indicated that penetration into the free stream was at least twice as large with the delta injector. This increase in penetration is based on measurements made relative to the injection orifice and along the vortex position. Comparison of the penetration at other angular positions may not yield the same degree of enhancement. The spread of helium in the lateral direction was found to occur over twice the angular range with the delta injector as with the angled flat plate. The experimental measurement of the jet boundary (along the vortex angle) was found to be in reasonable agreement with the mean vortex position near the trailing edge of the injector. (Author)

PRELIMINARY RESULTS FROM AN EXPERIMENTAL INVESTIGATION OF NOZZLE WALL BOUNDARY LAYER AT MACH NUMBERS RANGING FROM 27 TO 47.
Joseph H. Kemp, Jr. and A. K. Sreekanth (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Fluid and Plasma Dynamics Conference, San Francisco, Calif., June 16-18, 1969, Paper 69-686. 8 p. 19 refs.
Members, $1.00; nonmembers, $1.50.

Results from pitot-pressure and total-temperature surveys of the boundary layer in the nozzle of the Ames M-50 helium tunnel. Included are data from four nozzle stations with Re_θ ranging from 1200 to 8100. From the measured values, velocity profiles, density profiles, momentum thickness, displacement thickness, and wall-friction coefficient are determined. Results indicate that the boundary layer has a very thick (30% to 65% of the 2.5- to 12-in. total thickness) inner region with laminar-like characteristics and an outer region with turbulent-like characteristics. The n value obtained by representing the turbulent region with a power law relationship varies from 9 to 20 depending on the density ratio across the boundary layer. The momentum thickness, displacement thickness, and wall-friction coefficient provide reasonable extensions to data obtained at lower Mach number. (Author)

Results of a study of transition in hypersonic flow over a wide range of test conditions in the Langley M = 20 helium tunnel. Direct measurements of the facility free-stream disturbances have been made with a constant current anemometer which has a frequency response capability of 500 kHz. In unheated flow, fluctuation mode diagrams identify the disturbances as sound waves produced by moving sources of sound (the turbulent nozzle wall boundary layer). The test section disturbance levels can be quite high with a maximum of about 3.5% rms mass flow fluctuation (which corresponds to about 6% rms static pressure fluctuation) when transition of the nozzle wall boundary layer occurs in the portion of the nozzle which can influence the test section disturbance level via direct acoustic radiation. For the same range of test conditions, transition measurements have been made on a 10° half-angle wedge. A strong correlation between the movement of transition on the model and the free-stream disturbance level is observed; transition appears to be dominated by the intense sound radiation of the nozzle wall boundary layer. The results show that the free-stream disturbances are a major contributor to the unit Reynolds number effect on transition Reynolds number. Heat-transfer transition data using heated flow (as opposed to unheated) indicated a significant effect of heating the flow, the transition Reynolds number decreasing with heated flow. (Author)

Members, $1.00; nonmembers, $1.50.

Analysis and classification of accelerated boundary layers in terms of the balance of pressure force, inertia force, entrainment momentum, and wall friction force. These quantities are defined in terms of a reference velocity U_b, a reference thickness δ_b, and a reference density ρ_b (or temperature t_b). These reference parameters are defined in terms of the flow deficiency, momentum deficiency, and enthalpy deficiency integrals and characterize a one-dimensional model boundary layer. A useful short-cut estimate of boundary layer development in a severe pressure gradient is illustrated and extended to the estimation of separation in adverse gradients. This method is used to discuss the diffusion factor D which is commonly used in compressor and cascade analysis. A method for classifying boundary layers according to the balance of integral forces is presented. (Author)

Solution, by a finite-difference procedure, of compressible turbulent boundary-layer equations. The Reynolds stress is modeled by an eddy viscosity function where the mixing length is assumed to depend on the distance from the wall and the boundary-layer thickness except in the near wall region where Van Driest's exponential damping function is used. For applications to wall blowing cases, comparisons with data show that the damping factor should be taken as a function of the blowing rate as determined from incompressible data. Nonequilibrium effects could be approximately accounted for by assuming that the mixing length in the midregion of the boundary layer is a function of a velocity profile shape factor. This shape factor is identical to the incompressible form factor, and the functional relation between it and the mixing length was based on incompressible data. The nearly quadratic relation between total temperature and velocity that is observed in wall boundary layers of hypersonic nozzles could be obtained in the calculations only by using values for the total turbulent Prandtl number of 1.5 or more. Tentative models for the fluctuating density terms were used in some of the calculations. The results indicated that these terms may have large effects on low-density, hypersonic boundary layers. COMBINED EFFECTS OF MASS ADDITION AND NOSE BLUNTNESS ON BOUNDARY-LAYER TRANSITION.
Joseph G. Marvin and Clifford M. Akin (NASA, Ames Research Center, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Fluid and Plasma Dynamics Conference, San Francisco, Calif., June 16-18, 1969, Paper 69-706. 10 p. 11 refs.
Members, $1.00; nonmembers, $1.50.

Transition measurements on a 5° half-angle cone, obtained from heat-transfer data. The cone, consisting of a short solid tip (sharp or blunt) followed by a uniformly porous section, was tested in a 3.5-ft wind tunnel at $M_{\infty} = 7.4$ and free-stream Reynolds numbers of 3×10^6 and 4.7×10^6, based on model length. The effects of argon, air, and helium injection (mass rates between 0 and 2.5% of free-stream rates) through the porous skin are determined. A significant decrease in transition Reynolds number was observed with increasing mass injection. The magnitude of the decrease is shown to depend on injection rate and molecular weight. For the same mass injection rate, the lighter injectant resulted in a greater decrease. Small nose bluntness moved transition location rearward, but the amount it moved depended on the injection rate and molecular weight. At the highest injection rates, transition location was the same as for the sharp cone. (Author)

A MODIFIED MODEL FOR VIBRATION-DISSOCIATION COUPLING PHENOMENA.
N. M. Reddy (NASA, Ames Research Center, Moffett Field, Calif.).
AIAA Journal, vol. 7, June 1969, p. 1179, 1180. 7 refs.

Study of the effect of allowing the parameter U, in a model discussed by Marrone and Treanor (1963), to vary with kinetic temperature. The variation is assumed to occur in such a way that the average energy of dissociating molecules corresponds to the energy of a critical vibrational level below the dissociation limit. The coupling between vibration and dissociation is discussed. The effect of letting U vary was studied by computing the flow quantities behind normal shock waves in oxygen. G.R.

PREDICTION OF THERMODYNAMIC EFFECTS OF DEVELOPED CAVITATION BASED ON LIQUID-HYDROGEN AND FREON-114 DATA IN SCALED VENTURIS
Royce D. Moore and Robert S. Ruggeri Washington Nov. 1968 25 p refs
(NASA-TN-D-4899) Avail: CFSTI CSCL 20M

Cavity-pressure-depression measurements made in cavitated regions of hydrogen and Freon-114 (dichlorotetrafluoroethane) in two scaled venturis were used to evaluate experimental exponents of previously reported equations for the prediction of thermodynamic effects of cavitation for venturis. This prediction method accounts for changes in liquid, temperature, flow velocity, cavity length, and venturi scale. Use of the method requires similarity of body and cavity and a known cavity-pressure depression at one operating condition. The experimental data used included a velocity range of 20 to 205 feet per second (6.1 to 62.5 m/sec) and cavity lengths from 0.2 to 2.7 free stream diameters. Author

WATER FLOW AND CAVITATION IN CONVERGING–DIVERGING BOILER-INLET NOZZLE
James R. Stone and Nick J. Sekas Washington Nov. 1968 23 p refs
(NASA-TM-X-1689) Avail: CFSTI CSCL 20D

Experimental flow-pressure relations were determined for water flowing through a 0.025-inch throat diameter converging-diverging conical nozzle. The nozzle was tested with and without a plug and wire helix insert downstream of the throat. Such nozzles are being studied for possible use as inlets for single tube once through Rankine cycle boilers. The test nozzle is made of transparent plastic. Cavitating and noncavitating data are reported for throat velocities from 49 to 94 ft/sec and temperatures from 57° to 171° F. In well-developed cavitation, the flow is insensitive to nozzle exit pressure, thus minimizing the possibility of feed-system-boiler coupling instability. The plug and wire helix insert reduces the tendency for slugging. Author

REAL-HELIUM HYPERSONIC FLOW PARAMETERS FOR PRESSURES TO 3600 ATMOSPHERES AND TEMPERATURES

TO 15,000°K
Charles G. Miller, III and Sue E. Wilder Washington Nov. 1968 43 p refs
(NASA-TN-D-4869) Avail: CFSTI CSCL 20D

The virial form of the equation of state is used to derive a method for determining reservoir, nozzle-throat, free-stream, and normal-shock conditions for real-helium flow. This method is derived primarily to meet the needs of hotshot-type wind tunnels where the basic input data are measured reservoir pressure and stagnation pressure behind a normal shock. However, the method is derived to include an additional measurement of free-stream density, free-stream velocity, or reservoir temperature. The method is applied for reservoir pressures to 3600 atmospheres, temperatures to 15,000°K, and a range of free-stream Mach numbers from 10 to 100, and the results are presented in the form of nondimensionalized reservoir thermodynamic and nozzle-throat parameters and as simple correction factors which may be applied to ideal-helium flow parameters. These calculations are restricted to reservoir densities less than the critical density of helium and to theoretically uncondensed free-stream flow. Author

USE OF BARONTI-LIBBY TRANSFORMATION AND PRESTON TUBE CALIBRATIONS TO DETERMINE SKIN FRICTION FROM TURBULENT VELOCITY PROFILES
Jerry M. Allen Washington Nov. 1968 41 p refs
(NASA-TN-D-4853) Avail: CFSTI CSCL 20D

A large number of velocity profiles with corresponding local skin friction measurements have been used to investigate the validity of the Baronti-Libby transformation as a skin friction measuring technique over a wide range of test conditions. The possibility of using existing Preston tube calibrations to calculate skin friction from velocity profiles is investigated, and a computational procedure is developed so that a Clauser-type determination of skin friction from velocity profiles can be accomplished without the necessity of plotting. The principal conclusions that result from this study are that the Baronti-Libby transformation gives good results for adiabatic flow but does not predict the correct trend with heat transfer and that using the Fenter-Stalmach law only as a Preston tube calibration is unduly restrictive since it is shown that the law can be used to calculate local skin friction from conventional velocity profiles with results that are comparable with those of the more complex Baronti-Libby method. SOME FLUID MECHANICAL PROBLEMS RELATED TO SUBSONIC AND SUPERSONIC AIRCRAFT
John T. Howe, ed. 1968 24 p refs
(NASA-SP-183) Avail: CFSTI CSCL 01A

Some of the problems connected with modern subsonic and supersonic aircraft and which have their origin in fluid mechanical phenomena are reviewed. The following topics are discussed and found to require further study: 1. Turbulent boundary layers, including the effects of three dimensionality and adverse pressure gradients; 2. Separated flows, such as are due to adverse pressure gradients, to shock boundary layer interactions including the transonic problem, and to concavities; 3. Vortex flows, such as arise from wings and fuselages at angles of attack; 4. Correlation of wind tunnel measurements with flight data and other wind tunnel data; and 5. Transonic flows, including two dimensional airfoil design, integration of wings and fuselage, and methods of increasing the critical Mach number. Author

BLUNT BODY STAGNATION REGION FLOW WITH NONGRAY RADIATION HEAT TRANSFER: A SINGULAR PERTURBATION SOLUTION
Walter B. Olstad Washington Nov. 1968 83 p refs
(NASA-TR-R-295) Avail: CFSTI CSCL 20D

A singular perturbation solution to the blunt-body stagnation region flow of an inviscid, radiating gas has been obtained by means of the Poincare-Lighthill-Kuo, or perturbation-of-coordinates, method. A number of results for a gray gas have been presented in order to provide some physical insight into the effects of various parameters on the shock-layer enthalpy profiles and the radiant heat-transfer rates. A nongray absorption coefficient model was developed which includes, in an approximate way, the important vacuum ultraviolet contributions of bound-free and line transitions. This model was used to obtain solutions pertinent to the case of reentry into the earth's atmosphere. While the results are restricted to small values of the radiation cooling parameter, which characterized the relative importance of radiation and convection as energy transport mechanisms, they cover broad ranges of vehicle velocity, altitude, and nose radius, which are of practical interest. Author

HEAT TRANSFER AND PRESSURE DISTRIBUTIONS DUE TO SINUSOIDAL DISTORTIONS ON A FLAT PLATE AT MACH 20 IN HELIUM
James P. Arrington Washington Nov. 1968 49 p refs
(NASA-TN-D-4907) Avail: CFSTI CSCL 01A

An experimental investigation was conducted to determine the effects of a two-dimensional repetitive sine-wave distortion on the pressure and heat-transfer distributions. Tests were made on a sharp flat plate with a distorted section in a relatively thick boundary layer which changed from laminar to transitional for certain test conditions. The tests were conducted in helium at free-stream Mach numbers of about 20, over a range of length Reynolds numbers varying from 2.72×10^6 to 8.80×10^6 with the flat-plate surface at angles of inclination of 0°, 5°, and 10°. The results of the present tests were similar to results obtained in air at lower free-stream Mach numbers and Reynolds numbers with relatively thinner boundary layers. The pressure and heat-transfer distributions were greatly altered in the distorted section (oscillating from maximum to minimum values) with the heating distribution being affected the most. The magnitude of these pressure and heat-transfer oscillations also depended on whether the flow was laminar or transitional. However, the values generally approached the undisturbed flat-plate results a short distance downstream of the distorted region. Author

USE OF PHOTOIONIZATION IN MEASURING VELOCITY PROFILE OF FREE-STREAM FLOW IN LANGLEY PILOT MODEL EXPANSION TUBE
Wilfred J. Friesen Washington Dec. 1968 46 p refs
(NASA-TN-D-4936) Avail: CFSTI CSCL 20D

Free-stream velocity profile measurements were made of expansion tube flows for flow core velocities of the order of 6300 m/sec, for flow core densities ρ/ρ_0 (where ρ is the gas density and ρ_0 is the gas density at standard conditions) from 3×10^{-4} to 2×10^{-3}, and over flow time intervals of about 150 μsec. The method of measurement was based on identifying a region of the flowing test gas by photoionization and, after a delay of a few microseconds, photographing the displaced position of the region by the light emitted when an electrical current was passed through it. The main conclusions reached are that there is a flow core with a radius between 50 and 60 percent of the tube radius, in which the velocity is uniform to within 5 percent, and that the method of measurement is a useful technique for obtaining velocity profiles within the range of test gas density. FLOW IN A TWO-DIMENSIONAL CHANNEL WITH A RECTANGULAR CAVITY
Unmeel B. Mehta and Zalman Lavan Washington NASA Jan. 1969 89 p refs
(Grants NGR-14-004-028; NsG-694)
(NASA-CR-1245) Avail: CFSTI CSCL 20D

The steady state flow characteristics in a rectangular cavity located in the lower wall of a two-dimensional channel whose upper wall was moved with a uniform velocity, were investigated by solving the complete Navier–Stokes equations for laminar imcompressible fluid in terms of the stream function and vorticity. Numerical results were determined for a range of Reynolds numbers from 1 to 500 and for cavity aspect ratios of 0.5, 1.0 and 2.0. A circulating flow extending the whole height was observed for shallow and square cavities. For deep cavity a secondary vortex near the bottom of the cavity was also noticed. Time dependent solutions for the vortex flow in a square cavity bounded by three motionless walls and a fourth moving in its plane were obtained. Author

THE STAGNATION-POINT BOUNDARY LAYER WITH SUCTION AND INJECTION IN EQUILIBRIUM DISSOCIATING AIR
Kenneth C. Weston Washington Dec. 1968 89 p refs
(NASA-TN-D-3889) Avail: CFSTI CSCL 20D

Calculations for the compressible, equilibrium dissociating stagnation point boundary layer with suction and injection were performed using a digital computer. Results are shown which reproduce both the perfect gas, linear viscosity-temperature relation calculations of Cohen and Reshotko, and the dissociating air results of Fay and Riddell. Calculations for the dissociated air boundary layer with air injection indicate significantly higher heating rates than those obtained for the perfect gas, linear viscosity-temperature relation model. A procedure is indicated which allows application of the results for air injection to engineering calculations for cases of foreign-gas injection. Author

INVISCID FLOW ANALYSIS OF TWO PARALLEL SLOT JETS IMPINGING NORMALLY ON A SURFACE
Richard T. Gedney and Robert Siegel Washington Dec. 1968 32 p refs
(NASA-TN-D-4957) Avail: CFSTI CSCL 20D

Conformal mapping was applied to obtain the flow pattern for two parallel jets of finite width originating from infinity and impinging normally on a plate. The ratio of the half spacing between the jets to the jet width (S/H) is the single parameter governing the flow. Analytical expressions and graphs are given for the free streamlines, internal streamlines, and pressure coefficient along the plate for various values of the S/H ratio. A portion of each jet flows outward along the plate and the remaining flow is a recirculation back toward infinity along the axis between the jets. The amount of recirculation is given as a function of the S/H ratio. Author

NONLINEAR DECAY OF A DISTURBANCE IN AN UNBOUNDED VISCOUS FLUID
Robert G. Deissler Washington Dec. 1968 29 p refs
(NASA-TN-D-4947) Avail: CFSTI CSCL 20D

The nonlinear decay of a disturbance was calculated by an iterative solution to the Navier–Stokes equations. The general expressions obtained for successive approximations were suitable for machine computations, within the limitations of the computer capacity. For the initial condition, a three dimensional cosine distribution with two harmonic terms was assumed. The nonlinear interaction of these harmonic terms then produced new harmonics. As the iteration process proceeded, a large number of harmonics, at wave numbers higher than, lower than, or the same as the original ones were generated. This process appeared to be similar to that occurring in the early stages of the development of turbulence by flow through a grid. Author

EMPIRICAL CHARACTERIZATION OF SOME PRESSURE WAVE SHAPES IN STRONG TRAVELING TRANSVERSE ACOUSTIC MODES
Marcus F. Heidmann Washington NASA Jan. 1969 12 p refs
(NASA-TM-X-1716) Avail: CFSTI CSCL 20D

Pressure wave shapes measured at the wall of a short cylindrical cavity containing a relatively pure traveling transverse acoustic mode were evaluated for harmonic content. The empirical relation $p' = \epsilon \cos t + \epsilon^2 \cos 2t + \epsilon^3 \cos 3t + \ldots$, was found to adequately represent wave shapes for peak-to-peak pressure amplitudes approaching the mean cavity pressure. The relation is relatively simple and provides a convenient method of characterizing strong wave shapes for many analytical and experimental purposes. Author

OBSERVATIONS OF INTERFACE BEHAVIOR DURING INFLOW TO AN ELLIPTICAL ENDED CYLINDER IN WEIGHTLESSNESS
Eugene P. Symons and Ralph C. Nussle Washington Jan. 1969 17 p refs
(NASA-TM-X-1719) Avail: CFSTI CSCL 20D

An experimental investigation was conducted during which liquid was pumped into a 4-cm-diameter cylindrical tank, initially void of liquid, in a weightless environment. The tank bottom, an inverted ellipse, was scaled from the Centaur propellant tank, as was the inlet line location. Three inlet diameters (0.2, 0.4, and 0.8 cm) were studied. The liquid–vapor interface during inflow became increasingly distorted as inflow velocity was increased. Furthermore, any increase in the ratio of inlet diameter to tank diameter necessitates lowering of inlet velocity to maintain a stable liquid–vapor interface. Author

ANALYSIS OF THE STABILITY OF A THIN LIQUID FILM ADJACENT TO A HIGH-SPEED GAS STREAM
Philip R. Nachtsheim Washington Jan. 1969 34 p refs
(NASA-TN-D-4976) Avail: CFSTI CSCL 20D

Oblique wave formation in the melt layer of a body entering the atmosphere is examined. The three-dimensional disturbance equations of the liquid including the effects of viscosity are formulated. The disturbance motion of the gas is taken into account neglecting viscosity. The Tollmien–Schlichting type of instability in the liquid is excluded and only those modes are considered for which the phase velocity of the disturbance is greater than the velocity of the basic liquid flow at the gas-liquid interface. Numerical and approximate analytic results are presented for waves in the liquid with supersonic flow over their crests. A comparison with the numerical solutions shows that the approximate analytic solutions are accurate for solving the eigenvalue problem when the Reynolds number of the liquid film is small, that is, for a highly viscous melt layer. The approximate solutions are obtained in closed form. It is demonstrated that the mechanism of liquid wave generation is supersonic wave drag. The relation between the wavelength of the disturbance and the other parameters involved in the eigenvalue problem is determined and is presented for a wide range of these parameters. Author

PRELIMINARY INVESTIGATION OF MOMENTUM DIFFUSION BETWEEN TWO SUPERSONIC AIRSTREAMS IN THE PRESENCE OF SHOCK WAVES

John P. Weidner and Carl A. Trexler Washington Jan. 1969 79 p refs

(NASA-TN-D-4974) Avail: CFSTI CSCL 20D

An experimental study of compressible two-dimensional mixing between two parallel supersonic airstreams passing through oblique shock waves has been performed, and the results have been compared with those of a computerized theoretical method. This experiment was restricted to measurements of momentum diffusion in the near region, with the purpose of the study being to determine the effect of the oblique shock waves on mixing. The model consisted of a two-dimensional rectangular duct mounted in a Mach 4 airstream operating at ambient temperature. The Mach 4 stream was the primary air through the duct, while the secondary air was injected at a higher total pressure and Mach number through three isentropic nozzles set into the bottom surface of the duct. The nozzles were oriented at such an angle relative to the primary stream as to create a set of shock waves each having a turning angle of about 6.0°. Total pressure measurements were taken across the mixing zone at several stations on either side of two crossing shock waves and were reduced to velocity profiles through the mixing zone. Average Mach numbers measured in the two streams were 3.5 and 4.4 ahead of the shock waves and 2.9 and 3.7 behind the shock waves. The theoretical solution indicated an increase in eddy viscosity in the vicinity of the shock waves. Author

REAL-GAS EFFECTS IN CRITICAL FLOW THROUGH NOZZLES AND THERMODYNAMIC PROPERTIES OF NITROGEN AND HELIUM AT PRESSURES TO 300 TIMES 10^5 NEWTONS PER SQUARE METER (APPROX. 300 ATM)

Robert C. Johnson Washington 1968 204 p refs

(NASA-SP-3046) Avail: CFSTI CSCL 20D

A critical-flow factor for gaseous nitrogen and helium flowing through critical-flow nozzles was calculated. This factor provides a convenient means for determining the mass-flow rate of these gases through critical-flow nozzles. In addition, the results include the nozzle throat velocity, the compressibility factor, the entropy, the enthalpy, the specific heat, the specific-heat ratio, the speed of sound, and the critical pressure, density, and temperature ratios. These results are tabulated as functions of the plenum pressure and temperature. The pressure range is 300 $\times$ 10^5 newtons per square meter (approx. 300 atm). For nitrogen, the temperature range is from 100° to 400°K. For helium, the range is from 15° to 400°K. The FORTRAN 4 subroutines used to calculate these results are also included. These routines permit three different sets of independent variables. In addition to the plenum pressure and temperature, the other independent variable is either the nozzle exit pressure, the nozzle exit Mach number, or the nozzle exit temperature. Author

ANALYTICAL AND EXPERIMENTAL STUDY OF THE DYNAMICS OF A SINGLE-TUBE COUNTERFLOW BOILER

H. L. Hess, J. R. Hooper, and S. L. Organ Washington NASA Feb. 1969 196 p refs

(Contract NAS3-9420)

(NASA-CR-1230) Avail: CFSTI CSCL 20D

An analytical and experimental study of a single tube counterflow boiler was conducted. The boiler geometry simulated one of the tubes of a typical boiler for a Rankine cycle space powerplant. Steady state, frequency response, and step response tests were conducted using water as the working fluid. The frequency response and step response tests were conducted by perturbing the boiling fluid flow rate at the inlet to the boiler. Experimental transfer functions were obtained from the frequency response test results. A linearized analysis of the boiler dynamics was performed to derive a theoretical expression for the boiling fluid exit pressure transfer function. A comparison was made between the theoretical and experimental transfer functions. Author

FREQUENCY RESPONSE OF A FORCED FLOW SINGLE TUBE BOILER WITH INSERTS AND EXIT RESTRICTION

Grady H. Stevens, Eugene A. Krejsa, and Jack H. Goodykoontz Washington Feb. 1969 43 p refs

(NASA-TN-D-5023) Avail: CFSTI CSCL 20M

The frequency response technique was used to measure some of the dynamic properties of a heat exchanger boiler. The boiling fluid, Freon-113, exhausted through an orifice to a constant pressure. The boiling fluid inlet flow rate was varied sinusoidally about a mean value. The magnitude and phase of the perturbations of the boiler inlet flow, inlet pressure, and orifice pressure drop were measured. The data were used to compute the boiler inlet impedance (the complex ratio of the perturbations of inlet pressure and inlet flow) and the transfer impedance (the complex ratio of the perturbations of orifice pressure drop and boiler inlet flow). THE ELLIPSOIDAL VELOCITY DISTRIBUTION FUNCTION

N. Stankiewicz Washington Feb. 1969 18 p refs

(NASA-TN-D-5026) Avail: CFSTI CSCL 20D

An ellipsoidal velocity distribution function is found as the result of maximizing the entropy with constraints on the number density, the mean velocity, and the stress energy tensor. The relation of this function to the macroscopic flow equations (continuity, momentum, etc.) is studied. The special case of one dimensional channel flow is analyzed. It is shown that the ellipsoidal distribution function gives a consistent description of viscous flow. That is, the parabolic flow profile and Newton's law of viscosity become natural consequences of the macroscopic flow equations. Author

LATERAL SLOSHING IN CYLINDER UNDER LOW-GRAVITY CONDITIONS

Jack A. Salzman and William J. Masica Washington Feb. 1969 35 p refs

(NASA-TN-D-5058) Avail: CFSTI CSCL 20D

An experimental investigation was conducted to determine liquid sloshing characteristics in cylinders with hemispherical bottoms under low Bond number conditions. Static contact angles were restricted to near 0° so that the equilibrium liquid surface was nearly hemispherical at very low Bond numbers. The experiments were conducted in both normal and low gravity environments. Data were obtained at Bond numbers ranging from 0 to greater than 800. The natural frequency and damping of the fundamental asymmetric sloshing mode at deep liquid depths were correlated in terms of known system parameters. The natural frequency data at shallow liquid depths were compared with existing theoretical studies. All results were compared with previous normal gravity experimental sloshing studies. Author

EFFECT OF FLOW RATE ON THE DYNAMIC CONTACT ANGLE FOR WETTING LIQUIDS

Thom A. Coney and William J. Masica Washington Mar. 1969 22 p refs

(NASA-TN-D-5115) Avail: CFSTI CSCL 20D

Experimental measurements were made of the dynamic contact angle over a previously wetted liquid surface as a function of interface velocity and liquid properties. The experiments were conducted in a weightless environment using glass tubing with a rectangular cross section. All liquids exhibited zero degree static contact angles. The study showed that existing theory adequately predicted the contact angle dependence on interface velocity and liquid properties. In addition, qualitative agreement was obtained between the theoretical and experimental interface shapes. Author

VISCOUS FLOW IN A SHORT CYLINDRICAL VORTEX CHAMBER WITH A FINITE SWIRL RATIO

Robert W. Hornbeck Washington Mar. 1969 34 p refs

(NASA-TN-D-5132) Avail: CFSTI CSCL 20D

The laminar incompressible viscous flow in a short cylindrical vortex chamber is analyzed numerically. The flow is assumed to enter the chamber periphery with an arbitrary ratio of tangential to radial velocity components and to exit at a line sink at the chamber axis. The numerical technique permits consideration of both the tangential and radial momentum equations. Comparisons are made with solutions available for the limiting cases of zero swirl and infinite swirl. Results are presented for a wide variety of swirl ratios, Reynolds numbers, and chamber aspect ratios. The results include radial and tangential velocity profiles, pressure distributions, and points of radial flow reversal. Author

CALCULATION OF COMPRESSIBLE TURBULENT BOUNDARY LAYERS WITH PRESSURE GRADIENTS AND HEAT TRANSFER

Larry L. Lynes, Jack N. Nielsen, and Gary D. Kuhn Washington NASA Mar. 1969 141 p refs

(Contract NAS2-4391)

(NASA-CR-1303; NEAR-TR-6) Avail: CFSTI CSCL 20D

The method of integral relations has been applied to the calculation of compressible turbulent boundary layer characteristics under the action of pressure gradients. In order to solve the problem it was necessary to specify an eddy-viscosity model. A computer program was developed to do the calculations for a class of two dimensional or axisymmetric configurations from low speeds to hypersonic speeds. At hypersonic speeds, comparisons were made between predicted and measured boundary layer quantities for curved plates and flat plates with and without oblique shock wave impingement. The computer program has been applied to a hypersonic axisymmetric configuration composed of a hollow cylinder culminating in a compression flare. A simple method is presented for estimating the magnitude of the normal pressure gradients and of adjusting the displacement and momentum thicknesses predicted by boundary layer theory for the gradients. FORCES AND MOMENTS DUE TO AIR JETS EXHAUSTING PARALLEL TO LARGE FLAT PLATES IN A NEAR VACUUM

Joseph J. Janos and Sherwood Hoffman Washington Apr. 1969 26 p refs

(NASA-TN-D-5147) Avail: CFSTI CSCL 20D

Three flat plates of equal length but with width-length ratios of 0.25, 0.50, and 1.0 were tested. The nozzles used were conical and had nominal exit Mach numbers of 1.0, 3.0, and 5.0. The locations of the nozzles were varied longitudinally and vertically. The plate widths were 48, 96, and 192 throat diameters. The ratios of total pressure to ambient pressure varied from 22×10^6 to 15.5×10^6, and the ratios of jet exit pressure to ambient pressure varied from 11.6×10^6 to 3.2×10^5. The pressure altitude was 312,000 feet (95 km). The impingement forces, moments, and center-of-pressure trends were similar for all three plates. The magnitudes of the impingement parameters were decreased by reducing the plate width or effective plate length, raising the nozzle location, increasing the exit Mach number, or decreasing the jet flow turning angle. For the nozzle positions surveyed, the normal force on the plate was as high as 47.5 percent of the thrust for a nozzle close to the widest plate and as low as 4.8 percent of the thrust for a nozzle relatively high above the narrowest plate. THE LEADING-EDGE EFFECTS ON THE LAMINAR FLATPLATE BOUNDARY LAYER AND THE AERODYNAMIC HEATING AT MACH 10.4

Howard W. Stone Washington May 1969 34 p refs

(NASA-TN-D-5160) Avail: CFSTI CSCL 20D

Wall pressure and heat transfer distributions and boundary layer impact pressure profiles were obtained on a flat plate with both sharp and cylindrically blunted leading edges. The range of free stream Reynolds number based on leading edge thickness was from 73 to 70,000. Although the boundary layer displacement effects behind a sharp leading edge are known to increase the wall pressure and heat transfer in the weak interaction regime, these tests show that boundary layer displacement effects result in only a slight change in the impact pressure and velocity profiles. Slight blunting of the leading edge had little effect on the pressure distribution but, with the boundary layer growing in an entropy gradient, the heat transfer was reduced. Large leading edge bluntness increased the heat transfer relative to the sharp leading edge. Author

EFFECT OF FREE STREAM TURBULENCE ON COAXIAL MIXING

R. A. Kulik, J. J. Leithem, and H. Weinstein Washington NASA May 1969 48 p refs

(Grant NsG-694)

(NASA-CR-1336) Avail: CFSTI CSCL 20D

The effects of free stream turbulence and boundary layer trip devices on mixing in a co-axial jet stream are presented. A screen of fine mesh placed in the outer infinite free stream effected both a boundary layer separation where screen and inner duct met, and a lowering of the free stream turbulence level. To determine the dominate effect of the screen, a boundary layer trip device was used to effect the boundary layer separation without reducing the free stream turbulence. Both air and air-Freon-12 systems with density ratios of 1 and 4 respectively, were studied. The outer stream velocity was kept constant at 51 ft/sec and the mass average velocity ratios varied from 2 to 20. Data are presented for the relative axial turbulence intensities as well as velocity, concentration, and mass holdup. Comparison of the screen and boundary layer trip device data taken without any such devices indicated that both devices effected the same preservation of the inner-stream integrity. Mixing is retarded by a factor of 2 to 4 for low velocity ratios. Author

PHOTOGRAPHIC STUDY OF A BROMINE JET FLOWING IN A COAXIAL AIRSTREAM AND IMPINGING ON A STAGNATION SURFACE

Charles C. Masser and Maynard F. Taylor Washington May 1969 22 p refs

(NASA-TN-D-5209) Avail: CFSTI CSCL 20D

A photographic study is made of a bromine jet issuing into a coaxially flowing airstream and impinging on a stagnation surface. The objective is to determine if the amount of bromine in the near jet region can be increased by the insertion of a stagnation surface in the jet. The diameter, shape and distance of the stagnation surface from the bromine injection point was varied. Several cases showed that a stagnation surface did slightly reduce the erratic behavior of the jet, and in other cases slightly increased the amount of bromine in the near jet region. However, no substantial increase of bromine in the near jet region was found by using a stagnation surface. Author

VAPOR INGESTION PHENOMENON IN WEIGHTLESSNESS

Kaleel L. Abdalla and Steven G. Berenyi Washington May 1969 32 p refs

(NASA-TN-D-5210) Avail: CFSTI CSCL 20D

An experimental program was conducted in which the vapor ingestion phenomenon during draining from flat-bottom, cylindrical tanks was studied in both weightlessness and normal gravity. The vapor ingestion phenomenon in weightlessness was correlated with the Weber number using the critical liquid height prior to vapor ingestion as the significant dimension. The normal gravity data agreed with a theoretical analysis predicting a Froude number correlation. Liquid residuals were generally higher in weightlessness than in normal gravity. Effects of initial liquid height and liquid properties on the vapor ingestion phenomenon and comparisons of vapor ingestion heights for both environments are also presented. Author

HYDRODYNAMIC STABILITY OF INVISCID ROTATING COAXIAL JETS

S. Leibovich Washington NASA May 1969 39 p refs

(Grant NGR-33-010-042)

(NASA-CR-1363) Avail: CFSTI CSCL 20D

The inviscid hydrodynamic stability of a swirling coaxial jet to axisymmetric disturbances is investigated when the flow is incompressible but density stratified. The axial and swirl velocity components and the density profiles are all allowed to be arbitrary functions of radius. Flow with a cylindrical vortex sheet is examined. The discontinuity sheet introduces an instability which cannot be stabilized by rotation as in the continuous case. Nevertheless, the presence of rotation reduces the growth rates of disturbances. The case of rapid rotation outside, and no rotation inside, is particularly simple to treat. Author

EXPERIMENTAL INVESTIGATION OF BASE FLOW FIELD AT HIGH ALTITUDE FOR A FOUR ENGINE CLUSTERED NOZZLE CONFIGURATION

Edwin B. Brewer and Charles E. Craven (Lockheed Missile and Space Co.) Washington NASA May 1969 100 p refs

(NASA-TN-D-5164) Avail: CFSTI CSCL 20D

Surveys of the base flow were made with static and pitot pressure probes, a constant current anemometer, condenser microphones, and wind vanes. The reverse flow was confined to the proximity of the model centerline and appeared to be an axisymmetric jet decaying from supersonic to subsonic flow. This reverse jet impinged on the center of the heat shield and spread out, forming a wall jet. A slowly circulating separated flow region was present in the base region formed from the viscous pumping of the nozzle jet plumes, the axisymmetric reverse jet, and the base wall jet. The static pressure in the circulating region was very nearly ambient. Hot-wire measurements indicated that the flow of the reverse jet had a relatively low turbulence level. The reverse jet originates from the detached shock portion of the inviscid plume–plume impingement line rather than the oblique shock recompression portion; therefore, the shear layer type of analysis for calculating the reverse flow is not applicable. Author

ON MINIMIZING THE WAKE OF DROPLETS

Franklin K. Moore Washington NASA May 1969 18 p refs

(Grant NGR-33-010-042)

(NASA-CR-1368) Avail: CFSTI CSCL 20D

The inviscid flow inside and outside a moving droplet is analyzed, allowing the shape to be nonspherical subject to surface tension. Specifically, the Weber number-drag relationship is sought which seems to assure the least tendency to form a separated wake. Two conditions of continuous velocity derivatives are imposed at the rear stagnation point for this purpose. The results give reasonable changes of shape (flattening) and reasonable but somewhat too low values of Weber number for minimum wake. Even rather small departures from spherical shape dramatically suppress internal circulation. Author

EXPLORATORY INVESTIGATION ON THE MEASUREMENT OF SKIN FRICTION BY MEANS OF LIQUID CRYSTALS

Enrique J. Klein and Angelo P. Margozzi Washington May 1969 12 p refs

(NASA-TM-X-1774) Avail: CFSTI CSCL 20D

A new method is proposed for directly measuring local skin friction in aerodynamic testing. It makes use of thin coatings of cholesteric liquid crystal mixtures that respond to shearing forces by changes in the wavelength of maximum light scattering. A calibration of shear versus wavelength was obtained for a sample substance; a static calibration was made to measure the effects of temperature, pressure, and angle of viewing; and the behavior of the substance was observed in a pipe-flow experiment. Preliminary results showed that the method appears feasible. Author

COMPRESSED GAS HANDBOOK

John S. Kunkle, ed., Samuel D. Wilson, ed., and Richard A. Cota, ed. 1969 572 p

(NASA-SP-3045) Avail: SOD $4.75; CFSTI CSCL 20D

A complete source of the theory and data required to analyze high pressure compressible flow systems found in space vehicle ground support equipment is provided. The theoretical equations of fluid flow by derivation are developed. Practical problem solving is treated qualitatively. In the section on applications, the theory is presented without the supporting derivations and treats practical problems quantitatively. It is intended as a ready reference for analysis. A feature is the full size working charts for the rapid solution of common compressible flow problems. A selection of basic thermodynamic data for air, nitrogen, oxygen, helium, and hydrogen is appended. The data range is as wide as possible for completeness, and special emphasis is given to data up to 6000 psig, and from +150°F to −100°F. Author

NONLINEAR PROBLEMS OF COMPRESSIBLE FLOW

A. G. Bagdoev 1969 172 p refs Transl. into ENGLISH of the publ. "Nekotorye Nonlineinye Zadachi o Dvizhenii Szhimaemoi Zhidkosti" Erevan, Izd. AN Arm. SSR, 1967 Published for NASA and NSF *Its* Cat. NO. 5436

(NASA-TT-F-560; TT-69-55023) Copyright. Avail: CFSTI CSCL 20D

The motion of a half-space of ideal compressible fluid due to an arbitrary pressure front moving over its surface is considered. Physically, such a situation arises in an explosion on or above the surface of a fluid. Since a liquid is a considerably denser medium than air, the pressure in the air may be considered as in the reflection of a shock wave from a rigid wall. Consequently, the pressure at the liquid surface will be known as a function of the time and coordinates. The problem consists in finding a solution of the gas dynamic equations for given discontinuity conditions at the boundary. For a liquid under pressures of the order of several hundreds of atmospheres, the parameter determining the liquid motion will be small, and a linear theory can be used. The linear theory, however, gives an incorrect picture in the vicinity of the sound wave, as well as near the free surface and at large time. It is also worthwhile to calculate approximations higher than the first. Here the problem is formulated nonlinearly for the pressure, a small parameter is introduced and an isentropic approximation used. It is shown that the linear theory can be greatly improved by using only the linear solution. Various methods of improving the linear solution are studied, and the pressure is determined in the second approximation. Author

SUMMARY AND CORRELATION OF SKIN-FRICTION AND HEAT-TRANSFER DATA FOR A HYPERSONIC TURBULENT BOUNDARY LAYER ON SIMPLE SHAPES

Edward J. Hopkins, Morris W. Rubesin, Mamoru Inouye, Earl R. Keener, George C. Mateer et al Thomas E. Polek Washington Jun. 1969 29 p refs

(NASA-TN-D-5089) Avail: CFSTI CSCL 01A

Local skin-friction and heat-transfer data were directly measured in air for turbulent boundary layers on flat plates, cones, and a wind-tunnel wall. The Mach number at the edge of the boundary layer ranged between 5 and 7.4 and the wall to adiabatic wall temperature ratio varied bwtween 0.1 and 0.6. The skin-friction and heat-transfer data are compared with other data obtained by direct measurement of surface shear with balances and accompanied by boundary layer surveys. The use of momentum thickness Reynolds number in the skin-friction comparison avoids arbitrary location of the virtual origin of the turbulent boundary layer. Adiabatic and cold wall data are employed to assess four theories for predicting turbulent skin friction. Analysis of the skin-friction data indicates that the theory of Van Driest II or Coles gives the best predictions for wall to adiabatic wall temperature ratios above 0.3. At wall to adiabatic wall temperature ratios below 0.3, none of the theories give the proper trend with wall to adiabatic wall temperature ratio. The heat-transfer analysis for nonadiabatic conditions generally substantiates the skin-friction analysis. Author

HIGH-VELOCITY HYDRODYNAMICS, NO. 4

I. L. Rozovskiy, ed. Washington NASA Jun. 1969 165 p refs Transl. into ENGLISH of the publ. "Gidrodinamika Bolshikh Skorostey" Kiev, Naukova Dumka Press, 1968

(Contract NASw-1695)

(NASA-TT-F-577) Avail: CFSTI CSCL 12A

The problem of complete approximation in some region of the Euclidian space of a new boundary value problem is discussed. The criteria for a uniform approximation are satisfied by allowing freedom in the selection of the mapping of the Euclidian space into the new space as well as in the choice of the new differential operator, the boundaries of the region and the boundary conditions. The complete approximation in the new space yields a linear problem which leads to satisfactory results in physical space for sufficiently large perturbation parameters. The Poincare–Lighthill–Go method is an example of a procedure based on the idea of complete approximation. Problems in hydrodynamics which may be solved by this method are examined. Author

HEAT TRANSFER TO THE WINDWARD SIDE OF A FINENESS-RATIO-2.9 CYLINDER WITH NEARLY SPHERICAL

ENDS AT A MACH NUMBER OF 6 AND ANGLES OF ATTACK OF 50°, 70°, AND 90°

James L. Hunt Washington Jul. 1969 45 p refs
(NASA-TN-D-5251) Avail: CFSTI CSCL 20D

An investigation was conducted in the Langley 20-inch Mach 6 tunnel to define the heat transfer to a fineness-ratio-2.9 cylinder with nearly spherical ends. Heat transfer data and schlieren photographs were obtained at a nominal Reynolds number, based on model diameter, of 1×10^6 at sweep angles of 0°, 20°, and 40°. Beckwith's laminar swept infinite-cylinder theory, small-cross-flow theory, and local similarity theory with Libby's three-dimensional stagnation-point theory were used piecewise to predict the laminar heat transfer with acceptable accuracy. Local flat-plate approximations for turbulent heat transfer, calculated by the method of Spalding and Chi, agreed with the data obtained in the turbulent flow regions. Author

FLOW-FIELD MEASUREMENTS DOWNSTREAM OF TWO PROTUBERANCES ON A FLAT PLATE SUBMERGED IN A TURBULENT BOUNDARY LAYER AT MACH 2.49 AND 4.44

Lana M. Couch Washington Jul. 1969 136 p refs
(NASA-TN-D-5297) Avail: CFSTI CSCL 20D

Pilot pressure, static pressure, and total temperature distributions were obtained on a flat plate and on the portion of a flat plate downstream of a plate-mounted cylinder and of a plate-mounted fairing at free-stream Mach numbers of 2.49 and 4.44. Velocity gradients adjacent to the plate surface downstream of both models were greater than those obtained on the plate surface and indicate higher shearing stress and heat transfer to the plate surface within the model wakes. The extent of mixing downstream of both models, as indicated by velocity profiles, decreased with increasing Mach number. Increasing the unit Reynolds number by a factor of 2 had only a negligible effect on the profiles obtained on the flat plate. Flow patterns on the plate surface (as shown by oil-flow photographs) downstream of both models indicated some regions of similarity. Author

TURBULENCE IN THE MIXING REGION BETWEEN DUCTED COAXIAL STREAMS

J. J. Leithem, R. A. Kulik, and H. Weinstein Washington NASA Jul. 1969 48 p refs
(Grant NsG-694SC)
(NASA-CR-1335) Avail: CFSTI CSCL 20D

An experimental investigation of both homogeneous and heterogeneous compound ducted jets is presented for axially symmetric coflowing streams. The flow system considered in one of a circular 3 inch inner stream issuing into a circular 6 inch, faster moving, outer stream. Air was used for the outer stream gas and both air and Freon-12 were used for the inner jet. This gave density ratios of 1 and 4, inner to outer stream, respectively. The velocity ratio was varied from 4.19 to 30.0 for both cases with absolute velocities of 1.5 to 40 ft/sec. All data were taken with a constant temperature hot wire anemometer system. Average velocity, radial and axial turbulence intensity profiles both near and far downstream are presented for the homogeneous cases. Average velocity, density and axial turbulence intensity profiles as well as mass holdup data both near and far downstream are presented for the heterogeneous cases. The ratio of axial to radial turbulence intensity was about 1.5, the same as found for unconfined coaxial flow. For the higher density ratio cases, the inner stream integrity was maintained better than for the homogeneous cases. The flow system was found to be one of combined wake-coaxial flow with possible backflow. Author

DRAG REDUCTION DUE TO GAS INJECTION THROUGH VARIOUS DISCRETE SLOTS ON A THREE-DIMENSIONAL WING AT MACH 2.01

Russell B. Sorrells, III, K. R. Czarnecki, and Lorraine F. Satchell Washington Jul. 1969 45 p refs
(NASA-TN-D-5307) Avail: CFSTI CSCL 20D

Force measurements were made of the drag reduction due to the injection of gas into a turbulent boundary layer through discrete slots of various sizes and configurations on a three-dimensional semispan wing at a Mach number of 2.01. Air, helium, and Freon were injected, transition was fixed, and the tests were conducted at Reynolds numbers, based on the mean geometric chord, ranging up to 4.48×10^6. The theoretically estimated and measured skin-friction reductions are compared. It was found that for the supersonic transport and for the slot drags incurred in this investigation, engine bleed air does not provide sufficient mass flow to warrant the use of air injection for drag reduction over an entire wing span. However, if the engine bleed air is injected only over the nacelles, it appears possible at Mach 2.0 to achieve a drag reduction equivalent to from 9 to 35 percent of the nacelle skin friction, the percentage depending on the amount of bleed plenum pressure energy that is used for thrust. Greater drag reductions were obtained by injecting helium into the boundary layer than by injecting air or Freon. In the design of an ejection system, the slot drag and the available thrust rather than the skin-friction reduction should be optimized, and the possible lift interference effects of an injected gas should be considered in selecting the location of an ejection slot or nozzle. UNIFIED ANALYSIS OF TURBULENT JET MIXING

Joseph A. Schetz Washington NASA Jul. 1969 32 p refs
Prepared jointly with Md. Univ., College Park
(NASA Order R-76; Contract NOw-62-0604-c) Avail: CFSTI CSCL 20D

A unified model for the eddy viscosity in jet mixing flows is presented. The successful boundary layer model due to Clauser is given a new interpretation that permits generalization to a wide variety of turbulent flows. The specific functional expression for a given flow problem is derived. Comparisons of experimental results and calculations using the unified model as well as models previously suggested are presented. The cases considered include planar and axi-symmetric flows, varying temperature, foreign gas injection, both subsonic and supersonic external flow, and a range of the mass flow parameter, $\rho_j u_j / \rho_e u_e$, from 0.04 to 4.0. The unified model provided results in better agreement with the data over this range of conditions than those for any previously suggested model. Author

SUMMARY OF RECENT GASEOUS REACTOR FLUID MECHANICS EXPERIMENTS

Robert G. Ragsdale and Chester D. Lanzo Washington Aug. 1969 16 p refs
(NASA-TM-X-1847) Avail: CFSTI CSCL 20D

Three recent gaseous-nuclear rocket related fluid mechanics experiments have shown ways of reducing the mixing of two coflowing streams. In a rocket engine, such a reduction would mean less uranium loss or a lower pressure reactor. Two of the experiments were conducted with room temperature gases. The third experiment used induction heating to simulate fission heating. In these experiments, no major flow recirculation and mixing was observed, as contrasted with previous studies. Author

A FLOW EXPERIMENT ON A CURVED-POROUS-WALL GAS-CORE REACTOR GEOMETRY
Chester D. Lanzo Washington Aug. 1969 14 p refs
(NASA-TM-X-1852) Avail: CFSTI CSCL 20B

An air-air fluid flow experiment was conducted to determine the merit of a curved, porous wall gas-core reactor concept. Photographs of the flow are shown, and fuel concentration profiles are presented. The fuel volume fraction varied from 0.51 to 0.28 as the propellant -to-fuel mass flow ration was increased from 25 up to 100. The concept looks useful and merits further research. Author

STABILITY OF TWO-FLUID WHEEL FLOWS WITH AN IMPOSED UNIFORM AXIAL MAGNETIC FIELD
Carl F. Monnin and John J. Reinmann Washington Aug. 1969 51 p refs
(NASA-TN-D-5372) Avail: CFSTI CSCL 20D

The stability of an incompressible two-fluid wheel flow to infinitesimal helical disturbances is studied. The inner fluid is heavy and has infinite electrical conductivity, while the outer fluid is light and is nonconducting. An axial magnetic field is externally imposed on both fluids. This configuration may be viewed as a Rayleigh-Taylor problem in the frame of the rotating fluid and is dynamically unstable. Growth rates increase with increasing axial wavelength and azimuthal mode numbers, but decrease with increasing axial magnetic field. By increasing the magnetic field sufficiently, the system can be made stable to short axial wavelength disturbances for any azimuthal mode. Author

THE INTERACTION AND PENETRATION OF GASEOUS JETS IN SUPERSONIC FLOW
R. C. Orth, J. A. Schetz, and F. S. Billig Washington NASA Jul. 1969 46 p refs
(NASA Order R-76; Contract NOw-62-0604-c)
(NASA-CR-1386) Avail: CFSTI CSCL 20D

Experiments and analysis of the penetration of a gaseous jet from a discrete orifice into a supersonic stream, and the associated interaction with the external flow, are discussed. Included in the interaction is the definition of the shape of the stand-off shock in the main flow. A governing parameter in this analysis is the degree of underexpansion of the jet which has been shown to be directly related to the ratio of jet static pressure to the pressure downstream of a strong disturbance in the main stream. For underexpanded jets the location of the Mach disk which is paramount to the definition of the penetration has been explicitly given. For matched pressure injection or for the region of flow downstream of the Mach disk, a solid body drag model has been revised and extended to describe the penetration into a supersonic stream. The study encompassed the effects of free stream Mach number, hole size and shape and the molecular weight, Mach number, and pressure of the injectant. An exemplary case of the design of the injectors for a typical supersonic combustor is given. Author

CAVITATION PERFORMANCE OF LINE-MOUNTED 80.6 DEG HELICAL INDUCER IN HYDROGEN
Royce D. Moore and Phillip R. Meng Washington Aug. 1969 20 p refs
(NASA-TM-X-1854) Avail: CFSTI CSCL 20D

The noncavitating and cavitating performance of a line-mounted 80.6° helical inducer was determined in hydrogen over a liquid temperature range of 34.1° to 42.2° R (18.9 to 23.4 K) and a flow coefficient range of 0.08 to 0.12 at rotative speeds of 25,000 and 30,000 rpm. The tank pressure requirement for this line-mounted inducer was compared with that for the same inducer closely coupled to the tank. The tank pressure requirement was determined to be greater for the line-mounted inducer. Inducer net positive suction head requirement increased with increasing flow coefficient and rotative speed and decreased with increasing temperature. Noncavitating head-rise coefficient, which decreased with increasing flow coefficient, was unaffected by temperature and rotative speed. Author

EXPERIMENTAL AND THEORETICAL TURBULENT BOUNDARY LAYER DEVELOPMENT IN A MACH 4.4 WATER-COOLED CONICAL NOZZLE
Donald R. Boldman, James F. Schmidt, and Robert C. Ehlers Washington Aug. 1969 43 p refs
(NASA-TN-D-5377) Avail: CFSTI CSCL 20D

Boundary layer temperature and velocity measurements were obtained at three stations in the supersonic portion of a 30°-50° C-D cooled nozzle operating with an adiabatic and a cooled inlet. Tests were performed with heated air at nominal Mach numbers 2.1 to 4.4. The ratio of wall-to-stagnation temperature was 0.8 at Mach 2.1 and 0.6 at Mach 4.4. The results indicated that the thermal boundary layer in supersonic flow was not described by a 1/7 power law. The experimental momentum and displacement thicknesses compared favorably to predictions based on the integral boundary layer theories. Author

LINEARIZED THEORY OF STAGNATION POINT HEAT AND MASS TRANSFER AT HYPERSONIC SPEEDS
Kenneth K. Yoshikawa Washington Aug. 1969 35 p refs
(NASA-TN-D-5246) Avail: CFSTI CSCL 20D

An explicit closed-form solution has been obtained for the compressible, viscous shock-layer energy equation with mass addition or suction. The solution is applicable at very high speeds, when the interactions between the heated gas behind the shock wave and the layer of injected or ablated gases from the surface must be considered as well as the effect of heat conduction across the shock layer. The solution consists of the energy equation decoupled from the other conservation equations and then linearized by the introduction of constant values for the thermal and transport properties. Results of using the solution show explicitly that the effect of gas injection on convective heat transfer depends on the Stanton number without mass addition and on the relative molecular weights, and thermal and transport properties of the free-stream and injected gases. The solution is substantiated by comparisons with more exact solutions. Author

NONEQUILIBRIUM GASDYNAMICS
William S. Watt Washington NASA Aug. 1969 39 p refs
(Contract NASr-109)
(NASA-CR-1411; CAL-AD-1689-A-10) Avail: CFSTI CSCL 20D

Theoretical and experimental studies of nonequilibrium phenomena pertinent to propulsion are reported. In particular, the emphasis was directed toward obtaining a better understanding of the chemistry, fluid mechanics and the coupling of these in hydrogen propulsion systems. Research has been concentrated in three areas: (1) development of a computer program for the numerical solution of nonequilibrium expansions of reacting gas mixtures and its application to recombination in rocket nozzles; (2) experimental studies of nonequilibrium phenomena in nozzle expansion flows;

and (3) experimental studies of dissociation kinetics behind shock waves. While this research program was initially concerned with dissociation and recombination in hydrogen and the effect of catalytic additives on these phenomena, the techniques developed have been extended to investigate other nonequilibrium systems of interest in the propulsion and aerospace fields. NATURAL FREQUENCY OF LIQUIDS IN ANNULAR CYLINDERS UNDER LOW GRAVITATIONAL CONDITIONS

Thomas L. Labus Washington Sep. 1969 30 p refs

(NASA-TN-D-5412) Avail: CFSTI CSCL 20D

As a part of the general study of liquid behavior in a low gravity environment, an experimental investigation was conducted to determine the natural frequency of liquid sloshing in annular cylinders. Static contact angles were restricted to near zero degrees. The experiments were conducted over a range of gravitational conditions, including normal gravity, such that the bond numbers ranged from approximately 200. The natural frequency for deep liquid depths was empirically correlated with known system parameters as a function of the Bond number. Author

COMPARISON OF PREDICTION METHODS AND STUDIES OF RELAXATION IN HYPERSONIC TURBULENT NOZZLE-WALL BOUNDARY LAYERS

Dennis M. Bushnell, Charles B. Johnson, William D. Harvey, and William V. Feller Washington Sep. 1969 35 p refs

(NASA-TN-D-5433) Avail: CFSTI CSCL 20D

Recent turbulent boundary-layer measurements on axisymmetric nozzle walls at Mach numbers of 6, 8, and 19 are presented and compared with the predictions of two theoretical methods. One of the methods was of the integral type; the other was a finite-difference solution to the governing differential equations. The integral method gave good predictions of the data at Mach 6 and 8 and a reasonable prediction at Mach 19. Results for the finite-difference approach were available only at Mach 8, for which good agreement with data was obtained. A survey of boundary-layer data indicates that the variation of total temperature with velocity for flat-plate type of flows can be represented within the scatter of the data by the linear Crocco relation, whereas for nozzle-wall flows, this relation is generally more nearly quadratic. A finite-difference solution for the Mach 8 nozzle-wall boundary layer resulted in a quadratic-type temperature-velocity relation in the strong favorable pressure-gradient region downstream of the throat. However, near the nozzle exit the theoretical solution tended to approach the linear variation of Crocco. Apparently, the observed quadratic variation in nozzle boundary layers can be at least partly accounted for by the pressure-gradient history of the flow. Author

A MODIFIED METHOD OF INTEGRAL RELATIONS APPROACH TO THE BLUNT-BODY EQUILIBRIUM AIR FLOW FIELD, INCLUDING COMPARISONS WITH INVERSE SOLUTIONS

L. Bernard Garrett, John T. Suttles, and John N. Perkins (N. C. State Univ.) Washington Sep. 1969 94 p refs

(NASA-TN-D-5434) Avail: CFSTI CSCL 01A

A modified approach to the first order approximation of the method of integral relations is presented for the numerical calculation of the inviscid, adiabatic flow field around a blunt nose body traveling at hypersonic speeds. Solutions have been obtained and computed flow field data are presented for the adiabatic steady flow of a perfect gas and air in chemical equilibrium. The results obtained by the present method of solution are compared with results obtained by using inverse methods, property derivative integral relations methods, and experiment. The results indicate that the present method provides an accurate, versatile solution of the blunt body flow field, and the relative simplicity of the method should allow extension to coupled radiating flow field analyses. POWER- AND CROSS-SPECTRA AND SPACE-TIME CORRELATIONS OF SURFACE FLUCTUATING PRESSURES AT MACH NUMBERS BETWEEN 1.6 and 2.5

Wei J. Chyu and Richard D. Hanly Sep. 1969 21 p refs

(NASA-TN-D-5440) Avail: CFSTI CSCL 20D

The statistical properties of pressure fluctuations that were measured on surfaces adjacent to attached and separated turbulent boundary layers developed on an ogive cylinder and on the cylinder ahead of a 45° cone frustum were studied. Power- and cross-spectra, space-time correlations, convection velocities embracing both broad and narrow frequency bands, and coherence of the pressure field are presented. The pressure field under the attached boundary layer exhibits properties similar to those at subsonic speeds. Correlations and coherence functions showed a strong dependence on Mach number. Convection velocities are nearly constant with frequency in attached flow, but they vary greatly with frequency in separated flow. Coherence functions are significantly lower in separated flow than under attached boundary layers. Under both attached and separated boundary layers the phase-shift relationship of cospectra and quadspectra is a function of wave number $f\xi_1/U_c(f)$, where f, ξ_1, and U_c represent frequency, spatial distance, and convection velocity, respectively. EFFECT OF ANGLE OF ATTACK AND INJECTION PRESSURE ON JET PENETRATION AND SPREADING FROM A DELTA WING IN SUPERSONIC FLOW

Frederick P. Povinelli, Louis A. Povinelli, and Martin Hersch Washington Sep. 1969 23 p refs

(NASA-TM-X-1889) Avail: CFSTI CSCL 20D

Helium injection into the vortex flow generated over the lee side of a half-delta model was studied in a Mach 2 airstream. Concentration contours were obtained at two positions downstream of the injection orifice. Angle of attack and injection pressure were varied. Oil-streak photographic data were used to determine the location of the vortex on the delta surface. Penetration and spreading of the injectant were enhanced with increasing angle of attack. Increasing injection pressure increased the penetration but had little effect on spreading. Maximum penetration occurred at the highest angle of attack and injection pressure tested. Author

UPWASH PATTERNS ON ABLATING AND NONABLATING CONES OF HYPERSONIC SPEEDS

John B. McDevitt and Jack A. Mellenthim Washington Jul. 1969 34 p refs

(NASA-TN-D-5346) Avail: CFSTI CSCL 20D

A study has been made of the upwash patterns on slender ablating and nonablating cones at angle of attack in the hypersonic flow regime. An oil-film technique was used to display the surface streamlines on the nonablating models and tests were conducted with both laminar and transitional boundary layers. The boundary-layer-edge Mach number and model wall temperature were found to have a strong influence on the magnitude of surface upwash angles. The measured surface upwash angles at small angles of attack agreed well with theoretical estimates in the laminar case. At transitional Reynolds numbers clear evidence was obtained that streamwise vortices are entrained within the boundary layer for cones at angle of attack. Tests of ablating cones at transitional Reynolds numbers resulted in upwash groove patterns eroded in the model surfaces. These grooves were interpreted to be the result of vortices intensifying local heating rates. The upward inclination of the grooves agreed closely with the inclination of the vortex paths measured on the nonablating cones under similar test conditions. Author

EFFECTS OF ANGLE OF ATTACK AND BLUNTNESS ON LAMINAR HEATING-RATE DISTRIBUTIONS OF A 15 DEG CONE AT A MACH NUMBER OF 10.6

Joseph W. Cleary Washington Oct. 1969 56 p refs

(NASA-TN-D-5450) Avail: CFSTI CSCL 20D

Distributions of laminar heating rates are presented from wind-tunnel tests in air at a free-stream Mach number of 10.6 and unit Reynolds numbers from 0.4×10^6 to 1.8×10^6 per foot. Results shown are for angles of attack from 0° to 20° and bluntness ratios from 0 to 0.183. Measurements are included of surface streamlines made by an oil-streak technique. Heating-rate measurements are compared with predictions of similarity theory for $0 \leq \alpha \leq 20°$ and good agreement is indicated. Author

INJECTION OF AN INVISCID SEPARATED JET AT AN OBLIQUE ANGLE TO A MOVING STREAM

Marvin E. Goldstein and Willis Braun Washington Oct. 1969 72 p refs

(NASA-TN-D-5460) Avail: CFSTI CSCL 20D

An analytical solution has been obtained to the problem of a two-dimensional incompressible jet injected into a moving stream from an orifice set at an oblique angle to the stream. It is assumed that the jet separates from the downstream edge of the orifice. The solution is valid when the normalized difference between the total pressure in the jet and the total pressure in the main stream is not too large. Typical flow patterns are shown to illustrate the effects of varying both the jet offset ratio and the total pressure within the jet. Author

DISCHARGE COEFFICIENTS FOR THICK PLATE ORIFICES WITH APPROACH FLOW PERPENDICULAR AND INCLINED TO THE ORIFICE AXIS

John E. Rohde, Hadley T. Richards, and George W. Metger Washington Oct. 1969 30 p refs

(NASA-TN-D-5467) Avail: CFSTI CSCL 20D

Experimental discharge coefficients were obtained for thick plate orifices with the approaching flow perpendicular or inclined to the orifice axis. Parameters investigated were temperature and pressure levels; orifice pressure differential; approach Mach number; orifice diameter, thickness, and inlet edge condition; orifice surface finish; interference of multiple orifices; and approach passage geometry and length. The discharge coefficients were found to be dependent on approach Mach number, static pressure differential across the orifice, inlet edge radius on the orifice, angle between the main flow and the axis of the orifice, and the ratio of the orifice thickness to diameter. MOTION OF SINGLE BUBBLES UNDER LOW GRAVITATIONAL CONDITIONS

John B. Haggard, Jr., and William J. Masica Washington Oct. 1969 32 p refs

(NASA-TN-D-5462) Avail: CFSTI CSCL 20D

An experimental study was undertaken to examine single, noncondensable bubble motion under low-gravity conditions. These data were compared with normal-gravity theory and empirical results. The M number (a characteristic dimensionless parameter containing gravity and the liquid properties) was found to be a significant parameter in correlating normal- and low-gravity data. This report, together with normal-gravity theory, predicts bubble shape and terminal velocity when the liquid properties, the bubble volume, and the applied gravity field are known. The results are applicable to a range of spherical and ellipsoidal bubbles with Reynolds numbers above 50. Author

FLOW-FIELD AND DRAG CHARACTERISTICS OF SEVERAL BOUNDARY-LAYER TRIPPING ELEMENTS IN HYPERSONIC FLOW

Allen H. Whitehead, Jr. Washington Oct. 1969 40 p refs

(NASA-TN-D-5454) Avail: CFSTI CSCL 20D

Flow field and drag characteristics of several tripping-element shapes were examined under laminar boundary layer conditions at a free-stream Mach number of 6.8 to assess the contribution of the elements to the drag of wind tunnel models and to examine flow field characteristics around individual element shapes. The element drag coefficient based on local conditions depends primarily on element shape, the spacing between the elements, and the ratio of the element height to boundary layer height. Advantageously, certain element shapes have drag coefficients which are relatively independent of the ratio of element height to boundary layer height for values of this ratio that have practical application for hypersonic wind tunnel facilities. NUMERICAL CALCULATION OF VISCOUS COMPRESSIBLE FLUID FLOW AROUND AN OSCILLATING RIGID CYLINDER

John G. Trulio and Leonard Walitt Washington NASA Oct. 1969 77 p refs

(Contract NAS8-18034)

(NASA-CR-1467) Avail: CFSTI CSCL 20D

A numerical investigation was conducted of viscous, compressible flow about a circular cylinder executing harmonic motion normal to the free stream flow direction. The oscillatory motion of the cylinder led to vortex shedding, and to a Karman vortex street. Calculations were made at a Mach number of .20, Reynolds numbers of 100 and 1000, a constant cylinder oscillation amplitude equal to 10% of the cylinder radius, and a range of cylinder oscillation frequencies. The variation with oscillation

frequency of the time-averaged-drag coefficient, root-mean-squared lift coefficient, and shedding frequency, are presented. In general, increasing the cylinder oscillation frequency decreased the time-averaged drag coefficient, increased the root-mean-squared lift coefficient, and had very little effect on the shedding frequency. Author

A METHOD OF CHARACTERISTICS FOR STEADY THREE-DIMENSIONAL SUPERSONIC FLOW WITH APPLICATION TO INCLINED BODIES OF REVOLUTION

John V. Rakich Washington Oct. 1969 61 p refs
(NASA-TN-D-5341) Avail: CFSTI CSCL 20D

Characteristics theory for three-dimensional compressible flow is reviewed and the compatibility equations are derived in terms of pressure and stream angles as dependent variables. The relative merits of bicharacteristic and reference plane methods are discussed. A reference plane method is described which employs a uniformly spaced finite difference mesh between the body and shock surfaces. Numerical procedures for differentiation and interpolation ensure second-order accuracy in terms of mesh spacing. Results for the flow around inclined, circular cones, both blunted and pointed, are presented to demonstrate the method described. Predictions of surface and pitot pressures are in good agreement with available experimental results for a 15° sphere-cone at 10° angle of attack. Bluntness effects on shock-layer properties far from the nose are reasonably well predicted. Author

A PHOTOGRAPHIC STUDY OF A BROMINE JET IN A COAXIAL AIRSTREAM WITH HONEYCOMBS AT THE INJECTION PLANE

Charles C. Masser Washington Oct. 1969 25 p refs
(NASA-TM-X-1900; E-5190) Avail: CFSTI CSCL 20D

A photographic study was made of a bromine jet issuing into a coaxially flowing airstream. Honeycomb sections were placed into either or both the airstream and the bromine jet. The objective was to determine if the amount of bromine in the near jet region can be increased by the presence of a honeycomb at the jet injection plane. It was found there was no increase of bromine in the near jet region by the presence of honeycomb sections in either or both the bromine tube or airstream at the jet injection plane. However, the presence of honeycomb sections influences the transition from laminar to nonlaminar appearing jets. Author

FLUCTUATING PROPERTIES OF TURBULENT BOUNDARY LAYERS FOR MACH NUMBERS UP TO 9

William D. Harvey, Dennis M. Bushnell, and Ivan E. Beckwith Washington Oct. 1969 51 p refs
(NASA-TN-D-5496) Avail: CFSTI CSCL 20D

Estimates of the variation in intensity of the longitudinal velocity fluctuations across hypersonic turbulent boundary layers at Mach numbers from 8.2 to 8.9 were made. These estimates were based on experimental measurements of fluctuating density and pitot pressure in the nozzle-wall boundary layer of a shock tunnel. Also, it is shown that reasonable estimates of the root-mean-square values of the fluctuating velocity, density, and temperature for Mach numbers from 1.72 to 8.9 can be made by using a mixing-length approach. Comparison with previous experimental data indicate that the intensity of these fluctuating quantities, expressed in terms of suitable normalizing parameters, may be essentially independent of Mach number up to about Mach 9. Author

N69-40200*# Nielsen Engineering and Research, Inc., Palo Alto, Calif.

THEORETICAL STUDY OF VORTEX SHEDDING FROM BODIES OF REVOLUTION UNDERGOING CONING MOTION

Gary D. Kuhn, Selden B. Spangler, and Jack N. Nielsen Washington NASA Oct. 1969 61 p refs
(Contract NAS2-4765)
(NASA-CR-1448; NEAR-TR-14) Avail: CFSTI CSCL 20D

Based on experimental evidence of the existence of a steady asymmetric vortex system on a slender body in coning motion, a theoretical flow model for vortex shedding was developed using potential flow methods and slender-body theory. The model provides for the calculation of the strength and position of each of the two vortices representing the areas of concentrated vorticity in the crossflow plane and the resulting force distribution induced on the body. Initial vortex locations very close to the body must be prescribed to start the computation. The flow model developed is felt to describe reasonably accurately the nature of the vortex-like separated flow over the body and the vortex-induced force distribution. Author

SHOCK WAVES IN REAL GASES

T. V. Bazhenova et al Oct. 1969 187 p refs Transl. into ENGLISH of the book "Udarnyye Volny v Realnykh Gazakh" Moscow, Nauka Press, 1968 p 15–195
(NASA-TT-F-585) Avail: CFSTI CSCL 20D

The propagation of strong shock waves are considered in terms of the real properties of the gas media, since the temperature increase behind the shock wave produces excitation and ionization. Visualization and photographic techniques for studying shock wave propagation in shock tubes are described. Gas dynamic flow variables, and the reflection of shock waves in various gases are discussed. Results of the study are tabulated. F.O.S.

N69-41213*# National Aeronautics and Space Administration. Lewis Research Center, Cleveland, Ohio.

ANALYSIS OF THE MIXING REGION FOR A TWO-DIMENSIONAL JET INJECTED AT AN ANGLE TO A MOVING STREAM

Willis Braun and Marvin E. Goldstein Washington Nov. 1969 25 p refs
(NASA-TN-D-5531; E-5163) Avail: CFSTI CSCL 20D

An analysis was made of the laminar and turbulent mixing of a two-dimensional jet issuing from an orifice whose two walls are parallel to the free-stream velocity but not necessarily coplanar with each other. The difference of total pressure between the jet and the stream is assumed small compared with the dynamic pressure of the stream. The results of previous inviscid analyses are used to obtain the velocity profiles in the mixing region and the thickness of the region for jets which are separated from the

downstream wall and for those which are attached. Results show that, when the orifice walls are coplanar, the attached jet has higher velocities than the separated jet as it turns into the stream; therefore, the attached jet has a thinner mixing region. Author

SPACECRAFT OCEANOGRAPHY - ITS SCIENTIFIC AND ECONOMIC IMPLICATIONS FOR THE NEXT DECADE.
John W. Sherman (NASA; U.S. Naval Oceanographic Office, Washington, D.C.) and Leroy Cheney (General Electric Co., Philadelphia, Pa.).
United Nations, Conference on the Exploration and Peaceful Uses of Outer Space, Vienna, Austria, Aug. 14-27, 1968, Paper 68-95878. 25 p. 7 refs.

Discussion of some of the contributions that spacecraft oceanography can make to man's increased knowledge and use of the sea. The development of remote sensors and oceanographic employment of research aircraft are considered in detail. Oceanographic achievements in connection with the determination of biological indices, sea state, and sea surface temperature are discussed, as well as the results of bathymetric and hydrographic studies and studies of coastal processes, sea ice, and the air-sea interaction. It is concluded that if a need for a daily global look at the world ocean is determined, orbiting satellites can provide all-weather oceanographic data for complementing the higher-resolution data gathered by the more conventional means of ships, buoys, and aircraft. Developments in spacecraft and allied satellite technologies offer promising results in these fields of operation. I.P.

OGO-2 MAGNETIC FIELD OBSERVATIONS DURING THE MAGNETIC STORM OF MARCH 13-15, 1966.
R. A. Langel and J. C. Cain (NASA, Goddard Space Flight Center, Greenbelt, Md.).
(International Association of Geomagnetism and Aeronomy, Symposium on Special Events, Saint-Gall, Switzerland, Oct. 2, 1967.) Annales de Géophysique, vol. 24, July-Sept. 1968, p. 857-869. 27 refs.

Analysis of magnetic field data from the OGO-2 spacecraft and from surface magnetic observatories for the period from Mar. 13 to 15, 1966. During this interval there occurred a magnetic storm with a Dst decrease of 122 γ. The results indicate a nonsymmetric inflation of the magnetosphere, with the field decrease in the dusk sector being a factor of about three more than that in the dawn sector. The evidence indicates that the sources of both Dst and Ds in low latitudes are external to the satellite altitudes (410 to 1510 km). Polar ionospheric currents were detected more than 1.5 hr before the main phase of the storm. These currents conform to the classical "2-celled" model, which includes a concentrated eastward current in the evening local time sector, and a concentrated westward current in the morning local time sector. F.R.L.

PROPAGATION OF THE SUDDEN COMMENCEMENT OF JULY 8, 1966, TO THE MAGNETOTAIL.
M. Sugiura, T. L. Skillman, B. G. Ledley, and J. P. Heppner (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Journal of Geophysical Research, vol. 73, Nov. 1, 1968, p. 6699-6709. 17 refs.

A sudden magnetic field increase associated with the July 8, 1966, sudden commencement (SC) was observed by the OGO 3 satellite in the magnetotail. By use of the IMP 3 and Explorer 33 observations made by Ness and Taylor (1968) of the interplanetary shock that caused the SC, it is shown that the magnetospheric propagation of the field increase toward the tail is faster than the propagation of the interplanetary shock just outside the bow shock. Conclusions drawn include (1) that the observed magnetic field increase in the tail is unlikely to be due to an increased lateral pressure of the post-shock solar wind gas from the side of the tail, and (2) that the transfer of additional polar magnetic flux to the tail due to the increase in the solar wind pressure on the front side of the magnetosphere can account for the observed tail field increase. PLASMA OBSERVATIONS ON EXPLORER 34.
K. W. Ogilvie (NASA, Goddard Space Flight Center, Greenbelt, Md.), T. D. Wilkerson (NASA, Goddard Space Flight Center, Greenbelt; Maryland, University, Institute for Fluid Dynamics and Applied Mathematics, College Park, Md.), and L. F. Burlaga.
Journal of Geophysical Research, vol. 73, Nov. 1, 1968, p. 6809-6824. 27 refs.
Grant No. NsG-283.

Description of the results of the observations of the Goddard Space Flight Center/University of Maryland plasma experiment on Explorer 34 during three magnetic storms, May 30, June 5, and June 25, 1967. Particular attention is given to the interaction of discontinuities with the earth and to changes in the abundance of helium in the plasma. Detailed comparisons with magnetic field observations on the same satellite are used to interpret the observations and to identify shocks and tangential discontinuities. The observations are consistent with the relationship derived by Siscoe (1966) between the magnitude of such sudden changes in the earth's magnetic field and the solar wind parameters. The local shock speeds are derived from data obtained at the time of the sudden commencements. An example of an si^+ si^- pair is discussed, and in this case the negative impulse is shown to be due to a tangential discontinuity rather than a shock, whereas the positive impulse is associated with a shock. Helium observations are described which show that during the main phase of some geomagnetic storms the abundance ratio n_a/n_p shows a marked increase. In the May 30 storm it attained a value of 0.15 ± 0.02, 5-1/2 hr after the SC, an increase of seven times over the value observed earlier. I.P

EARTH'S BOW SHOCK - ELAPSED-TIME OBSERVATIONS BY TWO CLOSELY SPACED SATELLITES.
E. W. Greenstadt, I. M. Green (TRW Systems Group, Space Sciences Laboratory, Redondo Beach, Calif.), and D. S. Colburn (NASA, Ames Research Center, Space Sciences Div., Moffett Field, Calif.).
Science, vol. 162, Nov. 22, 1968, p. 898-901. 14 refs.

Coordinated observations of the earth's bow shock were made as Vela 3A and Explorer 33 passed within six earth radii of each other. Elapsed time measurements of shock motion give directly determined velocities in the range 1 to 10 km/sec and establish the existence of two regions, one of large amplitude magnetic "shock" oscillations and another of smaller, sunward, upstream oscillations. Each region is as thick as 1 earth radius, or more. (Author)

THE PLASMAPAUSE AND ITS RELATION TO THE ION COMPOSITION IN THE TOPSIDE IONOSPHERE.
H. G. Mayr (NASA, Goddard Space Flight Center, Aeronomy Branch, Greenbelt, Md.).
Planetary and Space Science, vol. 16, Nov. 1968, p. 1405-1414. 14 refs.

Investigation of the concept that the high O^+ - H^+ transition level at latitudes above 50° and the plasmapause with its characteristic density plateau may be strongly correlated. It is shown that plasma escape can produce sufficiently large fluxes at latitudes where the field lines are open, thus significantly decreasing the hydrogen-ion density. As a result, plasma diffusion across lines is induced - coupled with upward fluxes of ionization along field lines, which leads to the formation of a plateau that characterizes the transition region from the open to the closed magnetosphere. Collision-type perpendicular diffusion would produce an enormously rapid transition over a distance of a few meters, which is not observed. This suggests that a turbulent state is built up in the transition region; thus, Bohm's coefficient for turbulent diffusion is employed, and this leads to a quantitatively satisfying description of the plasmapause. M.M.

FRICTIONAL FORCES AND COLLISION FREQUENCIES BETWEEN MOVING ION AND NEUTRAL GASES.
Peter Stubbe (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
Journal of Atmospheric and Terrestrial Physics, vol. 30, Dec. 1968, p. 1965-1985. 26 refs.

Study of the frictional force between moving ions and neutral gases, showing how the corresponding collision frequencies have to be defined in order to maintain the validity of the terms used. An expression is derived for the momentum transfer collision frequency ν_{in} between ions and neutral particles as a function of temperature and the relative flow velocity $|v_i - v_n|$. The result indicates that for most practical applications ν_{in} may be considered as independent of $|v_i - v_n|$. However, for very high velocities - i.e., a convection flow from the magnetosphere into the ionosphere, this dependence may be significant. Numerical values for ν_{in} are presented. P.v.T.

AVERAGE MAGNETIC FIELD CONFIGURATION OF THE OUTER MAGNETOSPHERE.
D. H. Fairfield (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
Journal of Geophysical Research, vol. 73, Dec. 1, 1968, p. 7329-7338. 24 refs.

Over 1500 hours of data from the satellites IMP 1, 2, and 3 have been used to study the configuration of the magnetic field in the outer magnetosphere between 5 and 18 $R_\oplus$. Hourly average field vectors were projected in the solar magnetic equatorial plane and in 24 meridian sections corresponding to each hour of local time. The plots show the sweeping back of the field toward the tail and the dawn and dusk transition from compressed dayside field lines to extended nightside field lines. Constant B contours in the equatorial plane were constructed, and flux conservation was used to establish a quantitative relationship between the equatorial crossing point of an outer magnetosphere field line and the latitude of its earth intersection. A contour diagram in the equatorial plane designating the latitude of field line origin permits the mapping of low-altitude phenomena to the equatorial plane and vice versa. Auroral oval field lines are found to come from the region of the magnetopause in the daylight hemisphere but from well within the magnetosphere in the night hemisphere. The outermost closed field line is found to come from approximately 78° throughout the dayside hemisphere. (Author)

COMBINED SOLUTION FOR LOW DEGREE LONGITUDE HARMONICS OF GRAVITY FROM 12- AND 24-HOUR SATELLITES.
Carl A. Wagner (NASA, Goddard Space Flight Center, Special Projects Branch, Greenbelt, Md.).
Journal of Geophysical Research, vol. 73, Dec. 15, 1968, p. 7651-7660. 17 refs.

Examination of over 600 near-stationary orbits of five high-altitude communications satellites for the strong effects on them of low-degree earth-gravity harmonics. The accelerated drift of these 12- and 24-hr orbits due to the earth's anomalous potential has been measured at 50 longitude locations. From these accelerations five low-degree earth-gravity harmonics which resonate with these orbits have been calculated (10 gravity coefficients). The best-determined harmonic is felt to be H_{22}, which dominates the accelerated drift of the three 24-hr satellites (Syncoms 2 and 3, and Early Bird), and the two 12-hr satellites (Molniya 1 and Cosmos 41). The normalized constants found for this harmonic, the other four harmonics in decreasing order of their estimated strength of absolute determination, and their normalized coefficients are given. The measured drift accelerations themselves are compared with accelerations calculated from a number of recently published geoids derived from satellite data and a combination of satellite and surface-gravity data. The "best" geoid representing these accelerations is a 1967 Smithsonian Astrophysical Observatory determination of Köhnlein. F.R.L.

TEMPERATURES OF THE EARTH'S UPPER ATMOSPHERE.
J. C. G. Walker (Yale University, Dept. of Geology and Geophysics, New Haven, Conn.) and N. W. Spencer (NASA, Goddard Space Flight Center, Laboratory for Atmospheric and Biological Sciences, Greenbelt, Md.).
Science, vol. 162, Dec. 27, 1968, p. 1437-1442. 70 refs.
Grant No. NGR-07-004-100.

Study of the electron, ion, and neutral-particle temperatures of the earth's upper atmosphere. At most altitudes the electron temperature exceeds the ion temperature and the ion temperature, in turn, exceeds the neutral-particle temperature. Since energy is exchanged between the gases, the different temperatures are related, but the relationship is complex. It is quite common, for example, for the electron temperature to increase while the neutral-particle temperature is decreasing. A similar multiplicity of temperatures in the upper atmospheres of the planets is expected. P.v.T.

A69-16261 *
DIRECT IN SITU MEASUREMENTS OF WAVE PROPAGATION IN THE NEUTRAL THERMOSPHERE.
George P. Newton, David T. Pelz, and Hans Volland (NASA, Goddard Space Flight Center, Aeronomy Branch, Greenbelt, Md.).
Journal of Geophysical Research, vol. 74, Jan. 1, 1969, p. 183-196. 19 refs.

Evaluation of local variations in the atmospheric density, measured by the density gauges on the Explorer 32 satellite, confirming that waves propagate in the neutral atmosphere. The waves were observed in the Northern Hemisphere over the altitude range from 286 km (satellite perigee) to at least 510 km. Apparently, four integrally related wavelengths have been measured, a "fundamental" and the second, third, and fourth harmonics. These waves are interpreted as free internal gravity waves propagating predominantly north-south, or south-north, with maximum horizontal wavelengths between 130 and 520 km. The altitude dependence of the apparent vertical half-wavelengths results from the satellite moving with varying vertical velocity through a slowly propagating wave pattern with nearly vertical phase planes. This interpretation is consistent with observations of large-scale traveling ionospheric disturbances by Thome (1964) and Georges (1968). P.v.T.

A69-16267 *
MEASUREMENTS OF ELECTRON COOLING RATES IN THE MID-LATITUDE AND AURORAL-ZONE THERMOSPHERE.
L. H. Brace, H. G. Mayr (NASA, Goddard Space Flight Center, Aeronomy Branch, Greenbelt, Md.), and G. R. Carignan (Michigan, University, Dept. of Electrical Engineering, Ann Arbor, Mich.).
Journal of Geophysical Research, vol. 74, Jan. 1, 1969, p. 257-266. 18 refs.

Two day-night pairs of thermosphere probe rockets, launched at Wallops Island, Va., in March 1965 and at Churchill, Manitoba,

in November 1965 have provided altitude profiles of electron temperature and concentration at midday and midnight. Altitude profiles of N_2 measured on the same four flights have in addition provided neutral gas temperature profiles. These data are employed to calculate electron cooling rate profiles, and these in turn are interpreted in terms of ionospheric heat sources. The daytime electron heat source for the F region, at both middle latitudes (L = 2.9) and in the auroral zone (L ≈ 8), appears consistent with solar ultraviolet heating. The nighttime F-region, however, appears to be heated by downward conduction from the protonosphere at middle latitudes and by particle heating in the auroral zone. The source of electron heating for the E region both day and night and at both locations cannot be explained by direct solar heating. This may be produced by neutral winds, electric currents, an unknown chemical reaction or, as Walker has suggested, selective heating of the electrons by excited N_2 having lifetimes in the E region of the order of a day. (Author)

MIDLATITUDE NEUTRAL THERMOSPHERE DENSITY AND TEMPERATURE MEASUREMENTS.

David T. Pelz and George P. Newton (NASA, Goddard Space Flight Center, Greenbelt, Md.).

Journal of Geophysical Research, vol. 74, Jan. 1, 1969, p. 267-271. 16 refs.

Description of an ensemble of six independent aeronomy experiments which was launched from Wallops Island, Virginia, on Mar. 2, 1966, at 1300 EST. Two Bayard-Alpert ionization gauges, similar to those on the Explorer 17 satellite, were flown to measure neutral atmospheric density and temperature. However, the Bayard-Alpert gauges appear to have pumped or adsorbed virtually all of the atmospheric atomic oxygen (O) to which they were exposed, and thus measured only the molecular nitrogen (N_2), molecular oxygen (O_2), and helium (He) in the region from 150- to 450-km altitude. The deduced N_2 number densities agree with nearly simultaneous measurements obtained from a neutral mass spectrometer and a solar EUV extinction experiment. Previous N_2 measurements from thermosphere probes, obtained under similar solar and geomagnetic conditions, agree well with these data. M.M.

DIURNAL VARIATION OF THE ION TEMPERATURE.

K. K. Mahajan (Cornell-Sydney University Astronomy Center, Arecibo Ionospheric Observatory, Arecibo, Puerto Rico; NASA, Goddard Space Flight Center, Greenbelt, Md.).

Journal of Atmospheric and Terrestrial Physics, vol. 31, Jan. 1969, p. 93-101. 18 refs.

Results on the diurnal variation of the ion temperature, obtained from the Thomson scatter spectra at Arecibo, in the height range 250-475 km are presented. At 250 km where the ion temperature (T_i) is expected to be nearly equal to the neutral temperature (T_n), T_i is generally observed to show diurnal maximum at 16 hr LT and diurnal minimum at 4 hr LT with no appreciable change in these times with solar activity. The average day to night T_i ratio at 250 km is found to be 1.45. These results are in apparent conflict with the satellite drag analysis in which T_n is found to have a diurnal maximum at 14 hr LT and day to night temperature ratio around 1.30. At 475 km where T_i is significantly above T_n, the diurnal behavior of T_i is observed to be different on different days. The day-to-day and hour-to-hour variations in T_i at this height are found to be due to changes in the electron density and electron temperature and seem consistent in terms of an energy budget that includes heating of the ion gas by the hotter thermal electrons and cooling by the neutral atmosphere. COORDINATED ROCKET MEASUREMENTS ON THE D-REGION WINTER ANOMALY. I - EXPERIMENTAL RESULTS.

C. F. Sechrist, Jr., E. A. Mechtly, J. S. Shirke (Illinois, University, Dept. of Electrical Engineering, Aeronomy Laboratory, Urbana, Ill.), and J. S. Theon (NASA, Goddard Space Flight Center, Greenbelt, Md.).

Journal of Atmospheric and Terrestrial Physics, vol. 31, Jan. 1969, p. 145-153. 11 refs.
Grant No. NsG-511.

Evaluation of nearly simultaneous rocket measurements of D-region temperatures and electron densities, conducted on Jan. 31, 1967, an anomalous winter day, at Wallops Island, Va. The electron density profile for Jan. 31, 1967, was generally similar to the one measured on the anomalous winter day of Jan. 10, 1966, the densities of 70 to 80 km height range being about five times greater than those on a normal winter day. The rocket grenade temperature profile for the anomalous day revealed a strong temperature inversion at 70 km and a warm layer extending from the inversion to 84 km; this temperature structure was significantly different from that at the same altitude on the normal day of Feb. 3, 1967. SOUNDING ROCKET MEASUREMENTS OF ION COMPOSITION AND CHARGED PARTICLE TEMPERATURES IN THE TOPSIDE IONOSPHERE.

E. J. R. Maier (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).

Journal of Geophysical Research, vol. 74, Feb. 1, 1969, p. 815-823. 19 refs.

Discussion of ion composition and charged-particle temperatures at altitudes from 300 to 600 km. The major ion constituent was found to be O^+ over the entire altitude range, decreasing from >99% of the total ion concentration at 300 km to 88% at 600 km. distinct populations. Both the local-time and magnetic latitude distribution of both classes of signals are investigated. When the magnetic latitude distributions are extrapolated downward to 1000-km altitudes, the results are consistent with previous satellite observations at these low altitudes. However, the equatorial distributions cannot be inferred by simply projecting the magnetic noise measured at low altitudes onto the equator along flux tubes. The in situ measurements cannot determine the exact location of the source of all the noise observed. However, it is found that steady noise is definitely generated near 45° magnetic latitude on the dayside of the magnetosphere for L values from 6 to 10, and that bursts are generated near the equator above L = 6 from 0400 to 1800 local time. Dordrecht, D. Reidel Publishing Co. (Astrophysics and Space Science Library. Volume 10), 1968, p. 301-375. 106 refs.

Summary of some of the basic ideas, both theoretical and experimental, that support the correspondence between the flow of the solar wind past the earth and its magnetosphere, and the problem of the external aerodynamics of round-nosed bodies in a supersonic stream. A connected account of many of the principal quantitative results that have been obtained through application and extension of methods developed originally for the aerodynamics of reentry vehicles is presented. In addition, the basic concepts of the theory of the solar wind itself are outlined in some detail in order to illustrate the basic unity of the entire theoretical description of the solar wind and its interaction with the geomagnetic field. Extensive discussions of the internal consistency of the theory and the degree to which the results correspond to conditions observed in space are included to provide an understanding of the overall reliability of the theory. Dordrecht, D. Reidel Publishing Co. (Astrophysics and Space Science Library. Volume 10), 1968, p. 461-484. 26 refs

A preliminary assessment of the geometry of the geomagnetic tail is made using data from the Ames magnetometer on the Explorer 33 satellite. The general shape corresponds to the earlier findings of Ness et al. The tail is regular to distances greater than 82 R_E. The field values vary for $K_p \leqslant 2+$ from a low of about 4 gamma to a high value of 40 gamma. Generally the values are in the neighborhood of 10-20 gamma. A distinct skewing of the field lines away from the solar-antisolar direction is observed, such that an added component of magnetic field in the direction of planetary motion is present on both sides of the null plane. The skewing appears to be greatest near the null plane. An increase in field magnitude with increasing K_p is observed. Little cross gradient is observed in the tail field. Strong evidence for reconnection of field lines is found, and statistics are presented for a dual effect regarding the residual Z field across the null plane. The interaction of the tail field with the moon is discussed in terms of the mechanism of Sonett and Colburn. (Author)

GENESIS OF CONTINENTAL DIABASES AND OCEANIC THOLEIITES CONSIDERED IN LIGHT OF RARE-EARTH AND BARIUM ABUNDANCES AND PARTITION COEFFICIENTS.
J. A. Philpotts and C. C. Schnetzler (NASA, Goddard Space Flight Center, Laboratory for Theoretical Studies, Geochemistry Laboratory, Greenbelt, Md.).
IN: ORIGIN AND DISTRIBUTION OF THE ELEMENTS; PROCEEDINGS OF THE INTERNATIONAL SYMPOSIUM, PARIS, FRANCE, MAY 8-11, 1967. [A69-20892 08-30]
Symposium sponsored by UNESCO and the International Union of Geological Sciences.
Edited by L. H. Ahrens.
Oxford, Pergamon Press, Ltd. (International Series of Monographs in Earth Sciences. Volume 30), 1968, p. 939-947. 19 refs.

Rare-earth and barium abundances in the chilled-contacts of four diabases and in the rock-standard W-1 have been determined by mass-spectrometric isotope dilution. The similarity of the abundances provides strong additional evidence of the compositional uniformity of diabases. This uniformity is interpreted to mean that diabase melts are probably the result of either very limited partial fusion or almost complete fusion of similar source materials. Application of rare-earth and barium partition-coefficients for clinopyroxene leads to the conclusion that diabases might be the result of very limited partial fusion of the same kind of source material from which oceanic tholeiites are derived by a process involving complete or almost complete fusion; a source material composed of clinopyroxene is implied in this model. The rare-earth and Ba data might also be compatible with the genesis of diabases by very limited partial fusion of hypersthene-achondrite-like material. (Author)

S. A. Korff, New York University, Physics Dept., Bronx, N.Y., 1968, p. 63-65.
Grant No. NsG-499.

Results of measurements of the solar radiation reflected by the surface and the atmosphere of the Antarctic, made by an Eppley radiometer. The main results are that (1) the average reflectivity of the surface atmosphere system over this region of Antarctica, under cloudless conditions, is 56 ± 6%, and (2) the reflectivity varies inversely as the solar zenith angle. This is mainly due to the increased atmospheric absorption for large zenith angles, about 15% per vertical thickness of the atmosphere. If the observed value of

the bubbles travel along their spiral paths more rapidly, the bubble velocity being directly proportional to the angular velocity of the liquid. M.M.

EFFECT OF NEUTRAL SHEET CURRENTS ON THE SHAPE AND MAGNETIC FIELD OF THE MAGNETOSPHERE TAIL.

John R. Spreiter and Alberta Y. Alksne (NASA, Ames Research Center, Space Sciences Div., Moffett Field, Calif.).

Planetary and Space Science, vol. 17, Feb. 1969, p. 233-246. 21 refs.

Modification of the usual first-order theory of the shape of the magnetosphere boundary that incorporates in a simple way the principal effects of the electrical currents in the neutral sheet of the extended geomagnetic tail. Numerical results presented for a variety of representative cases show that an additional flaring out of the magnetosphere tail ultimately of the order of a few earth radii occurs over a distance of several tens of earth radii, and that there is an associated decrease in the intensity of the magnetic field because of the need to approximately conserve the total magnetic flux in each half of the tail cross section. Comparisons with data obtained in space with Explorer 18 and 33 satellites and Pioneer 6 and 7 spacecraft show that this modification of the theory leads to a substantial improvement in the agreement between the calculated and observed dimensions of the magnetosphere tail and the strength of the magnetic field contained therein. THE POLAR-CAP ABSORPTION ON 7-10 JULY 1966.

Y. Hakura (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IN: THE PROTON FLARE PROJECT (THE JULY 1966 EVENT). [A69-23725 10-29]
Edited by A. C. Stickland.
Cambridge, Mass., MIT Press (Annals of the IQSY. Volume 3), 1969, p. 337-352. 24 refs.

The time history of a PCA event on July 7-10, 1966 was analyzed using 16 riometers in the northern polar region and concurrent satellite observations of solar cosmic radiations. The first onset of PCA was noticed at 0120 UT at Shepherd Bay, Canada, and the slight enhanced ionization of a few tenths of 1 dB covered the whole North Pole region before 0200 UT. On the other hand, auroral zone stations observed the PCA after 0200. The two-stepped onset of the PCA corresponds to the differential arrival of ionizing electrons and protons at the earth, detected by the satellites. The flux of 40-keV electron busts observed by the satellites Explorer 33 and IMP-3 can explain the first onset of a slight PCA near the geomagnetic pole. The PCA in the polar region marked a maximum of 2.5 dB on 30 MHz at 1300 on July 7, and then decayed gradually until it went down below 0.3 dB after 2345 on July 8. The lowest latitude of the PCA during the geomagnetically calm period was some 63° in corrected geomagnetic latitude. After the onset of geomagnetic disturbances, the PCA superposed upon it the auroral zone absorption that appeared even in the lower auroral zone. (Author)

EVIDENCE OF CONTRACTION OF THE EARTH'S THERMAL PLASMASPHERE SUBSEQUENT TO THE SOLAR FLARE EVENTS OF 7 AND 9 JULY 1966.

H. A. Taylor, Jr., H. C. Brinton, and M. W. Pharo, III (NASA, Goddard Space Flight Center, Aeronomy Branch, Greenbelt, Md.).

IN: THE PROTON FLARE PROJECT (THE JULY 1966 EVENT). [A69-23725 10-29]
Edited by A. C. Stickland.
Cambridge, Mass., MIT Press (Annals of the IQSY. Volume 3), 1969, p. 389-394. 12 refs.

Direct measurements of thermal H^+ and He^+ in the magnetosphere have been obtained from ion mass spectrometers on OGO 1 and 3 satellites. Typical H^+ profiles exhibit a gradual decrease in concentration with altitude within the plasmasphere, while the outer boundary of the plasmasphere is characterized by an abrupt decrease in concentration to 5 ions cm^{-3} or less. This boundary, the plasmapause, is observed to move inward and outward in an inverse correlation with the magnetic activity index Kp. The magnetosphere was disturbed during the solar flare period July 7-9, 1966, and on July 9, the plasmapause was observed to be unusually low, at L = 3.3. This observation contrasted with measurements of the plasmapause on both preceding and succeeding orbits, when in the absence of flares and magnetic disturbance the H^+ boundary was observed to expand to L values as high as 6. These measurements correlate well with "knee" whistler observations of the plasmapause. (Author)

FULL WAVE CALCULATIONS OF GRAVITY WAVE PROPAGATION THROUGH THE THERMOSPHERE.

H. Volland (NASA, Goddard Space Flight Center, Greenbelt, Md.).

Journal of Geophysical Research, vol. 74, Apr. 1, 1969, p. 1786-1795. 17 refs.

Results of full-wave calculations performed within the frequency range of gravity waves ($10^{-3} \leq \omega \leq 10^{-2}$ sec^{-1}) for a thermospheric model between 150 and 500 km in altitude. In this altitude range, gravity waves are coupled with heat conduction waves. Reflection, transmission, conversion, and coupling from one wave type into the other one are described by the elements of the scattering matrix. The dependence of these elements on height and angle of incidence is discussed. The transmission coefficients of gravity waves calculated by full-wave theory are compared with simple ray calculations, and the results show that ray treatment is a sufficient approximation for obliquely upward propagating gravity waves and that gravity waves predominate throughout the thermosphere. The thermosphere reacts like a selective filter with respect to upward propagating gravity waves. (Author)

MULTI-EXPERIMENT DETECTION OF THE PLASMAPAUSE FROM EOGO SATELLITES AND ANTARCTIC GROUND STATIONS.

D. L. Carpenter, C. G. Park (Stanford University, Stanford Radioscience Laboratory, Stanford, Calif.), H. A. Taylor, Jr., and H. C. Brinton (NASA, Goddard Space Flight Center, Laboratory for Atmospheric and Biological Sciences, Greenbelt, Md.).

Journal of Geophysical Research, vol. 74, Apr. 1, 1969, p. 1837-1847. 12 refs.
NSF-supported research; Contract No. NAS 5-2131.

Correlation study of plasmapause position measured by three independent experiments involving: (1) ion mass spectrometers on OGO 1 and OGO 3; (2) broadband vlf receivers (0.3-12.5 kHz) on OGO 1 and OGO 3; and (3) broadband vlf recordings at Antarctica, near the 90° meridian. In the satellite vlf data, the plasmapause crossings are identified by abrupt changes in observed whistler and vlf noise activity, and by noise bands of limited duration. In two cases of simultaneous vlf and ion data from the same satellite, plasmapause crossings were detected by both experiments within less than 0.1 R_E in L value. In eight cases of OGO 1 ion data and simultaneous ground whistler data spaced from 1 to 12 hours from OGO in local time, good agreement was found between the measured plasmapause positions. The comparisons provide new verification of the worldwide extent of the plasmapause. Previous indications that the radius of the plasmapause is frequently about constant, over large local-time sectors in the range 0-18 LT, are also verified. B.H.

ION-EXOSPHERE WITH VARIABLE CONDITIONS AT THE BAROPAUSE.
R. E. Hartle (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
Physics of Fluids, vol. 12, Feb. 1969, p. 455-462. 12 refs.

The model ion-exosphere of Eviatar et al. (1964) for a nonrotating planet with a static, centered-dipole magnetic field is generalized by permitting the density and temperature to vary over the baropause. In particular, the density and/or temperature are allowed to differ at the conjugate magnetic field points of the baropause. For this case, the ion and electron velocity-distribution functions, satisfying the Vlasov equations in the drift approximation, are constructed. Then, the species densities are determined from the distributions, and are compared with the corresponding results of Eviatar et al. for the case of uniform density and temperature at the baropause. In addition, the particle current densities, pressures, and temperatures are derived. (Author)

ON THE SEMIANNUAL VARIATION OF THE UPPER ATMOSPHERE.
Isadore Harris (NASA, Goddard Space Flight Center, Greenbelt, Md.) and Wolfgang Priester (Bonn, Universität, Astronomisches Institut, Bonn, West Germany; NASA, Goddard Space Flight Center, Goddard Institute for Space Studies, New York, N.Y.).
Journal of the Atmospheric Sciences, vol. 26, Mar. 1969, p. 233-240. 36 refs.

Investigation of several possible mechanisms which could be invoked to explain the observed semiannual density variation in the thermosphere and exosphere. A variation of the height of the mixtopause leads to a large density variation for heights above 700 km. Below that height, however, the density is essentially invariant to this process. This invariance is to some degree caused by the neglect of downward heat transport by eddy diffusion at the bottom of the thermosphere. The limitations of using the simple mixtopause scheme in this context are discussed. A small permanent heat flux conducted into the lower exosphere from above can be ruled out on the grounds that it fails to explain the observed amplitude at a height of 200 km. A variation of this flux by 3×10^{-2} erg/cm^2-sec would yield a sufficiently large density variation only for heights above 300 km. The recent observations at heights below 200 km indicate that the temperature and density at the bottom of the thermosphere (90 to 120 km) vary with a semiannual period. (Author)

THE UPPER ATMOSPHERE AS A MULTIPLY REFRACTIVE MEDIUM FOR NEUTRAL AIR MOTIONS.
H. Volland (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Journal of Atmospheric and Terrestrial Physics, vol. 31, Apr. 1969, p. 491-514. 13 refs.

Under the influence of gravity and heat conduction four plane characteristic waves obliquely incident on a horizontally stratified atmosphere can propagate, two of them upward and the two other downward. The two pairs of characteristic waves are the well-known acoustic gravity waves and the heat conduction waves. Molecular viscosity generates two more pairs of characteristic waves, the ordinary and the extraordinary viscosity waves. Ion drag and Coriolis force make the atmosphere anisotropic with respect to the characteristic waves. Their propagation characteristics for east to west and north to south propagation differ from each other. Some analytical solutions of the eigenvalues of these eight characteristic waves are given in this paper. Numerical calculations of the eigenvalues depending on the parameters of the thermosphere and on frequency, azimuth, and angle of incidence are presented and discussed in some detail. (Author)

OCEAN CIRCULATION AND CLIMATIC CHANGES.
S. I. Rasool (NASA, Goddard Space Flight Center, Goddard Institute for Space Studies, New York, N.Y.) and J. S. Hogan (New York University, New York, N.Y.).
(Conference on Ocean Circulation and Climatic Changes, Goddard Institute for Space Studies, New York, N.Y., Mar. 7, 8, 1968.) American Meteorological Society, Bulletin, vol. 50, Mar. 1969, p. 130-134.
Grant No. NsG-499.

Discussion of the role of the ocean as a regulator of climate and a key to the solution of the problem of climatic change. It is pointed out that the causes of climatic change may be a variable energy input from solar radiation or lunar tidal friction. The problem reduces then to determining how fluctuations in an extraterrestrial source of energy are translated into variations in global temperature. A first step toward the eventual solution of the problem can be made by investigating the manner in which the input of the solar energy over the globe is redistributed by the oceans. Several investigations of the large-scale interaction between the atmosphere and ocean are discussed. G.R.

THE GEOMAGNETIC TAIL.
Norman F. Ness (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
(U.S. National Academy of Sciences and NASA Goddard Space Flight Center, International Symposium on the Physics of the Magnetosphere, Washington, D.C., Sept. 3-13, 1968.)
Reviews of Geophysics, vol. 7, Feb.-May 1969, p. 97-127. 72 refs.

Review of past experimental and theoretical models of the geomagnetic tail in the magnetosphere. The geometry of the geomagnetic tail and the earth's bow shock in cislunar space and the orbits of the satellites that have studied the geomagnetic tail are illustrated. The magnetic field measurements of the geomagnetic tail near the midnight meridian plane made by the satellite IMP 1 in 1964 are discussed. Significant measurements (performed by IMP 2) of the outer geomagnetic field demonstrating the gradual formation of the geomagnetic tail in the dawn-to-midnight region of the magnetosphere are presented. Spectra of electron counting rates measured in the magnetosheath and the plasma sheet by the Vela satellites are presented. Measurements of the magnetic-field intensity and electron velocity and density by Pioneer 7 are also given. M.G.

FRICTION BETWEEN MANTLE AND CORE OF THE EARTH AS A CAUSE OF THE SECULAR CHANGE IN OBLIQUITY.
Shinko Aoki (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Astronomical Journal, vol. 74, Mar. 1969, p. 284-291. 21 refs.

Investigation of the causes of the discrepancy between the observed and theoretical values of the secular change in the obliquity of the orbital motion of the earth. A suggestion that this difference might come from an interaction between the mantle and the core of the earth is investigated. A very simple model of two rigid components with friction between them is considered. It is found that a damping time for the friction of about 40 years is required. This solution implies a drift of the core relative to the mantle of the order of $0\overset{\circ}{.}3$ per year, which is almost the same as the observed "west drift." G.R.

FEASIBILITY OF DETERMINING ATMOSPHERIC OZONE FROM OUTGOING INFRARED ENERGY.
C. Prabhakara (NASA, Goddard Space Flight Center, Greenbelt, Md.; NASA, Goddard Space Flight Center, Goddard Institute for Space Studies, New York, N.Y.).
Monthly Weather Review, vol. 97, Apr. 1969, p. 307-314. 19 refs.

The high-resolution (5 cm^{-1}) measurements of the outgoing IR energy in the region of the 9.6-μ ozone band offer a means of determining the vertical distribution and total amount of ozone in the earth's atmosphere. With the application of radiative transfer theory and perturbation technique, a method is developed to deduce such information. The method hinges on a two-parametric representation of the ozone distribution in the earth's atmosphere. An error analysis based on four case studies is presented to show how well the atmospheric ozone could be determined. It is found that a small error in radiance value is magnified considerably in the inferred atmospheric ozone. (Author)

D-REGION ELECTRON DENSITY MEASUREMENTS DURING THE SOLAR ECLIPSE OF MAY 20, 1966.

J. A. Kane (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).

Planetary and Space Science, vol. 17, Apr. 1969, p. 609-616. 9 refs.

Rocket (Underwood and Muney, 1967) and satellite observations of 2 to 8 Å X-ray emission indicate that the solar eclipse of May 20, 1966, occurred during a period in which the sun was moderately active. The Goddard Space Flight Center conducted a series of small sounding rocket experiments to measure the ionospheric D-region electron density profile during successive stages of the eclipse. Compared to the uneclipsed profile, an order of magnitude reduction is observed in the D-region profile obtained near totality. From the electron density measurements together with the X-ray spectral data of Underwood and Muney it is concluded that on May 20, 1966, 2 to 8 Å X rays were not the dominant source of D-region ionization below approximately 80 km. THE POLAR EXOSPHERE NEAR SOLAR MAXIMUM.

Gerald M. Keating, James A. Mullins, and Edwin J. Prior (NASA, Langley Research Center, Hampton, Va.).

COSPAR, Plenary Meeting, 12th, Prague, Czechoslovakia, May 11-24, 1969, Paper. 23 p. 17 refs.

Investigation of the neutral polar exosphere between 550 and 900 km near the period of maximum solar activity by the satellites Explorer 19 and Explorer 24. With the increased heating in the upper atmosphere, atomic oxygen concentrations have increased to the extent that the drag effects of constituents other than atomic oxygen were negligible near 550 km. Thus the global distribution of atomic oxygen could be determined from the drag measurements of Explorer 24. Nighttime atomic oxygen concentrations were much lower than expected, but daytime concentrations were close to predictions. The most significant result of the high-latitude measurements is that polar atomic oxygen concentrations are found to be 30% higher than expected, and inferred polar exospheric temperatures are higher by 60 K. G. R.

IMPLICATIONS FOR IONOSPHERIC CHEMISTRY AND DYNAMICS OF A DIRECT MEASUREMENT OF ION COMPOSITION IN THE F2 REGION.

H. C. Brinton, M. W. Pharo, III, H. G. Mayr, and H. A. Taylor, Jr. (NASA, Goddard Space Flight Center, Laboratory for Atmospheric and Biological Sciences, Greenbelt, Md.).

Journal of Geophysical Research, vol. 74, June 1, 1969, p. 2941-2951. 25 refs.

Description of spectrometric rocket measurements of the concentrations of O^+, N^+, H^+, He^+, NO^+, O_2^+, and N_2^+ between 200 k and peak altitude, 630 km, at 1300 EST on Mar. 2, 1966, above Wallops Island. The dominant ion throughout the altitude range was O^+, with a maximum concentration of 5×10^5 ions/cm^3 at 260 km. The first detection of H^+ occurred at 230 km, its concentration increasing to 7×10^3 ions/cm^3 at peak altitude. The H^+/He^+ ratio was never lower than 6.0, the value at 420 km. The molecular ions NO^+ and O_2^+ were important constituents at 200 km, the concentration of each being 5×10^4 ions/cm^3; the concentrations of these ions fell off rapidly above this altitude. M. M.

BANDED CHORUS - A NEW TYPE OF VLF RADIATION OBSERVED IN THE MAGNETOSPHERE BY OGO 1 AND OGO 3.

W. J. Burtis (Stanford University, Radioscience Laboratory, Stanford; NASA, Ames Research Center, Moffett Field, Calif.) and R. A. Helliwell (Stanford University, Radioscience Laboratory, Stanford, Calif.).

Journal of Geophysical Research, vol. 74, June 1, 1969, p. 3002-3010. 11 refs.
Contract No. NAS 5-2131; Grants No. NsG-174-05-020-008; No. NGR-05-020-288.

Satellites OGO 1 and OGO 3 observe vlf discrete emissions in the magnetosphere primarily in a single, variable frequency band. The frequency, f, of this "banded chorus" depends on the equatorial electron gyrofrequency, f_{H0}, for the field line passing through the satellite, typical ratios of f/f_{H0} being 0.2-0.5. Evidently the emissions are produced near the equator at a fraction of the electron gyrofrequency, as predicted by electron cyclotron resonance generation mechanisms. A secondary dependence of the banded chorus frequency on dipole latitude, such that the lower ratios of f/f_{H0} are found at higher latitudes, is interpreted to mean that the emissions are generated at about half the electron gyrofrequency, but deviate inward from the field line to lower L values as they propagate earthward. Theoretical support is given by ray tracings showing the inward deviation of nonducted whistler-mode radiation due to the curvature of the magnetic field. Banded chorus has been observed at all local times, but is most common in the morning magnetosphere, outside the plasmapause. (Author)

F-REGION IONIZATION AND HEATING DURING MAGNETIC STORMS.

S. Chandra and J. R. Herman (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).

Planetary and Space Science, vol. 17, May 1969, p. 841-851. 27 refs.

Solution of the continuity and heat conduction equations for electrons, ions, and neutral species simultaneously from the viewpoint of studying the F-region magnetic storm behavior. It is shown that many of the observed changes in the F region during the main phase of a magnetic storm can be successfully explained by assuming a decrease in oxygen concentration at the turbopause level. The specific changes in neutral composition, electron density, and electron, ion, and neutral temperatures during magnetic storms are discussed for different solar conditions. (Author)

TRANSMISSION OF ALFVEN WAVES THROUGH THE EARTH'S BOW SHOCK.

James F. McKenzie (California, University, Dept. of Applied Electrophysics, La Jolla, Calif.) and Karl O. Westphal (NASA, Ames Research Center, Theoretical Studies Branch, Moffett Field, Calif.).

Planetary and Space Science, vol. 17, May 1969, p. 1029-1037. 11 refs.
Grant No. NGR-05-009-081.

Calculation of the transmission of Alfvén waves through the earth's bow shock on the basis of the theory of hydromagnetic shocks. For conditions typical of the solar wind it is shown that the amplitude of the magnetic field of the transmitted Alfvén wave is about three times larger than that of the incident, and, in addition, another Alfvén wave is generated with amplitude roughly equal to the incident wave amplitude. Since longitudinal waves are greatly amplified on passage through strong shocks and, as shown in the paper, transverse Alfvén waves undergo only moderate amplification, the energy flux of long wavelength waves in the magnetosheath ought to be predominantly in acoustic-type waves rather than in transverse waves. (Author)

THE ROLE OF ATOMIC OXYGEN IN THE IONOSPHERIC E- AND F-REGION BEHAVIOR.
J. R. Herman and S. Chandra (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
Planetary and Space Science, vol. 17, June 1969, p. 1247-1256. 8 refs.

Simultaneous solution of the continuity and heat conduction equations for the electron, ion, and neutral gases to show the effect of using the heat loss arising from the excitation of the fine structure levels of atomic oxygen and the heat input from a height-dependent electron heating efficiency. The solutions are compared to Thomson backscatter data obtained under conditions similar to those used in the theoretical model. A family of solutions is presented for three different values of the atomic oxygen density at the turbopause level and compares favorably to certain widely observed features of the main phase of a magnetic storm. From the comparison, it is shown that the results of decreasing the atomic oxygen density at the turbopause level are consistent with the observed changes in both the neutral and ionized constituents relative to quiet magnetic conditions. (Author)

THEORETICAL SPECTRAL SCATTERING OF ICE CLOUDS IN THE NEAR INFRARED.
James E. Hansen and Howard Cheyney (NASA, Goddard Space Flight Center, Goddard Institute for Space Studies, New York, N.Y.).
Journal of Geophysical Research, vol. 74, June 20, 1969, p. 3337-3346. 19 refs.
Grants No. NsG-499; No. NsG-33-016-013.

Calculation of the spectral reflectivity of clouds of ice spheres for the near-infrared wavelength region ($1 \lesssim \lambda \lesssim 4\,\mu$) for comparison with laboratory observations of ice clouds. The laboratory cloud particles were highly nonspherical ice crystals; however, it is shown that the major feature of the theoretical spectrum is in close agreement with the observations when spheres of equal volume are employed in the radiative transfer problem. The results provide some support for the contention that randomly oriented nonspherical particles may be replaced by equivalent spheres for calculations of reflected intensities. The reflectivities are shown to be sensitive to the particle size, especially the reflectivity minima near 1.5 and 2.0 μ. Changes by a factor of 2 in the particle size cause significant variations in the major reflectivity features; this result verifies that spectral reflectivity measurements can be of considerable value for cloud identification. The agreement of the theoretical and experimental spectra also indicates that it should be possible to obtain meaningful conclusions from IR reflectivity measurements of planetary atmospheres, such as the observations that have been made on the atmosphere of Venus. (Author)

EXPLORER 12 MAGNETOPAUSE OBSERVATIONS - LARGE-SCALE NONUNIFORM MOTION.
Richard L. Kaufmann (New Hampshire, University, Dept. of Physics, Durham, N. H.) and Andrei Konradi (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Journal of Geophysical Research, vol. 74, July 1, 1969, p. 3609-3627. 17 refs.
NSF Grants No. GP-5255; No. GA-1131.

Study of a number of events that provide evidence that relatively small portions of the magnetopause occasionally become severely distorted. The largest distortions are generally elongated in the north-south direction, and the magnetosheath magnetic field is usually either nearly parallel or antiparallel to the magnetospheric field. As a result, the distortions do not involve severe bending of any magnetic field lines. The distortion is frequently triggered by a change in the properties of the solar wind. A model involving propagation of a thin discontinuity past the earth is consistent with the observations. Observationally the severe distortions are distinct from the small-scale, more or less uniform radial excursions of the magnetopause that are seen on a large fraction of all magnetopause crossings. They are also distinct from the expansions and contractions of the entire magnetosphere in response to changing solar wind pressure. (Author)

IONOSPHERIC AND MAGNETIC OBSERVATIONS AT 1000 KILOMETERS DURING THE GEOMAGNETIC STORM AND AURORA OF MAY 25-26, 1967.
J. A. Findlay, P. L. Dyson, L. H. Brace (NASA, Goddard Space Flight Center, Greenbelt, Md.), A. J. Zmuda, and W. E. Radford (Johns Hopkins University, Applied Physics Laboratory, Silver Spring, Md.).
Journal of Geophysical Research, vol. 74, July 1, 1969, p. 3705-3712. 18 refs.
Contract No. NOw-62-0604-C.

Comparison of electron temperature and number density measurements and of transverse magnetic disturbances obtained at 1000 km before, during, and after the magnetic storm and aurora of May 25, 26, 1967, with visual observations of the aurora. A degree of correlation is apparent. Throughout the latitudinal region of visual aurora the electron temperature and its latitudinal variations were much greater than are observed under quiet conditions. Temperatures in excess of 6500°K and temperature variations of greater than 500°K within less than 4 km along the satellite path were measured. Temperatures this high suggest a heat source other than auroral electron bombardment. The electron number density was also extremely structured through the region of visual aurora. Horizontal gradients were observed in which the number density changed by greater than 50% in less than 100 m along the satellite path. The greatest number density measured was $\sim 6.5 \times 10^4$ cm^{-3} (at $\Lambda = 53°$). The magnetometer recorded a number of disturbances (as large as 306 γ) in the region of unusual concentration and temperature behavior. (Author)

MANGANOAN ILMENITE FROM A SIERRAN ADAMELLITE.
Kenneth G. Snetsinger (NASA, Ames Research Center, Space Sciences Div., Moffett Field, Calif.).
American Mineralogist, vol. 54, Mar.-Apr. 1969, p. 431-436. 14 refs.

Study of manganoan ilmenite occurring as a late minor accessory constituent of an adamellite in the northwest part of the Bass Lake quadrangle, Mariposa County, Calif. The mineral is not zoned, but it does show appreciable grain-to-grain variation in manganese and iron. Electron microprobe analysis of a grain containing highest manganese gives manganous oxide 11.1, ferrous oxide 28.8, titanium dioxide 52.0, ferric oxide 4.5, manganese sesquioxide 3.3, aluminum oxide 0.3, and vanadium trioxide 0.06 wt %. Valence states of manganese and iron were estimated with the electron microprobe by comparing line intensity ratios of these elements with an analyzed ilmenite and a synthetic oxide. G.R.

PREDICTION OF GEOMAGNETIC SECULAR CHANGE CONFIRMED.
Anne B. Kahle, R. H. Ball (RAND Corp., Santa Monica, Calif.), and J. C. Cain (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Nature, vol. 223, July 12, 1969, p. 165. 7 refs.

Study of the correlation between the eccentric dipole motion and the change in length of day. A new model of the geomagnetic field was recently derived from data recorded by the OGO-2 and OGO-4 spacecraft. Using this model the eccentric dipole motion is westward at 0.114 deg/year. This new value confirms the predicted decrease some time during this period to a level about equivalent to that forty years earlier. G.R.

THE REDUCTION OF TOPSIDE IONOGRAMS TO ELECTRON-DENSITY PROFILES.
John E. Jackson (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IEEE, Proceedings, vol. 57, June 1969, p. 960-976. 26 refs.

Review of the basic principles of the ionosonde technique for ionospheric electron-density determination, with special emphasis on the satellite version. It is shown that the lamination method of data reduction, developed initially for the analysis of ionograms obtained with ground-based ionosondes, can be used to calculate the electron density N vs true height h in the topside ionosphere provided a number of refinements are introduced. These refinements are required because the extraordinary wave data have to be used to obtain N(h) profiles from topside ionograms, and because these data are very sensitive to the magnetic field variation over the great altitude range of topside soundings. A complete procedure for analyzing topside ionograms, based upon a parabolic-in-log N lamination method is presented which incorporates (1) the actual values of the earth's magnetic field at all heights, (2) a change in

variable which renders the group path integrand finite at the reflection point, and (3) iteration until successive calculations agree to within 0.01 km. A procedure was also developed to insure and accelerate the convergence of the iteration process. The importance of each refinement is discussed and illustrated quantitatively. It is shown that this new N(h) reduction technique can, in theory, yield topside electron-density profiles with an altitude accuracy of a few kilometers over a 3000 to 400 km altitude range. This theoretical accuracy can be achieved using typically ten to twenty data points per ionogram. In practice, the errors in the N(h) profiles arise primarily from the limited resolution of the ionograms, calibration inaccuracies, and deviations from vertical propagation. (Author)

GLOBAL ELECTRON DENSITY DISTRIBUTIONS FROM TOPSIDE SOUNDINGS.
K. L. Chan and Lawrence Colin (NASA, Ames Research Center, Space Sciences Div., Moffett Field, Calif.).
IEEE, Proceedings, vol. 57, June 1969, p. 990-1004. 62 refs.

Global morphology of electron density distributions in the topside ionosphere during sunspot minimum as deduced from Alouette 1 and 2 ionograms. Graphs are shown illustrating the variations of electron density with altitude (400 to 3000 km), dip latitude (plus or minus 90 deg), local time (24 hours), and season (December and June solstices; equinox) for both quiet and disturbed geomagnetic field conditions. Average daytime and nighttime electron density distributions, based on the analysis of large quantities of Alouette 1 quiet-time data, are presented for the lower altitudes (less than 1000 km) and for low and middle dip latitudes for each season. Large-scale anomalous features are summarized and discussed with respect to their bottomside counterparts where such exist. (Author)

COMPARISON OF RESULTS OF EXPLORER XXXI DIRECT MEASUREMENT PROBES.
J. L. Donley, L. H. Brace, J. A. Findlay (NASA, Goddard Space Flight Center, Greenbelt, Md.), John H. Hoffman (Southwest Center for Advanced Studies, Dallas, Tex.), and Gordon L. Wrenn (London, University, University College, Mullard Space Science Laboratory, London, England).
IEEE, Proceedings, vol. 57, June 1969, p. 1078-1084. 6 refs.

Comparison of measurements of the major ionospheric parameters of ion and electron density and temperature and ionic species made by direct measurement probes on the Explorer 31 satellite. Plasma density results are compared with simultaneous data from the Alouette 2 satellite. Probe results are from the following experiments: planar ion trap, planar electron trap, cylindrical electrostatic probes, high-resolution magnetic ion mass spectrometer, planar Langmuir plate, and spherical ion probe. The plasma densities measured by the various probes generally agree with simultaneous Alouette 2 sounder values to within 20 per cent. Electron temperatures measured by three different types of probes generally agree within 10 per cent. Ion composition measurements by the planar ion trap and spherical probe show good agreement with the high-resolution magnetic mass spectrometer. Ion temperature measurements from the ion trap are consistently higher than spherical ion probe results. (Author)

A69-37887 *
DIFFUSIVE EQUILIBRIUM IN THE TOPSIDE IONOSPHERE.
S. J. Bauer (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
IEEE, Proceedings, vol. 57, June 1969, p. 1114-1118. 41 refs.

Discussion of the general features of a diffusive equilibrium model for the topside ionosphere. The question of the applicability and limitations of such a concept is debated. It is noted that, although diffusive equilibrium may not always be strictly applicable, the concept provides a readily available analytical model for the general features of the topside ionosphere. M.M.

A69-37888 *
A REVIEW OF THE THEORIES CONCERNING THE EQUATORIAL F2 REGION IONOSPHERE.
Richard A. Goldberg (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
IEEE, Proceedings, vol. 57, June 1969, p. 1119-1126. 55 refs.

Review of the major theories dealing with the equatorial F region, as categorized into two basic groups, causal and semi-phenomenological. It is pointed out that the mechanisms postulated in the electrodynamic drift theory are consistent in that they produce agreement between observations and theoretical results, but are lacking in direct experimental verification. It is noted that the transequatorial neutral winds currently postulated as the basic cause of transhemispheric asymmetries during solstice conditions require further investigation. M.M.

A69-37893 *
MODEL STUDIES OF THE KINKED Z TRACE IN TOPSIDE IONOGRAMS.
Lawrence Colin and K. L. Chan (NASA, Ames Research Center, Moffett Field, Calif.).
IEEE, Proceedings, vol. 57, June 1969, p. 1143-1147.

Review of the propagation characteristics of the Z trace observed on topside ionograms, with special consideration of the "kinked" Z trace. It is shown that the kink can be explained by a simple magnetoionic theory. A confirmation of this contention is found by a ray propagation analysis. V.P.M.

A69-37896 *
TEMPERATURE AND ION ABUNDANCE PROFILES DEDUCED FROM SIMULTANEOUS EXPLORER XXXI AND ALOUETTE II DATA.
Lawrence Colin, Stuart W. Dufour, and Dora S. Willoughby (NASA, Ames Research Center, Space Sciences Div., Moffett Field, Calif.).
IEEE, Proceedings, vol. 57, June 1969, p. 1154-1158. 9 refs.

Combination of field-aligned electron concentration profiles from the Alouette 2 sounder with simultaneous measurements of ion and electron temperatures and relative ionic abundances measured by the Explorer 31 satellite at its orbit, to deduce plasma temperature and ion concentration profiles, using a diffusive equilibrium theory. Analysis of eleven Alouette 2-Explorer 31 passes during December 1965, and January 1966 indicates that regions of constant or slightly decreasing plasma temperature with height are common in the lower exosphere. These results imply the presence of regions of negative or zero ion temperature gradients since experiment and theory generally yield nonnegative electron temperature gradients over the altitude range considered. M.M.

A69-38084 *
AN IMPROVED MODEL EQUATORIAL ELECTROJET WITH A MERIDIONAL CURRENT SYSTEM.
M. Sugiura (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.) and D. J. Poros (Vitro Corporation of America, Vitro Services; NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).
Journal of Geophysical Research, vol. 74, Aug. 1, 1969, p. 4025-4034. 13 refs.

The effective-conductivity model for the equatorial electrojet presented earlier is revised by including a meridional current system, thus making the current density divergence-free. Using a spherical harmonic expansion for the geomagnetic field, a model electrojet is constructed for each of the east longitudes of 0, 40, 80, 180, and 280 deg. It is shown that the essential feature of the meridional current system is the existence of two current loops, one on each side of the dip equator, with an equatorward current in the lower E region, an upward current over the dip equator, and a return current flowing in the upper E region. The intensities of the electrojet and the associated meridional current are significantly dependent on longitude, being strongest over Peru and weakest over India. The new model predicts a reversed (westward) current in a thin, narrow layer

located at several degrees off the dip equator, which is due to a reversal of the vertical polarization field. The meridional current loop creates a toroidal magnetic field of an intensity comparable with that of the main electrojet. (Author)

DIURNAL AND SEASONAL VARIATION OF ATMOSPHERIC ION COMPOSITION; CORRELATION WITH SOLAR ZENITH ANGLE.
H. C. Brinton, R. A. Pickett, and H. A. Taylor, Jr. (NASA, Goddard Space Flight Center, Laboratory for Atmospheric and Biological Sciences, Greenbelt, Md.).
Journal of Geophysical Research, vol. 74, Aug. 1, 1969, p. 4064-4073. 23 refs.

Global measurement of the diurnal and seasonal variations of the primary atmospheric ions in the earth's topside ionosphere between 280 and 2700 km, using the ion mass spectrometer on Explorer 32. Evidence of direct correlation between solar zenith angle and the low and midlatitude distributions of thermal positive O, N, He, and H ions was obtained as the satellite orbit plane traversed one complete diurnal cycle between June 11 and Oct. 5, 1966. M.M.

LATITUDINAL VARIATIONS IN THE NEUTRAL ATMOSPHERIC DENSITY.
George P. Newton and David T. Pelz (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Journal of Geophysical Research, vol. 74, Aug. 1, 1969, p. 4169-4174. 22 refs.

Summary of in-situ atmospheric density measurements from the Explorer 32 density gauges for the time period from May through October 1966 revealing a latitudinal density structure in the neutral thermosphere during geomagnetically undisturbed times. For altitudes between 300 and 700 km the summer northern latitude densities are greater than the equatorial densities. For latitudes greater than 55 deg N, the northern latitude to equatorial latitude density ratio is smallest during the day (near 1.3) and increases at night to values greater than 2. Large (greater than 3) high-latitude to equatorial density ratios are observed near or in the auroral zone. These large ratios are observed even on geomagnetically quiet days. These results suggest that auroral zone and high latitude heating is a permanent feature of the summer thermosphere. (Author)

INFRARED MEASUREMENTS OF VARIATIONS IN STRATOSPHERIC WATER VAPOUR.
P. M. Kuhn, M. S. Lojko (ESSA, Boulder, Colo.), and E. W. Petersen (NASA, Ames Research Center, Moffett Field, Calif.).
Nature, vol. 223, Aug. 2, 1969, p. 462-464. 10 refs.

Determination of water vapor profiles in the stratosphere over long aircraft traverses from infrared radiometric observations under cloudless conditions by an inverse solution of the radiative transfer equation of Wark and Fleming (1966). The measurements indicate frequent variations of stratospheric water vapor apparently associated with tropospheric meteorological features. F.R.L.

NITRIC OXIDE IN THE MESOSPHERE AND ITS VARIATIONS.

A. P. Mitra (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).

IN: SPACE RESEARCH IX; COSPAR, PLENARY MEETING, 11TH, TOKYO, JAPAN, MAY 9-21, 1968, PROCEEDINGS. (A69-38334 21-13)

Meeting co-sponsored by the Japanese Committee on Space Research.

Edited by K. S. W. Champion, P. A. Smith, and R. L. Smith-Rose.

Amsterdam, North-Holland Publishing Co., 1969, p. 418-432. 20 refs.

Discussion of the distributions, seasonal variations, and the resulting ionospheric implication of mesospheric nitric oxide. Attention is given to the principal features of an average distribution for this constituent that would be consistent with photochemical considerations, with the diurnal and solar cycle variations in D-region ionization, and with the relative abundances of the molecular nitric oxide and oxygen ions. The extent to which the average profile may vary seasonally in middle latitudes is examined. Large winter enhancements occur in NO concentrations at all D region heights above about 70 km due to the winter warming at these heights. The enhanced region is limited roughly between 70 and 90 km, the lower limit being controlled by the rapid loss of nitric oxide through reactions with ozone. Ionospheric implications of these NO distributions are also discussed. (Author)

FINE STRUCTURE IN THE ENERGY SPECTRUM OF LOW ENERGY AURORAL ELECTRONS.

D. S. Evans (NASA, Goddard Space Flight Center, Greenbelt, Md.). IN: ATMOSPHERIC EMISSIONS; PROCEEDINGS OF THE NATO ADVANCED STUDY INSTITUTE, AGRICULTURAL COLLEGE OF NORWAY, ÅS, NORWAY, JULY 29-AUGUST 9, 1968. (A69-38482 21-13)

Institute supported by NATO, the U.S. Air Force, and the U.S. Navy.

Edited by B. M. McCormac and Anders Omholt.

New York, Van Nostrand Reinhold Co., 1969, p. 107-118. 18 refs.

Study of the energy spectrum of primary auroral particles for the purpose of determining some unique characteristics which may be linked to specific acceleration or precipitation mechanisms. A review of a number of rocket investigations of the energy spectra of low-energy auroral electrons is presented. It is concluded that auroral energy spectra exhibiting structure, especially peaks, must now be viewed as a common, if not typical occurrence, indicating that electrostatic fields have played a role in the acceleration process. B.H.

MAGNETOSPHERIC CONVECTION PATTERNS INFERRED FROM HIGH LATITUDE ACTIVITY.

J. P. Heppner (NASA, Goddard Space Flight Center, Greenbelt, Md.).

IN: ATMOSPHERIC EMISSIONS; PROCEEDINGS OF THE NATO ADVANCED STUDY INSTITUTE, AGRICULTURAL COLLEGE OF NORWAY, ÅS, NORWAY, JULY 29-AUGUST 9, 1968. (A69-38482 21-13)

Institute supported by NATO, the U.S. Air Force, and the U.S. Navy.

Edited by B. M. McCormac and Anders Omholt.

New York, Van Nostrand Reinhold Co., 1969, p. 251-266. 22 refs.

Discussion of high-latitude magnetospheric convection in terms of the information provided and restrictions imposed by the distribution of ionospheric current. Models of magnetospheric convection are drawn after Axford and Hines (1961), Taylor and Hones (1965), Nishida (1966), and Brice (1967). A study is made of the current pattern from magnetic disturbance plots, the convective boundary from OV1-10, and the magnetospheric convection pattern. The convection implications of the disturbance pattern are discussed and are related to the plasmapause, the solar wind, Nishida's patterns, midday auroral belt convection, and dawn-to-dusk and noon-to-midnight asymmetries. V.P.M.

Institute supported by NATO, the U.S. Air Force, and the U.S. Navy.

Edited by B. M. McCormac and Anders Omholt.

New York, Van Nostrand Reinhold Co., 1969, p. 305-316. 13 refs.

Review of direct measurements of dc electric fields from sounding rockets. Although the first attempts at these measurements were made almost a decade ago, it is only in the last several years that quantitative measurements of geophysical electric fields have been obtained. The magnitudes of several recent direct probe measurements of dc electric fields in the ionosphere are in essential agreement with measurements made with the cloud technique, and there is considerable agreement with the predictions of the magnitude of these fields based on theories of ionosphere Sq currents at lower latitudes. At auroral latitudes a strong anticorrelation of the measured electric fields with auroral luminosity has been observed. This anticorrelation effect is not completely understood, but it places several strong restrictions on the location, the impedance, and the direction of the auroral dynamo. (Author)

THE SIMULTANEOUS INVESTIGATION OF ATTENUATION AND EMISSION BY THE EARTH'S ATMOSPHERE AT WAVELENGTHS FROM 4 CENTIMETERS TO 8 MILLIMETERS.

George G. Haroules and Wilfred E. Brown, III (NASA, Electronics Research Center, Microwave Laboratory, Cambridge, Mass.).

Journal of Geophysical Research, vol. 74, Aug. 20, 1969, p. 4453-4471. 19 refs.

Daily solar measurements of atmospheric absorption and atmospheric emission were conducted simultaneously for a period of nine months during 1967 and 1968. Nighttime observations of emission followed daytime observations of absorption and emission. The month of June 1968 provided a fortuitous opportunity to observe absorption during rain since 23 out of 30 days had light to heavy rainfall. The brightness temperature of clouds was measured by the multifrequency instrument during the observation period. The observational frequencies of 8, 15, 19, and 35 GHz were used to determine the frequency correlation between meteorological phenomena and the atmospheric parameters associated with the fine structure characteristics of absorption and emission. (Author)

MEASUREMENTS IN THE IONOSPHERE OF THE ASPECT DEPENDENCE OF ANTENNA REACTANCE. I—VARIATIONS ARISING FROM THE INHOMOGENEOUS PLASMA DISTRIBUTION ABOUT THE VEHICLE.

Robert G. Stone, Joseph Fainberg, and J. K. Alexander (NASA, Goddard Space Flight Center, Laboratory for Space Sciences, Greenbelt, Md.).

Planetary and Space Science, vol. 17, Aug. 1969, p. 1437-1447. 9 refs.

Measurements of the antenna reactance from a sounding rocket traveling through the ionosphere, showing variations related to the rocket spin period. The observed variations can be resolved into components with periodic time structure equal to the spin period, half the spin period, or a mixture of these. The relative importance of these components depends on the experiment configuration and the flight trajectory, as well as on the magnetoionic parameters. To account for the observations, it is necessary to take into consideration the response of an antenna to the magnetoionic medium and to the disturbance produced in the ambient plasma by the rocket motion. Examples of the plasma distribution about the rocket, as inferred from the antenna reactance measurements, are shown and discussed. (Author)

DIURNAL VARIATIONS IN THE THERMOSPHERE FROM A SERIES OF MARSHALL-UNIVERSITY-OF-MICHIGAN PROBES.

Don K. Weidner and Gary R. Swenson (NASA, Marshall Space Flight Center, Aero-Astrodynamics Laboratory, Aerospace Environment Div., Huntsville, Ala.).

Journal of Geophysical Research, vol. 74, Sept. 1, 1969, p. 4755-4764. 23 refs.

Results of rocket measurements of the diurnal variation in the concentration and temperature of molecular nitrogen. Omegatron mass spectrometers measured the molecular nitrogen concentration from 150 to 320 km, and temperature was derived from the molecular nitrogen scale height. Under the assumption of diffusive equilibrium, molecular and atomic oxygen concentration profiles were calculated. The calculated concentration profiles of molecular oxygen and nitrogen are in excellent agreement with other direct observations but are in poor agreement with theoretical model atmospheres that are based on satellite-drag-determined densities. Diurnal variations in the constituent concentrations, temperature, and mass density are found to be completely reasonable with maximum values near 1400 hours and minimum values near 0400 hours. For rocket-borne mass spectrometer measurements, the wall loss coefficient is indicated to be near 1 for atomic oxygen. The well-known controversial factor-of-two difference between density determined from satellite-drag data and that obtained from mass spectrometers can be resolved when reasonable physical assumptions are made. RUBIDIUM-STRONTIUM CORRELATION STUDY OF MOLDAVITES AND RIES CRATER MATERIAL.
C. C. Schnetzler, John A. Philpotts, and W. H. Pinson, Jr. (NASA, Goddard Space Flight Center, Planetology Branch, Greenbelt, Md.).
(Corning Glass Works and Smithsonian Institution, International Tektite Symposium, 3rd, Corning, N.Y., Apr. 16-18, 1969.)
Geochimica et Cosmochimica Acta, vol. 33, Sept. 1969, p. 1015-1021. 18 refs.

Study of moldavites and material from the Ries Crater carried out in order to ascertain whether a rubidium-strontium isochronal relationship, analogous to that between the Ivory Coast tektites and material from the Bosumtwi Crater, exists in this particular case. The results indicate that the Rb/Sr values of the Ries Crater material are different from those of the moldavites and that in contrast to the Ivory Coast tektite/Bosumtwi Crater relationship, no definite isochronal correlation or chemical similarity was detected between the moldavites and the Ries Crater material. Thus this work supports previous suggestions that the moldavites are not simply melted equivalents of the Ries materials. O.H.

Sr ISOTOPE PATTERNS WITHIN THE SOUTHEAST AUSTRALASIAN STREWN-FIELD.
W. Compston (Australian National University, Dept. of Geophysics and Geochemistry, Canberra, Australia) and Dean R. Chapman (NASA, Ames Research Center, Moffett Field, Calif.).
(Corning Glass Works and Smithsonian Institution, International Tektite Symposium, 3rd, Corning, N.Y., Apr. 16-18, 1969.)
Geochimica et Cosmochimica Acta, vol. 33, Sept. 1969, p. 1023-1036. 14 refs.

Study of the Rb-Sr isotope patterns within the tektites from the Southeast Australasian strewn-field. In an analysis of ten specimens of Southeast Australasian tektites, an attempt was made to define isochrones for particular chemical types, and to correlate the distribution of Rb and Sr within the types with that of the major elements of the types, in order to clarify the meaning of the isochrones. The results show that in the formation of these tektites, Rb volatization played only a negligible role. Instead, the separate isochrones found within the strewn-field characterize their different source rocks, and may contribute to their eventual identification. O.H.

RESPONSE OF THE 1000-KILOMETER IONOSPHERE TO MAGNETIC STORMS.
B. M. Reddy, D. R. Lakshmi (National Physical Laboratory of India, New Delhi, India), and L. H. Brace (NASA, Goddard Space Flight Center, Greenbelt, Md.).
(International Symposium on Equatorial Aeronomy, 3rd, Ahmedabad, India, Feb. 3-10, 1969.)
Radio Science, vol. 4, Sept. 1969, p. 851-857. 18 refs.

Use of measurements of electron concentration and electron temperatures by the Langmuir probe experiment of the Explorer 22 satellite during 1966 to study the response of the topside ionosphere, at 1000 km, to magnetic storms. The analysis was limited to the American longitudes (50 to 130 deg W) over a latitude range from 50 deg S to 70 deg N geomagnetic. The day-time response is characterized by various degrees of electron-density enhancements over the entire latitude range, with the winter high latitudes undergoing the highest enhancement. The electron-temperature changes are not so unique. An attempt is made to explain some of these features qualitatively, based on thermal expansion of the upper atmosphere during storms and the "viscous drag" of the solar plasma on the magnetosphere. (Author)

SOME SYSTEMS POSSIBILITIES FOR GLOBAL ATMOSPHERIC RESEARCH PROGRAM.
Morris Tepper (NASA, Office of Space Science and Applications, Washington, D.C.) and Stanley Ruttenberg (National Center for Atmospheric Research, Boulder, Colo.).
American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-120. 22 p.

Discussion of a space-based observing system which, coupled with expanded surface and nonspace observational techniques now being actively developed as part of the World Weather Watch, could provide in the next years a substantial step toward actual realization of complete global atmospheric observations. Measurements of winds with the aid of balloons located by statellites are considered as well as wind tracing by clouds. Infrared and microwave sounding of the atmosphere for temperature and water vapor is discussed, and the suitability of measurements of the mass field as numerical inputs for a general circulation model is estimated. The proposed satellite-based system for the early Global Atmospheric Research Program experiment is described. P.G.

POTENTIAL CONTRIBUTIONS OF ORBITAL EARTH RESOURCES DATA TO URBAN PLANNING.
Charles T. N. Paludan (NASA, Marshall Space Flight Center, Astrionics Laboratory, Huntsville, Ala.).
American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-483. 12 p. 10 refs.

Discussion of some possible applications of multispectral orbital photography to the urban planning problem. In order to overcome the major problem of maintaining up-to-date land-use data, a coverage of all major U.S. cities is suggested by multispectral photography. Orbital cameras yielding scales as small as 1:1,000,000, can efficiently answer the problem of frequent and low-cost acquisition of relevant data. Some potential contributions of such data are discussed. Several commercial aspects and consequences are described. As an example of the investigation of urban land-use patterns, simulated orbital data pertaining to portions of the city of Denver are examined. O.H.

HYDROMAGNETIC RADIATION FROM ELECTRIC AND MAGNETIC DIPOLES IN THE MAGNETOSPHERE.
A. K. Sundaram (NASA, Langley Research Center, Hampton, Va.).
Canadian Journal of Physics, vol. 47, Aug. 15, 1969, p. 1643-1656. 15 refs.

Investigation of the radiation characteristics of elementary electric and magnetic dipoles in a homogeneous, anisotropic, cold plasma of infinite extent with a uniform magnetostatic field. The cases treated include the electromagnetic sources taken parallel and perpendicular to the magnetostatic field. In all cases, expressions for the field components are obtained which are valid at frequencies well below the ion cyclotron frequency. It is found that electric and magnetic dipole sources when oriented perpendicularly to the

magnetic field excite both ordinary and extraordinary modes. For the ordinary mode, the waves are guided in both directions within cones of small apex angle aligned with the static field. When the dipole sources are aligned with the magnetic field, it is found that the electric dipole excites only the ordinary mode leading to guided wave propagation, while the magnetic dipole excites only the extra-ordinary mode. In all cases, the waves propagate at Alfvén speed. The radiation characteristics are isotropic for the extraordinary mode excited by the perpedicular electric dipole and are nearly isotropic for the aligned magnetic dipole. For other cases, the radiated power is concentrated in opposite directions along the static field. (Author)

LATITUDINAL OBSERVATIONS OF THE THERMAL BALANCE IN THE NIGHTTIME PROTONOSPHERE.
K. K. Mahajan and L. H. Brace (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Journal of Geophysical Research, vol. 74, Oct. 1, 1969, p. 5099-5112. 20 refs.

Results of Alouette 2 electrostatic probe measurements of the nighttime electron temperature and concentration in the height range from 2000 to 3000 km on global basis. The major feature of the protonosphere at this altitude is a broad minimum in electron temperature at the low altitudes with values around 1800 deg K. The electron temperature increases sharply to over 3000 deg K at the middle latitudes. The electron concentration exhibits a pair of maxima at about 30 deg north and south with values ranging from 4000 per cu cm in fall to 8000 per cu cm in local summer. No definitive seasonal dependence is apparent in electron temperature. Comparison of the present Alouette 2 measurements with nearly simultaneous measurements on Explorer 22 during summer 1966 reveal positive temperature gradient of electron temperature along field lines. These gradients are consistent with the thermal energy stored in the nocturnal protonosphere, and therefore no external souce of heat is required to explain the observations. (Author)

APPLICATION OF BIOGEOCHEMISTRY TO MINERAL PROSPECTING A Survey
Washington NASA 1968 135 p refs
(Contract NAS8-5604)
(NASA-SP-5056) Avail: CFSTI CSCL 08G

The application of a combination of disciplines into the hybrid science termed biogeochemistry has gained momentum in recent decades, bringing the benefit of research into the overlapping areas of geology, biology, and chemistry. This report coalesces these technologies in a coherent interrelationship for application to mineral prospecting. Theoretical concepts are presented, including the geochemical cycle through which chemical elements pass in the process of becoming plant nutrients, the physiological requirements necessary for plant growth, and the interrelationship of these two bodies of knowledge which are directly applicable to the solution for the problem of prospecting. A series of articles is presented covering a broad range of subjects by a group of Soviet scientists writing on some of the problems of modern science, such as the structure of matter, the nature of physical fields, the formation and evolution of the Earth and the universe, solar activity and the Earth, and the interaction between the Earth's biosphere and physical fields. Some facts from the history of science which are related to the emergence of science into the reaches of outer space are also presented. Many of the ideas expressed in the articles of this collection draw upon the works of great Russian scientists of the past whose topical interest has been revived with the onset of the space age. A PRELIMINARY STUDY OF THE DETECTION OF GEOMORPHOLOGICAL FEATURES OVER NORTHEAST AFRICA BY SATELLITE RADIATION MEASUREMENTS IN THE VISIBLE AND INFRARED
Jean Pouquet and Ehrhard Raschke Washington Dec. 1968 20 p refs
(NASA-TN-D-4648) Avail: CFSTI CSCL 08F

Measurements from the meteorological satellite Nimbus 2 of reflected solar and emitted infrared radiations, day and night, over Northeast Africa were used to investigate some geomorphological features of the ground. It was found; (1) The daytime measurements of emitted longwave radiations are deceptive because of the differences in local solar times across a scan, (2) Nighttime measurements are closely related to solar reflectances over the same areas, (3) When nighttime infrared measurements depart from the general trend shown by the reflectance, this opposition helps in the detection of such geomorphological features as rock formation and soil moisture. It is pointed out that these investigations are no more than a tentative approach restricted chiefly because of the low resolution of the medium resolution infrared channels of Nimbus 2. Author

AN APPROACH TO THE REMOTE DETECTION OF EARTH RESOURCES IN SUB-ARID LANDS
Jean Pouquet Washington Dec. 1968 26 p refs
(NASA-TN-D-4647) Avail: CFSTI CSCL 08I

The purpose was to find a better geological tool utilizing the nighttime infrared radiations emitted by the ground, and thereby obtain a better knowledge of the agricultural possibilities of arid and sub-arid lands. The equivalent black body temperatures derived from Nimbus 2 high resolution infrared radiometer in the spectral range 3.5–4.2μ (atmospheric window) were analyzed for all available orbits from May until mid-November 1966. From this preliminary study certain predominant features emerged and were used as a basis for the interpretation of data. For the final interpretation only a few examples were selected: Death Valley and surroundings, and Salton Sea–Colorado River region. The principal results are: detection of tectonic accidents, already known, with emphasis upon the western branch of the San Andreas Fault system; reconstitution of the upper Pleistocene hydrographic patterns showing the link between Saline, Panamint, and Death Valleys, and the Colorado River, and the former courses of this river; the possibilities of humidity storage suggested by areas showing slightly higher nighttime temperatures than expected; close relationships between the agricultural possibilities involved in the preceding statement and the geomorphological stage reached by the different valleys and basins. L. M. Fishkova et al *In its* Aurorae and Airglow. Collection of Articles, no. 13 Jan. 1969 p 50–56 refs (See N69-16539 06-13)

Avail: CFSTI CSCL 04A

Variations in OH emission were obtained during a solar cycle. The minimum intensity for 1962–1963 had a greater amplitude than that for 1954–1955. The seasonal variations in rotational temperature have a greater amplitude for the bands from the upper vibrational levels. A study of the intensity variations in the OH bands, in relation to the zenith distance, shows that an increase in T (OH) corresponds to a lowering of the emitting layer. Author

THEORETICAL COMPARISON OF BEADS, WIRES, AND FILMS AS ROCKETSONDE TEMPERATURE SENSORS IN THE MESOSPHERE

Forrest L. Staffanson Washington NASA Feb. 1969 52 p refs

(Grant NGR-45-003-025)

(NASA-CR-1286; UTEC-MR-67-055) Avail: CFSTI CSCL 04A

Parameters are compared for three basic sensor shapes: the small sphere, the thin circular cylinder in cross flow, and the thin flat plate in parallel flow. For quantitative comparisons arbitrary sensor specifications and environmental conditions are shosen. The thickness dimension is as thin as practical for the respective shape. The volume specific heat corresponds to a material commonly used for the respective shape. For uniformity in absorptivity and emissivity each of the three shapes is assumed to have a thin opaque coat of aluminum with solar absorptivity, long wave absorptivity, and emissivity. The air flow and radiation environment is approximately that encountered by a sensor mounted on a stable parachute sonde system having weight and dimension of the ARCAS system and falling in the altitude interval 90 to 50 km. From the theroetical comparison of the thermometric performance of the three basic shapes, it is found that the two dimensional or pianar shape appears generally the most promising for future immersion sensor designs. Its principal features are: small recovery factor associated with its larger aerodynamic characteristic length, small thermal mass associated with its thinness, etc. B.P.

METEOROLOGICAL ROCKET RESEARCH SINCE 1959 AND CURRENT REQUIREMENTS FOR OBSERVATIONS AND ANALYSIS ABOVE 60 KILOMETERS

Roderick S. Quiroz Washington NASA Feb. 1969 69 p refs

(NASA Order L-719)

(NASA-CR-1293) Avail: CFSTI CSCL 04A

A detailed survey is made of routine rocket soundings since 1959, yielding measurements of neutral parameters up to 60 km, and of special rocket soundings giving data to ca. 100 km. The distribution of soundings, of which only 21% have been taken in latitudes north of 40°N, is given by station and year for more than 30 rocket sites, including foreign locations. Observational accuracies are examined in sufficient depth to permit an evaluation of the broad validity of the measurements. The observational errors may be appreciable, depending on the conditions of measurement, yet the observations are considered to efficiently delineate the broad atmospheric structure and circulation above radiosonde levels. Error contamination, however, may be critical in small-scale analysis. Author

A TECHNIQUE TO INFER ATMOSPHERIC TEMPERATURE FROM HORIZON RADIANCE PROFILES

Thomas B. McKee, Ruth I. Whitman, and Jules J. Lambiotte, Jr. Washington Feb. 1969 33 p refs

(NASA-TN-D-5068) Avail: CFSTI CSCL 04A

A technique is presented to infer atmospheric temperature structure from horizon radiance profiles. The technique was implemented for a spectral region of absorption due to the CO_2 molecule (615 cm^{-1} to 715 cm^{-1}). Inferred temperature accuracy is shown when input data are errorless and when input data have been perturbed with errors for the altitude range from 20.5 km to 55.5 km. Atmospheric temperatures were inferred from measured horizon radiance profiles and compared with estimated temperature structure as an example of the application of the technique to real data. AN ATLAS OF TIROS 7 MONTHLY MAPS OF EMITTED RADIATION IN THE 8/12 MICRON ATMOSPHERIC WINDOW OVER THE INDIAN OCEAN AREA

Earl R. Kreins and Lewis J. Allison Washington Apr. 1969 28 p refs

(NASA-TN-D-5101) Avail: CFSTI CSCL 04B

The Tiros 7 meteorological satellite contained a five channel

medium resolution scanning radiometer. One of the channels responded to emitted radiation in the 8- to 12-micron portion of the electromagnetic spectrum, where gaseous absorption in the atmosphere is minimal and, therefore, the radiation detected at the satellite originates mainly from the earth's surface and/or clouds. Data from this channel have been compiled and mapped in a series of one 12-day mean map (June 1963) and 18 monthly mean maps (July 1963 through December 1964) of equivalent blackbody temperatures. The maps cover the area enclosed by 45 degrees north latidue, 50 degrees south latitude, 20 degrees east longitude, and 155 degrees east longitude. These satellite observations were originally analyzed in support of the International Indian Ocean Expedition. They are presented in a separate, compact form for users who are interested primarily in the radiation data and in details concerning the processing, display, analysis, and interpretation of these data. COMPUTATION OF TOPSIDE IONOGRAMS FROM N(h) PROFILES

Lawrence Colin, Kwok-Long Chan, and Jack G. K. Lee (Informa[illegible]s, Inc., Palo Alto, Calif.) Washington Apr. 1969 35 p refs

(NASA-TN-D-5052) Avail: CFSTI CSCL 04A

Model profiles of plasma frequency and gyrofrequency are chosen to simulate typical conditions observed in the topside ionosphere by the Alouette I sounder (1000 km) and the Alouette II sounder near apogee (3000 km). Examples of group refractive index profiles for these models are presented. By means of parabolic-in-log X lamination techniques applied to the plasma frequency profiles, cumulative delays are computed to illustrate the relative delays contributed by each lamination to the formation of topside ionograms. Complete ionograms (ordinary, extraordinary, and Z traces) are presented for all the models. Implications of the results to the inverse experimental problem of scaling ionogram data and computing electron concentration profiles are discussed. Author

SURVEY AND COMPARATIVE ANALYSIS OF CURRENT GEOPHYSICAL MODELS

Jesco von Puttkamer Washington May 1969 66 p refs

(NASA-TN-D-5163) Avail: CFSTI CSCL 08E

By using currently accepted constants of geodesy, especially several different sets of oblateness coefficients, seven models of the geometry of the earth and its gravitational field are numerically derived and compared with each other and with a newly developed geopotential based on recent measurements of the secular and periodic perturbations of artificial satellite orbits. Conclusions are drawn which show, among other things, that the currently used NASA standard model deviates significantly from the best geoid, and that there are better analytical, as well as numerical, models by which improved approximation can be achieved. Also, it is shown that improvements in the numerical values of the used oblateness coefficients, rather than in their number, appear to have little influence on the values of the gravity, but that they affect the geometries significantly. Increasing the number of zonal harmonics coefficients, however, can lead to considerable improvements in the gravity model, at least in the range studied (up to and including J_{14}). Author

A TECHNIQUE TO INFER ATMOSPHERIC WATER-VAPOR MIXING RATIO FROM MEASURED HORIZON RADIANCE PROFILES

Thomas B. Mc Kee, Ruth I. Whitman, and Jules J. Lambiotte, Jr. Washington Jun. 1969 36 p refs

(NASA-TN-D-5252) Avail: CFSTI CSCL 08H

A technique is presented to infer atmospheric water-vapor mixing-ratio structure from measured horizon radiance profiles when a method exists for calculating radiance profiles. The technique was implemented for the spectral interval, 315 cm^{-1} to 475 cm^{-1} of the rotational water-vapor band but the technique is not limited to that interval. Inferred mixing-ratio accuracy for the 10-km to 35-km altitude range is shown when the computer program input data contain no errors and when the computer program input is perturbed by errors normally found in measurements. Water-vapor mixing ratios were inferred from horizon radiance profiles measured in the summer in a latitude range from 17° North to 58° North from an NASA Project Scanner flight. No significant latitudinal variation existed above an altitude of 18 km. Below 18 km a latitudinal variation does exist that is consistent with the large variations that are known to exist in the troposphere. The mixing ratio decreases with altitude to a minimum at a point ranging from 3 km to 5 km above the tropopause altitude. Above an altitude of 20 km the mixing ratio shows a slight increase to 35 km. GEOS I TRACKING STATION POSITIONS ON THE SAO STANDARD EARTH (C-5)

Francis J. Lerch, James G. Marsh, Maurice D. D'Aria (Wolf Res. and Develop. Corp.), and Ronald L. Brooks (Wolf Res. and Develop. Corp.) Washington Jun. 1969 38 p refs

(NASA-TN-D-5034) Avail: CFSTI CSCL 08E

For the purpose of long-arc satellite data reduction and intercomparison, all GEOS 1 participating tracking stations were transformed to a common datum. The common datum selected is the Smithsonian Astrophysical Observatory (SAO) Standard Earth C-5 model, in which the Baker–Nunn station positions are used as the controlling stations for all other stations to be transformed. Descriptions and formulation are presented to effect the transformations from major and isolated datums. An empirical transformation technique is explained in detail which may be employed advantageously when datum shifts are not known or when the control stations within a local datum are allowed to adjust independently on the world datum (SAO C-5). The transformation of local datum station coordinates is important to perform, since the datum shifts are quite large. Original and transformed station positions are presented in geodetic and Cartesian coordinates. Author

EVALUATION OF THE GODDARD RANGE AND RANGE RATE SYSTEM AT ROSMAN BY INTERCOMPARISON WITH GEOS I LONG-ARC ORBITAL SOLUTIONS

Francis J. Lerch, James G. Marsh, and Brian O'Neill (Wolf Res. and Develop. Corp., Bladensburg, Md.)
Washington Jun. 1969 52 p refs
(311-07-21-01-51)
(NASA-TN-D-5036) Avail: CFSTI CSCL 22C

The large volume of high precision optical observations of geos one provided the first opportunity to analyze the GRARR data recorded from the same satellite for systematic errors and biases. For this analysis, definitive long-arc optical orbital solutions determined from the GEOS one flashing lamp and passive data provided a very accurate standard for estimating these errors. The GRARR zero-set range bias and timing error estimates for the two satellite transponder channels, A and C, differed significantly. Twenty-six A channel passes analyzed had a mean zero-set range bias error of −7.8 meters with a standard deviation of 10.3 meters and a timing error of −2.1 milliseconds with a standard deviation of 4.0 milliseconds. Four C channel passes analyzed had a mean zero-set range bias error of 25.0 meters and a mean timing error of −0.6 milliseconds. This discrepancy can be explained in part by inaccuracies in the transponder delay curve. A timing error of up to 2 milliseconds can possibly be attributed to the orbital solution; however, the consistent results obtained from the shorter overlapping solutions indicate that these errors are due to other sources, either the GRARR system itself or station survey errors, etc. Further analysis and a possible expansion of the error model will be necessary before a complete explanation of these errors is possible.

MOTIVE FORCES IN THE DEVELOPMENT OF THE EARTH AND PLANETS

V. V. Kesarev
Washington NASA Jun. 1969 136 p refs Transl. into ENGLISH of the Book "Dvizhushchiye Sily Razvitiya Zemli I Planet" Leningrad, Nedra Press, 1967
(Contract NASw-1692)
(NASA-TT-F-532) Avail: CFSTI CSCL 03B

An original concept is set forth concerning the nature of the earth and the planets. The hypothetical composition of primary planetary matter is developed on a wide physical and chemical basis. Changes in planetary characteristics are connected in the closest way with the evolution of planetary matter. It is shown that the proposed chemical model of the earth can be extended to other inner and outer planets. The book is intended for geologists, physicists, chemists, and for all those who are interested in modern problems of natural science.

THE FACE OF THE EARTH AND ITS ORIGIN

G. N. Katterfeld Jun. 1969 134 p refs Transl. into ENGLISH of the book "Lik Zemli i ego Proiskhozhdeniye" Moscow, State Publishing House of Geograph. Lit., 1962
(NASA-TT-F-533) Avail: CFSTI CSCL 08E

The terrestrial deforming forces derived, from its rotation, and from alternate compression and expansion of the terrestrial body (pulsation), associated with the action of gravity and with that of internal physicochemical reactions are studied. It is shown that the net result of the interaction of these forces over the course of enormous periods of time has been the establishment of lines of maximal stress which have given rise to tectonic movements in the mantle. This has led to the well-known antipodal character of terrestrial relief: land masses (elevations) on one side of the globe are counterbalanced by water masses (depressions) on the other; and also to a number of other peculiarities, such as the wedge shape exhibited by the continents, and the distribution of volcanic activity. It is believed that the tidal action of the moon (which originated in nearby space at the same time as the earth) was an important factor leading to the imbalance in terrestrial relief.

STUDY OF AIR POLLUTANT DETECTION BY REMOTE SENSORS
C. B. Ludwig, R. Bartle, and M. Griggs Washington NASA Jul. 1969 160 p refs
(Contract NAS12-630)
(NASA-CR-1380; GDC-DBE68-011) Avail: CFSTI CSCL 04A

The feasibility of detecting the major air pollutants by earth-oriented, satellite-borne sensors is investigated. The major pollutants considered are carbon monoxide, sulfur dioxide, ozone, ammonia, nitrogen dioxide, typical hydrocarbons, and peroxyacetyl nitrate. The spectral region considered extends from the ultraviolet to the microwave region. The detection is to be accomplished by observing the change in radiation level due to the presence of air pollutants. In the ultraviolet and visible region, the reflected sunlight provides the radiation, while in the infrared and microwave region the thermal emission from the earth and its atmosphere is the source of radiation. In the first case, the detection is adversely affected by Rayleigh and Mie scattering of the sunlight in the atmosphere, which is not readily accounted for, particularly for satellite observations. In the second case, the detection is influenced by meteorological conditions, which must be obtained by independent measurements either from the satellite directly or from the global weather-station network. Considerations of the number of species accessible to optical detection, the matter of day and night detection, and of specificity indicate that the infrared region extending from 3.5μ to 13μ is the most useful one. SYNOPTIC ANALYSIS OF THE SOUTHERN HEMISPHERE STRATOSPHERE
Alvin J. Miller (Natl. Meteorol. Center, Hillcrest Heights, Md.) and Frederick G. Finger (Natl. Meteorol. Center, Hillcrest Heights, Md.) Aug. 1969 24 p refs
(NASA-TM-X-1814) Avail: CFSTI CSCL 04B

Rawinsonde data from 84 stations in the Southern Hemisphere are combined with constant-level balloon information to construct weekly hemispheric analyses for the 30-mb level for the month of June, 1967. Rocket information from Chamical, Argentina; Natal, Brazil, and Ascension Island are employed to infer the circulation at higher levels. During the period of study, the lower stratosphere of the Southern Hemisphere was dominated by a polar low with a subtropical ridge present at about 20°S. The lateral extent of the westerlies increased with height with the result that westerly winds existed in the tropical region at upper levels. Author

MAGNETOSPHERIC DUCT PROPAGATION RESEARCH USING ALOUETTE-2 TOPSIDE-SOUNDER OBSERVATIONS
Jayaram Ramasastry and Edward J. Walsh Washington Aug. 1969 75 p refs
(NASA-TN-D-5332) Avail: CFSTI CSCL 04A

This report presents a discussion of the intesne field-aligned propagation activity in the longitudes of Singapore observed by the Alouette-2 topside sounder. The frequency occurrence of sequences of ionograms containing conjugate echo traces is discussed in detail and attributed to the presence of field-aligned irregularities over a wide L-value range in the magnetosphere. Also described is the development of a unified model of field-aligned ducts in the magnetosphere from the analysis of the fine structure and diffuseness of the conjugate echo traces observed by the Alouette-2 sounder. The proposed model for the magnetospheric ducts is a large-scale, field-aligned, gaussian enhancement of electron density with a superimposed fine structure of small-scale gaussian ripples so that the large-scale variation has a ribbed rather than a smooth structure. Mathematical and digital ray-tracing analyses of the new model, along with illustrative ionograms which were used in postulating the model, are presented. Author

DEVELOPMENT OF A BARIUM CHEMICAL RELEASE SYSTEM
C. S. Stokes, E. W. Smith, and W. J. Murphy Washington NASA Aug. 1969 43 p refs
(Contracts NAS1-6199; NAS1-7070)
(NASA-CR-1415) Avail: CFSTI CSCL 04A

A method for producing Ba° and Ba^{+} in a gaseous medium was developed utilizing a liquid propulsion system. The fuel consisted of $BaCl^2$ and $Ba(NO^3)_2$ salts dissolved in hydrazine. The oxidizers tested were OF_2, ClF_3 and F_2. The Ba^{o} and Ba^{+} yield for all systems at varying oxidizer/fuel ratios was measured using spectroscopic techniques. The chemical system producing the highest yield of Ba^{o} and Ba^{+} consisted of a 17% $BaCl_2$-16% $Ba(NO^3)_2$-67% N_2H_4 fuel mixture tested with fluorine. Author

HYDRATION, OXIDATION, AND THE ORIGIN OF THE CALC-ALKALI SERIES
Robert F. Mueller Washington Nov. 1969 32 p refs
Grant NSF GA-307)
(NASA-TN-D-5400) Avail: CFSTI CSCL 08G

A physicochemical interpretation is given for the calc-alkali differentiation series of igneous rocks as distinguished particularly from gabbroic series such as the Skaergaard complex. It is found that, contrary to previous assumptions, the oxygen fugacity decreases markedly during calc-alkaline differentiation and in this way resembles the situation in gabbroic complexes. The affinity of water for the melt has the important consequence of increasing the solubilities of the quartzofeldspathic components more than those of the ferromagnesian components, so that the phase boundaries are shifted toward lower liquidus temperatures. The result is that the courses of the crystallization paths are directed into a region of quartzo-feldspathic rather than gabbroic liquids. Author

ATMOSPHERIC DENSITIES MEASURED BY THE EXPLORER 17 DENSITY GAUGES: ANALYSIS OF ERRORS AND THEIR EFFECTS UPON THE MEASUREMENTS
G. P. Newton and Richard Horowitz Washington Nov. 1969 36 p refs
(NASA-TN-D-5447) Avail: CFSTI CSCL 04A

The atmospheric total density data from the Explorer 17 Atmospheric Density Experiment are presented. The equations used for interpretation of the gauge output currents in terms of atmospheric density are derived. Possible systematic error due to gauge calibration, energetic gas beam-surface interaction, adsorption-desorption effects, chemical compound production, and gauge nonlinearity are evaluated; and it is concluded that the previously reported density values should be increased by 35 percent. The effects of variations in atmospheric composition on the density values are as follows: If an atmosphere of 100% atomic oxygen was assumed, but the atmosphere was really 100% helium, the density values should be increased by a factor of 1.6. Correspondingly, if the atmosphere was really 100% molecular nitrogen, the density values should be decreased by a factor of 0.72. Author

ULTRASONIC DETECTION AND MEASUREMENT OF FATIGUE CRACKS IN NOTCHED SPECIMENS.
S. J. Klima and J. C. Freche (NASA, Lewis Research Center, Cleveland, Ohio).
Society for Experimental Stress Analysis, Fall Meeting, San Francisco, Calif., Oct. 28-Nov.1, 1968, Paper. 34 p. 9 refs.

Description of an ultrasonic technique used to observe the formation and growth of fatigue cracks in notched cylindrical specimens subjected to reversed axial cyclic loading. Fatigue curves of life-to-initial detectable cracks as well as life-to-fracture are obtained for an aluminum, a titanium, and a cobalt base alloy as well as a maraging steel. Depth of initially detectable cracks ranged approximately from 0.013 to 0.10 mm. Curves are also obtained relating ultrasonic system output-voltage to crack depth up to 0.76 mm for three materials. These curves are used to demonstrate the capability of the device for monitoring crack growth. Z.W.

X-RAY FLUORESCENCE OF ROCK SAMPLES AS APPLIED TO GEOLOGICAL PROBLEMS.
Richard A. Laidley (NASA, Manned Spacecraft Center, Houston, Tex.).
Applied Spectroscopy, vol. 22, Sept.-Oct. 1968, p. 420-422. 5 refs.

Three methods of sample preparation of rock specimens have been evaluated for precision and accuracy. A fusion technique was found to give the best precision. Standard deviations (1 σ) using this method and expressed as percent of the amount present for several elements are Al 0.83, Si 0.64, K 0.43, Ca 0.43, Mn 0.48, and Fe 0.24. Three recent studies of compositional variation were performed on volcanic rocks. Analyses of samples from the Hopi Buttes, Ariz., on obsidian flows from Newberry Caldera, Ore., and on igneous rocks collected from grids or linear traverses give data which, in each case, are useful in making significant interpretations about the geologic history of the rocks concerned. These examples illustrate the rapidity and high quality of quantitative chemical analyses which can be obtained by application of X-ray fluorescence analytical techniques. (Author)

A69-10927 *
VACUUM DISTILLATION TECHNIQUE FOR RECOVERY OF ALKALI-METAL REACTION PRODUCTS.
Randall F. Gahn (NASA, Lewis Research Center, Cleveland, Ohio).
Analytical Chemistry, vol. 40, May 1968, p. 996-998. 9 refs.

Description of the vacuum technique for the isolation and recovery of alkali-metal reaction products. The procedure described is designed to minimize reaction-product contamination by carrying out all operations in high-vacuum or inert-gas atmospheres. The separation of reaction products from excess alkali metal is accomplished by vacuum distillation to avoid the use of solvent or reactants. This procedure is applied to the recovery of products from the reactions of potassium and lithium with tantalum, niobium, vanadium, and oxygen. Two examples are cited as an indication of the application and reproducibility of the procedure - namely, the isolation of the reaction products from the potassium-tantalum-oxygen system, and the isolation of the reaction products from the potassium-oxygen system. Z.W.

PLANETARY ATMOSPHERE MASS SPECTROMETRY.
N. W. Spencer (NASA, Goddard Space Flight Center, Greenbelt, Md.).
American Astronautical Society, Conference on Advanced Space Experiments, Ann Arbor, Mich., Sept. 16-18, 1968, Paper 68-183. 27 p. 10 refs.

Description of the conceptual basis for and the details of two systems representative of the existing instrumental technology in planetary (chiefly Mars and Venus) atmospheric composition determination. One of these systems is the one which has been developed to optimize data systems capability. It employs the adaptive scan approach - i.e., it searches for a mass of sufficient concentration to provide a useful measurable output signal and then measures and stores the magnitude of the output signal using only a single digital word. It also records the identity of the mass of the gas measured. For the quantitative detection and measurement of the positive-ion constitution of planetary atmospheres, a system using a Bennett ion spectrometer sensor has been derived from systems in use in earth satellites, such as the OGO and the Atmosphere Explorer series. The planetary design also employs a data system optimization scheme. In contrast to a neutral spectrometer, however, flat-topped peaks are not possible, and thus the output signal maximum is measured by a "peak-detecting" device. P.v.T.

THERMODIELECTRIC RADIOMETER.
Larry D. Russell (NASA, Ames Research Center, Moffett Field, Calif.) and Benjamin H. Beam (NASA, Ames Research Center, Radiations Research Branch, Moffett Field, Calif.).
(American Institute of Aeronautics and Astronautics, Aerodynamic Testing Conference, 3rd, San Francisco, Calif., Apr. 8-10, 1968, Paper 68-403.)
Journal of Spacecraft and Rockets, vol. 5, Dec. 1968, p. 1501-1503. 7 refs.

A new type of fast-response, thermal detector has been developed for measuring transient radiant flux. The detector operates on a mechanism of thermally induced depolarization of a polymer film dielectric. The film is charged to a voltage gradient of approximately 100 v/μ and, when it is heated by absorbed radiation, it produces a proportional open-circuit voltage increment. The detector is designed to measure the total energy or power of a transient, short-duration pulse of radiant flux. Polymer thermal-dielectric radiometers have been built and used for measuring the total power radiated by a high-speed shock wave. Sensitivities on the order of 20 v/joule/cm^2 and a time response on the order of microseconds have been achieved. (Author)

ADAPTIVE DATA COMPRESSION FOR VIDEO SIGNALS.
R. L. Kutz, J. A. Sciulli, and R. A. Stampfl (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: ADVANCES IN COMMUNICATION SYSTEMS: THEORY AND APPLICATIONS. VOLUME 3.
Edited by A. V. Balakrishnan.
New York, Academic Press, Inc., 1968, p. 29-66. 11 refs.

Discussion of experiments with several prediction schemes to maximize the probability of prediction (p). The results show that

the average value of p attained was nearly the same for all methods considered. In pure prediction capability, the adaptive sample-conditioned mode predictor yielded the best performance of all methods. Its superiority is minimized, however, when its implementation requirements are compared with those of the nonadaptive Markov predictor. Since all prediction methods provided nearly the same prediction efficiency, a study was made of the effects of channel errors on one of the simplest of possible systems - namely, a system consisting of the Markov predictor and the word-pair encoder.

MICROSECOND RESPONSE SYSTEM FOR MEASURING SHOCK ARRIVAL BY CHANGES IN STREAM ELECTRICAL IMPEDANCE IN A SHOCK TUBE.
Robert E. Dannenberg and Donald E. Humphry (NASA, Ames Research Center, Moffett Field, Calif.).
Review of Scientific Instruments, vol. 39, Nov. 1968, p. 1692-1696. 6 refs.

An instrument is described that is suitable for measuring the position and velocity of high-speed compression waves, rarefaction waves, and gas interface regions in shock tubes. The sensor is a twin-electrode probe mounted in the wall of the tube with a small dc voltage impressed across the electrodes. A simple power supply amplifier, and gate pulse generator complete the instrument. The probe provides a sensitive microsecond reponse to changes in the electrical impedance of the gas stream flowing across the sensor. In addition, the probe is inexpensive, rugged, and easy to install. It has been possible to correlate the output signals from this instrument with the different regions of shock tube flow at shock speeds from 2.29 to 7.01 km/sec into air. (Author)

A LUNAR-SURFACE ELECTRIC-FIELD DETECTOR.
B. W. Sherman (Missouri, University, Dept. of Electrical Engineering, Columbia, Mo.), R. H. Manka (NASA, Manned Spacecraft Center, Space Physics Div., Houston, Tex.), H. R. Anderson (William Marsh Rice University, Dept. of Space Science, Houston, Tex.), M. C. Terry, and J. D. Droppleman (Lockheed Aircraft Corp., Lockheed Electronics Co., Houston, Tex.).
IN: EASCON '68; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ELECTRONICS AND AEROSPACE SYSTEMS CONVENTION, WASHINGTON, D.C., SEPTEMBER 9-11, 1968, RECORD. [A69-13176 03-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 339-344.

Description of the electron-beam meter as an instrument to be used for monitoring the lunar-surface electric field. This instrument, currently being developed, performs its task by directing a beam of electrons over the lunar surface and measuring the deflection of the beam caused by the electric field. The theory of operation of the instrument is presented, and several factors affecting the performance of the instrument are discussed. Important factors are the alignment, cross section, and energy of the beam and environmental parameters, such as plasma-particle currents and the ambient magnetic field. The potential of the instrument is considered. A breadboard model of the instrument has been built, and its performance characteristics are given. P.v.T.

A69-13851 *#
AEROSPACE SENSOR SYSTEMS.
Gene G. Mannella (NASA, Electronics Research Center, Cambridge, Mass.).
Astronautics and Aeronautics, vol. 6, Dec. 1968, p. 26-35. 9 refs.

Discussion of aerospace sensor systems designed to meet the challenge of demanding modern tasks and increasing complexity. With the present emphasis on systems, there has rapidly developed a diverse spread of sensor-system requirements. The discussion depicts the state of affairs in several representative areas such as adaptive multimode sensors and multispectral sensing. The latter is a new approach assuming that some component in an image can be recognized by an electronic system through size, shape, feature, tone, texture, and pattern characteristics. In the spectrum-matching imaging system, each resolution element is simultaneously scanned in many spectral bands. In atmospheric probing by laser, "laser radar" closely parallels conventional microwave radar. Another technique that may prove important utilizes "Raman scattering" - a small amount of light scattered at a wavelength different from the wavelength of the laser beam. P.v.T.

PHOTOGRAPHIC CONTROL SYSTEM FOR PROJECT APOLLO LAUNCHES.
A. N. Greene (NASA, Kennedy Space Center, Cocoa Beach, Fla.).
Society of Motion Picture and Television Engineers, Technical Conference, 104th, Washington, D.C., Nov. 10-15, 1968, Paper 104-20. 10 p.
$0.50.

The engineering, documentary, and metric photography requirements for Project Apollo manned launches demand hundreds of cameras located in an environment of extreme heat, vibration, and sound pressure. Photographic measurements of engine ignition in millisecond steps, valve closures, mechanical arm retractions, umbilical disconnect, and vehicle trajectory are made from the launcher deck, umbilical tower, and perimeter camera sites. Emergency cameras are positioned to cover an explosive area in case of failure. Film speeds of 1000 frames/sec with magazine-size limitation require sequence timing of 1/10 sec resolution. Fifty programable sequences are available with interlocks consistent with the launch countdown computer. (Author)

MEASUREMENT OF GAS TEMPERATURE AND THE RADIATION COMPENSATING THERMOCOUPLE.
Glenn E. Daniels (NASA, Marshall Space Flight Center, Huntsville, Ala.).
Journal of Applied Meteorology, vol. 7, Dec. 1968, p. 1026-1035. 21 refs.

The achievement of a high degree of accuracy in gas-temperature measurement has been a problem in many investigations. The theory of such measurement is presented together with an analysis of a device known as the radiation compensating thermocouple, which is designed to cancel out errors from the radiation environment inherent in other systems of measurement. The mathematical concepts and results of experimental work are included. Results of tests provided data on the errors of air-temperature measurement with single thermocouples used without shields, and proved that carefully fabricated radiation compensated thermocouples measure the true air temperature with very small errors. (Author)

A69-15028 *
LASER DISPLAY SYSTEMS. I - SCANNERS.
D. W. Kennedy, C. R. Grauling, A. J. Devaney, and R. D. Wright (NASA, Electronics Research Center, Cambridge, Mass.).
Instruments and Control Systems, vol. 41, Dec. 1968, p. 59-63. 21 refs.

Discussion of scanned laser-beam display techniques, which are adapted from CRT technology with lasers and appropriate controllers substituted for the CRT and its deflection apparatus. The laser beam can be deflected mechanically, refractively, or diffractively. Gas ion lasers are presently most attractive for display applications, because they produce continuous emission. The helium-neon laser seems inherently limited to less than 1 W of light output. Argon and krypton lasers, capable of higher power output, are four orders of magnitude less efficient in converting electric to optical power. One

watt of optical power is sufficient for a moderate-size display. An argon laser can illuminate a 1 m^2 screen with brightness of about 30 ft-lambert. A flying-spot scanner illuminates both an object and the display screen. The simultaneous scanning of the scene and the display screen provides automatic synchronization of the video signal with the scan pattern, and obviates the need for a sawtooth scanning device. P.v.T.

ENTRY VEHICLE INSTRUMENTATION FOR HEAT SHIELD ABLATION MEASUREMENTS.

Peter J. LeBel and James M. Russell (NASA, Langley Research Center, Hampton, Va.).

(Instrument Society of America, Annual Conference and Exhibit, 20th, Los Angeles, Calif., Oct. 4-7, 1965, Paper.)
ISA Transactions, vol. 7, no. 3, 1968. p. 187-193. 11 refs.

Calculation of expressions for the Zener tunneling current and optical-absorption coefficient in the presence of crossed and parallel electric and magnetic fields, using WKB solutions to the two-band model. The results obtained are supported by the photon-assisted tunneling experiments of a preceding paper and by other tunneling experiments. Apart from differences not resolved by these experiments, the results obtained for crossed fields are the same as those obtained by Aronov and Pikus, who used a quite different treatment of a model identical to the authors', except for the inclusion of spin effects, which do not appear to alter the results significantly. It is shown that the main features of electron tunneling in crossed and parallel fields can be adequately explained by using a semiclassical WKB treatment, which, in addition, provides a good physical picture of the tunneling process. M.F.

HEAT-TRANSFER TELEMETRY FOR MODELS USING THERMOCOUPLE SENSORS.

Dean R. Harrison and William K. Lockman (NASA, Ames Research Center, Moffett Field, Calif.).

(American Institute of Aeronautics and Astronautics, Aerodynamic Testing Conference, 3rd, San Francisco, Calif., Apr. 8-10, 1968, Paper 68-407.)
Journal of Spacecraft and Rockets, vol. 6, Jan. 1968, p. 76-78. 16 refs.

A telemetry technique has been developed utilizing thermocouple sensors for determining low afterbody heating rates on free-flight blunt cone models under test in a high-enthalpy shock tunnel. Signals generated by a thermocouple calorimeter type of heat-transfer sensor were amplified and used to control the frequency of an rf transmitter. Electrical noise introduced by the flow of ionized air past the model was greatly reduced by electrostatic shielding of the electronics and the sensing thermocouple. Tests were conducted in a 1-ft shock tunnel to measure the base heating of blunt 15° half-angle cones in a high-enthalpy (11 mjoules/kg) flow. Under these conditions, an unshielded model produced SNRs of approximately 1. The addition of shielding reduced noise to the point where it was negligible. Heating rates determined from these tests were in the order of 1 to 4 watts/cm^2. (Author)

VENTURI METER WITH SEPARABLE DIFFUSER.

T. J. Dudzinski, R. C. Johnson, L. N. Krause (NASA, Lewis Research Center, Cleveland, Ohio).

American Society of Mechanical Engineers, Winter Annual Meeting and Energy Systems Exposition, New York, N.Y., Dec. 1-5, 1968, Paper 68-WA/FM-2. 5 p. 18 refs.
Members, $0.75; nonmembers, $1.50.

The effects on venturi meter efficiency and discharge coefficient of a radial, outward step at the transition from throat to diffuser are reported over a Reynolds number range of 1 x 10^4 to 5 x 10^5 and over a Mach number range of 0.2 to 1.0. Step size was varied from 0 to 12.5% of the throat radius. The efficiency increases with increasing Reynolds number, decreases with increasing Mach number, and decreases as step size increases beyond 2%. The discharge coefficient was independent of Mach number, step size, and back-pressure variation at critical flow. (Author)

ADVANCED AIR DATA SENSING TECHNIQUES.

Rodney K. Bogue and Lannie D. Webb (NASA, Flight Research Center, Edwards AFB, Calif.).

IN: INTERNATIONAL AEROSPACE INSTRUMENTATION SYMPOSIUM, 5TH, CRANFIELD, BEDS., ENGLAND, MARCH 25-28, 1968, PROCEEDINGS. [A69-16747 05-14]
Symposium sponsored by the College of Aeronautics and the Instrument Society of America.
London, Peter Peregrinus, Ltd., 1968, p. 66-75. 14 refs.

Determination of the feasibility of using a fluidic-type temperature sensor for measuring total temperature on an aircraft traveling at hypersonic speeds within the atmosphere. Problem areas that do not severely limit the application but do require further study to assess the total effect of each problem in the system operation were revealed. A partial total-temperature time history of X-15 flight 53 (Oct. 3, 1967) up to peak Mach number is shown, together with radar measurements of the X-15 Mach number and altitude, in addition to the data obtained from the shielded thermocouple sensor and the fluidic sensor. EFFECTS OF ENERGETIC PARTICLES ON PHOTOMULTIPLIERS IN EARTH ORBITS UP TO 1500 KM.

Walter B. Fowler, Edith I. Reed (NASA, Goddard Space Flight Center, Greenbelt, Md.), and Jacques E. Blamont (Centre Nationale de la Recherche Scientifique, Paris, France).

Optical Society of America, Annual Meeting, Pittsburgh, Pa., Oct. 9-11, 1968, Paper. 19 p. 7 refs.

Discussion of the response of several types of photomultipliers to energetic particles in terms of observed background current. Examples are drawn primarily from photometers for observation of the earth's airglow on OGO 2 and OGO 4; brief reference is made to other OGO photometers. The largest background current was observed on OGO 2 from an EMR 541E, a sapphire end-window tube with an S-20 photocathode. At a maximum of the inner electron belt, cathode current exceeded 10^{-9} A at about 1500 km. Several components are noted in the background current, with the most prominent due to the inner radiation belt and a component with the latitude distribution characteristic of cosmic rays. Estimated instantaneous proton and electron fluxes are compared with background current in order to obtain an approximate responsivity to energetic particles. P.v.T.

Δ-T CURVES FOR MEASURING MAGNETIC TAPE LINK JITTER.

J. Y. Sos (NASA, Goddard Space Flight Center, Advanced Equipment Design Section, Processor Development Branch, Greenbelt, Md.), J. M. Cole (U.S. Army, Electronics Command, Fort Monmouth, N.J.), W. B. Poland, Jr. (NASA, Goddard Space Flight Center, Greenbelt, Md.), and G. Weiss.

Telemetry Journal, vol. 3, Oct.-Nov. 1968, p. 43-46, 48-52. 5 refs.

A method for measuring the root-mean-square time delay error (Δ) between points on a record vs their separation in playback time (T) has been described in the literature. The present work derives the theoretical relationships between the Δ-T curve and the

autocorrelation function of a pure sine wave recorded on the tape, and uses this correspondence to establish a connection between jitter spectra and Δ-T curves. A simple instrument for measuring these curves with high accuracy is described, and results of measurements made on a number of intermediate-band tape units are presented. These measurements show that a low-mass tape unit may be superior to high-mass units by more than an order of magnitude. The utility of the Δ-T measurement technique is discussed on the basis of its direct relationship to PCM and coherent recording applications, and its value as a standard means for evaluating time delay error in magnetic tape links is described. COMPUTER ANALYSIS OF TRACKS IN NUCLEAR EMULSION UTILIZING DIGITIZED VIDEO SCAN.

D. V. Reames (NASA, Goddard Space Flight Center, Greenbelt, Md.) and C. H. Ehrmann.

(Institute of Electrical and Electronics Engineers, Nuclear Science Symposium, 15th, Montreal, Canada, Oct. 23-25, 1968, Paper 2 A-7.)

IEEE Transactions on Nuclear Science, vol. NS-16, Feb. 1969, p. 127-131.

A system has been developed to make density measurements on particle tracks in nuclear emulsions. The output signal of a vidicon viewing the track through a microscope is digitized to detect developed grains in the emulsion. This digitized information is transferred in real time to a computer which selects grains falling in the track, sums their volumes, and computes parameters related to their spatial distribution. Analysis of tracks of arbitrary angles is accomplished by rotating the track image in the focal plane with a Pechan prism and by driving the focal plane through the emulsion while taking data. DISPLAY REQUIREMENTS FOR ADVANCED MANNED SPACECRAFT.

Robert C. Duncan (NASA, Electronics Research Center, Cambridge, Mass.).

(NASA, Symposium, Cambridge, Mass., Sept. 19, 20, 1967.)

Spaceflight, vol. 11, Mar. 1969, p. 95-101.

Discussion of displays and controls in manned space vehicles, a fundamental purpose of which is to integrate man into the vehicle system. Displays take the form of dials, attitude indicators, and computer-derived status and maneuver data. The unique capabilities of man as a controller of systems are the ability to perform an almost unlimited diversity of tasks. The instrumentation of the Mercury, Gemini, and Apollo spacecraft is described. The relative role of man and automated systems for control during the Apollo mission is considered. F.R.L.

PICOSECOND PULSE MEASUREMENT BY TWO-PHOTON EXCITATION OF PHOTOGRAPHIC FILM.

David C. Burnham and Kenneth W. Billman (NASA, Electronics Research Center, Cambridge, Mass.).

Applied Physics Letters, vol. 13, Dec. 15, 1968, p. 419-421. 6 refs.

A simple technique for observing picosecond light pulses is demonstrated. The overlap between two light beams is measured by two-photon excitation of a photographic film which is below threshold for one-photon excitation. The resolution of the method is variable and limited only by the bandwidth of the photographic film. (Author)

OPTICAL DESIGN OF A GLANCING INCIDENCE X-RAY TELESCOPE.

J. D. Mangus and J. H. Underwood (NASA, Goddard Space Flight Center, Greenbelt, Md.).

Applied Optics, vol. 8, Jan. 1969, p. 95-102. 19 refs.

Description of the optical design of a Wolter type-1 glancing incidence X-ray telescope for the wavelength region from 6 to 100 Å. The theoretical performance of the instrument is evaluated by ray tracing. The results of laboratory and rocket flight tests on a prototype instrument are described. It is concluded that it is theoretically possible to obtain high resolution in the imaging of celestial objects in X rays through the use of the glancing incidence telescope. B.H.

LASER DISPLAY SYSTEMS. II.

D. W. Kennedy, C. R. Grauling, R. D. Wright (NASA, Electronics Research Center, Cambridge, Mass.), and A. J. Devaney.

Instruments and Control Systems, vol. 42, Feb. 1969, p. 109-112. 26 refs.

Discussion of holographic display and its applications. Ultrasonic vibrations can be used as the "illuminating" source to produce holograms. These waves have lengths two or three orders of magnitude greater than those of light, and produce correspondingly larger records. A conventional hologram can be made by reducing the original pattern to optical proportions. A similar effect has been noted using microwave radiation. Materials other than photographic emulsions respond to laser light. Alkali-halide crystals can be induced to form electron holes by displacing atoms. The holes respond to light in unique ways and give the potential for recording digital data. The applications mentioned include an aircraft landing display system and a movie system. The ability to generate holograms by computer offers a valuable potential interface between man and computer. G.R.

APPLICATION OF LASER DOPPLER VELOCITY INSTRUMENTATION TO THE MEASUREMENT OF JET TURBULENCE.

Robert M. Huffaker (NASA, Marshall Space Flight Center, Huntsville, Ala.), Charles E. Fuller (Hayes International Corp., Birmingham, Ala.), and T. R. Lawrence (Lockheed Aircraft Corp., Lockheed Missiles and Space Co., Huntsville, Ala.).

Society of Automotive Engineers, International Automotive Engineering Congress, Detroit, Mich., Jan. 13-17, 1969, Paper 690266. 50 p. 10 refs.

Members, $1.00; nonmembers, $1.50.

Design considerations and description of a three-dimensional laser Doppler velocity (LDV) instrument, capable of measuring the mean velocity and the velocity fluctuations of three components at a point in a flow. An application of the instrument to mean velocity and turbulence measurement in a subsonic jet shear layer is considered, and the appropriate data are presented. Comparison with the data obtained with the LDV instrument and a hot-wire anemometer indicates good agreement. From theoretical considerations and the data presented, it is concluded that the LDV instrument is a proven tool for the study of turbulent flow. P.v.T

HIGH RESOLUTION BALLOONBORNE TEMPERATURE SENSOR.

Dennis W. Camp (NASA, Marshall Space Flight Center, Huntsville, Ala.) and Frank E. Caplan (GCA Corp., Bedford, Mass.).

Journal of Applied Meteorology, vol. 8, Feb. 1969, p. 159-166.

Description of a high-resolution lightweight temperature sensor

for use on the Jimsphere balloon. An error analysis of the temperature sensor is presented which shows the sensor to have an rms error of 0.44°C at the surface (ground level), and that the rms error increases to 0.89°C at 18 km. Three flight tests of the sensor are briefly discussed. The temperature data from these flight tests are compared with temperature data obtained from rawinsonde measurements made simultaneously with the Jimsphere temperature sensor tests. (Author)

IMPROVED METHOD OF REMOVING PLASTIC BACKING FILMS FROM CARBON ELECTRON MICROSCOPE REPLICAS.
Gilbert H. Walker and Boyd L. Williams (NASA, Langley Research Center, Hampton, Va.).
Review of Scientific Instruments, vol. 39, Dec. 1968, p. 1968-1970.

Description of a modification of the Beals and Bigelow method of removing plastic backing films from carbon replicas. The main feature of the modification is provision for maintaining the specimens in a horizontal position, allowing the more effective removal of plastic backing films and producing less breakage of delicate replicas made from such materials as carbon. The modification is more effective and results in fewer losses of delicate replicas than when other removal methods are used. M.M.

INSTRUMENTATION USED TO DEFINE PERFORMANCE OF SMALL SIZE, LOW POWER GAS TURBINES.
Samuel M. Futral, Milton Kofskey, and Harold E. Rohlik (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Mechanical Engineers, Annual Gas Turbine Conference and Products Show, 14th, Cleveland, Ohio, Mar. 9-13, 1969, Paper 69-GT-104. 8 p.
Members, $0.75; nonmembers, $1.50.

Discussion of problems encountered in testing a 6-in. radial-inflow turbine engine. The inlet pressure at design Reynolds number was 3.4 psia, and the actual torque was 13 in.-lb. The shaft rotated at 21,600 rpm and the turbine developed 4.5 horsepower. Weight flow was 0.28 lb/sec. Factors affecting measurement accuracy are discussed along with a description of the instruments, the recording systems, and calibration techniques - e.g., miniaturized probes, low-pressure level transducers, precise power absorbers. Precision of the measurements and resulting accuracy of the performance variables - namely, flow, torque, speed, and efficiency - are included. M.G.

ROCKET SPECTROHELIOGRAPH FOR THE Mg II LINE AT 2802.7 Å.
Kerstin Fredga (NASA, Goddard Space Flight Center, Greenbelt, Md.).
Applied Optics, vol. 8, Feb. 1969, p. 333-343. 21 refs.

Description of a rocket-borne spectroheliograph designed to take monochromatic pictures of the sun in the Mg II line at 2802.7 Å. The photographic system consists of a Questar telescope, a Solc type birefringent filter, and an automatic Robot camera. The double Solc filter has a spectral bandwidth of 3.5 Å. The two units in the double filter have been thoroughly tested and are compared with theoretically calculated transmission curves. Two new types of linear film polarizers for the UV region have been tested and used in the filter. A temperature control unit was developed which stabilized the filter temperature in flight to within ±0.2°C. The instrument has been tested in vacuum and to the Aerobee-150 vibration specifications. It has been flown and successfully recovered three times and performed excellently during each flight. (Author)

AN INVESTIGATION OF THE DECOUPLING EFFECTS IN A MAGNETIC FORMING BERYLLIUM COIL ASSEMBLY.
M. E. Davis, Jerry W. Rogers, D. D. Wier (Mississippi State University, Dept. of Electrical Engineering, State College, Miss.), and J. D. Bennight (NASA, Marshall Space Flight Center, Huntsville, Ala.).
IN: INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ANNUAL REGION III CONVENTION, 7TH, COCOA BEACH, FLA., NOVEMBER 18-20, 1968, RECORD. [A69-25288 11-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. S9-4p1 to S9-4p6. 8 refs.

A beryllium coil assembly was developed by NASA for the purpose of forming metallic materials by making use of intense magnetic fields. The work described was performed in order to determine the force exerted by the coil on a plate as it becomes decoupled from the coil. The mutual coupling between the coil and plate as a function of distance of separation was determined. Differential equations with time varying coefficients were derived which describe the currents in a two ring coil and plate circuit. The solution of these equations was accomplished by the analog computer. With the solution currents, the force of repulsion between the coil and plate was calculated. (Author)

APPLICATION OF THE LASER DOPPLER FLOWMETER TO FLUID FLOW MEASUREMENTS.
J. W. Dunning, Jr. (NASA, Lewis Research Center, Cleveland, Ohio), J. C. Angus, and R. Edwards (Case-Western-Reserve University, Cleveland, Ohio).
American Institute of Chemical Engineers, National Meeting, 64th, New Orleans, La., Mar. 16-20, 1969, Paper. 19 p. 10 refs.

Discussion of a laser Doppler flowmeter for heterodyne detection of laser light scattered from a moving fluid. The flowmeter may be used to obtain the velocity of the fluid and the velocity distribution in the scattering volume (30 μ diam). The technique has a wide dynamic range (10^{-3} to 10^{5} cm/sec). An analysis of the scattering indicates that the velocity distribution is very closely related to the spectrum of the scattered light. The spatial resolution obtainable is on the order of 10 μ (4×10^{-4} in.), and is limited by optical considerations. M.G.

SPACE-BORNE OPTICAL TELESCOPES - AN INTRODUCTION.

Hector C. Ingrao (NASA, Electronics Research Center, Cambridge, Mass.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, Mar. 1969, p. 240, 241.

Discussion of the requirements for a space-borne optical telescope and review of work concerning its development. Space telescopes of very large diameter, with resolution corresponding to an aperture of at least 120 in. and detecting radiation between 800 Å and 1 mm are becoming technically feasible and will be uniquely important. A series of papers is mentioned as representative of the work under way in some of the problem areas. G.R.

EVALUATION OF MULTIPOINT INTERACTION IN THE DESIGN OF A THIN DIFFRACTION-LIMITED ACTIVE MIRROR.

Jeremiah F. Creedon (NASA, Langley Research Center, Hampton, Va.) and Hugh J. Robertson (Perkin-Elmer Corp., Norwalk, Conn.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, Mar. 1969, p. 287-293. 6 refs.

Active control of a thin, deformable mirror is one approach to obtaining diffraction-limited performance from large orbiting telescopes. The control system design requires knowledge of the mirror reaction to the multiple forces used to maintain the desired mirror figure. A structural analysis program is used to obtain estimates of the static deflections of a point-loaded, thin, shallow, spherical primary mirror. The calculated deflections are compared to experimentally measured deflections for a specific configuration. (Author)

PRECISE ATTITUDE STABILIZATION OF A LARGE ORBITING TELESCOPE COUPLED TO A CREW COMPARTMENT.

Frederick R. Morrell (NASA, Langley Research Center, Hampton, Va.).

IEEE Transactions on Aerospace and Electronic Systems, vol. AES-5, Mar. 1969, p. 294-299.

Description of computer simulation results for the planar equations of motion of an attitude-stabilized orbiting telescope passively coupled to a manned service module. This coupling is provided through a set of soft springs and a two-axis gimbal aligned with the telescope center of mass. Principal nonlinearities in the suspension system and the telescope control system are included. The simulation indicates preliminary feasibility of this operational mode. (Author)

AN APPLICATION OF OPTICAL TELEMETRY TO SHOCK TUBE MEASUREMENTS.

Robert E. Dannenberg (NASA, Ames Research Center, Moffett Field, Calif.) and Howard Katzman (Dacom, Inc., Palo Alto, Calif.).

Review of Scientific Instruments, vol. 40, May 1969, p. 640-642.

Description of an optical carrier, single-channel telemetry system. The system provides complete electrical isolation between data acquisition instrumentation and data storage or recording facilities. It has a bandwidth from dc to 50 kHz and has been used successfully in a shock tube facility where high voltage isolation is required for protection of instrumentation. G.R.

MEASUREMENT OF THE VELOCITY AND ATTENUATION OF ULTRASONIC PULSES IN THE PRESENCE OF NOISE.

R. C. Williamson (NASA, Electronics Research Center, Cambridge, Mass.).

Review of Scientific Instruments, vol. 40, May 1969, p. 666-670. 14 refs.

The well developed techniques of coherent detection and signal averaging may be used to extend the range and accuracy of measurements of ultrasonic velocity and attenuation. Significant improvements in SNR are obtained by averaging a coherently detected echo train in a signal averager such as a multichannel analyzer or boxcar integrator. A standard circuit of this type is described and analyzed. Comparison of coherent detection and rectification shows the inherent advantages of coherent detection for signal-to-noise enhancement. (Author)

DETERMINATION OF THERMODYNAMIC PROPERTIES WITH OPTICAL CROSS-CORRELATION METHODS.

F. R. Krause (NASA, Marshall Space Flight Center, Huntsville, Ala.), W. O. Davies, and M. W. P. Cann (IIT Research Institute, Chicago, Ill.).

(American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 5th, New York, N.Y., Jan. 23-26, 1967, Paper 67-149.)
AIAA Journal, vol. 7, Apr. 1969, p. 587-592. 17 refs.

Results of an experimental study concerning the spectrum (and its variation with time) of the laser action from a $CaF_2:Sm^{2+}$ crystal when it is excitation by ruby-laser radiation at temperatures from ~65°K to >77°K. It is demonstrated that the laser action (beginning at a pure electron line of 708 μ) moves towards the long-wave direction with increasing temperature while the intensity of the long-wave components increases. The variation of lasing intensity with time is described. T.M.

BURIED COLLECTOR GAUGE FOR MEASUREMENTS IN THE 10^{-11} TORR PRESSURE RANGE.
Leonard T. Melfi, Jr. (NASA, Langley Research Center, Hampton, Va.).
Journal of Vacuum Science and Technology, vol. 6, Mar.-Apr. 1969, p. 322-325. 9 refs.

Description of a new ionization gauge in which a shielded collector is used to lower the X-ray current. Pressures as low as 4×10^{-12} torr have been indicated with an estimated X-ray current corresponding to a pressure below 2.6×10^{-12} torr. Calibration of the gauge on an orifice flowrate system in the pressure range between 10^{-6} and 10^{-9} torr with 4-mA emission and a collector to filament voltage of -300 V yielded a gauge constant of 20 $torr^{-1}$. For pressure below 10^{-9} torr the buried collector gauge was compared to the bent-beam Helmer gauge. Data from tests performed on the bent-beam Helmer gauge are also given. These include a calibration and a plot of gauge constant as a function of emission current in the range between 0.1 and 10 mA. (Author)

A69-32326 *
EXPERIMENTAL EVALUATION OF THE RATE-OF-RISE METHOD FOR MEASURING OUTGASSING RATES OF THREE GASES BETWEEN 10^{-6} AND 10^{-3} TORR.
Gerald L. Gregory (NASA, Langley Research Center, Hampton, Va.).
Journal of Vacuum Science and Technology, vol. 6, Mar.-Apr. 1969, p. 344-346.

Experimental determination of the accuracy to which known leak rates of three gases can be measured with the rate-of-rise technique. The study consists in measuring known leak rates of nitrogen, methane, and helium gases in the leak range from 5×10^{-6} to 5×10^{-4} torr-liter/sec, although only the results for a leak rate of 1×10^{-5} torr-liter/sec are discussed. M.G.

FLOW-DIRECTION MEASUREMENT WITH FIXED-POSITION PROBES IN SUBSONIC FLOW OVER A RANGE OF REYNOLDS NUMBERS.
Lloyd N. Krause and Thomas J. Dudzinski (NASA, Lewis Research Center, Cleveland, Ohio).
Instrument Society of America, National Aerospace Instrumentation Symposium, 15th, Las Vegas, Nev., May 5-7, 1969, Paper. 15 p. 7 refs.

Study of the correlations between measured fixed-probe pressures and flow direction over a range of Reynolds number, Mach number, and flow angle encountered in investigations of subsonic flow. Only a single type of probe design, consisting of clustered tubes, with the flow-direction tubes cut off at 45°, was checked experimentally. It was found that flow direction is measurable to within about 1° over most combinations of flow conditions in the range investigated. G.R.

A FAMILY OF PORTABLE VERSATILE AEROSOL PARTICLE ANALYZERS.
E. Rosenblum, L. Long (NASA, Electronics Research Center, Cambridge, Mass.), W. Burgess, and P. Reist (Harvard University, School of Public Health, Boston, Mass.).
(Association for the Advancement of Medical Instrumentation, Annual Meeting, 3rd, Houston, Tex., July 1968.)
Association for the Advancement of Medical Instrumentation, Journal, vol. 3, Jan. 1969, p. 18-24. 5 refs.

Description of a family of instruments developed for the measurement of aerosols both during space flight and in the laboratory. The instruments can be used to measure the concentration and size distribution of aerosol particles in the size range of 0.5 to 100 μ. A self-contained, hand-held, battery-operated aerosol particle analyzer was designed, fabricated, and flight qualified. This instrument, whose principle of measurement is based on forward angle light scattering, weighs less than 5-1/2 lb, and has envelope dimensions of 3.75 x 5 x 7.2 in. It samples 1/60 ft^3 of air during a 1-min operating period, and sorts the information obtained on the light scattered from each particle into its appropriate size group. G.R.

A REVIEW OF THE IMAGE DISSECTOR METEOROLOGICAL CAMERAS AND A VIEW OF THEIR FUTURE.
Edward W. Koenig (International Telephone and Telegraph Corp., Aerospace/Optical Div., Fort Wayne, Ind.) and Gilbert A. Branchflower (NASA, Goddard Space Flight Center, Greenbelt, Md.).
IN: SPACE, TECHNOLOGY, AND SOCIETY; CANAVERAL COUNCIL OF TECHNICAL SOCIETIES, SPACE CONGRESS, 6TH, COCOA BEACH, FLA., MARCH 17-19, 1969, PROCEEDINGS. VOLUME 1. [A69-35070 18-34]
Edited by L. E. Jones, III.
Cape Canaveral, Fla., Canaveral Council of Technical Societies, 1969, p. 16-23 to 16-41.
Contracts No. NAS 5-9619; No. NAS 5-9671; No. NAS 5-11617; No. NAS 5-11618.

Description of the operation and achievements of the ATS-III IDC (Applications Technology Satellite III Image Dissector Camera) and the NIMBUS IDCS (Image Dissector Camera System). The ATC III contains an image dissector, a sun sensor for the spin rate, and the electronics required to synchronize camera timing and operation with spacecraft spin, and to retain proper phasing for earth viewing once initial phase has been commanded from the ground. The camera generates one line of video with each spacecraft rotation and is unique in that the IDC output contains all the frame and line synchronization information necessary to display the video with a minimum of special ground support equipment. The NIMBUS IDCS is an 800 TV line system with a line rate of 4 Hz and a video bandwidth of 1800 Hz. The video will be transmitted to earth in real-time AM/FM with an AM subcarrier of 2400 Hz and will be simultaneously recorded on spacecraft recorders. Camera resolution is 25% at 800 TV lines, and the output video has a highlight SNR of 38 dB (p-p/rms). Some applications of the image dissector camera are discussed, the most important being its potential use as an earth resources sensor. B.H.

PHOTOMULTIPLIER AREA SENSITIVITY MEASUREMENTS USING A MULTICOLOR DISPLAY TECHNIQUE.
Otto Youngbluth, Jr. (NASA, Langley Research Center, Hampton, Va.).
IN: ICIASF '69; INTERNATIONAL CONGRESS ON INSTRUMENTATION IN AEROSPACE SIMULATION FACILITIES, 3RD, POLYTECHNIC INSTITUTE OF BROOKLYN, FARMINGDALE, N.Y., MAY 5-8, 1969, RECORD. (A69-35714 19-11)
New York, Institute of Electrical and Electronics Engineers, Inc. (IEEE Publication 69 C 19-AES), 1969, p. 86-91, 321-325.

Description of a method for rapidly obtaining color-coded area sensitivity maps of photomultiplier tubes (PMTs). The PMT area sensitivity can be recorded in color contour form, a mesa form, or in a combination of these forms and colors. The technique provides a fast simple means of obtaining important PMT input-output characteristics. The mapping technique is practical for studying fatigue and circuit design effects on photodetector output characteristics. The best uniformity is obtained when the focus-electrode voltage is adjusted between that of the cathode and the dynode voltage. B.H.

SURVEYING EARTH RESOURCES WITH REMOTE SENSORS.
John D. Koutsandreas (NASA, Washington, D.C.).
IN: NTC 69; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, NATIONAL TELEMETERING CONFERENCE, WASHINGTON, D.C., APRIL 22-24, 1969, RECORD. (A69-36237 19-07)
New York, Institute of Electrical and Electronics Engineers, Inc., 1969, p. 132-144. 15 refs.

Description of the progress of the NASA Earth Resources Survey Aircraft Program. From an initial Convair 240 aircraft with six elementary remote sensors, the program has progressed to where in 1969 nearly two dozen advanced sensors will be evaluated with additional NASA aircraft. These aircraft include the NASA MSC Electra P-3A, and Lockheed C-130B for sensor experimentation up to 35,000 ft. For flights above 50,000 ft, an agreement with the U.S. Air Force allows for remote sensor system testing on board and RB-57F aircraft of the Air Weather Service. With the increased payload, altitude, and range capabilities of these aircraft, electromagnetic sensors operating in the microwave, IR, visible, and UV parts of the spectrum are being evaluated. The remote sensors are evaluated for their application as a space system for the detection of oceanographic, geologic, geographic, hydrologic, and agricultural

phenomena. Federal user agencies and cooperating scientists participating in the program are being exposed to a new technology for conducting geoscience research from spaceborne platforms. Future sensor systems for the geoscientists are introduced. (Author)

AN IMPROVED COLLIMATOR FOR EXTREME ULTRAVIOLET AND X RAYS.
J. H. Underwood (NASA, Goddard Space Flight Center, Solar Physics Branch, Greenbelt, Md.).
Review of Scientific Instruments, vol. 40, July 1969, p. 894-896. 5 refs.

Description of a mechanical collimator using random arrays of apertures for the observation of the sun and other celestial objects at very short wavelengths. The instrument is an improvement over collimators using regular arrays of apertures. A technique is discussed for producing random arrays of apertures of various shapes on film. An alternative method of making the plates for the X-ray and UV regions is described in which the random coordinates generated by the computer are recorded on magnetic tape, and the tapes are used in conjunction with a tape-controlled drilling machine. The use of a random array of apertures in a spectrometer is described, and it is shown that with this scheme fewer plates are required to suppress off-axis radiation. B.H.

A 2-¼- BY 2-¼-INCH PHOTOGRAMMETRIC CAMERA SYSTEM FOR THE MOON.
Richard E. Thompson (NASA, Manned Spacecraft Center, Houston, Tex.).
IN: NEW HORIZONS IN COLOR AERIAL PHOTOGRAPHY; PROCEEDINGS OF THE SEMINAR, NEW YORK, N.Y., JUNE 9-11, 1969. (A69-40985 22-14)
Seminar sponsored by the American Society of Photogrammetry and the Society of Photographic Scientists and Engineers.
Falls Church, Va., American Society of Photogrammetry, 1969, p. 175-183.

Description of a unique photogrammetric camera system developed from NASA requirements to document the lunar-surface environment during manned space-flight exploration. For this photographic situation (which is constrained by weight limitations, restricted manual ability of the photographer, safety considerations, and a harsh environment), NASA has modified its general-purpose Hasselblad camera system to enable the recording of photogrammetric data. Specially designed lenses are used on the NASA version of the Hasselblad 500 EL-camera body in which a precision glass-plate reseau grid system has been installed and calibrated. With this photogrammetric system, more meaningful photographic data will be returned from the lunar surface than has been possible before in the manned space-flight program. Furthermore, because of its general-purpose design, this camera system may have valuable applications on earth. (Author)

GAUGE COMPARISON STUDY OF THE MAGNETRON, BURIED COLLECTOR, BENT-BEAM, AND NUDE MODULATED BAYARD-ALPERT GAUGES.
William S. Lassiter (NASA, Langley Research Center, Hampton, Va.).
Journal of Vacuum Science and Technology, vol. 6, May-June 1969, p. 418, 419. 5 refs.

Investigation of the linearity of a bent-beam ionization gauge, using as a reference a calibrated, nude Modulated Bayard-Alpert (MBA) gauge. Also included in the study were a nude, single buried collector gauge, and a tubulated magnitron gauge. The linearity of the bent-beam gauge was determined by plotting the indicated pressure of the bent-beam gauge against equivalent nitrogen pressure as calculated from the results of the nude MBA gauge. Operating parameters for the nude MBA, buried collector, and bent-beam gauges are shown in a table. It is shown that the bent-beam gauge is linear down to 7 (10^{-12}) torr. B.H.

A COMPARISON OF INFRARED-EMITTANCE MEASUREMENTS AND MEASUREMENT TECHNIQUES.
John P. Millard and Elmer R. Streed (NASA, Ames Research Center, Moffett Field, Calif.).
Applied Optics, vol. 8, July 1969, p. 1485-1492. 12 refs.
Contracts No. NAS 2-2839; No. NAS 2-3769.

Values of directional and hemispherical emittance of twelve coatings were needed in support of a spacecraft experiment. Laboratory measurements were made by two calorimetric and four reflectance techniques and with two portable devices designed for field or laboratory operation. The measurement results are compared, primarily on the basis of hemispherical emittance values deduced from each. The limitations and uncertainties of each technique are summarized. (Author)

A RADIOMETER FOR MEASURING SOLAR FLUX VARIATIONS.
Roger C. Linton (NASA, Marshall Space Flight Center, Space Sciences Laboratory, Huntsville, Ala.).
American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-254. 13 p. 10 refs.

The lack of sufficient radiometric precision and the inability to eliminate effects of atmospheric turbulence have prevented a satisfactory determination of the actual stability of the solar constant. If variations do exist, the magnitude is probably less than the sensitivity of most radiometers. A radiometer was developed to provide a plus or minus one-per cent accuracy and a precision of 0.01 per cent. The designed performance was verified using an evacuated hohlraum cavity as a standard. The novel features which give this instrument its extreme sensitivity are discussed, together with the advantages of using such a sensor for spacecraft measurements. The essential feature of this radiometer which distinguishes it from all others involves the utilization of alternating current circuitry to limit the controlling parameter to a frequency. The radiometer concept has been validated and a working unit is being tested. (Author)

THE USE OF ^{184}W AS A THERMAL FLUX MONITOR AT HIGH TEMPERATURES.
Lauren L. Ball, Paul J. Richardson, and Dean W. Sheibley (NASA, Lewis Research Center, Plum Brook Station, Sandusky, Ohio).
Nuclear Applications and Technology, vol. 7, Oct. 1969, p. 393-396. 7 refs.

Description of the use of naturally occurring W-184 as a dosimeter for thermal neutrons at temperatures up to 3000 deg K in short irradiations of 40 hr or less. The W-184 thermal-neutron capture cross section is found to be 1.94 plus or minus 0.08 b. The radiochemical separation methods and counting techniques for W-185 are described. Z.W.

RESOLUTION CHANGES IN LITHIUM-DRIFTED SILICON SEMICONDUCTOR DETECTORS IRRADIATED WITH 0.5, 1.0, 2.0, AND 3.0 MeV ELECTRONS
Herbert D. Hendricks and Donald H. Phillips Washington Nov. 1968 32 p refs
(NASA-TN-D-4901) Avail: CFSTI CSCL 07E

Lithium-drifted silicon semiconductor detectors (2 mm deep and 80 mm^2 surface area) were irradiated with 0.5, 1.0, 2.0, and 3.0 MeV electrons. Fluence thresholds for damage were measured by monitoring resolution changes in the 0.972 MeV conversion electrons from ^{207}Bi. The fluence for 100-percent change in detector resolution was found to be approximately 10^{12} e/cm^2. Irradiations with 1 MeV electrons made at 10^7, 10^8, and 10^9 e/cm^2-sec gave no apparent flux dependence in the damage effects. Author

A RADIOMETER FOR USE IN THERMAL STUDIES OF SPACECRAFT
George E. Sweet and Howard B. Miller Washington Dec. 1968 36 p refs
(NASA-TN-D-4925) Avail: CFSTI CSCL 14B

A new disk radiometer that is essentially a modification of a loss measuring slug transducer has been designed for space vacuum-thermal environmental studies. The device is operable in vacuums less than 1.3×10^{-3} N/m^2 at ambient temperature levels from 80° K to 450° K. Both steady state and time-varying total irradiances with magnitudes between 200 and 1500 W/m^2 can be measured with an error of about 10 percent. Once the radiometer is calibrated by using an extended black body reference source, it can be used in a variety of thermal study situations without recalibration. Because it is small in size (2.3-cm diameter by 0.5-cm height) and external cooling or constant temperature references are not required, it effects a minimal thermal disturbance to the test surface. The major feature of this radiometer is a shield which is located between the sensor and mounting surface. This shield is instrumented so that an empirical correction can be applied to the radiometer measurements to compensate for unwanted heat transfer between the sensor and mounting surface. Criteria are presented for designing the sensor so that it will remain in temperature equilibrium with relevant heat sources and thus simplify data reduction. Example applications of the radiometer to a thermal control balloon model are also presented. Author

LASER DOPPLER VELOCITY INSTRUMENT
E. Rolfe, J. K. Silk, S. Booth, K. Meister, and R. M. Young Washington NASA Dec. 1968 332 p refs
(Contract NAS8-20413)
(NASA-CR-1199; R67-4450) Avail: CFSTI CSCL 14B

Analytical and experimental data are presented on the development of a laser Doppler velocity instrument for measuring gas velocity. The instrument measures the Doppler shift of light scattered from particles moving with the gas, using Mie (Raleigh–Gans) scattering. The velocity thus measured is independent of particle temperature. An experimental comparison of the hot wire anemometer with the laser Doppler velocity instrument demonstrated excellent correspondence between the two. Measurements of velocity up to approximately Mach 2 in the seven inch wind tunnel compared well with simultaneous velocity measurements using the existing conventional tunnel instrumentation. Measurements were made with a one watt argon laser, and with a 50 milliwatt helium–neon laser. Several methods of signal processing were investigated and an optimum design concept established. This consisted of a wide range narrow band frequency tracker, whose output can be directly recorded on tape to give all necessary information on turbulence and velocity. Author

AN OPTICAL SYSTEM FOR RECORDING SCHLIEREN IMAGES WITH A CONTINUOUS WRITING ULTRA HIGH SPEED FRAMING CAMERA
Lemuel E. Mauldin, III and E. Conrad Compton Washington Jan. 1969 33 p refs
(NASA-TN-D-4986) Avail: CFSTI CSCL 14E

The integrated system comprising the ultrahigh speed camera, the f/8 Z-light-path schlieren system, the focusing lenses, the square-wave-pulse light generator, and the two-beam knife-edge assembly affords up to 72 consecutive schlieren photographs at a recording rate up to 1,200,000 frames per second. The generator provides selectable pulse durations of 60, 250, and 1000 microseconds. This controlled-duration light source eliminates the need for an elaborate high speed shutter normally used with continuous light sources. A two-beam knife-edge assembly splits the Z-type schlieren beam into two separate and complete schlieren images of the test area and direct them into the camera. The system provides good quality pictures of supersonic particles and hypersonic gas flow. Author

EXPERIMENTAL STUDY IN VACUUM OF THE RATE-OF-RISE OUTGASSING-MEASUREMENT TECHNIQUE
Gerald L. Gregory Washington Jan. 1969 45 p refs
(NASA-TN-D-4973) Avail: CFSTI CSCL 14B

A parametric study was conducted to determine the capabilities of the rate-of-rise outgassing-measurement technique. In the rate-or-rise technique the rate of pressure rise due to outgassing in a closed volume is a measure of the outgassing rate. The study consisted in experimentally measuring, at room temperature, with the rate-of-rise technique known leak rates of nitrogen, methane, and helium gases in the leak range of 5×10^{-6} to 5×10^{-4} torr-liter-second^{-1} and in the high vacuum range of 10^{-6} to 10^{-3} torr. Nitrogen and methane leak rates were measurable to within an experimental accuracy of ±20 percent of the known leak rate; whereas helium leak rates were measurable to within an accuracy of ±25 percent of the known leak rate. Errors as large as a factor of 10 in the measurement of leak rates were found to exist as the result of ionization-gage pumping. These errors were reduced by reducing gage pumping effects. Within the experimental uncertainty of the investigation for the gases considered, adsorption phenomena were not observed to influence rate-of-rise results. Author

THE USE OF THERMODYNAMIC PROPERTIES OF METAL-GAS SYSTEMS AS REDUCED-PRESSURE STANDARDS
Charles E. Lundin Washington NASA Jan. 1969 34 p refs
(Contract NAS1-7391)
(NASA-CR-1271) Avail: CFSTI CSCL 14B

The erbium-hydrogen binary system was investigated by means of a Sievert's apparatus to determine the applicability of such a metal-gas system for a low-pressure standard. A thermodyanmic relationship was empirically determined for the two-phase region, erbium solid solution plus erbium dihydride, for the pressure range N69-15873 10^{-4} to 10 torr and the temperature range of 550 to 950°C. This relationship, the van't Hoff equation, is a first-order equation representing the dissociation of hydrogen gas from the dihydride phase to form the metal solid solution as a function of temperature. The coefficient of determination for the data presented was computed to be 0.999. Data is presented on the feasibility of using metal-oxygen and metal-nitrogen systems as secondary low-pressure standards. Author

DESIGN AND PERFORMANCE OF FLUERIC SHOCK POSITION SENSOR FOR A MIXED-COMPRESSION SUPERSONIC INLET
William S. Griffin Washington Jan. 1969 57 p refs
(NASA-TM-X-1733) Avail: CFSTI CSCL 01C

A flueric sensor for normal shock position has been developed and tested on a Mach 2.5 mixed compression axisymmetric supersonic inlet. The sensor detects shock position by sensing the most rearward minimum in static wall pressure profile. Static and dynamic responses of the sensor were evaluated. Static response agreed relatively well with theory, but dynamic response indicated further improvements to the sensor as well as suggestions for improving the sensor's dynamic performance. Author

DYNAMIC CALIBRATION OF TURBINE FLOWMETERS BY MEANS OF FREQUENCY RESPONSE TESTS
Grady H. Stevens Washington Feb. 1969 15 p refs
(NASA-TM-X-1736) Avail: CFSTI CSCL 14B

A technique for dynamic calibration of turbine flowmeters for small-amplitude sinusoidal perturbations was investigated. The investigation included a theoretical analysis and an experimental evaluation of a typical flowmeter for a range of frequencies and mean flow rates. The indicated flow was related to the actual flow by a first-order lag function. This lag function was completely defined by a breakpoint frequency which was directly proportional to mean flow rate. The proportional constant was determined experimentally for a typical flowmeter. This calibration constant was sufficient for completely specifying the flowmeter dynamics over the range of mean flows investigated. Author

N69-17944*# National Aeronautics and Space Administration. Langley Research Center, Langley Station, Va.
REQUIREMENTS OF MARTIAN TELEVISION EXPERIMENT FOR THREE POINT-MASS DESCENT TRAJECTORIES
Friedrich O. Huck, Leonard P. Kopia, and Robert B. Spiers, Jr. Washington Feb. 1969 37 p refs
(NASA-TN-D-5062) Avail: CFSTI CSCL 17B

An analytical approach is used to specify the transmission rate and field-of-view requirements of a television experiment on board a spacecraft as it descends through the Martian atmosphere to land a surface laboratory. The objectives of this experiment are to provide a chain of overlapping images between orbiter and surface-laboratory pictures and a 1-meter-resolution survey of the landing site before impact. Preliminary estimates of the requirements and prediction of the performance are based on three point-mass trajectories, which are the result of numerical integrations of the spacecraft motion through two different Martian atmospheric models. It is found that a single television system can achieve the experiment objectives. For a 200-line television system, the required transmission rates range from 1.4 ± 10^5 to 2.7 ± 10^5 bits per second, and the fields of view range from 12° to 22°, depending on the descent trajectory and the camera viewing direction. This required transmission rate may be halved by employing two television systems. Author

ANALYSIS OF TWO ALTERNATE DAMPING SYSTEMS FOR GEOS GRAVITY GRADIENT STABILIZED SATELLITE
Washington NASA Feb. 1969 137 p refs
(Contract NASw-1503)
(NASA-CR-1282; R-4035-30-1) Avail: CFSTI CSCL 09E

Eddy current rod and magnetically anchored eddy current rod dampers were analyzed to derive the theoretical performance characteristics of each system and to determine which was the more suitable for GEOS satellites. Major operating conditions were simulated, and the two systems were compared as to space flight factors such as altitude and size limitations. It was found that the eddy current rod damper performs considerably better than the magnetically anchored one for polar orbits of 600 n. mi. altitude, but deteriorates more rapidly for non-polar orbits or at higher altitudes. Although this damper could be improved by adding more rods, a significant improvement would require more rods than could be carried on this satellite, but might be possible on other spacecraft. Magnetically anchored dampers are therefore better suited for GEOS; however two factors heretofore unexplored in the laboratory tests should be investigated. One is the fact that the axis of relative rotation between the two major components is generally not stationary with respect to either part. In addition, evidence that only a certain component of the damper generated torque is effective in damping satellite librations has also been found. A.C.R.

DEGRADATION OF MULTIPLIER PHOTOTUBES EXPOSED TO SPATIAL RADIATIONS
M. John Brown, M. S. Bae, and S. Dark Washington NASA Mar. 1969 246 p refs
(CONTRACT NASI-7648)
(NASA-CR-1304) Avail: CFSTI CSCL 09A

The degradation of multiplier phototubes was determined from properties measured in situ during exposure to simulated spatial radiations. A complete analysis of the orbital environments for a specific spacecraft was accomplished to determine operational parameters of a phototube detector. The experimental apparatus was then arranged to provide the spatial environments at real time conditions. Exposure of four identical phototubes was conducted to evaluate the synergistic effect of combined radiations including solar, lunar, and earth irradiances and electron-proton accelerated particle radiations over a seven month period. The phototubes were fabricated for high stability using beryllium copper dynodes in each of fourteen stages and their spectral sensitivity was from 250 to 700 nanometers. Selection of the phototube was based on detector requirements in starmapping from an orbiting spacecraft. Laboratory test results indicate that the phototube is relatively stable when exposed to single radiation sources of solar and charged particles, but degrades when exposed to combined radiations, especially when the irradiation profile included lunar viewing. THE DESIGN AND UNCERTAINTY ANALYSIS OF AN IMPROVED TOTAL HEMISPHERICAL EMITTANCE TRANSIENT CALORIMETER
William R. Wade and Donald J. Progar Washington Mar. 1969 21 p refs
(NASA-TN-D-5106) Avail: CFSTI CSCL 14B

This paper presents the design, the uncertainty analysis, and the test results for several selected materials of a transient calorimetric apparatus for measurement of the total hemispherical emittance of materials for a temperature range from 223° K to 523° K. The uncertainties of the system define the type and magnitude of systematic errors when the calorimetric method of measuring emittance is utilized. The design details which minimize or eliminate these errors are emphasized in the description of the system design. Maximum probable uncertainty has been determined for this system and the results of test runs on highly polished samples of copper and aluminum compare favorably with values of total emittance published by other investigators. Author

ON THE RESOLUTION AND IMAGE INTENSITY OF THE FIELD-ION MICROSCOPE
Victor G. Weizer and Americo F. Forestieri Washington Mar. 1969 15 p refs
(NASA-TN-D-5125) Avail: CFSTI CSCL 14B

The voltage required to produce blurring of a field-ion image spot was measured as a function of tip temperature. The results indicate that the ion current causing the blurring originates at an adsorbed phase on the surface, and a transit time blurring mechanism operates at low temperatures, whereas at higher temperatures an orbit time blurring mechanism best explains the data. The explanation of the failure of the plane in tungsten to image successfully above 5K is shown to lie in the imaging process itself, not in the action of the blurring mechanisms. Maximum resolution was obtained at 5 K, not at 21 K as generally believed. A method of image intensification is described that has advantages over other existing methods. Author

MEASUREMENT OF LIQUID AND TWO-PHASE HYDROGEN DENSITIES WITH A CAPACITANCE DENSITY METER
George E. Turney and Roger W. Snyder Washington Apr. 1969 42 p refs
(NASA-TN-D-5015) Avail: CFSTI CSCL 14C

A three-dimensional, wire matrix, capacitance density meter was used to measure the density of liquid and two-phase hydrogen flow. The measurements were made in a 4-inch (10.6-cm) nominal diameter propellant feedline of a full-scale, simulated, nuclear-rocket test system. An evaluation of this capicitance density meter was made by comparing the density meter measurements with corresponding calculated densities in the feedline. The local hydrogen densities measured with the density meter were in relatively close agreement with the calculated densities. For the most part, the calculated and measured densities differed by less than ±15 percent of the full-scale (liquid hydrogen) density. Author

SURFACE TEMPERATURE MAPPING WITH INFRARED PHOTOGRAPHIC PYROMETRY FOR TURBINE COOLING INVESTIGATIONS
Frank G. Pollack and Robert O. Hickel Washington May 1969 49 p refs
(NASA-TN-D-5179) Avail: CFSTI CSCL 14B

An infrared photographic pyrometry system was investigated to map surface temperature distribution in the range of 1000° to 2500°F. The system was designed to determine the surface temperature distribution of cooled turbine vanes installed in a static cascade facility. A relative energy measurement technique was used for calibrating film density to surface temperature. The calibration method was independent of surface emissivity and viewpath attenuation factor, and compensates for photographic variations. Experimental test targets in air and a hot gas stream were photographed. These thermal images of the targets are evaluated. Temperature information is reduced from each thermal image. The data are presented in the form of calibrated temperature contour maps. Temperature measurements with this method were within the 1-percent accuracy of the calibration point reference temperature over a considerable portion of the film response curve. Author

AIR POLLUTION MONITORING INSTRUMENTATION A Survey
Alvin Lieberman and Peter Schipma Washington NASA 1969 78 p refs
(Contract NASw-1716)
(NASA-SP-5072) Avail: CFSTI CSCL 14B

The purpose of this survey is to aid in transferring air-pollution-monitoring technology developed in aerospace research to the general industrial domain. Information from two sources is presented. First, a comprehensive literature search was made, resulting in the bibliography included. Second, NASA centers and industrial and research organizations were contacted. Thirty-two instruments and techniques, originally developed for aerospace needs, are covered in this survey. These items were found to be novel and/or improvements in the area of air pollution monitoring. A summary of the state of the art in this field precedes the discussion of the above items so that the aerospace-developed items can be compared to current practice. The state of the art articles cover gas and vapor analyses and control methods, while the NASA developed contributions cover spacecraft cabin atmosphere monitors, hazardous-gas and trace-gas analyses, welding gas analyzers, clean-assembly-area monitoring, contaminants in fluids, biosphere studies, air pollution monitors, and fuel cell applications in monitoring. PLANETARY FILM RECONNAISSANCE SYSTEM
Robert Bashe and Ira Schwartz Washington Jun. 1969 94 p ref
(Contract NASI-7688)
(NASA-CR-1358) Avail: CFSTI CSCL 14C

A planetary film system was designed and fabricated that incorporates film as the recording medium in conjunction with automatic film processing and a solid state electro-mechanical readout device. Initial performance evaluation tests are discussed and the direction of continuing effort in the devleopment of such future scientific reconnaissance film systems is indicated. The camera portion of the system incorporates a variable framing rate and a reversible film transport drive. The format is 3 inches by 1 inch, on 35mm film. The processing section utilizes a monobath impregnated web for complete processing and drying of exposed film. The web is encapsulated to prevent evaporation of the processing chemicals, a technique well suited for the processing of film on long duration reconnaissance missions. The conversion of developed scene images into equivalent time-varying video signals is accomplished by an electro-mechanical scanner which uses precision lead screw drives and a semiconductor source and detector for scanning. The use of a mechanical scanner results in high linearity for film readout. The selectable scan rate is compatible with projected unmanned interplanetary space craft data transmission rates. Author

STUDY OF LOW PRESSURE APPLICATION OF NEW ORBITRON AND IRON GAUGE DESIGNS
Charles M. Gosselin Washington NASA Jun. 1969 41 p refs
(Contract NAS1-7458)
(NASA-CR-1300) Avail: CFSTI CSCL 14B

Three experimental orbitron gauges were designed and fabricated. These gauges were designed so as to use the technique of reduced ion-collector area which was introduced by Bayard and Alpert, and the technique of suppression of photoemission from the ion collection introduced by Schuman. The basic concepts of UHV measurements and a basic model of orbitron gauge operation are reviewed. Also fabrication techniques are described. Pressure response curves are displayed. The combination of the suppressor grid with the orbitron gauge appear to offer significant promise for operation below 10^{-11} torr. A second type gauge was also studied viz. the buried collector gauge. A pressure response curve is also displayed for this device. Author

DESIGN OF AN ELECTRONICALLY SCANNED STAR SENSOR WITH DIGITAL OUTPUT
Aaron J. Ostroff and K. C. Romanczyk Washington Jun. 1969 37 p refs
(NASA-TN-D-5281) Avail: CFSTI CSCL 14B

A technique for detecting the change in position of a star on the focal plane of a telescope is described. In this technique an image dissector is used to scan the focal plane and to generate position information. Both theoretical and experimental data are presented. The theoretical analysis contains information on signal-to-noise ratio and relationships between star magnitude, system stability, and sweep frequency. Statistical methods are included for determining the standard deviation for detecting any signal pulse, and for calculating the error involved for one or for several measuring periods. The experimental data contain information on the variation of system stability with star magnitude as functions of sweep frequency, threshold level, and averaged data. All testing is for a simulated 3 meter diameter telescope operating at f/100. Results show that for a triangular sweep frequency of 100 hertz and a star magnitude of +10, the system is stable to within ±26.4 nanoradians. This represents a system signal-to-noise ratio of 370. Other results indicate that the system is linear within ±0.6 percent of best straight line over a total field of view of ±9.76 milliradians. Author

THERMAL ELECTROMOTIVE FORCE CHANGE FOR 87PT13Rh/PT THERMOCOUPLES IN 1530 K, 10 TO THE MINUS 8 TORR ENVIRONMENT FOR 3700 HOURS
Andrew J. Szaniszlo Washington Jun. 1969 24 p refs
(NASA-TN-D-5287) Avail: CFSTI CSCL 14B

The thermal-emf change for 87Pt13Rh/Pt thermocouples was determined by recalibrations in air after 3700 hours exposure to a low-impurity environment with a temperature of 1530°K and a nitrogen equivalent pressure of 3×10^{-8} torr. Wire size was 0.05 cm (0.020 in.), with two-hole, high-purity alumina (99.5 percent) as the insulator. The range of the thermal-emf changes was −2.0° to −3.6°K (average value, −2.8°K). Wire-impurity concentration along the wire was determined by emission spectrographic analysis, which showed iron to have the highest concentration increase at the junction and the largest concentration gradient near the junction. The change in the ratio of resistance at 300°K to the resistance at 4.2°K was determined for samples of the platinum-wire leg, and test-induced grain-structure changes determined with photomicrographs. Author

EMPIRICAL OBSERVATIONS ON THE SENSITIVITY OF HOT CATHODE IONIZATION TYPE VACUUM GAGES
Robert L. Summers Washington Jun. 1969 47 p refs
(NASA-TN-D-5285) Avail: CFSTI CSCL 14B

A study of empirical methods of predicting the relative sensitivities of hot cathode ionization gages is presented. Using previously published gage sensitivities, several rules for predicting relative sensitivity are tested. The relative sensitivity to different gases is shown to be invariant with gage type, in the linear range of gage operation. The total ionization cross section, molecular and molar polarizability, and refractive index are demonstrated to be useful parameters for predicting relative gage sensitivity. Using data from the literature, the probable error of predictions of relative gage sensitivity based on these molecular properties is found to be about 10 percent. A comprehensive table of predicted relative sensitivities, based on empirical methods, is presented. Author

A THERMOCOUPLE TECHNIQUE FOR MEASURING HOT-GAS-SIDE WALL TEMPERATURES IN ROCKET ENGINES

Ronald G. Huff Washington Jun. 1969 32 p refs
(NASA-TN-D-5291) Avail: CFSTI CSCL 14B

A technique is given for installing small-size, quartz-insulated, single-wire thermocouples on thin-wall rocket cooling tubes to measure the hot-gas-side wall temperatures. The lead and junction are protected from the hot gases by electroplating metal on the wall, which buries the lead and junction. The plating is faired to the wall to prevent disruption of the boundary layer. The upper temperature limit, which is due to the breakdown of the quartz electrical insulation, is 2060° R (1144°K). Calibrations are given. Author

EVALUATION OF AN INDIRECT VIEWING SYSTEM FOR LIFTING-BODY TERMINAL-AREA NAVIGATION AND LANDING TASKS

Harold G. Gaidsick, William H. Dana, and Robert C. McCracken Washington Jul. 1969 29 p refs
(NASA-TN-D-5299) Avail: CFSTI CSCL 14B

A short-eye-relief optical system, consisting of two monocular periscopes with overlapping fields of view, was mounted in an F-104B airplane to evaluate the feasibility of using an indirect viewing system in place of normal vision for performing simulated lifting-body approaches and landings. Three approach techniques were used in the study. Performance was evaluated by measuring touchdown distance from a marked touchdown point and rate of sink and airspeed at touchdown. Results obtained with the optics system were compared with normal vision results. The ability of the pilots to perform simulated lifting-body tasks was not noticeably reduced with the optics system. The workload and other pilot acceptance factors, however, indicated that this particular system required improvement in design, even though the pilots could readily adapt to its use. Although the results of this flight evaluation are acceptable in terms of optics system evaluation, it was apparent that more effort is required in the development of local-area navigational techniques, specifically to include limited visibility conditions. PERFORMANCE OF TWO MODELS OF COMMERCIAL UNBONDED STRAIN-GAGE-TYPE ABSOLUTE PRESSURE TRANSDUCER AT 260 DEG C

Ralph D. Lewis Washington Jul. 1969 23 p ref
(NASA-TN-D-5327) Avail: CFSTI CSCL 14B

Four transducers of each model were tested. Probable error for the sample transducers was 1 percent of span if each transducer was calibrated at 260°C and zero shifts were corrected for. Zeros shifted with time, storage at room temperature after initial testing for 650 hours at 260°C, and temperature cycling. Maximum rate of zero shift was about 0.01 percent of span per hour. Rate of zero shift usually decreased with time at 260°C. Mean sensitivity change in 650 hours at 260°C was 0.07 percent of initial value. Mean nonlinearity at 260°C was 40 and 0.51 percent of span, respectively, for the two models. Mean hysteresis at 260°C was 0.55 and 0.11 percent of span. Author

HOLOGRAPHIC MICROSCOPY FOR THE DETERMINATION OF FAILURE MECHANISMS IN MONOLITHIC CIRCUITS

Raoul F. van Ligten Washington NASA Jul. 1969 54 p refs
(Contract NAS12-584)
(NASA-CR-1394) Avail: CFSTI CSCL 14B

Described is a holographic microscopic technique for testing integrated circuits through the various stages of design and production. Holographic interferometry is used in the various stages of metallization, shadowing, surface contamination, and inspection for over or under etching of integrated circuit wafers. The local phase variation of gold–aluminum bonds at the pads on the chips where gold leads are connected is measured by illuminating the wafer from the substrate side with infrared light to which silicon is transparent. Interferometry techniques yield from the refracted wavefront the optical path difference proportional to the refractive index change multiplied by diffusion depth. The refractive index in turn is related to the diffusion concentration. G.G.

SIMULATION STUDIES OF SOME SUPERSONIC TRANSPORT INSTRUMENTATION REQUIREMENTS AND OPERATING PROBLEMS

Norman S. Silsby Washington Aug. 1968 40 p refs
(NASA-TN-D-5280) Avail: CFSTI CSCL 14B

Results pertinent to some supersonic transport (SST) flight instrumentation requirements and operating problems are presented. The results were obtained during departures and arrivals in simulated operations in air traffic control (ATC) environments representing both present-day systems and future concepts and in some special tests. An SST airplane flight simulator and the Federal Aviation Administration's ATC simulation facilities were used to create the real-time simulations. Airline crews operated the SST simulator and experienced air traffic controllers operated the ATC simulation facilities. The tests were conducted under instrument flight rules (IFR) with two design study configurations of the SST. Author

EVALUATION OF A PARACHUTE LOAD DISTRIBUTION MEASURING SYSTEM DURING LOW ALTITUDE DROP TESTS

Ira S. Hoffman Washington Jul. 1969 22 p refs
(NASA-TM-X-1832) Avail: CFSTI CSCL 01C

In conjunction with the low-altitude preflight drop test phase of the NASA supersonic high altitude parachute experiments (SHAPE) program, canopy-load-distribution measurements were made on each of three types of parachute during deployment (by means of a mortar) from an aircraft-dropped payload. Loads were measured with miniature load cells at various locations on the canopies and in the suspension lines of 30- and 40-foot-diameter (9.14 and 12.19 meters) parachutes, with a total of seven measurements of this type being made on each of seven instrumented parachute drops. Out of a total of 49 such individual measurement attempts, there were six individual load-cell problems, which included one of lead-wire breakage during parachute deployment. Total parachute load measurements were also made during each test by means of a tensiometer in the main riser line. In addition, for the total parachute instrumentation program, data from approximately 40 percent of the channels were not obtained due apparently to onboard telemetry malfunction. A commercially available stretch cable was used in the hard wire data transmission link between all transducers and their corresponding telemetry channels in the payload. Author

EVALUATION OF A VOLUME-RATIO SYSTEM FOR VACUUM GAGE CALIBRATION FROM 10 TO THE MINUS 8 POWER TO 10 TORR
Raymond Holanda Washington Sep. 1969 23 p refs Avail: CFSTI
(NASA-TN-D-5406) Avail: CFSTI CSCL 14B

An evaluation was made of a volume-ratio calibration system in the range from 10^{-8} to 10 torr. An error analysis showed that the pressures could be produced with a limit of error of about $\pm 1\text{-}1/2$ percent at 10^{-6} torr to ± 4 percent at 10^{-8} torr. An analysis was made of the effects of volume-ratio and reference pressure-gage inaccuracies, temperature effects, ionization-gage pumping, ultimate pressure, transfer-volume-cycle gas generation, out-gassing, and adsorption. Sample calibrations of vacuum gages are provided. The upper and lower pressure limitations of this system are discussed. Author

CALIBRATION OF PEGASUS AND EXPLORER 23 DETECTOR PANELS
Robert J. Naumann, David W. Jex, and Clyde L. Johnson Washington Sep. 1969 40 p refs
(NASA-TR-R-321) Avail: CFSTI CSCL 14B

Several series of tests were conducted to establish the ballistic limit for the various detector panels. In these tests extremely small, carefully sized beads were launched in a velocity range that included the perforation threshold. By varying the size, a ballistic limit curve was established on a mass-velocity plot. Such curves were then extrapolated to average meteor velocity to obtain the characteristic mass for each sensor. Additional tests were conducted on the Pegasus panels using the Pegasus test tool, which contains the identical electronic circuitry used by the flight models. These tests included hot and cold tests, thermal cycling after impact, and oblique impacts. Several types of anomalous events noted in the operation of the spacecraft could be simulated in this manner. Some indication of the dependence of detection threshold upon size was obtained. Author

ANALYTICAL STUDY OF CONTAMINANT AND ATMOSPHERIC SENSOR, PHASE 1
Washington NASA Sep. 1969 137 p refs
(Contract NAS1-7260)
(NASA-CR-1375; SPO-20224) Avail: CFSTI CSCL 14B

Research was directed towards the modification of the previously designed two gas atmospheric sensor system (mass spectrometer) to measure the partial pressures of oxygen, nitrogen, carbon dioxide, and water vapor within a space vehicle environment. An analytical study of the necessary modifications which would allow the two gas sensor to monitor the atmospheric constituents, selected contaminants, and summation of contaminants has been performed for both helium-oxygen and nitrogen-oxygen atmospheres. Several approaches utilizing the two gas sensor as the basic component were analyzed. The accumulator cell approach offered the most feasible solution of the problems encounted. The results of the study lead to the definition of a contaminant and atmospheric sensor, utilizing the accumulator cell, meeting the performance goals while still having acceptable weight, power, and size specifications. ABSOLUTE RADIOMETERS FOR USE IN BALLISTIC-RANGE AND SHOCK-TUBE EXPERIMENTS
Roger A. Craig and William C. Davy Washington Oct. 1969 61 p refs
(NASA-TN-D-5360) Avail: CFSTI CSCL 14B

This report is a discussion of the design, calibration, and use of radiometers to measure absolute spectral emission in ballistic range and shock tube experiments. These radiometers are characterized by a frequency response and a dynamic range sufficient to span the widely different frequencies and intensities of calibration and experiment sources. Radiometers discussed consist of a filter (transmission filter or monochromator), a detector (multiplier phototube or infrared photodiode), and a close-coupled amplifier. Response equations are developed that relate the test data to emission from a calibration standard. The principal problems of use of these radiometers (e.g., multiplier phototube stability and saturation. Infrared photodiode rise time and linearity, limiting noise, filter side-band transmission and standard lamp operation) are discussed. Three currently operating ballistic range and shock tube applications are described in detail. Author

AN IMPROVED DELAYED NEUTRON FISSION PRODUCT MONITOR
James D. Heckelman and Konstanty Semenchuk Washington Oct. 1969 21 p refs
(NASA-TM-X-1886) Avail: CFSTI CSCL 18D

This fission product monitor (FPM) was developed at NASA's 60-megawatt (thermal) test reactor at the Plum Brook Station. Two neutron detectors are used to monitor the delayed neutrons at two different locations in the primary collant system. The ratio (detector 1 count rate)/(detector 2 count rate) is used to indicate the presence of fission products. During normal reactor operation when significant fission products are not present in the primary cooling water (PCW), the neutrons present at the detectors are from the decay of nitrogen 17. When fission products appear in the PCW, their half-lives are different from the half-life of N^{17} The ratio will thus change, and the change may be uniquely related to the fission product activity in the PCW. The activity of the fission product iodine 134 in the PCW of the Plum Brook Reactor is routinely determined. Calculations provided the theoretical FPM ratios for assumed I^{134} levels. The theoretical curve was then verified by actual measurements taken during many reactor operating hours. Calibration of the FPM system is easily accomplished by interchanging the detectors at one detector location and adjusting the electronics so that the counting rates of both detector channels are equal. The monitor is in operation and has demonstrated reliable results. Author

FLOW-DIRECTION MEASUREMENT WITH FIXED-POSITION PROBES

Thomas J. Dudzinski and Lloyd N. Krause Washington Oct. 1969 16 p refs

(NASA-TM-X-1904) Avail: CFSTI CSCL 14B

Because of space limitations and system complexity in many aeronautical applications, movable probes cannot be used to measure flow direction. This report presents correlations between measured fixed-probe pressures and airflow direction over a range of Reynolds number, Mach number, and flow angle. Flow direction is measurable to within about 1° over combinations of flow conditions in the range $1000 \leq Re \leq 40\,000$, $0.3 \leq M \leq 0.9$, $-30° \leq \text{angle} \leq +30°$. Author

THE EFFECT OF OBJECT MOTION IN FRAUNHOFER HOLOGRAPHY WITH APPLICATION TO VELOCITY MEASUREMENTS

William P. Dotson, Jr. Washington Nov. 1969 23 p refs

(NASA-TN-D-5515) Avail: CFSTI CSCL 14E

The in-line Fraunhofer hologram is analyzed with the assumption that the object moves a significant distance during the observation tiem. An equation is derived which predicts the effect that object motion has upon the recorded fringe pattern. An analysis of the fringe pattern recorded on the film consequently yields the total motion of the object during the observation time. It is also possible to reconstruct the resultant hologram so that the path the object traveled during the exposure time is reproduced. This knowledge, coupled with the exposure time, yields the desired measurement of the object velocity. Author

PRELIMINARY EVALUATION OF GREASES TO 600 F AND SOLID LUBRICANTS TO 1500 F IN BALL BEARINGS.

H. E. Sliney and R. L. Johnson (NASA, Lewis Research Center, Cleveland, Ohio).

(American Society of Lubrication Engineers, Annual Meeting, 23rd, Cleveland, Ohio, May 6-9, 1968, Preprint 68AM 7C-2.)

ASLE Transactions, vol. 11, Oct. 1968, p. 330-337. 17 refs.

A special apparatus designed for the evaluation of high-temperature lubricants in 20-mm-bore ball bearings is described. The results of bearing runs at temperatures up to 1500°F in air are reported. Of the greases evaluated, a fluorocarbon grease, provided bearing lubrication for longer times at 450 and 600°F than either polyphenyl ether or silicone greases thickened with dyes and/or MoS_2. Cobalt alloy ball bearings, lubricated either with barium fluoride-calcium fluoride coatings bonded to the cages, or with porous metal cages impregnated with these fluorides, ran successfully at 1200 and 1500°F under a thrust load of 30 lb and at a shaft speed of 5000 rpm.

EHD LUBRICATION.

Erwin V. Zaretsky (NASA, Lewis Research Center, Bearing Materials and Fatigue Section, Cleveland, Ohio) and William J. Anderson (NASA, Lewis Research Center, Bearings Branch, Cleveland, Ohio).

Machine Design, vol. 40, Nov. 7, 1968, p. 167-173. 8 refs.

Discussion of the conditions necessary for the formation of elastohydrodynamic (EHD) films and their use in lubrication. The formation of EHD films is found to depend on two mutually dependent factors: the hydrodynamic properties of the fluid and the deformation of the contact zone. Surface topography is shown to be important in the EHD lubrication process. The fact that some measurements of EHD film thicknesses were less than half the value predicted by theory is attributed to the non-Newtonian behavior of the lubricant. On the basis of EHD theory, the basic design procedures for the use of EHD films in lubricating gears, roller bearings, and ball bearings are outlined.

CRYOGENIC POSITIVE EXPULSION BLADDERS.

R. F. Lark (NASA, Lewis Research Center, Cleveland, Ohio).

IN: CRYOGENIC PROPERTIES OF POLYMERS; PROCEEDINGS OF THE NASA-CASE CONFERENCE ON THE PROPERTIES OF POLYMERS AT CRYOGENIC TEMPERATURES, NASA LEWIS RESEARCH CENTER AND CASE-WESTERN-RESERVE UNIVERSITY, CLEVELAND, OHIO, APRIL 25-27, 1967. [A69-16485 05-18]

Edited by T. T. Serafini and J. L. Koenig.

New York, Marcel Dekker, Inc., 1968, p. 1-15.

NASA-Lewis in-house and contractual experimental programs were conducted to determine the cryogenic flexibility of single and multiple plies of thin polymeric films at 77 and 20 K. Results of cryogenic flexibility or "twist-flex" testing showed that thin Mylar films are the most flexible of the films tested. The relation between cryogenic cycle life, film thickness, and the number of plies for Mylar film is reported at 77 and 20 K, and results of contractual testing of Mylar, Kapton, and polyethylene film bladders at 20 K are summarized. Bladder material combinations showing the lowest helium gas porosity after 25 liquid hydrogen cycles are Mylar and an organic filament-reinforced polyethylene film laminate and Kapton/Nomex-Nylon.

DEPOSITION OF MoS_2 FILMS BY PHYSICAL SPUTTERING AND THEIR LUBRICATION PROPERTIES IN VACUUM.

T. Spalvins (NASA, Lewis Research Center, Cleveland, Ohio).

(American Society of Mechanical Engineers and American Society of Lubrication Engineers, Lubrication Conference, Atlantic City, N. J., Oct. 8-10, 1968, ASLE Paper 68 LC-15.)

ASLE Transactions, vol. 12, Jan. 1969, p. 36-41; Discussion, Mel Lavik (Midwest Research Institute, Kansas City, Mo.) and A. J. Haltner (General Electric Co., Philadelphia, Pa.), p. 41, 42; Author's Closure, p. 42, 43. 19 refs.

Physical dc sputtering of MoS_2 was used to apply MoS_2 films for use as a solid lubricant on rotating and sliding components. This method does not utilize binders or burnishing. Friction experiments in vacuum (10^{-11} torr) were conducted on these films (~2000 Å thick). The coefficient of friction for these films was similar to the reported values for resin bonded films. The long endurance life of these films in friction experiments indicates good adherence. The good adherence results from cleanliness of the surface (etched) and the relatively high energies of the sputtered material on arrival at the surface. These sputtered MoS_2 films were consistent in regard to stoichiometry, adherence, thickness, and uniformity when the sputtering conditions were accurately controlled from run to run.

COOLING STUDIES WITH HIGH-SPEED BALL BEARINGS OPERATING IN COLD HYDROGEN GAS.

David E. Brewe, Harold H. Coe, and Herbert W. Scibbe (NASA, Lewis Research Center, Cleveland, Ohio).

(American Society of Mechanical Engineers and American Society of Lubrication Engineers, Lubrication Conference, Atlantic City, N. J., Oct. 8-10, 1968, ASLE Paper 68 LC-2.)

ASLE Transactions, vol. 12, Jan. 1969, p. 66-75; Discussion, J. B. Accinelli (Aerojet-General Corp., Sacramento, Calif.) and M. F. Butner (North American Rockwell Corp., Canoga Park, Calif.), p. 75, 76; Authors' Closure, p. 76. 8 refs.

Experiments and analyses were performed to determine the cooling requirements for 40-mm bore ball bearings using 60°R (-400°F) hydrogen gas. The bearings were run at shaft speeds to 35,000 rpm and thrust loads to 400 lb. A bronze-filled polytetrafluoroethylene (PTFE) retainer was used to lubricate the bearings. Bearing outer-race temperature varied as the inverse of hydrogen gas flow rate through the bearing. From this inverse relation, a minimum flow equation was developed for the range of bearing operating conditions. The minimum flow rate required for bearing cooling was more sensitive to speed than to load increases. Film transfer to the inner-race grooves and retainer wear is indicated and discussed.

Members, $1.50; nonmembers, $3.00.

Study of the failures of pressure vessels storing gaseous hydro-

gen, and recommendations for the use of new materials. It is found that the A517-F steel vessels, as currently fabricated, are not satisfactory for hydrogen. More rigid manufacturing controls might produce an acceptable vessel. All large hydrogen pressure vessels should have an access for periodic internal inspection by magnetic-particle, dye-penetrant, or other nondestructive methods. Bourdon tubes in pressure gauges must be made from materials that are less susceptible to hydrogen deterioration. A 300 series stainless steel or a Be-copper alloy may be satisfactory. Z. W.

FABRICATION OF UNIAXIAL FILAMENT-REINFORCED EPOXY TUBES FOR STRUCTURAL APPLICATIONS.

John G. Davis, Jr. (NASA, Langley Research Center, Hampton, Va.).

IN: ADVANCED TECHNIQUES FOR MATERIAL INVESTIGATION AND FABRICATION; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBIT, 14TH, COCOA BEACH, FLA., NOVEMBER 5-7, 1968, PROCEEDINGS. [A69-22301 09-15]

North Hollywood, Calif., Western Periodicals Co. (Science of Advanced Materials and Process Engineering Proceedings, Volume 14), 1968, II-2A-1 (14 p.). 8 refs.

Description of a process for fabricating uniaxial filament-reinforced epoxy tubes. The process utilizes hand layup techniques, a Teflon mandrel, and a heat-shrinkable Teflon sleeve. At the present, over 40 tubes of boron-epoxy and S-glass-epoxy have been fabricated using the process reported. The tubes are essentially void free, exhibit less dimensional variation than the tolerances set for commercially available extruded aluminum tubing, and display a smooth surface finish. Short sections of both types of tubing have been subjected to axial compression tests. The boron-epoxy and S-glass-epoxy tubes exhibited average strengths of 309 ksi and 207 ksi, respectively. ASSURING SATURN QUALITY THROUGH NONDESTRUCTIVE TESTING.

Robert W. Neuschaefer (NASA, Marshall Space Flight Center, Huntsville, Ala.).

American Society for Nondestructive Testing, Spring Conference, Los Angeles, Calif., Mar. 10-13, 1969, Paper. 27 p. 9 refs.

The Saturn V space vehicle is briefly described. The organizational responsibilities of NDT groups are discussed along with the approach to management of research and development activities. Applications of the various NDT methods employed to evaluate the materials and processes used in the manufacture of the various stages and major components are described. Emphasis is placed on a discussion of the special NDT methods and equipment developed to satisfy the unique requirements of the Apollo program. Advancements in the state-of-the-art, including a solid-state radiographic image amplifier and an rf device suitable for measuring the thickness of nonmetallics on metallic objects, are described. VARIOUS MODES OF WEAR AND THEIR CONTROLLING FACTORS.

E. E. Bisson (NASA, Lewis Research Center, Fluid System Components Div., Cleveland, Ohio).

(American Society for Testing and Materials, Annual Meeting, 71st, San Francisco, Calif., June 23-28, 1968, Paper.)

IN: EVALUATION OF WEAR TESTING; AMERICAN SOCIETY FOR TESTING AND MATERIALS, ANNUAL MEETING, 71ST, SYMPOSIUM, SAN FRANCISCO, CALIF., JUNE 23-28, 1968, PROCEEDINGS. [A69-27230 13-15]

Symposium sponsored by the Committee on Simulated Service Testing.

Philadelphia, American Society for Testing and Materials (ASTM Special Technical Publication No. 446), 1969, p. 1-22. 23 refs.

Discussion of the various modes of wear, the mechanisms involved in each, and the mitigation of wear in some of the modes. The various modes of wear include adhesion, abrasion, corrosion and surface fatigue. Fretting (fretting corrosion or friction oxidation) is a special combination of adhesive, corrosive, and abrasive wear. Adhesive wear involves adhesive forces which are strong enough to form cold welds at the contacting asperities. During relative motion, shear takes place at the welds. The shear strength at these welds is strongly influenced by contamination, either deliberate or accidental. There is a marked influence of crystal structure on friction and adhesive wear. In general, the hexagonal structure gives lower friction and wear than the cubic structure. Experimental studies show that the lattice parameters in hexagonal crystals also affect friction. Abrasive wear involves damage to a soft surface by a hard surface, either one of the two surfaces, or a third body. Hardness, work hardness, crystallite orientation, and elastic modulus of the contacting surfaces can all influence wear. Corrosive wear involves corrosion, followed by wear of the corrosive film. Surface fatigue normally appears as local pitting or flaking. Wear damage of this type is a function of a number of stress cycles. All modes of wear lead to loss of dimen-

sional tolerances, high operating cost, and excessive expense (in time and money) for replacement of worn parts. A complete understanding of the basic mechanisms of wear permits alleviation and mitigation. P.v.T.

EXPERIMENTAL STABILITY STUDIES OF THE HERRINGBONE-GROOVED GAS-LUBRICATED JOURNAL BEARING.
Robert E. Cunningham, David P. Fleming, and William J. Anderson (NASA, Lewis Research Center, Cleveland, Ohio).
(American Society of Mechanical Engineers, Lubrication Symposium, Las Vegas, Nev., June 17-20, 1968, Paper 68-LubS-25.)
ASME, Transactions, Series F - Journal of Lubrication Technology, vol. 91, Jan. 1969, p. 52-57; Discussion, A. W. Lawrence (Hamilton Standard Systems Center, Farmington, Conn.) and C. C. W. Ng (United Aircraft Corp., East Hartford, Conn.), p. 57, 58; Authors' Closure, p. 58, 59. 15 refs.

Experimental studies were conducted on six rotors, 1-1/2 in. diameter by 12-1/4 in. long operating in ambient air to high compressibility numbers. Herringbone-groove geometries and clearances were varied to determine their effect on half-frequency whirl (HFW). All rotors were operated vertically and without any applied radial load. Results show that half-frequency-whirl onset is very sensitive to radial clearance. Limited test results indicate that a fully grooved bearing is more stable than a partially grooved one, other parameters being equal. Generally fair agreement between theory and experiment was achieved for predicting HFW onset speeds. (Author)

CONFIGURATIONS FOR GAS TURBINE COMPRESSOR END SEALS.
J. W. Bjerklie, H. S. Cheng, D. F. Wilcock (Mechanical Technology, Inc., Latham, N.Y.), L. Ludwig, and D. Townsend (NASA, Lewis Research Center, Cleveland, Ohio).
(American Society of Lubrication Engineers, Annual Meeting, 23rd, Cleveland, Ohio, May 6-9, 1968, Preprint 68AM 4B-4.)
Lubrication Engineering, vol. 25, Apr. 1969, p. 169-175.
Contract No. NAS 3-7605.

Modern high performance multistage axial flow compressors have several air leakage paths which reduce compressor performance. The most significant leakage occurs past the labyrinth seal at the high pressure end of the compressor. Since it was estimated that this leakage reduced the compressor efficiency by 1%, a project was undertaken to develop low-leakage-rate noncontact seals which would reduce compressor end-seal leakage by an order of magnitude. A large number of seal concepts and ideas were examined for suitability. Each concept was evaluated on the basis of leakage rate, tracking capability, gas film stability, thermal and elastic distortion, wear, and reliability. Since the concepts involved combinations of the several types of primary seal and secondary seal, these are examined separately, followed by a screening analysis of the most viable concepts. The screening results in the selection of concepts for detailed design study. (Author)

COMPUTER-GENERATED GRAPHICS IN AEROSPACE DESIGN AND ANALYSIS.
Frederic A. Hills (NASA, Electronics Research Center, Cambridge, Mass.).
American Society of Mechanical Engineers, Design Engineering Conference and Show, New York, N.Y., May 5-8, 1969, Paper 69-DE-65. 6 p. 13 refs.
Members, $0.75; nonmembers, $1.50.

Discussion of NASA's direct and indirect use of computer-driven graphical techniques. Though emphasis is placed upon NASA application of these techniques to the specific areas of design, analysis, and simulation, the paper attempts to synthesize a more extensive computer-graphics context within which the design usage may be assessed, correlated, and projected into the future. Examples of the use of graphics in space-related design are given, and relevant techniques are cited. (Author)

ENERGETICS IN VACUUM DEPOSITION METHODS FOR DEPOSITING SOLID FILM LUBRICANTS.
T. Spalvins (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Lubrication Engineers, Annual Meeting, Philadelphia, Pa., May 5-8, 1969, Paper. 16 p. 6 refs.

High energy or plasma deposition methods (dc, RF sputtering, and ion plating) as new approaches to the application of solid film lubricants to components requiring lubrication. Films can be deposited under controlled operational conditions. The strength and durability of the film are related to adhesion, which depends on the interfacial and film characteristics. These are directly related to the kinetic energy of the impinging metal atoms. If the deposition conditions are standardized during the film application, composition, adherence thickness, and uniformity can be accurately repeated and controlled. B.H.

A SURVEY OF LEAK DETECTION FOR AEROSPACE HARDWARE.
Frederic E. Wells (NASA, Marshall Space Flight Center, Huntsville, Ala.).
(American Society for Nondestructive Testing, National Conference, 28th, Detroit, Mich., Oct. 14-17, 1968, Paper.)
Materials Evaluation, vol. 27, May 1969, p. 97-101.

Survey of leak detection equipment, practice, and philosophy applicable to external leak testing of aerospace hardware. The survey is based on experimentation and evaluation work performed at the Marshall Space Flight Center (MSFC), engineering analysis of work by others, and the experience gained at MSFC during extensive checkout work on three major vehicle programs. The three principal areas covered are (1) setting acceptance limits, (2) techniques currently available, and (3) selecting a technique for a particular job. Systems and components are leak checked because of danger from leaking fluids, possible depletion of system fluids, quality control of manufacturing processes and assembly techniques, and detection of degraded components. The techniques described are liquid leak detector agents, thermal detectors, halogen detectors, and helium mass spectrometers. F.R.L.

NUMERICAL SOLUTIONS FOR THE FLOW AND PRESSURE FIELDS IN AN IDEALIZED SPIRAL GROOVED PUMPING SEAL.
John Zuk and Harold E. Renkel (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Lubrication Engineers, British Hydromechanics Research Association, and American Society of Mechanical Engineers, International Conference on Fluid Sealing, 4th, Philadelphia, Pa., May 5-9, 1969, ASLE FICFS Preprint 30. 13 p. 20 refs.
Members, $0.75; nonmembers, $1.50.

Spiral-grooved pumping seal model formulated for laminar, incompressible flow for the limiting case of zero land clearance. The numerical solutions of the exact governing equations show a bidirectional (pumping and leakage) vortex flowfield. Results are compared to classical models of the groove axial flow (general Couette flow which is used in deriving Reynolds' lubrication equation and moving wall duct flow) which neglect the coupling of the groove crossflow. The solutions show that the crossflow shifts the pumping flow toward the land leading edge. For a Reynolds number of 100 and groove depth-to-width ratio less than or equal to 1/8, the classical models are shown to be good approximations for the relation of axial pressure gradient to net volume flow. The groove cross-section static pressure is nearly constant except near the moving surface region. A low pressure region suggests the possibility of degassing and cavitation, whereas a high pressure region near the land leading edge results in a lift force acting on the moving surface. (Author)

SHAFT FACE SEAL WITH SELF-ACTING LIFT AUGMENTATION FOR ADVANCED GAS TURBINE ENGINES.
Robert L. Johnson and Lawrence P. Ludwig (NASA, Lewis Research Center, Cleveland, Ohio).

American Society of Lubrication Engineers, British Hydromechanics Research Association, and American Society of Mechanical Engineers, International Conference on Fluid Sealing, 4th, Philadelphia, Pa., May 5-9, 1969, ASLE FICFS Preprint 27. 11 p. 9 refs.
Members, $0.75; nonmembers, $1.50.

Indication of the need to incorporate in advanced engines shaft seals with improved pressure, temperature, and speed capabilities. In particular, the high-speed requirement suggests that the seals must not have rubbing contact. Labyrinth seals have disadvantages in high leakage (efficiency loss) and debris entrainment, and conventional face seals are subject to high wear, because face deformation can increase seal closing force and thus cause heavy rubbing contact. It is shown that incorporation of self-acting lift pads to the conventional face seal prevents rubbing contact, even though face deformation occurs; feasibility was demonstrated in 560 hr of operation at 100-psi (69-N/cm^2) pressure differential, 600°F (589 K) gas temperature, and 380-ft/sec (116-m/sec) sliding speed. Positive separation of the sealing faces with acceptable leakage rates was obtained. Proposed advanced systems using seals with self-acting lift pads are described. P. v. T.

A69-30610 *
SLIDING FRICTION OF COPPER ALLOYS IN VACUUM.
Jane Jellison, Roamer Predmore, and C. L. Staugaitis (NASA, Goddard Space Flight Center, Greenbelt, Md.).
(American Society of Mechanical Engineers and American Society of Lubrication Engineers, Lubrication Conference, Atlantic City, N.J., Oct. 8-10, 1968, ASLE Paper 68 LC-5.)
ASLE Transactions, vol. 12, Apr. 1969, p. 171-180; Discussion Morton Antler (Burndy Corp., Norwalk, Conn.) and M. Cocks (SKF Industries, Inc., King of Prussia, Pa.), p. 181, 182. 15 refs.

Results of sliding friction experiments which involve copper and Cu-Be alloy plates in contact with copper, Cu-Be alloy, steel, and titanium alloy sliders and were performed in air and vacuum. Microhardness and metallographic examination of plate and slider interface suggests friction and wear by the adhesive friction mechanism with prow formation. Transfer of strain-hardened metal wear debris across the sliding interface was observed. The friction coefficient and the prow size generally increased in vacuum. (Author)

CONTACT CONFORMITY EFFECTS ON SPINNING TORQUE AND FRICTION.
M. W. Dietrich, R. J. Parker, E. V. Zaretsky, and W. J. Anderson (NASA, Lewis Research Center, Cleveland, Ohio).
(American Society of Mechanical Engineers and American Society of Lubrication Engineers, Lubrication Conference, Atlantic City, N.J., Oct. 8-10, 1968, ASME Paper 68-Lub-10.)
ASME, Transactions, Series F - Journal of Lubrication Technology, vol. 91, Apr. 1969, p. 308-313. 5 refs.

Lubricated and unlubricated tests were conducted in the NASA spinning friction apparatus with SAE 52100 steel specimens with ball-race conformities of infinity (a ball on a flat), 60, 55, and 51%. For a constant conformity under lubricated conditions, the coefficient of spinning friction decreased from approximately 0.5 to 0.05 with increasing load and stress. At a constant stress, the coefficient of spinning friction increased with decreasing conformity (increasing percent conformity). Under unlubricated conditions, the coefficient of spinning friction remained relatively constant regardless of load, stress, or conformity, having values within a scatter band of 2.5 to 6.0. For a constant stress under both lubricated and unlubricated conditions, the greater the conformity (the smaller the percent conformity), the higher the torque. (Author)

EFFECT OF THREE ADVANCED LUBRICANTS ON HIGH-TEMPERATURE BEARING LIFE.
E. N. Bamberger (General Electric Co., Cincinnati, Ohio), E. V. Zaretsky, and W. J. Anderson (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Mechanical Engineers, Lubrication Symposium, San Francisco, Calif., June 17-19, 1969, Paper 69-LubS-18. 9 p. 14 refs.
Members, $0.75; nonmembers, $1.50.

Rolling-element fatigue tests conducted with 120-mm bore angular-contact ball bearings made of AISI M-50 steel with a synthetic paraffinic oil, a fluorocarbon, and a 5P4E polyphenyl ether. At 600°F under a low-oxygen environment, the synthetic paraffinic oil and the fluorocarbon gave bearing lives approximately 14 and 3 times AFBMA-predicted (catalog) life, respectively. With the polyphenyl ether, bearing life was less than AFBMA-predicted (catalog) life in an air environment at 600°F. At temperatures of 400 and 500°F with the synthetic paraffinic oil, there was no statistical difference in life from those bearings tested with the same fluid at 600°F. For the synthetic paraffinic oil and the fluorocarbon, bearing fatigue was subsurface-initiated. For the polyphenyl ether, bearing failure was mainly from surface distress, wear, and superficial pitting. (Author)

ELASTOHYDRODYNAMIC LUBRICATION OF A SPINNING BALL IN A NONCONFORMING GROOVE.
C. W. Allen (Chico State College, Chico, Calif.), D. P. Townsend, and E. V. Zaretsky (NASA, Lewis Research Center, Cleveland, Ohio).
American Society of Mechanical Engineers, Lubrication Symposium, San Francisco, Calif., June 17-19, 1969, Paper 69-LubS-11. 6 p. 12 refs.
Members, $0.75; nonmembers, $1.50.

Elastohydrodynamic solution for the spinning torque of a ball spinning without rolling in a nonconforming groove. The solution is compared with experimental results using a synthetic paraffinic oil as the lubricant. A modified pressure-viscosity relation is proposed. The theory predicts increase in torque with stress and spinning speed and decreasing conformity. Good agreement was obtained between theoretical predictions and experimental results. (Author)

TRANSIENT PUMPING PERFORMANCE OF A TWO SPEED, HYDRAULIC TURBINE DRIVEN INDUCER SYSTEM.
J. Farquhar, B. K. Lindley (Aerojet-General Corp., Sacramento, Calif.), and W. A. Rostafinski (NASA, Lewis Research Center, Cleveland, Ohio).
American Institute of Aeronautics and Astronautics, Propulsion Joint Specialist Conference, 5th, U.S. Air Force Academy, Colorado Springs, Colo., June 9-13, 1969, Paper 69-551. 14 p. 14 refs.
Members, $1.00; nonmembers, $1.50.

Description of the analysis, design, and experimental evaluation of a two speed, hydraulic turbine driven pump inducer system. The system incorporates an inducer which is driven by a hydraulic turbine. The hydraulic turbine is in turn driven by a flow supplied by an axial flow rotor which is running at a higher speed and is mounted between the inducer and the hydraulic turbine. All three blade rows operate at essentially full system flow rate. The system is representative of a rocket engine liquid hydrogen boost pump where the rotor would be attached to the main stage pump. General expressions relating the significant design variables of such systems are presented together with expressions defining limits for stable (hydraulically locked) operation. Testing of the system in water is described together with comparisons of steady state and transient behavior with predictions. A digital computer model for the transient behavior of the system is described. (Author)

EFFECT OF OXYGEN CONCENTRATION ON SYNTHETIC PARAFFINIC AND ADVANCED ESTER BASE LUBRICANTS IN BEARING TESTS AT 400° AND 450°F.

Richard J. Parker and Erwin V. Zaretsky (NASA, Lewis Research Center, Cleveland, Ohio).

American Society of Mechanical Engineers, Spring Lubrication Symposium, San Francisco, Calif., June 17-19, 1969, Paper. 26 p. 16 refs.

Determination of the effects of oxygen concentration on the oxidation of a synthetic paraffinic oil and an advanced Type II ester by means of bearing tests run at 400 and 450°F. The 20-mm bore ball bearings were run at 10,600 rpm and 70 lb thrust load. The oxygen content of the gas in the bearing chamber was varied from less than 0.1% to approximately 21% by volume. The increase in bearing torque, lubricant viscosity, and acid number were used as indicators of lubricant oxidation and degradation. The advanced ester exhibited less oxidation than did the synthetic paraffinic oil under similar test conditions. A time limitation on the effectiveness of oxidation inhibitors in both lubricants was indicated. Tests with the bearing not rotating produced relatively small increases in lubricant viscosity. THE INFLUENCE OF ORDERING ON THE FRICTION AND WEAR OF METALS IN VACUUM.

William A. Brainard and Donald H. Buckley (NASA, Lewis Research Center, Cleveland, Ohio).

American Vacuum Society and American Institute of Mining, Metallurgical, and Petroleum Engineers, Vacuum Metallurgical Conference, Pittsburgh, Pa., June 16-19, 1969, Paper. 20 p. 20 refs.

Determination of the effect of atomic ordering on the friction and wear of alloys in a vacuum environment. The classic copper-gold system and the iron-cobalt system were investigated. Alloys were prepared in the range Cu_3Au, CuAu, and FeCo. All of these solid solutions exhibit atomic ordering. Sliding friction experiments were conducted in vacuum (10^{-9} to 10^{-7} torr) utilizing a 0.476-cm radius rider specimen sliding on a 6.35-cm-diam disk. Friction and wear were examined at various temperatures, various loads, and various sliding velocities. It was found for all the solid solutions that friction is markedly lower in the ordered state than in the disordered state. Further wear is also significantly decreased by ordering. Sliding velocity and temperature were found to effect the friction of the ordered materials. The type of ordering and the friction coefficient as the critical temperature are compared. Initial investigation of a vanadium-iron cobalt alloy which has an ordered alpha phase shows this alloy to have promise as a potential bearing material. (Author)

DIELECTRIC PROCESSING FOR LOW-COST ABLATION HEAT SHIELDS.

Charles B. King (NASA, Langley Research Center, Hampton, Va.).

IN: MATERIALS AND PROCESSES FOR THE 70'S; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBITION, 15TH, LOS ANGELES, CALIF., APRIL 29-MAY 1, 1969, PROCEEDINGS. (A69-35501 19-15)

North Hollywood, Western Periodicals Co.; Azusa, Calif., Society of Aerospace Material and Process Engineers (Science of Advanced Materials and Process Engineering Proceedings. Volume 15), 1969, p. 445-453.

A heat-shield concept which simplifies fabrication and application of ablative panels to entry vehicles is described. Results from an experimental program where typical panels were fabricated using dielectric heating are presented and discussed. The relative costs of this approach and state-of-the-art heat-shield fabrication are discussed. (Author)

PLASMA ELECTRON BEAM DEVELOPMENT FOR WELDING APPLICATIONS.
Richard M. Poorman (NASA, Marshall Space Flight Center, Manufacturing Engineering Laboratory, Huntsville, Ala.) and Kenneth L. Boring (General Electric Co., Research and Development Center, Schenectady, N.Y.).
IN: MATERIALS AND PROCESSES FOR THE 70'S; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBITION, 15TH, LOS ANGELES, CALIF., APRIL 29-MAY 1, 1969, PROCEEDINGS. (A69-35501 19-15)
North Hollywood, Western Periodicals Co.; Azusa, Calif., Society of Aerospace Material and Process Engineers (Science of Advanced Materials and Process Engineering Proceedings. Volume 15), 1969, p. 633-648.

A new electron source, called plasma electron beam, is described. This source derives its beam current from secondary emission by ion bombardment and gives long life and good performance under poor vacuum conditions. A brief summary is given of its characteristics and of recent developments in its design and control. Chamber designs for use with this electron source are shown, with emphasis on advantages in gas pressures higher than required for most electron beam welding. Descriptions of material welded and specific test results are presented for several materials of interest for large space vehicle construction. Predictions as to further development and application are discussed. (Author)

THE RELEASE OF HYDROGEN ON BALL MILLING CHROMIUM IN WATER.

Alan Arias (NASA, Lewis Research Center, Cleveland, Ohio).

International Journal of Powder Metallurgy, vol. 4, Oct. 1968, p. 7-15. 5 refs.

Study of the reaction which occurs on ball milling chromium in water in gas tight ball mills. The pressure of the hydrogen released was determined as a function of ball milling time. The amount of oxygen reacted with the chromium was calculated, and the nature of the oxide formed by the reaction was determined. From the data so obtained, the thickness of the chromium oxide layer was calculated. G.R.

A FEASIBILITY STUDY OF A TECHNIQUE FOR SORTING PARTICLES BY SHAPE.

Norman S. Land (NASA, Langley Research Center, Environmental Systems Section, Hampton, Va.).

Materials Research and Standards, vol. 9, June 1969, p. 26-29, 77. 6 refs.

Description of a possible sieving method, which, with further research, could be used for sorting particles by shape. A consideration of the basic process involved in sieving indicates that the elongated particle should pass through a sieve at a slower rate than short particles with the same minimum dimension. This basic premise suggests a convenient technique for sorting by shape utilizing standard sieving equipment. Results of experiments with specially prepared particles and with randomly crushed gravel are reported. V.P.M.

EXPERIMENTS IN HYDRODYNAMIC GREASE BEARINGS.

John L. Burch and Peter H. Broussard (NASA, Marshall Space Flight Center, Astrionics Laboratory, Huntsville, Ala.).

American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-836. 11 p. 8 refs.

Members, $1.00; nonmembers, $1.50.

NASA-supported research.

Investigation of the suitability of using hydrodynamic conical- and spherical-shaped spiral-grooved grease bearings as a replacement for gyro ball bearings. It is noted that gyro bearings used in extended space missions should have low friction, be relatively stiff, be capable of multiple starts and stops, and operate in a smooth stable manner without attention for a year or longer. Grease bearings have been built and tested for rotors which vary in diameter from a few centimeters to 30.5 cm and vary in weight from a few grams to 22.7 kg. Speeds ranging from 12,000 to 50,000 rpm have been maintained for hundreds of hours in both air and vacuum environments. Generally, these bearings have operated satisfactorily and retained their lubricant. P.G.

SPACE TOOL STATE-OF-THE-ART, AND CONSIDERATIONS FOR FUTURE SPACE TOOL-EQUIPMENT DESIGN.

Charles C. Kubokawa (NASA, Ames Research Center, Moffett Field, Calif.).

American Astronautical Society and Operations Research Society of America, Joint National Meeting, Denver, Colo., June 17-20, 1969, AAS Paper 69-438. 21 p. 11 refs.

Results of a study to catalog tools and equipment specifically designed for extravehicular and intravehicular activities in space and on the lunar surface. The present state of development of space tools is described. Details of existing equipment and tool designs, their development status, evaluation tests, and specifications are outlined. A total of 97 space tools have been identified and are qualified as new space tools expressly designed and fabricated for space operations. The problems encountered in designing new space tools are discussed, citing a recently developed latch system as an example. It is stressed that consideration should be given to the idea of keeping reusable tools, unused life-support supplies, parts, fuel, and similar materials either in lunar or planetary orbits or on planetary surfaces for future use as logistics-support and safety backup, and to help reduce the payload of future space flights. SPUTTERING OF SOLID LUBRICANTS.

T. Spalvins (NASA, Lewis Research Center, Cleveland, Ohio).

University of Rochester and Bendix Corp., Symposium on the Deposition of Thin Films, 3rd, Rochester, N.Y., Sept. 9, 10, 1969, Paper. 13 p. 5 refs.

Solid film lubricants (Au, molybdenum disulfide, and tungsten disulfide) were deposited by dc triode sputtering on Ni, Ni-Cr, and Nb surfaces. These thin (2000 Å) sputtered films were tested in friction experiments under ultrahigh vacuum conditions to determine their effectiveness as a lubricant. It was found that these films had a low coefficient of friction and displayed exceptionally long endurance lives. The structure and characteristics of the films were

investigated using electron transmission microscopy and electron diffraction techniques. The sputtered Au films were crystalline and the particle size could be measured. The particle sizes for molybdenum disulfide, and tungsten disulfide were smaller than the limit of resolution by the above methods. Accordingly, they would be considered amorphous. (Author)

EXPLOSIVE BONDING OF METAL MATRIX COMPOSITES.
Orvil Y. Reece (NASA, Marshall Space Flight Center, Astronautics Laboratory, Huntsville, Ala.).
IN: AIRCRAFT STRUCTURES AND MATERIALS APPLICATION; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL TECHNICAL CONFERENCE, SEATTLE, WASH., SEPTEMBER 9-11, 1969, PROCEEDINGS. (A69-43416 24-15)
North Hollywood, Calif., Western Periodicals Co. (National SAMPE Technical Conference. Volume 1), 1969, p. 399-415.

High-strength steel wire filaments and modular filament sheets were explosively bonded in metal matrices to form unidirectional filament reinforced composites. The lay-up procedures, explosives used, and problem areas are discussed. Tensile data and photomicrographs of the explosively bonded interfaces are presented.

PERFORMANCE AND ANALYSIS OF SEALS FOR INERTED LUBRICATION SYSTEMS OF TURBINE ENGINES
Robert L. Johnson, William R. Loomis, and Lawrence P. Ludwig Washington Aug. 1968 24 p refs
(NASA-TN-D-4761) Avail: CFSTI CSCL 11A

An inerted lubricating system incorporating a 125-millimeter ball bearing and 6.33-inch(161-mm-) diameter face contact seals was operated for short duration screening runs in a simulated turbine engine sump at speeds to 14,000 rpm and bulk oil temperatures to 500°F. The ball bearings operated satisfactorily to 600°F outer race temperature under a 3280-pound (14,590 N) thrust load with four of the five lubricants evaluated in these short time runs. A peristent problem encountered was wear and leakage of the shaft seals. Additional experimental studies and analysis identified seal thermal deformation as a major factor in seal wear and leakage. New seals, revised to mitigate thermal deformations, were designed, analyzed, and subjected to preliminary experimental studies.

EXPERIMENTS ON THE STABILITY OF WATER LUBRICATED HERRINGBONE-GROOVE JOURNAL BEARINGS. 1: THEORETICAL CONSIDERATIONS AND CLEARANCE EFFECTS
Frederick T. Schuller, David P. Fleming, and William J. Anderson Washington Nov. 1968 30 p refs
(NASA-TN-D-4883) Avail: CFSTI CSCL 13I

Hydrodynamic journal bearing stability tests were conducted with three different herringbone journal configurations. The bearings had a 1.5-inch (3.8-cm) diameter and were tested in water at 80°F (300°K) at speeds to 12,000 rpm, with unit loads to 36.9 psi (25.4×10^4 N/m^2). The stability of herringbone-groove journal bearings was far superior to that of a 100° partial-arc bearing, especially at zero load. No significant differences in the zero load threshold of stability were observed among the three different configurations of herringbone journal bearings tested. Theoretical analysis for herringbone-groove journal bearings predicts a larger range of stable operation than was observed experimentally.

INCOMPRESSIBLY LUBRICATED RAYLEIGH STEP JOURNAL BEARING. 2: INFINITE-LENGTH SOLUTION
Bernard J. Hamrock and William J. Anderson Washington Nov. 1968 28 p refs
(NASA-TN-D-4873) Avail: CFSTI CSCL 13I

A theoretical analysis of pressure distribution, load capacity, attitude angle, and friction force was performed for an eccentric Rayleigh step journal bearing with varying numbers of steps and infinite length. The results indicated that one step placed around the journal was optimal. For small eccentricity ratios the optimal film thickness ratio was 1.7, while there were three optimal ratios of the angle subtended by the ridge to the angle subtended by the pad of 0.4, 0.45, and 0.5. These ratios depend on whether load capacity, or stability, or both load capacity and stability is more important in the application being considered.

INFLUENCE OF SURFACE FILMS ON FRICTION AND DEFORMATION OF SINGLE CRYSTAL AND POLYCRYSTALLINE GOLD
Donald H. Buckley Washington Nov. 1968 23 p refs
(NASA-TN-D-4875) Avail: CFSTI CSCL 11F

Sliding friction experiments were conducted with single crystal and polycrystalline gold with various media present. These

included air, water, hexadecane, and hexadecane with 0.02 weight percent stearic acid; experiments were also conducted with various gold halide films formed on the surface. The alloying of copper with gold was also employed to improve the adsorbability of various media to gold. Results of the investigation indicate that ordinary atmospheric contaminants influenced the friction and deformation of gold. Water will not wet clean gold and thus provides the same friction and deformation behavior as that observed in air. The halides of gold all reduced friction and deformation of gold; the most effective halides were the chlorides for friction and iodides for deformation. The addition of a small concentration of copper to gold improved the ability of an organic acid to lubricate gold. Author

STUDY OF PRETESTING EFFECTS ON ELECTROEXPLOSIVE DEVICES
M. G. Kelly and R. G. Amicone Washington NASA Nov. 1968 70 p refs
(Contract NAS1-6281)
(NASA-CR-1203; F-C1859) Avail: CFSTI CSCL 19A

The answers to a questionnaire sent to various NASA installations and suppliers dealing with the currently used pretesting practices are discussed. The currents used for bridge resistance and continuity checks vary from 20 μ amps to 20 mamps. No-fire and/or "1 amp, 1 watt" pretests are applied by almost all users and suppliers. Voltage breakdown and dielectric strength tests use voltages ranging from 50 to 1400 volts. Electrostatic tests involve voltages of from 9 to 25 KV applied to the EED from a 500 pf capacitor. The no-fire test was judged to be one of the most severe pretests if applied to EEDs intended for actual use. Experiments were performed on EEDs using the results of the questionnaire as a guide. A severe version of the voltage breakdown test was used to condition COMMAND squibs, FOX squibs and MASSEY-1000 igniters. Subsequent tests showed no significant changes in the constant current sensitivity, functioning time, electrostatic sensitivity, and bridgewire power sensitivity due to the conditioning. A technique for the theoretical analysis of pretest effects is presented. Some knowledge of the EED thermal parameters is required for this approach. Author

INFLUENCE OF NUMBER OF OPERABLE SLIP SYSTEMS ON FRICTION CHARACTERISTICS OF SINGLE-CRYSTAL AND POLYCRYSTALLINE MAGNESIUM
Donald H. Buckley Washington Jan. 1968 14 p refs
(NASA-TN-D-4351) Avail: CFSTI CSCL 11F

An investigation was conducted to determine the influences of a change in the number of operable slip systems in magnesium on its friction behavior. Friction experiments were conducted with a hemisphere sliding on a flat disk surface. The load was 50 grams and the sliding velocity was 0.001 centimeter per second. Single crystals of basal and prismatic orientations and polycrystalline magnesium were examined over the temperature range of $-195°$ to 90°C. The results of this investigation indicate that the friction properties of magnesium, like other hexagonal metals, are anisotropic. Friction is lower on the basal than on the prismatic plane by a factor of 2. Multiple slip introduces greater ductility in polycrystalline magnesium and increases the friction. Friction is the lowest for polycrystalline magnesium at those temperatures where basal is the primary deformation slip mechanism. Author

SLIDING FRICTION OF COPPER ALLOYS IN VACUUM
Jane Jellison, Roamer Predmore, and C. L. Staugaitis Washington Nov. 1968 20 p refs
(NASA-TN-D-4824) Avail: CFSTI CSCL 11F

Sliding friction experiments involving copper and Cu-Be alloy plates in contact with copper, Cu-Be alloy, steel and titanium alloy sliders were performed in air and vacuum. Microhardness and metallographic examination of plate and slider interface suggests friction and wear by the adhesive friction mechanism with prow formation. Transfer of strain hardened metal wear debris across the sliding interface was observed. The friction coefficient and the prow size generally increased in vacuum. Author

STABILITY ANALYSIS FOR UNLOADED EXTERNALLY PRESSURIZED GAS-LUBRICATED BEARINGS WITH JOURNAL ROTATION
David P. Fleming, Robert E. Cunningham, and William J. Anderson Washington Dec. 1968 35 p refs
(NASA-TN-D-4934) Avail: CFSTI CSCL 13I

A small eccentricity analysis was performed for a bearing with two feeding planes, each of which is assumed to be a line source. Numerical results were obtained for a range of bearing number, pressure ratio, feeding parameter, and orifice recess volume A digital computer program was written to obtain these results and is included. Steady-state load and attitude angle were obtained, as well as stability data. Stability decreased markedly with increasing recess volume; moreover, for large recess volume and low bearing number, an increase in pressure ratio decreased stability. There was no correlation between stability and steady-state attitude angle for any of the cases studied. Fair agreement was obtained with available experimental data. Author

STUDY, FABRICATION AND TESTING OF A FOIL-BEARING ROTOR SUPPORT SYSTEM
L. Licht and A. Eshel Washington NASA Nov. 1968 233 p refs
(Contract NASw-1456)
(NASA-CR-1157; RR-68-2) Avail: CFSTI CSCL 13I

Tests are conducted in both the vertical and horizontal attitudes, in excess of rated speed, 60,000 rpm, with the foil bearing stable and free from "half-frequency whirl" encountered in conventional gas-lubricated journal bearings. External pressurization is applied briefly to separate the foil surfaces from the journal during the initial and final stages of rotation only, with adequate self-acting support and foil separation established at approximately 6000 rpm. The response of the foil-rotor system to residual unbalance and to impact is studied. The foil-rotor assembly housing is mounted on a vibrator and subjected to excitation normal to the axis of rotation. Measured gap widths and results predicted by theory are compared, and an attempt is made to account for the effects of inertia and compressibility of the fluid, of extensibility and temperature increase of the foil, and of friction of the foil supports. The potential and practicality of gas-lubricated foil bearings for high-speed turbomachines is demonstrated, with the following advantages: (1) Stability (freedom from "half-frequency whirl); (2)

Tolerance of distortion and misalignment, coupled with excellent wipe-wear characteristics; and (3) Ability to accommodate excursions of journals exceeding by an order of magnitude the clearance of rigid-surface gas bearings. Author

JOINING CERAMICS AND GRAPHITE TO OTHER MATERIALS
H. E. Pattee, R. M. Evans, and R. E. Monroe 1968 89 p refs
(NASA-SP-5052) Avail: SOD $1.00 CSCL 13H

In discussing the joining of bulk ceramics to metals and other materials, this report emphasized ceramic-to-metal joining as applied in the electronics industry. However, the techniques developed for joining ceramics to the metals of interest to the electronics industry can usually be applied to other materials as well. Data are summarized on joining ceramics to other materials available from Government and industrial research. Much of the research was prompted by a need to develop joining or sealing techniques for specific applications which are related throughout the report in hope that the information can be applied to applications that are similar or involve unusual materials or service conditions. The sections include: a review of ceramics, metals, and brazing filler metals; joint configurations and surface preparation; the theory of ceramic-to-metal joining; fusion, solid phase, gas-pressure, and solid liquid phase joining; and fusion and nonfusion joining of graphite. THE BOSSLER COUPLING
R. J. Mayerjak and R. B. Bossler, Jr. Washington NASA Jan. 1969 119 p refs
(Contract NASw-1554)
(NASA-CR-1241; KAMAN-R-741) Avail: CFSTI CSCL 13I

A flexible drive-shaft coupling which is suitable for any level of power transmission is reported. This report presents the results of an investigation of the mechanical characteristics of the couplings. The investigation included analyses and tests. Simplified coupling analysis methods, parameter studies, and design guidelines were developed. The test areas include torsion, stiffness, strain, fatigue, constancy of velocity, critical speed, and balancing. The tests substantiated the analyses for predicting internal forces and moments, steady and alternating stress, bending and change-of-length stiffness, critical speeds, and the effects of unbalance. The coupling has unusual capability for accommodating combined axial motion, misalignment, and torque. The coupling can survive shock-torque greatly in excess of ultimate continuous torque and transient misalignments over three times the design continuous operating angle. Author

THE EFFECT OF ORIENTATION AND THE PRESENCE OF SURFACE ACTIVE MATERIALS ON THE FRICTION, DEFORMATION AND WEAR OF ALUMINUM
Donald A. Buckley Washington Jan. 1969 25 p refs
(NASA-TN-D-4994) Avail: CFSTI CSCL 20K

Sliding friction experiments were conducted on single crystal and polycrystalline aluminum surfaces. The influence of the following on friction, deformation and wear were determined: (1) orientation of single crystals and textured polycrystalline sheet, (2) liquid metal embrittlement, (3) surface active organics, and (4) alloying with silver. Results indicate that friction and wear of aluminum is highly anisotropic. With single crystals, friction and wear are sensitive both to atomic plane and crystallographic direction of sliding. The presence of embrittling liquid metals on the surface of aluminum was found to reduce surface deformation during sliding. The presence of organic acids and alcohols were found to increase the deformability of oxidized aluminum surfaces. Author

ROLLING-ELEMENT BEARING LIFE FROM 400° TO 600°F
Edwin V. Zaretsky, William J. Anderson, and Eric N. Bamberger (GE, Cincinnati) Washington Jan. 1969 23 p refs
(NASA-TN-D-5002) Avail: CFSTI CSCL 13I

Rolling-element fatigue tests were conducted with 120-mm bore angular-contact ball bearings made of AISI M-50 steel using a synthetic paraffinic oil at temperatures of 400° to 600°F. Bearing life in this temperature range exceeded AFBMA-predicted (catalog) life by a factor greater than 13. Failure was by classical subsurface rolling-element fatigue. Under simulated conditions EHD minimum film thicknesses ranged from 10 to 5 microinches for temperatures from 400° to 600°F, respectively. Author

BRAYTON-CYCLE TURBOMACHINERY ROLLING-ELEMENT BEARINGS
R. Cohen, H. Means, and P. Heyl Washington NASA Jan. 1969 288 p refs
(Contract NAS3-7635)
(NASA-CR-1229) Avail: CFSTI CSCL 13I

Evaluated were candidate Brayton-cycle turbomachinery configurations incorporating gas bearings. Pratt and Whitney Aircraft has conducted a development effect on a flight-type rolling element rotor support system to provide a backup to the gas bearing approach. This program included the design of two-shaft results of welded specimens. The first two proofmass assemblies to be welded by the laser method were experimental vehicles in the effort to isolate the source of null bias shifts observed on a standard Model 7 instrument after exposure to sterilization temperature. Modifications of the design will be necessary to reduce the constrainment current from approximately 100 ma. Author

HIGH PERFORMANCE TURBOALTERNATOR AND ASSOCIATED HARDWARE. 3. DESIGN OF BACKUP GAS BEARINGS

15 MACHINE ELEMENTS AND PROCESSES

W. Shapiro, J. T. McCabe, T. W. Chu, and V. Castelli Washington NASA Feb. 1969 150 p refs Prepared for Pratt and Whitney Aircraft
(Contract NAS3-6013)
(NASA-CR-1292; F-B2263; PWA-3070-Vol-3) Avail: CFSTI CSCL 13I

A detailed description of a program is presented for the analysis and design of a gas (argon) bearing system for a Brayton cycle turbo-alternator that produces electric power in a space vehicle. Because of the complex nature of the lubrication problem, the analysis was accomplished by numerical methods programmed on a digital computer. For both the thrust and journal bearings, steady-state and dynamic analyses were accomplished. The steady-state results provided parametric performance over a wide range of operating conditions. The more complicated and lengthy dynamic analysis was used to establish the stability of the bearings and bearing-rotor system using geometric variables selected on the basis of steady-state results. Steady-state performance of both the journal and thrust bearings is considered excellent and stability characteristics of the journal bearings are marginal. Author

EXPERIMENTAL AND ANALYTICAL INVESTIGATIONS ON MULTIPLE LIQUID IMPACT EROSION
A. Thiruvengadam and S. L. Rudy Washington NASA Mar. 1969 102 p refs
(Contract NASw-1608)
(NASA-CR-1288; TR-719-1) Avail: CFSTI CSCL 11F

Results are summarized concerning the erosion of 1100-O aluminum and 316 stainless steel. A rotating-disk facility was used to test six specimens simultaneously at three different velocities. High speed and conventional motion pictures with stroboscopic illumination were taken to show the qualitative phenomenon of liquid jet impact. The threshold impact velocity at which erosion was observed after ten million impacts was determined. The threshold water hammer stress on the material corresponding to this threshold velocity was correlated with the high frequency endurance limit corresponding to ten million fatigue cycles using the magnetostriction vibratory apparatus. The ratio between the fatigue endurance limit and the water hammer stress is 1.7 for the aluminum and 3.0 for the stainless steel. A mathematical theory to predict the rate of cavitation erosion as a function of exposure time was extended to multiple liquid impact erosion. The results indicate that the peak rate of erosion varies as the fifth power of the velocity of impact; the observed time of the peak rate varies as the one-fifth power of the impact velocity. Scanning electron microphotographs of specimens eroded both by cavitation and by liquid impingement were compared, and an apparent similarity in the material removal processes further justifies the use of a common theory. FRICTION AND WEAR OF NINE SELECTED POLYMERS WITH VARIOUS FILLERS IN LIQUID HYDROGEN
Donald W. Wisander and Robert L. Johnson Washington Mar. 1969 20 p refs
(NASA-TN-D-5073) Avail: CFSTI CSCL 11I

Experiments were conducted with a 0.1875-inch- (0.476-cm-) radius hemisphere of nine polymers in sliding contact with a rotating 17-4 PH disk in liquid hydrogen. Sliding velocity was 2300 feet per minute (701 m/min) at a load of 1 kilogram. Results indicate that several filled polymers show promise. Graphite-filled polyamide (nylon), graphite filled and glass-fiber-filled polytrifluorochlorethylene (PTFCE), and a 50-percent polytetrafluoroethylene (PTFE)–50-percent polyparaphenyl have friction and wear similar to filled-PTFE composites commonly used in cryogenic applications. LUBRICATION WITH SOME POLYPHENYL ETHERS AND SUPERREFINED MINERAL OILS IN A 600° F (316° C) INERTED VANE PUMP LOOP
William R. Jones, Jr., William F. Hady, and Max A. Swikert Washington Mar. 1969 18 p refs
(NASA-TN-D-5096) Avail: CFSTI CSCL 11H

A vane pump loop was used to determine the lubricating ability as well as thermal and shear degradation of some polyphenyl ethers and superrefined mineral oils. Experimental conditions included 250 psig pump pressure, 425° F (219° C) fluid temperature at the pump inlet, 600° F (316° C) fluid temperature at the heater outlet, 1.73×10^4 m/hr surface velocity and an inert cover gas (nitrogen). Low vane wear was obtained with a 77 centistoke (100° F) (38° C) napthenic mineral oil and two naphthenic-paraffinic blends. Higher wear was obtained with a 15 centistoke (100° F) (38° C) paraffinic mineral oil, a four and a five ring polyphenyl ether, and a modified polyphenyl ether (C-ether). Author

PRELIMINARY INVESTIGATION OF GRAPHITE FLUORIDE $(CF_x)_n$ AS A SOLID LUBRICANT
Robert L. Fusaro and Harold E. Sliney Washington Mar. 1969 20 p refs
(NASA-TN-D-5097) Avail: CFSTI CSCL 11H

Friction and wear life studies were conducted on burnished (rubbed on) films of a potential, new, solid lubricant $(CF_x)_n$. Results were compared with those of similar tests for graphite and MoS_2. The comparisons showed that, at any one specific temperature, the wear lives of $(CF_x)_n$ films exceeded those of graphite or MoS_2. Also, the friction coefficient of $(CF_x)_n$ was less than that of graphite and approximately equal to that of MoS_2. The upper temperature limitation of the $(CF_x)_n$ burnished films is about 400° C. The influence of the fluorine-to-carbon ratio in the compound was investigated and did not seem to be of importance in the range considered (1.12 to 0.7). Author

(NASA-CR-1291; MTI-67TR29; PWA-3070-Vol-2) Avail: CFSTI CSCL 13I

The National Aeronautics and Space Administration is conducting an evaluation of Brayton cycle turbomachinery configurations. As part of this program, a turboalternator incorporating a two stage axial-flow turbine driving an inductor alternator supported on gas bearings has been designed. The gas bearings were designed and successfully tested in a gas bearing dynamic simulator. Testing of the simulator under full electrical load and under certain electrical fault conditions indicated satisfactory operation of the rotor system. Author

PERFORMANCE AND EVALUATION OF TWO LIQUID-METAL PUMPS FOR SODIUM-POTASSIUM SERVICE
Sol H. Gorland, Thomas P. Hecker, and Roy A. Lottig Washington Apr. 1969 16 p refs
(NASA-TM-X-1765) Avail: CFSTI CSCL 13L

Two identical hermetically-sealed motor-driven centrifugal pumps operated for 1483 hours in NaK loops, one at 1150° F

(895 K) and the other at 450° F (505 K). The pumps incorporate NaK-lubricated tilting-pad journal and thrust bearings, and were designed to withstand a nuclear radiation environment. The induction motors were "canned" inside the pump housings to eliminate the need for absolute seals between the pump and the motor. Both pumps operated successfully for the 1483 hours without maintenance. There were no parametric excursions outside the envelopes considered safe for 10,000 or more hours of operation. Author

THE THERMAL STABILITY AND FRICTION OF THE DISULFIDES, DISELENIDES, AND DITELLURIDES OF MOLYBDENUM AND TUNGSTEN IN VACUUM

William A. Brainard Washington Apr. 1969 24 p refs

(NASA-TN-D-5141) Avail: CFSTI CSCL 11F

Thermal stability and friction experiments were conducted with the disulfides, diselenides, and ditellurides of molybdenum and tungsten in ultrahigh vacuum. Weight loss rates were plotted as a function of temperature: thermal dissociation temperatures were observed by mass spectrometry. Friction experiments showed the materials were limited as high temperature lubricants by evaporation, dissociation, and wear. Generally, as lubricants, the diselenides provided the best performance up to 1400° F, whereas the ditellurides provided the poorest because of a low thermal dissociation temperature. Author

SHAFT FACE SEAL WITH SELF-ACTING LIFT AUGMENTATION FOR ADVANCED GAS TURBINE ENGINES

Robert L. Johnson and Lawrence P. Ludwig Washington Apr. 1969 23 p refs

(NASA-TN-D-5170) Avail: CFSTI CSCL 11A

The need in advanced engines for shaft seals with improved pressure, temperature, and speed capabilities is pointed out. In particular, the high speed requirement suggests that the seals must not have rubbing contact. Labyrinth seals have disadvantages in high leakage (efficiency loss) and debris entrainment, and conventional face seals are subject to high wear because face deformation can increase seal closing force and thus cause heavy rubbing contact. It is shown that incorporation of self-acting lift pads to the conventional face seal prevents rubbing contact even though face deformation occurs; feasibility was demonstrated in 560 hours of operation at 100-pound-per-square-inch pressure differential, 600° F gas temperature, and 380-feet-per-second sliding speed. Positive separation of the sealing faces with acceptable leakage rates was obtained. Proposed advanced systems using seals with self-acting lift pads are described. Author

VIBRATION OF SHAFT FACE SEALS AND STABILIZING EFFECT OF VISCOUS AND FRICTION DAMPING

Thomas N. Strom, Lawrence P. Ludwig, and John C. Hudelson Washington Apr. 1969 20 p refs

(NASA-TN-D-5161) Avail: CFSTI CSCL 13I

In inert and reducing environments both at room and elevated temperatures, undamped seals operated with severe vibration which caused early bellows fatigue and high leakage rates of a 1.57 inch (3.99 cm) mean diameter seal operating to speeds of 165 feet per second (50.3 m/sec) at 24 000 rpm. Friction damping by mechanical dampers and the viscous damping by oil in the bellows were both effective in maintaining seal stability. Nosepiece temperatures caused by the sliding contact were high enough to reduce hardness of the mating seal seats. Author

EXPERIMENTAL STUDY OF PUMP AND SEAL CHARACTERISTICS OF HELICAL GROOVE GEOMETRY INCORPORATED IN A COMBINED BEARING AND PUMP

Lawrence P. Ludwig, Thomas N. Strom, and Robert L. Johnson Washington May 1969 27 p refs

(NASA-TN-D-5225) Avail: CFSTI CSCL 13I

Combined bearing and pump rotors with 14.5° and 20° helix grooves were evaluated in a hermetically sealed pump. Oil, water, freon, and mercury were used in the studies at Reynolds numbers (based on clearance) between 2 and 2800. As predicted by theory, the pump pressure rise was linearly related to rotor peripheral velocity at low Reynolds numbers (2 to 12); however, between the investigated Reynolds numbers of 300 to 2800, the pump pressure rise varied with velocity raised to a power between 1.76 and 1.85. Above a Reynolds number of 1000, experimental friction factors were greater than those of other published experimental data. Maximum pump efficiencies were in the range of 2 to 3 percent for operation with water and freon. Torque data indicate that full fluid film lubrication was obtained with oil, water, freon, and mercury. Author

EXPERIMENTS ON POWER LOSS IN HERRINGBONE GROOVED, GAS-LUBRICATED JOURNAL BEARINGS

David P. Fleming, Robert E. Cunningham and William J. Anderson Washington May 1969 22 p refs

(NASA-TN-D-5224) Avail: CFSTI CSCL 13I

Power loss was determined for herringbone journal bearings operating in air to speeds of 60,000 rpm. Power loss (relative to that calculated for a plain bearing of the same dimensions) did not vary widely for the range of geometric variables used. Relative power loss increased with speed and was generally higher than for a plain bearing. The dimensional value of power loss was higher than that in a reference tilting pad bearing at a speed of 38,500 rpm. Author

EFFECT OF OXYGEN CONCENTRATION ON AN ADVANCED ESTER LUBRICANT IN BEARING TESTS AT 400° AND 450°F

Richard J. Parker and Erwin V. Zaretsky Washington Jun. 1969 14 p refs

(NASA-TN-D-5262) Avail: CFSTI CSCL 13I

Tests were run with 20-mm bore angular-contact ball bearings at 400° and 450°F (477 and 505 K) to determine the effects of oxygen concentration on the oxidation of an advanced Type II ester. The bearings were run at 10 600 rpm and 70-pound thrust load. Oxygen content of the gas in the bearing chamber was varied from less than 0.1 percent to approximately 21 percent by volume. Increases in bearing torque, lubricant viscosity, and acid number

were used as indicators of lubricant oxidation and degradation. The advanced ester exhibited less oxidation than did a synthetic paraffinic oil under similar test conditions. A time limitation (induction period) on the effectiveness of the oxidation inhibitor in the ester was indicated. Author

N69-26314*# National Aeronautics and Space Administration. Lewis Research Center, Cleveland, Ohio.
EFFECT OF OXYGEN CONCENTRATION ON THE PERFORMANCE OF SYNTHETIC PARAFFINIC OILS IN SHORT TERM BEARING TESTS FROM 400° TO 500°F
Richard J. Parker and Erwin V. Zaretsky Washington May 1969 18 p refs
(NASA-TN-D-5152) Avail: CFSTI CSCL 13I

The effect of ambient oxygen concentration on the performance of a synthetic parafinic oil with and without an oxidation inhibitor was studied in bearing tests at 400° to 500°F. Bearing torque increase was correlated with increases in lubricant viscosity due to lubricant oxidation. The viscosity and total acid number of the uninhibited oil increased as oxygen concentration increased. The viscosity increases were attributed to bearing operation in the presence of oxygen. Tests with the bearing not rotating produced relatively small increases in viscosity. The oxidation inhibitor significantly reduced oxidation of the oil at 400°F for oxygen concentrations up to 21 percent. Longer term bearing tests at 400°F show a limitation on the effective life (induction period) of the lubricant with the oxidation inhibitor. Author

EXPERIMENTS ON ROTATING EXTERNALLY PRESSURIZED, AIR JOURNAL BEARINGS. PART 1: LOAD CAPACITY AND STIFFNESS
Robert E. Cunningham, David P. Fleming, and William J. Anderson Washington Jun. 1969 17 p refs
(NASA-TND-5191) Avail: CFSTI CSCL 13I

A series of tests was conducted to determine the load and stiffness characteristics of a pair of orifice-compensated, externally pressurized journal bearings. The diameters were a nominal 6.3 cm and the length 9.5 cm. Each bearing was equipped with 12, 0.56-mm diameter orifices. The orifices were arranged in two circumferential planes, six equally spaced in each plane. Results were obtained at an average radial clearance of 0.034 mm over a speed range of 0 to 25,000 rpm. Radial loads were varied up to 189 pounds per bearing or 20.2 psi unit load and air supply pressure ratios from 1.7 to 6. The results of these tests show that load capacity is generally less than that predicted by linearized PH theory or by pressure perturbation theory. Agreement is fair at eccentricity ratios up to 0.1 and at higher supply pressures. A comparison of test results with the two perturbation theories shows that the observed load capacity data agree better with the pressure perturbation theory. Overall load capacity is increased by shaft rotation (self-acting effects). The increase is greatest at the higher eccentricity ratios and lower supply pressures. Experimental data of stiffness as a function of compressibility number are in close agreement with theory at the higher supply pressures. Author

N69-27955*# National Aeronautics and Space Administration. Lewis Research Center, Cleveland, Ohio.
EXPERIMENTS ON THE STABILITY OF WATER LUBRICATED HERRINGBONE-GROOVE JOURNAL BEARINGS. 2: EFFECTS OF CONFIGURATION AND GROOVE TO RIDGE CLEARANCE RATIO
Frederick T. Schuller, David P. Fleming, and William J. Anderson Washington Jun. 1969 24 p refs
(NASA-TN-D-5264) Avail: CFSTI CSCL 13I

Hydrodynamic stability tests in water were performed on six 1.5-in.-(3.8-cm-) diameter herringbone-grooved journals having 10, 20, or 40 full or partial grooves. A maximum speed of 11,500 rpm with stable operation at zero load was attained. The number and length of grooves did not appreciably affect the zero load stability limits of the herringbone-grooved journal bearings. Generally, the herringbone-grooved journals had maximum stability (a maximum fractional frequency whirl onset speed) when the groove to ridge clearance ratio was closest to 2.1 as predicted by incompressible flow theory. Author

EXPERIMENTS ON ROTATING EXTERNALLY PRESSURIZED AIR JOURNAL BEARINGS. 2: ATTITUDE ANGLE AND AIR FLOW
Robert E. Cunningham, David P. Fleming, and William J. Anderson Washington Jun. 1969 15 p refs
(NASA-TN-D-5192) Avail: CFSTI CSCL 13I

Experimental attitude angles and airflow are compared with theory for a pair of 2-1/2-inch (6.3-cm) diameter by 3-3/4-inch (9.5-cm) long externally pressurized air bearings. Attitude angles vary with shaft speed as predicted by small-eccentricity pressure perturbation theory but are generally larger in magnitude. The attitude-eccentricity locus of the journal center for a supply pressure ratio of 1.7 is similar to that of a plain selfacting bearing. Measured airflows were in excellent agreement with calculated values. Shaft speeds varied from 0 to 25,000 rpm, and radial loads varied up to 20.2 psi (139 kN/m^2). The supply pressure range covered was approximately 24 to 88 psia (169 to 610 kN/m^2). Author

A PROCEDURE FOR FURNACE BRAZING BUTT JOINTS IN TUNGSTEN-URANIUM DIOXIDE CERMET CYLINDERS AT 3000°C
Thomas J. Moore and Donald W. Adams Washington Jun. 1969 22 p refs
(NASA-TM-X-1815) Avail: CFSTI CSCL 13H

A procedure was developed to successfully join the longitudinal

seam of a tungsten–uranium dioxide cermet cylinder by furnace brazing. Brazing was done in helium at 3000°C with a tungsten – 25-weight-percent osmium braze alloy. A moderate loss of tensile strength of the cermet parent material at 2500°C occurred due to the brazing cycle. The loss in strength was attributed to increased grain size of the tungsten matrix and possibly to migration of UO_2 along the grain boundaries of the tungsten matrix. Author

METHOD FOR PREDICTION OF PUMP CAVITATION PERFORMANCE FOR VARIOUS LIQUIDS, LIQUID TEMPERATURES, AND ROTATIVE SPEEDS

Robert S. Ruggeri and Royce D. Moore Washington Jun. 1969 33 p refs

(NASA-TN-D-5292) Avail: CFSTI CSCL 13K

A method for predicting the cavitation performance of pumps with various liquids, liquid temperatures, and rotative speeds is presented. Both theoretical and experimental studies used in formulating the method are discussed. Good agreement was obtained in comparisons between experimental and predicted results of cavitation performance for several pumps operated in liquids that exhibit a wide range of physical properties. Use of the method requires that two sets of test data be available for the pump and operating conditions of interest, but these data need not be for the same liquid, temperature, or pump speed. Numerical examples are presented. Author

INVESTIGATION OF TWO-PHASE HYDROGEN FLOW IN PUMP INLET LINE

Donald C. Urasek, Phillip R. Meng, and Robert E. Connelly Washington Jul. 1969 17 p refs

(NASA-TN-D-5258) Avail: CFSTI CSCL 13K

An investigation was conducted to evaluate the vapor- to mixture-volume ratio present in the inlet line of a pump when liquid hydrogen is pumped in a boiling condition from a sealed tank. Both an experimental and an analytical approach were used. The good agreement obtained between the experimental and analytical results indicated that the vapor- to mixture-volume ratio can be predicted with reasonable accuracy. These estimated values of vapor- to mixture-volume ratio, when used with previously reported results, may be useful in predicting pump inducer performance with two-phase flow. Author

RARE EARTH FLUORIDES AND OXIDES: AN EXPLORATORY STUDY OF THEIR USE AS SOLID LUBRICANTS AT TEMPERATURES TO 1800 DEG F (1000 DEG C)

Harold E. Sliney Washington Jul. 1969 25 p refs

(NASA-TN-D-5301) Avail: CFSTI CSCL 11H

Powdered lanthanide trifluorides such as LaF_3 and CeF_3, used as solid lubricants, significantly reduced the wear of Inconel 600 riders in sliding contact with Inconel 750 during lubrication experiments in air and in argon at temperatures up to 1800°F (1000°C). Rare earth oxides were poor lubricants compared to the fluorides. Fluoride powders were good film-formers; they were smeared into adherent film on the wear track by the stresses in the zone of sliding contact. The oxides were not film-formers. It was also shown that fusion-bonded LaF_3 and CeF_3 coatings, containing CaF_2–BaF_2 eutectic or LiF as melting point depressants, have possibilities as solid lubricant coatings. Author

EFFECT OF FLUID TEMPERATURE ON THE CAVITATION PERFORMANCE OF A HIGH HUB-TIP RATIO AXIAL FLOW PUMP IN WATER TO 250 DEGREES F (394 K)

Walter S. Cunnan, George Kovich, and Dean C. Reemsnyder Washington Jul. 1969 32 p refs

(NASA-TN-D-5318) Avail: CFSTI CSCL 13K

An axial flow pump was tested in deaerated water at temperatures to 250°F. Noncavitation performance is independent of fluid temperature in this range. A reduction in the required net positive suction head of 2.0 to 6.0 feet was measured in 250°F water under that in 80°F water at similar operating conditions. This improvement in cavitation performance increases with increasing flow coefficient and decreasing head-rise coefficient ratios. Cavitation formations in the rotor were visually observed and photographed in 80°F water. Slight suction surface cavitation damage occurred near the tip leading edges during the 162 hours of operation. Author

FRICTION AND CONTACT RESISTANCE DURING SLIDING IN VACUUM OF SOME LOW-RESISTIVITY METALS

15 MACHINE ELEMENTS AND PROCESSES

LUBRICATED WITH SPUTTERED MOLYBDENUM DISULFIDE FILMS

John S. Przybyszewski and Talivadis Spaluins Washington Jul. 1969 22 p refs

(NASA-TN-D-5349) Avail: CFSTI CSCL 13I

Thin films of MoS_2 were applied by direct-current sputtering to copper, silver, and beryllium disk specimens and to copper disk specimens ion plated with gold, rhodium, or palladium. Low-speed sliding friction tests in ultrahigh vacuum showed that adherent, low-friction ($0.01 < f < 0.1$) films were obtained on all specimens except oxygen-free high conductivity copper. However, the average dynamic contact resistance was high (> 1 ohm) for all specimens except silver. High resistance peaks were a feature of all specimens throughout the duration of all tests. Author

SPACE MANUFACTURING MACHINE

Hans F. Wuenscher, inventor (to NASA) Filed 28 Apr. 1969 28 p (NASA-Case-MFS-20410; US-Patent-Appl-SN-819599) Avail: CFSTI CSCL 13I

An apparatus or machine for use in the low and zero gravity environment of orbital space flight for various manufacturing operations is described. The apparatus includes a cylindrical tank-like capsule in which manufacturing operations are carried out. An environmental control system is provided for controlling the atmosphere and pressure. High and low frequency coils along with electrostatic field coils are mounted in the capsule for positioning, spinning, transporting, and agitating materials being processed. Heating means are included for the melting of materials, and various probes are provided for adding liquid or gaseous materials to the materials or workpieces being processed. A mixing apparatus is included for preparing and placing mixtures of materials in the capsule for processing. Various equipment is provided for alloying, casting, molding, drawing, blowing, and other manufacturing and processing operations. NASA

EXPERIMENTS ON THE STEADY STATE CHARACTERISTICS OF HERRINGBONE-GROOVED AIR-LUBRICATED JOURNAL BEARINGS

Robert E. Cunningham, David P. Fleming, and William J. Anderson Washington Aug. 1969 28 p refs

(NASA-TN-D-5386) Avail: CFSTI CSCL 13I

Experiments were conducted with five rotors 3.81 cm in diameter and equipped with two herringbone-grooved patterns. Results showed that a range of groove-to ridge-clearance ratios of 2.0 to 2.4 has greater load capacities than do ratios greater or less than this optimum range. Load capacity increases with eccentricity ratio at a rate greater than linear. Agreement with a small-eccentricity pressure perturbation theory was good for groove-to ridge-clearance ratios in this optimum range but only at eccentricity ratios less an 0.3. These rotors were operated under unidirectional loading to a maximum compressibility number of 45. Author

COMPUTER PROGRAM FOR VISCOUS, ISOTHERMAL COMPRESSIBLE FLOW ACROSS A SEALING DAM WITH SMALL TILT ANGLE

John Zuk and Patricia J. Smith Washington Aug. 1969 89 p refs

(NASA-TN-D-5373) Avail: CFSTI CSCL 13I

An analysis of the flow across a sealing dam of the type that appears in gas turbine seals was developed for steady, laminar, subsonic, isothermal compressible flow. The analysis is valid for both parallel sealing dam surfaces and surfaces separated by a small tilt angle. The computer program determines mass flow rate, pressure and velocity distributions, Mach number, force, center of pressure, axial film stiffness rotational flow and pressure flow Reynolds numbers, power loss, and approximate temperature rise resulting from viscous shearing. The output is in both English units and the International System of Units. Some of the results can be automatically plotted. Author

DESIGN OF BRAYTON ROTATING UNIT ON ROLLING-ELEMENT BEARINGS

R. Cohen and J. Clausi Washington NASA Aug. 1969 98 p (Contract NAS3-10949)

(NASA-CR-1401; PWA-3549) Avail: CFSTI CSCL 13I

The National Aeronautics and Space Administration is developing a Brayton-cycle space power system as part of its evaluation of potential long-life nuclear and solar electrical power sources. The candidate Brayton-cycle system under active investigation incorporates a single-shaft rotating unit consisting of a compressor, turbine and alternator rotating on gas bearings. This study was conducted to design such a Brayton rotating unit operating on oil-lubricated rolling-element bearings. Design of the bearing system was based on the technology demonstrated in two 2500-hour endurance tests successfully conducted in previous programs. Therefore, the bearing system design should be capable of development for mission lifetimes in excess of 10,000 hours with no significant oil contamination of the power system. Author

DEVELOPMENT OF A WELD QUALITY MONITOR

J. G. Etzel and J. A. Munford Washington Aug. 1969 11 p refs

(NASA-TN-D-5304) Avail: CFSTI CSCL 13I

Development of a nondestructive method of evaluating crosswire resistance welded joints used in electronic packaging is discussed. Mechanical strength and reproducibility of strength were determined for several alloy combinations. Data indicated that an optimum degree of embedment exists for each combination of materials. This report describes the development of an electromechanical device that automatically measures and displays the embedment of each welded joint and locks out the welding machine if the embedment value is not within preset upper and lower limits. INFLUENCE OF VARIOUS FABRICATION METHODS ON THE COMPRESSIVE STRENGTH OF TITANIUM SKIN-STRINGER PANELS

Richard A. Pride, Dick M. Royster, and James E. Gardner Washington Aug. 1969 44 p refs

(NASA-TN-D-5389) Avail: CFSTI CSCL 20K

Thirty-seven skin stringer panels were fabricated from Ti-8Al-1Mo-1V titanium alloy by riveting, resistance and arc spotwelding, tungsten inert gas and electron beam fusion welding, and diffusion bonding in order to investigate the effect of the various fabrication methods on the compressive strength. Also included in the investigation were two integrally stiffened panels machined from thick plate. The panels were representative of airplane wing or fuselage surfaces. Experimental buckling and maximum loads were determined for each panel. Results of strength tests for

the various joining techniques were compared with each other and with compressive strength calculations. The quality of the joining methods was generally good as evidenced by the behavior of the skin stringer panels in end compression. The joining methods maintained the integrity of the joint through buckling up to the maximum compressive strength of the panels. The maximum strengths of the panels showed good conformity with calculated results obtained from existing compressive strength analyses. Author

TORQUE AND LEAKAGE RATES OF VARIOUS LUBRICATED LIP SEAL DESIGNS AT A PERIPHERAL VELOCITY OF 120 FEET PER SECOND

Lawrence P. Ludwig, Thomas N. Strom, and Robert L. Johnson Washington Sep. 1969 16 p refs

(NASA-TN-D-5411) Avail: CFSTI CSCL 11A

Lip-type shaft seals were run at peripheral velocities representative of requirements in mechanical components for rocket engines. The seals with butyl rubber lips had prominent wear-in torque peaks that were attributed to lip temperature rise and subsequent lip shrinkage (Gow-Joule effect). This effect could cause sudden failure; gradual wear-in, however, reduced failure probability. The seals with glass-filled polytetrafluoroethylene lips also exhibited wear-in torque peaks. The seals with graphite-filled polytetrafluoroethylene lips exhibited low leakage and good wear characteristics. Running torques of the various lip seal types were similar to that of a segmented-carbon shaft seal. For butyl and graphite-filled polytetrafluoroethylene lip seals, the dynamic gas leakage rates were similar to the static leakage rates. Author

LUBRICANTS FOR INERTED LUBRICATION SYSTEMS IN ENGINES FOR ADVANCED AIRCRAFT

William R. Loomis, Dennis P. Townsend, and Robert L. Johnson Washington Sep. 1969 22 p refs

(NASA-TN-D-5420) Avail: CFSTI CSCL 11H

The feasibility of using presently available liquid lubricants in advanced high-speed aircraft engines was studied with both nitrogen inerted recirculating and once-through mist lubrication systems. Three fluids (a mixed ester, a synthetic paraffinic hydrocarbon, and a perfluorinated polymeric fluid) performed satisfactorily with the recirculating system in 3- to 10-hour runs in a full-scale simulated aircraft bearing and seal assembly at outer race bearing temperatures to 700° F (644K) and with a bulk fluid temperature of 500° F (533K). The principal problem was excessive leakage of the oil-side bellows face seal. Only one lubricant (synthetic paraffinic hydrocarbon) performed satisfactorily with the once-through mist system at a bearing temperature of 600° F (589K). Author

INVESTIGATION OF ISOTHERMAL, COMPRESSIBLE FLOW ACROSS A ROTATING SEALING DAM. 1: ANALYSIS

John Zuk and Lawrence P. Ludwig Washington Sep. 1969 36 p refs

(NASA-TN-D-5344) Avail: CFSTI CSCL 11A

The flow across a parallel sealing dam of the type that appears in gas turbine seals is analyzed for steady, laminar, subsonic, isothermal compressible flow with relative rotation of the sealing dam surfaces. Rational effects in velocity profiles pressure profiles, and other physical quantities of interest are found. Conditions are given under which a hydrostatic analysis of the radial pressure flow is a valid approximation. The error in estimating the mass leakage by using the hydrostatic radial flow formula is given. Author

RIGID ROTOR DYNAMICS

Edgar J. Gunter, Jr. and P. De Choudhury Washington NASA Aug. 1969 173 p refs

(Grant NGR-47-005-050)

(NASA-CR-1391) Avail: CFSTI CSCL 13I

The dynamic motion of an unbalanced rigid body rotor in general linearized bearings is analyzed and is applicable to fluid film as well as rolling elements bearings for small bearing displacements. The complete nonlinear dynamical equations of motion, including motor acceleration, are derived by Lagrange's equations to include the influence of damped, flexibly mounted bearing supports. The dynamical equations of motion are linearized by assuming constant angular shaft velocity and shaft displacements, which are small in comparison to the rotor characteristic length. Computer programs to analyze the rotor steady state motion due to unbalance and the stability and complete transient response are presented. As an example, these computer programs are applied to evaluate the characteristics of a NASA experimental hybrid gas bearing rotor system. Author

CAVITATION DAMAGE AND THE EFFECT OF FLUID TEMPERATURE ON THE PERFORMANCE OF AN AXIAL-FLOW PUMP IN LIQUID SODIUM

Walter S. Cunnan and Dean C. Reemsnyder Washington Oct. 1969 25 p refs

(NASA-TN-D-5484) Avail: CFSTI CSCL 13L

An axial flow pump with three different blade materials was tested for 232 hours in liquid sodium at temperatures of 1000° and 1500° F (811° and 1089°K). Noncavitation performance is essentially independent of fluid temperature in this range. A maximum reduction in required net positive suction head of 13 feet (4 m) under that at 1000° F (811°K) was obtained in 1500° F (1089°K) sodium. The reduction increased with increasing flow coefficient, increasing rotative speed, and decreasing head rise coefficient ratio. Severe suction surface cavitation damage occurred near the blade tip leading edges after a 32-hour cavitation damage test. Rene 41 is more resistant to cavitation damage from sodium than either the 316 or 318 stainless steel blades. Cavitation damage increases significantly with rotative speed at constant suction specific speed. Author

15 MACHINE ELEMENTS AND PROCESSES

SPEED EFFECTS ON BALL SPINNING TORQUE

Dennis P. Townsend, Marshall W. Dietrich, and Erwin V. Zaretsky
Washington Nov. 1969 18 p refs
(NASA-TN-D-5527) Avail: CFSTI CSCL 13H

Tests were conducted in the NASA spinning friction apparatus to determine the effect of ball spinning speed on torque and coefficient of spinning friction. Reasonably good agreement was obtained between experimental torque values and theoretical torque predictions using an elastohydrodynamic analysis with a modified pressure-viscosity relation. Spinning torque increased with spinning speed, but the rate of increase was less than predicted from theory. This difference in the rate of increase in torque with speed was attributed to shearing of the lubricant which reduced the lubricant viscosity in the contact ellipse. No correlation was found between experimental and theoretical coefficients of spinning friction using a dry contact friction model. Author

METHODS FOR THE MEASUREMENT OF FREQUENCY AND STABILITY OF LASER GENERATORS IN THE INFRARED.

L. Frenkel (NASA, Electronics Research Center, Cambridge, Mass.) and M. A. Pollack (Bell Telephone Laboratories, Inc., Holmdel, N. J.).

IN: MOGA 68; INTERNATIONAL CONFERENCE ON MICROWAVE AND OPTICAL GENERATION AND AMPLIFICATION, 7TH, HAMBURG, WEST GERMANY, SEPTEMBER 16-20, 1968, PROCEEDINGS [MOGA 68; INTERNATIONALE TAGUNG ÜBER ERZEUGUNG UND VERSTÄRKUNG VON SCHWINGUNGEN IM OPTISCHEN UND MIKROWELLENBEREICH, 7TH, HAMBURG, WEST GERMANY, SEPTEMBER 16-20, 1968, PROCEEDINGS]. [A69-18420 07-09]
Berlin, VDE-Verlag GmbH (Nachrichtentechnische Fachberichte. Volume 35), 1968, p. 757-763. 12 refs.

The frequencies of several laser lines in the far-infrared region have recently been measured. These measurements consist of the mixing of the laser radiation with radiation from either a second precisely known laser line or with the high-order harmonics of a millimeter wave source in a special point-contact mixer. The specific example of the very accurate measurement of the 118.6 μ line is given in detail, and the stability of the beats between the sources is discussed. The extension of these techniques to even higher frequencies is considered. (Author)

IODINE INFRARED LASER.

Hongsuk H. Kim, Roy A. Paananen, Philip L. Hanst (NASA, Electronics Research Center, Cambridge, Mass.), and Thomas F. Deutsch (Raytheon Co., Research Div., Waltham, Mass.).

(Institute of Electrical and Electronics Engineers, International Quantum Electronics Conference, Miami, Fla., May 14-17, 1968, Paper T-5.)
IEEE Journal of Quantum Electronics, vol. QE-4, Nov. 1968, p. 908-911. 7 refs.

CW laser emission, attributed to electronic transitions in the iodine atom, has been obtained at 8 wavelengths between 3.0 and 9.0 μ. The strongest CW lines are at 3.429 and 4.862 μ. One of the weaker CW lines, 5.497 μ, becomes relatively strong when the laser is operated in a pulsed mode. The laser self-pulses under certain operating conditions. The gain on the strong lines is high, and oscillation can be obtained with very little optical feedback. A maximum power output of 325 mW from all the lines has been obtained to date. The power is shifted from line to line by placing a prism or a selective absorber within the cavity. (Author)

A69-19641 *#

WAVELENGTH DEPENDENCE OF LASER-BEAM SCINTILLATION.

Michael W. Fitzmaurice, Jack L. Bufton, and Peter O. Minott (NASA, Goddard Space Flight Center, Greenbelt, Md.).

(Optical Society of America, Spring Meeting, Washington, D.C., Mar. 13-16, 1968.)
Optical Society of America, Journal, vol. 59, Jan. 1969, p. 7-10. 7 refs.

An experiment has been performed to confirm the proportionality between log-amplitude variance and the 7/6 power of wavenumber predicted by Tatarski for horizontal propagation from a spherical-wave transmitter to a point detector. The validity of this proportionality was tested for two wavelengths: 0.632 and 10.6 μ. Beams from a helium-neon and a CO_2 laser were simultaneously transmitted over a folded 1.2-km horizontal path and were detected with a photomultiplier and a gold-doped germanium detector. The primary scintillation statistic (log-amplitude variance) was evaluated for each wavelength with a digital computer, and the ratio of variances at 0.632 and 10.6 μ was found to be in close agreement with predic-

tions. Power spectral density, autocorrelation, and cumulative probability density were also evaluated for each wavelength. Scintillation statistics at 10.6 μ were found to be log normal, as in the visible. (Author)

A69-21088 *
A WAVELENGTH-SELECTIVE, REPETITIVELY PULSED CO_2 LASER.
Philip L. Hanst and John A. Morreal (NASA, Electronics Research Center, Cambridge, Mass.).
Applied Optics, vol. 8, Jan. 1969, p. 109-115. 7 refs.

A CO_2 laser has been constructed and operated with two gas absorption cells built into the cavity. One of the cells contains a gas that controls the wavelength of emission. The other cell contains a gas that forces the laser into a high-frequency pulsed mode of operation. Details of the laser construction are given. The pulsing and wavelength shifting are accounted for by the spectroscopic and kinetic properties of the gases. The proper choice of absorbing gases has produced high-power pulsed operation at various wavelengths between 9.08 and 10.6 μ at repetition rates of up to 100 kHz. Applications and advantages of the wavelength-selective, repetitively pulsed laser are discussed. (Author)

SIMULTANEOUS HCN AND H_2O LASER EMISSION IN MIXTURES CONTAINING H, C, N, AND O.
T. M. Hard, F. A. Haak (NASA, Electronics Research Center, Cambridge, Mass.), and O. M. Stafsudd (California, University, Los Angeles, Calif.).
IEEE Journal of Quantum Electronics, vol. QE-5, Feb. 1969, p. 132.

Observation of simultaneous laser emission at 337 and 118 μ in a pulsed discharge through a mixture of N_2, O_2, and either CH_4 or $(C_2H_5)_2O$. A search for the 469-μ line in $(C_2H_5)_2O$ plus N_2 was unsuccessful. The line is regarded as spurious, in view of air leaks and the observation of simultaneous HCN and H_2O laser emission. F.R.L.

A69-42187 *
OPTICAL PUMPS FOR ORGANIC DYE LASERS.
H. W. Furumoto and H. L. Ceccon (NASA, Electronics Research Center, Cambridge, Mass.).
Applied Optics, vol. 8, Aug. 1969, p. 1613-1623. 28 refs.

Several types of low energy, ultrafast flashlamp systems have been investigated as optical pumps for lasers using fast decaying fluorescent materials, in particular, organic dyes. Of the various systems examined, the coaxial lamp with a spark gap switch proved to be the most useful for pumping the organic dyes. Parameters optimized were the gas type, gas pressure, discharge volume, and electrical circuitry. At optimum operation, the annular volume of the coaxial lamp is completely filled with the discharge and the current rise time is determined mainly by the external circuit inductance. The rapidity and uniformity of the discharge is attributed to photoionization of the gas fill. Current rise times are typically 140 nsec for energies up to 100 J. Because of the photoionization process, these coaxial lamps are considered to be a different class of flashlamps from the standard capillary discharge lamp, the sliding spark lamp, and the ablating wall lamp. Less useful systems that were investigated are described, and the reasons for their deficiencies are analyzed. (Author)

A PROGRAM TO EVALUATE DYE LASERS AS HIGH POWER, PULSED, VISIBLE LIGHT SOURCES
Michael Bass, Thomas Deutsch, and Marvin Weber Washington NASA 11Jul. 1969 81 p refs
(Contract NAS12-635)
(NASA-CR-1374; S-1112) Avail: CFSTI CSCL 20E

Experimental and theoretical efforts to understand dye laser operation are discussed. The approach used by McCumber for treating phonon-terminated lasers was applied to investigate the gain properties of dye lasers and was extended to include effects arising from population buildup in the triplet-level system and associated triplet–triplet absorptive losses. The gain is expressed in terms of time-dependent excited-state populations, spectral emission, and/or absorption functions. For a given optical-pump pulse, a computer program was used to solve rate equations for the populations up to threshold and to calculate the gain as a function of time and frequency. The gain varies with frequency over the broad fluorescence bands characteristic of dye molecules and with time until the threshold for laser action is reached. Experiments using rhodamine 6G verify the predicted dependence of the laser frequency and time of threshold on cavity Q and demonstrate laser frequency tuning by adjusting the opening time of an intracavity Q switch. THE COMPATIBILITY OF MATERIALS.

Walter H. Kohl (NASA, Electronics Research Center, Cambridge, Mass.).

IEEE Spectrum, vol. 6, Jan. 1969, p. 67-74. 40 refs.

The success of space-age endeavors depends greatly upon the materials used to construct a certain module, part, or subsystem, and on the interaction between these materials and their immediate environment. A metal, for example, must retain its physical integrity in shape, ductility, and tensile strength over stringent stress and temperature ranges; it must be able to withstand proximity with other materials, metallic and nonmetallic, while maintaining chemical stability. Nonmetallic materials must be compounded to prevent such reactions as outgassing or decomposition at high altitudes; others, such as ablative ceramics, must disintegrate in a certain manner. The demand for more specialized, more durable substances has created a new materials technology. (Author)

SOLAR ABSORPTANCE AND HEMISPHERICAL EMITTANCE OF VARIOUS METALS AT SPACE CONDITIONS.

John R. Jack (NASA, Lewis Research Center, Environmental Physics Section, Cleveland, Ohio) and Ernie W. Spisz (NASA, Lewis Research Center, Cleveland, Ohio).

American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-60. 8 p. 12 refs.

Members, $1.00; nonmembers, $1.50.

A cyclic incident radiation technique has been used to determine the thermal radiation properties (total hemispherical emittance and normal solar absorptance) of twelve metals over the temperature range from 200 to 560 K. The thermal radiation data for the metals were obtained using the "as received" surface of one-mil-thick foil material with only an alcohol bath to clean the surface. For the temperature range covered, the total hemispherical emittance of the metals increased with increasing temperature, the normal solar absorptance was approximately constant, and the absorptance-emittance ratio decreased with increasing temperature due to the increase in emittance. A comparison is made between the experimental emittance data and the emittance values calculated from electromagnetic relationships to establish whether these theories can be used to predict thermal radiative property data for real metals. Symposium sponsored by the American Institute of Mining, Metallurgical and Petroleum Engineers and NASA.
Edited by I. Machlin, R. T. Begley, and E. D. Weisert.
New York, Plenum Press, 1968, p. 325-372. 144 refs.

The status of columbium alloys is reviewed with respect to major applications, production, cost, and selected properties. Alloys with low to moderate strength and good ductility, and that are readily fabricated and weldable, are commercially available. These alloys were the first of the columbium base alloys to receive serious consideration for use in components on actual flight systems. Emphasis in the development of new columbium alloys over the past several years has been directed toward the achievement of greater creep strength in the 2000 to 2400°F temperature range and more recently, toward improved oxidation resistance in combination with varying levels of strength and ductility. ADVANCED PROCESSING TECHNOLOGY AND HIGH TEMPERATURE MECHANICAL PROPERTIES OF TUNGSTEN BASE ALLOYS (A REVIEW).
H. G. Sell (Westinghouse Electric Corp., Lamp Div., Metals Research Section, Bloomfield, N.J.).
IN: REFRACTORY METAL ALLOYS: METALLURGY AND TECHNOLOGY; PROCEEDINGS OF A SYMPOSIUM ON METALLURGY AND TECHNOLOGY OF REFRACTORY METALS, WASHINGTON, D.C., APRIL 25, 26, 1968. [A69-18790 07-17]
Symposium sponsored by the American Institute of Mining, Metallurgical and Petroleum Engineers and NASA.
Edited by I. Machlin, R. T. Begley, and E. D. Weisert.
New York, Plenum Press, 1968, p. 395-450. 100 refs.

Review of advances in the manufacturing of tungsten-base alloys by powder metallurgy, fusion, and chemical-vapor deposition techniques. The mechanical properties of many alloys are discussed in terms of the effect of alloying on the ductile-brittle transition temperature and on the high-temperature tensile and creep strength. An attempt is made to assess the state of the tungsten-alloy technology, and to determine how successful numerous development efforts have been in achieving high-temperature strength and in improving low-temperature ductility. M.M.

THE LESS COMMON REFRACTORY METALS (RHENIUM, TECHNETIUM, HAFNIUM, NOBLE METALS).
Joseph Maltz (NASA, Washington, D.C.).
IN: REFRACTORY METAL ALLOYS: METALLURGY AND TECHNOLOGY; PROCEEDINGS OF A SYMPOSIUM ON METALLURGY AND TECHNOLOGY OF REFRACTORY METALS, WASHINGTON, D.C., APRIL 25, 26, 1968. [A69-18790 07-17]
Symposium sponsored by the American Institute of Mining, Metallurgical and Petroleum Engineers and NASA.
Edited by I. Machlin, R. T. Begley, and E. D. Weisert.
New York, Plenum Press, 1968, p. 451-488. 78 refs.

Previous reviews of the status of the less-common refractory metals are cited and supplemented with discussions of newer developments. The physical metallurgy of rhenium and of technetium, an artificial element which has only recently become available in sufficient amount for metallurgical studies to be possible, are surveyed. New data on phase equilibria, mechanical and physical properties, and availability are included. Special attention is also given to the roles of hafnium-tantalum alloys and of iridium as oxidation-resistant coatings suitable for special situations. Insofar as the potential usage of the less-common refractory metals in applications which depend upon their high melting point is concerned, high cost and low availability preclude any radical changes in the near future. (Author)

YIELDING AND FRACTURE IN TUNGSTEN AND TUNGSTEN-RHENIUM ALLOYS.
P. L. Raffo (NASA, Lewis Research Center, Cleveland, Ohio).
Journal of the Less-Common Metals, vol. 17, Feb. 1969, p. 133-149. 44 refs.

A study was made of the mechanical properties of vacuum arc-melted tungsten and tungsten-rhenium alloys in the temperature range 77 to 810 K in order to elucidate the mechanism by which rhenium additions lower the ductile-brittle transition temperature of tungsten. The temperature and strain rate dependency of the yield stress of tungsten are reduced by alloying with rhenium, inferring a reduction in the Peierls stress. The reduction in the transition temperature is attributed to the reduced Peierls stress through its effect on the mobility and rate of multiplication of dislocations. (Author)

FIBER-METAL MATRIX COMPOSITES.
John W. Weeton (NASA, Lewis Research Center, Composite Materials Branch, Cleveland, Ohio).
Machine Design, vol. 41, Feb. 20, 1969, p. 142-156. 9 refs.

Discussion of the state of the art of fiber-reinforced metal-matrix materials. The importance of fiber-reinforced metals is based upon using to advantage the high strength of fiber materials by imbedding them into a metallic matrix. Today's fibers have fantastically high strengths. Strength of whiskers of some materials ranges from 3 to 5 x 10^6 psi. Most fiber-metal matrix composites produced thus far have been used for R&D work. The composites are being seriously considered for many of the hot components in gas-turbine engines. Total use of fiber-metal matrix composites in the U.S. in 1968 is estimated at 1000 lb; use in 1969 is expected to be about 10,000 lb; and by 1973, the total will probably approach 500,000 lb. G.R.

A DISLOCATION MODEL PERTAINING TO THE STRENGTH OF ELASTICALLY INHOMOGENEOUS MATERIALS.
Dhanjoo N. Ghista (NASA, Ames Research Center, Moffett Field, Calif.) and William D. Nix (Stanford University, Dept. of Materials Science, Stanford, Calif.).
Materials Science and Engineering, vol. 3, Jan. 1969, p. 293-298. 10 refs.
ARPA-supported research.

Description of a dislocation model of the strength of elastically inhomogeneous crystalline materials which is based on the elastic interactions between dislocations and periodic fluctuations of the shear modulus. The model rests on the assumption that the elastic energy of a dislocation in an inhomogeneous material can be treated as if the shear modulus varies radially from the axis of the dislocation. For simplicity, the shear modulus is assumed to vary according to a Bessel function of the first kind of order either 0 or 1. The variation in the elastic energy of a dislocation with position in an inhomogeneous material is accounted for by a variable phase factor which is included in the argument of the Bessel functions. The model suggests that the critical stress required to initiate plastic flow increases linearly with the amplitude of the shear modulus variation and inversely with the wavelength. The predictions of the model are consistent with some of the findings on the strength of alloys strengthened by spinodal decomposition. (Author)

SUPERPLASTICITY IN TUNGSTEN-RHENIUM ALLOYS.
M. Garfinkle, W. R. Witzke, and W. D. Klopp (NASA, Lewis Research Center, Refractory Metals Section, Cleveland, Ohio).
Metallurgical Society of AIME, Transactions, vol. 245, Feb. 1969, p. 303-308. 21 refs.

The tensile properties of binary W-Re alloys containing up to 33 at. % Re were determined at temperatures from 78 to 3630°F. Elongations as high as 260% were observed in electron-beam-melted

tungsten containing 23 at. % Re when tensile-tested at 3630°F after a 1-hr anneal at 3090°F. All alloys tested under these conditions with rhenium contents between 20 and 28 at. % exhibited elongations of at least 200%. These alloys also showed enhanced grain growth rates. The values of strain-rate sensitivity ranged between 0.2 and 0.3 for the alloys exhibiting high elongations. However, for swaged alloys tested just above the recrystallization temperature, strain-rate sensitivities as high as 0.8 were observed. The high-temperature strengths of the high-rhenium-content alloys were also less than those of alloys with intermediate rhenium contents. (Author)

PROTECTIVE COATINGS FOR CHROMIUM ALLOYS.
Salvatore J. Grisaffe and Robert E. Oldrieve (NASA, Lewis Research Center, Cleveland, Ohio).
American Society for Metals and American Society of Tool and Manufacturing Engineers, Western Metal and Tool Conference and Exposition, Los Angeles, Calif., Mar. 10-14, 1969, Paper. 23 p. 15 refs.

Summary of studies aimed at providing combined protection of chromium alloys against nitrogen embrittlement and air oxidation. Both ductile metal clads and coatings of silicides, aluminides, and noble metals were investigated. The results of furnace air exposures at temperatures to 2400°F show that most systems greatly reduce nitrogen contamination and oxidation attack as compared to the unprotected chromium alloy substrates. However, most systems cause at least partial enbrittlement in themselves by harmful interdiffusion with the substrates. Of the systems studied, iron silicide coatings appeared to cause the least embrittlement while still providing adequate furnace oxidation resistance. At this time, no protection systems appear ready for engine applications. Z. W.

PLANE STRAIN FRACTURE TOUGHNESS TESTS ON TWO-INCH-THICK MARAGING STEEL PLATE AT VARIOUS STRENGTH LEVELS.
J. E. Srawley (NASA, Lewis Research Center, Cleveland, Ohio).
International Conference on Fracture, 2nd, Brighton, Sussex, England, Apr. 13-18, 1969, Paper. 28 p. 19 refs.

Results of tests of 1.8-in.-thick three-point bend and compact (tension) specimens substantiate the current ASTM recommended practice for plane strain fracture toughness (K_{Ic}) testing. Erroneously low results were obtained with 0.5-in. thick bend specimens when the ratio of K_{Ic} to yield strength exceeded 0.45 $in.^{1/2}$, thus emphasizing the importance of requiring minimum specimen dimensions proportional to the square of this ratio. Shallow face grooves in 0.5-in.-thick specimens had no useful effect. The maraging temperatures ranged from 700 to 1100°F, yield strength from 173 to 260 ksi, and K_{Ic} from 67 to 147 ksi-$in.^{1/2}$. The K_{Ic} values were approximately proportional to the reciprocal of the square of yield strength, and also to a strain hardening index derived from the ratio of yield to ultimate tensile strength. STAGE-I INTERSTITIALS IN ELECTRON-IRRADIATED TUNGSTEN.
J. A. DiCarlo (Brookhaven National Laboratory, Upton, N.Y.; NASA, Lewis Research Center, Cleveland, Ohio), C. L. Snead, Jr., and A. N. Goland (Brookhaven National Laboratory, Upton, N.Y.).
Physical Review, 2nd Series, vol. 178, Feb. 15, 1969, p. 1059-1072. 40 refs.
AEC-NASA-supported research.

Single crystals and polycrystalline 5-mil tungsten wires of high purity were irradiated at 20 K with 2.5-MeV electrons. Stage-I defect behavior was studied by internal friction, dynamic Young's modulus, and resistivity measurements. The friction and modulus samples were electrostatically driven at their fundamental flexural mode (~600 Hz). After irradiation, a prominent but transient internal-friction peak was observed at 30 K. Simultaneous resistivity and mechanical-property measurements during isochronal annealing indicate that the friction peak recovers during a major close-pair recovery substage and that long-range interstitial motion occurs between 45 and 100 K. Arguments are presented which identify the stress-induced ordering of the interstitial members of close Frenkel pairs as the source of the 30 K relaxation peak. Single crystal results on relaxation strength vs stress direction suggest that the interstitials are not ⟨111⟩ but most probably are ⟨110⟩ split interstitials. Defect asymmetry and activation energies for reorientation (E_r = 0.066 ± 0.01 eV) and annealing (E_a = 0.11 ± 0.01 eV) are determined for the 30 K process. Internal-friction background increase with heavy irradiation is discussed. (Author)

TUNGSTEN ALLOY FIBER REINFORCED NICKEL BASE ALLOY COMPOSITES FOR HIGH TEMPERATURE TURBOJET ENGINE APPLICATIONS.
D. W. Petrasek and R. A. Signorelli (NASA, Lewis Research Center, Cleveland, Ohio).
American Society for Testing and Materials, Symposium on Composite Testing and Design, New Orleans, La., Feb. 10-14, 1969, Paper. 16 p. 7 refs.

The potential of tungsten-2% thoria, 218 tungsten, and tungsten-1% thoria wire reinforced nickel-base superalloy composites for turbine bucket applications was evaluated based on stress-rupture strength and oxidation and impact resistance. The results indicate that refractory metal alloy fiber-superalloy composites have potential for turbine bucket use based on the properties measured. Composites were produced having stress-rupture properties superior to conventional cast superalloys at use temperatures of 2000 and 2200°F. The 100- and 1000-hr stress-rupture strength of the composite at 2000°F was 49,000 and 37,000 psi, respectively. A few thousands of an inch of matrix or cladding material was found to be sufficient to protect the fibers from oxidation at 2000°F for times up to 300 hr. At 300°F and above the impact resistance of the composite compares favorably with that of superalloys. (Author)

ENGINEERING FRACTURE DESIGN. [A69-33564 17-17]
Edited by Harold Liebowitz.
New York, Academic Press, Inc., 1969, p. 45-68. 26 refs.

The general concept of the K_{Ic} plane strain fracture toughness is reviewed, and the current (tentative) standard procedure for determination of K_{Ic} with crack-notched bend specimens is discussed in detail. The standard procedure constitutes an operational definition of K_{Ic} which is somewhat arbitrary, but no more so than is the definition of offset yield strength. Experimental data for high-strength steels, titanium, and aluminum alloys validate the standard procedure for determination of K_{Ic}, and confirm that it is reasonable to regard K_{Ic} as an inherent material property which controls fracture under conditions of sufficiently high constraint. However, the required specimen dimensions increase in proportion to the square of the ratio of K_{Ic} to yield strength, and impractically large specimens may be required for tough, low-strength materials. The standard test procedure for bend specimens can be adapted to other types of specimens with the aid of information given in an appendix. (Author)

CREEP OF POWDER METALLURGY RHENIUM AT 0.43 TO 0.72 T_m.
Peter L. Raffo and Walter R. Witzke (NASA, Lewis Research Center, Cleveland, Ohio).
Metallurgical Society of AIME, Transactions, vol. 245, Apr. 1969, p. 889, 890. 6 refs.

Description of some exploratory experiments designed to study the creep rate/stress/temperature relation and other facets of the creep of rhenium. The tests were carried out in vacuum in the temperature range from 2200 to 4000°F at stresses ranging from 4 to 20 ksi. The variation of minimum creep rate with stress and temperature is shown for recrystallized unalloyed rhenium, and the stress dependence of the temperature-compensated minimum creep rate for recrystallized unalloyed rhenium is given. G.R.

A STUDY OF ADHESION TO A RHENIUM SURFACE WITH LEED.
Donald H. Buckley (NASA, Lewis Research Center, Cleveland, Ohio).
American Vacuum Society and American Institute of Mining, Metallurgical, and Petroleum Engineers, Vacuum Metallurgy Conference, Pittsburgh, Pa., June 16-19, 1969, Paper. 27 p. 12 refs.

Study, in a LEED apparatus, of the adhesion of a quartz fiber to a rhenium (10$\bar{1}$0) plane. Forces applied to the fiber in contact with the surface as well as those required to separate the solid surfaces were measured. LEED patterns were obtained before and after adhesive contact for both clean surfaces and surfaces with an oxygen layer. Two adsorption structures were seen to develop with the admission of oxygen to the (10$\bar{1}$0) surface of rhenium, a near (2 x 2) structure and also a (1 x 3) structure. Adhesion of the quartz to rhenium occurred in the presence and in the absence of the oxygen layers. On surface separation, brittle fracture of quartz was observed to occur. (Author)

EFFECT OF TEMPERATURE AND PRESSURE ON CAVITATION DAMAGE TO A COBALT BASE ALLOY IN SODIUM.
Stanley G. Young and James R. Johnston (NASA, Lewis Research Center, Cleveland, Ohio).
American Society for Testing and Materials, Annual Meeting, 72nd, Atlantic City, N. J., June 22-26, 1969, Paper. 25 p. 15 refs.

A vibratory apparatus was used to subject the cobalt-base alloy, L-605, to cavitation damage in sodium at 400, 800, and 1200°F. Cover gas pressures were varied from 1 to 4 atm (1 to 4 x 10^5 N/m^2) at each temperature. Increasing pressure increased the cavitation damage at each test temperature. Damage was greatest at the 800°F test temperature for all pressures. A volume loss rate contour diagram was constructed to show cavitation damage in terms of the combined temperature and pressure of the sodium. (Author)

INVESTIGATIONS OF THE UNIQUE MEMORY PROPERTIES OF 55-NITINOL ALLOY.
John E. Cooper, David E. Bowker (NASA, Langley Research Center, Applied Materials and Physics Div., Hampton, Va.), and William B. Cross (Goodyear Aerospace Corp., Akron, Ohio).
IN: MATERIALS AND PROCESSES FOR THE 70'S; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBITION, 15TH, LOS ANGELES, CALIF., APRIL 29-MAY 1, 1969, PROCEEDINGS. (A69-35501 19-15)
North Hollywood, Western Periodicals Co.; Azusa, Calif., Society of Aerospace Material and Process Engineers (Science of Advanced Materials and Process Engineering Proceedings. Volume 15), 1969, p. 265-274. 16 refs.

An analysis is presented of experimental investigations conducted to evaluate certain mechanical properties associated with the unique memory effect of 55-Nitinol alloy. Tests were conducted on 100-, 20-, 15-, and 10-mil-diam wires and 6- and 3-mil-thick foil specimens. The analysis included determination of degree of shape recovery, restoring force, and mechanical work capability as a function of temperature and initial strain levels. Stress-strain and electrical resistivity measurements as a function of temperature are also presented. (Author)

EFFECT OF STRESS RATIO ON FATIGUE-CRACK GROWTH IN 7075-T6 ALUMINUM-ALLOY SHEET.
C. Michael Hudson and Joseph T. Scardina (NASA, Langley Research Center, Hampton, Va.).
(National Symposium on Fracture Mechanics, Lehigh University, Bethlehem, Pa., June 19-21, 1967.)
Engineering Fracture Mechanics, vol. 1, Apr. 1969, p. 429-446. 14 refs.

Results of axial-load fatigue-crack-propagation tests conducted on 12-in.-wide sheet specimens made of 7075-T6 aluminum alloy. These tests were made at stress ratios R (ratio of the minimum stress to the maximum stress) ranging from -1.0 to 0.8 and at maximum stress levels ranging from 5 to 50 ksi to study the effects of stress ratio on fatigue-crack growth. The fatigue-crack-propagation data were analyzed using Paris' stress-intensity analysis (1964). The data from tests at negative R values fell into a relatively narrow scatter band, along with the results from the R equals 0 tests on a plot of rate against stress-intensity range. Apparently, the compression portion of the loading cycle did not significantly affect crack-growth in these tests. The data from tests at different positive stress ratios fell into discrete bands on these plots. These bands varied systematically with R—i.e., the higher the stress ratio at a given range of the stress-intensity factor, the higher the rate of fatigue-crack growth. This spread in rates was small at the lower stress-intensity range, but became progressively larger as the stress-intensity range was increased. Semiempirical equations developed by Forman et al.,

(1966), by Broek and Schijve (1963), and by Paris were fitted to the data from this investigation, using a least-squares fit. Forman's equation gave the best fit to the data. The fracture surfaces of the specimens changed from the normal mode to a shear mode within a reasonably narrow range of crack growth rates for all R values.The stress-intensity range at transition was approximately a constant for tests at negative stress ratios. Forman's equation adequately represented the variation between the stress ratio and the stress-intensity range at positive stress ratios. A.B.K.

MASS DEPENDENCE OF SELF-DIFFUSION IN IRON.
D. Graham (NASA, Lewis Research Center, Cleveland, Ohio).
Journal of Applied Physics, vol. 40, May 1969, p. 2386-2390. 12 refs.

Study of the mass dependence of self-diffusion in iron by serial sectioning in the alpha, gamma, and delta phases of iron. Values for the isotope effect, assuming a single vacancy exchange, are 0.71 ± 0.06 at 1452 C (bcc), 0.79 ± 0.05 at 1338 C (fcc), and 0.69 ± 0.14 at 869 C (bcc). Thus, in each case the isotope effect equals the correlation factor within experimental error. Measurements at 720 and 770 C appear to be influenced by diffusion along grain boundaries, producing a marked reduction in the apparent isotope effect. Z.W.

HOT SALT STRESS CORROSION OF A TITANIUM ALLOY—GENERATION OF HYDROGEN AND ITS EMBRITTLING EFFECT.
H. R. Gray (NASA, Lewis Research Center, Cleveland, Ohio).
Corrosion, vol. 25, Aug. 1969, p. 337-341. 18 refs.

Alloy specimens of Ti-8Al-1Mo-1V were salt-coated and exposed to conditions conducive to hot salt stress corrosion. Subsequent tensile tests revealed that ductility was strain-rate and temperature sensitive. Embrittlement was more pronounced at slow crosshead speeds in the vicinity of ambient temperature. After salt exposure, ductility was restored by vacuum annealing. Substantial increases in hydrogen content were measured in embrittled specimens. These results demonstrate that hydrogen can be generated during elevated temperature exposure to salt, and that the subsequent embrittlement is a manifestation of "slow strain rate" hydrogen embrittlement. NASA PROGRAMS FOR DEVELOPMENT OF HIGH-TEMPERATURE ALLOYS FOR ADVANCED ENGINES.
John C. Freche and Robert W. Hall (NASA, Lewis Research Center, Cleveland, Ohio).
(International Council of the Aeronautical Sciences, Congress, 6th, Munich, West Germany, Sept. 9-13, 1968, Paper 68-26.)
Journal of Aircraft, vol. 6, Sept.-Oct. 1969, p. 424-431. 34 refs.

Description of an extensive program to develop improved materials for advanced air-breathing engines. Considerable progress has been made in several areas. Of most immediate importance is the development of an advanced cast nickel-base alloy, NASA-TRW VI-A. This alloy shows approximately a 50°F (28°C) improvement in temperature over the strongest superalloys currently in use. Even larger improvements over the strengths of currently used superalloys have been achieved in chromium alloys and metal-matrix composite materials. However, many problems remain to be solved before the opportunities indicated by these latter developments can be used in aircraft engines. Foremost among the needs at this time is that for improved oxidation, nitridation, and erosion-resistant coatings to permit use of these stronger materials at temperatures consistent with their strength potential. AN EVALUATION OF COATED MOLYBDENUM AND COLUMBIUM ALLOYS IN HIGH-TEMPERATURE SUPERSONIC AIRSTREAMS
Irvin M. Miller Washington Nov. 1968 32 p refs
(NASA-TN-D-4877) Avail: CFSTI CSCL 11F

An experimental study was made to investigate the oxidation behavior of four commercially coated refractory metal systems in supersonic airstreams: Durak B and Vought IX coated TZM, and Cr-Ti-Si and Cr-$MoSi_2$ coated Cb-752. Cyclic coating life and temperature data were obtained on 0.375-inch-diameter (0.953 cm) blunt-nose models at surface temperatures from 2600° to 3000°F (1700° to 1920°K) and at air stagnation pressures behind the shock wave of 0.03, 0.10, and 5.5 atmospheres. The oxidation behavior of uncoated molybdenum- and columbium-alloy models of the same size and shape was also studied in the same test environments. Coating life of the TZM/Durak B, Cb-752/Cr-Ti-Si, and Cb-752/Cr-$MoSi_2$ systems was significantly lower at air stagnation pressures of 0.10 and 0.03 atmosphere than at 5.5 atmospheres. At these low-pressure conditions, the coating life of these three coating systems did not exceed 32 minutes. The uncoated columbium alloys oxidized catastrophically at air stagnation pressures of 0.10 and 0.03 atmosphere in less than 20 seconds at temperatures well below the melting points of the alloys. FEASIBILITY OF PRODUCING DISPERSION STRENGTHENED CHROMIUM BY BALL-MILLING IN HYDROGEN HALIDES
Alan Arias Washington Nov. 1968 39 p refs
(NASA-TN-D-4912) Avail: CFSTI CSCL 11F

Chromium, with and without 4 volume percent thoria, and nickel powders were ground to fine powder sizes by ball milling in gaseous hydrogen halides. After reducing the milled chromium in flowing hydrogen under pulsating pressure at about 680°C, submicron size powders with 4 to 500 ppm residual halogens were obtained. The compacted chromium-thoria alloys had interparticle spacings ranging from 2.1 to 6.5 micrometers. After 100 hours at 1318° C the interparticle spacing of the 2.1-micrometer alloy increased to 5.2 micrometers. Submicron size chromium and nickel powders were also obtained by pulsating hydrogen reduction of their chlorides. Author

ABSORPTION RATE STICKING PROBABILITIES FOR OXYGEN ON COLUMBIUM AND DILUTE COLUMBIUM-ZIRCONIUM ALLOYS
Charles A. Barrett Washington Nov. 1968 41 p refs
(NASA-TN-D-4885) Avail: CFSTI CSCL 11F

Sticking probabilities for oxygen on columbium and dilute columbium–zirconium alloys were derived from ratios of oxygen absorption rates to their corresponding oxygen fluxes. Oxygen test pressures were varied from 10^{-7} to 10^{-5} torr over temperatures between 1158 and 1373 K. The absorption rates were derived from a pressure-drop technique and fluxes from constant pressure measurements. The kinetics of the reaction are discussed as well as characteristics of the test method. Author

COMPRESSIVE PROPERTIES AND COLUMN EFFICIENCY OF METALS REINFORCED ON THE SURFACE WITH BONDED FILAMENTS

George W. Zender and H. Benson Dexter Washington Nov. 1968 47 p refs

(NASA-TN-D-4878) Avail: CFSTI CSCL 11D

Compressive tests were performed on metal tubes axially reinforced with filaments bonded to the tube outer surface. Sixty-eight magnesium, aluminum, and titanium tubes reinforced with boron or S-glass filaments were tested. The specimens consisted, by volume, of approximately 50 percent metal, 25 percent filament, and 25 percent epoxy resin. Remarkable mechanical properties indicating substantial weight-saving potential for aerospace structures were obtained. Mass-strength comparisons using the experimental results showed the boron-reinforced metals to weigh from 25 to 40 percent of the weight ot titanium for compressive crushing strength and from 40 to 60 percent for column instability. Magnesium or aluminum reinforced with S-glass filaments weighs less than 50 percent of the weight titanium for compressive crushing strength and about 70 percent for column instability. The concept of bonding high-performance filaments to metal structures builds upon the large existing background of fabrication technology for aerospace structures. This advantage along with the potential weight saving indicated by test data suggests important practical application in structural design. Author

CERTAIN PHYSICAL PROPERTIES AND APPLICATIONS OF NITINOL

H. U. Schuerch Washington NASA Nov. 1968 67 p refs

(Contract NAS7-426)

(NASA-CR-1232; ARC-R-280) Avail: CFSTI CSCL 11F

Experimental investigations have been performed on a number of physical properties of the nickel-titanium alloy known as Nitinol. The program was limited to wires and tapes of two specific compositions. Four types of tests were undertaken to characterize some of the thermomechanical memory effects observed in this alloy: (1) Stress-strain, for repeated load applications at constant temperature; (2) Temperature-elongation, for repeated temperature cycles at constant stress level; (3) Temperature-elongation for repeated temperature cycles at discontinuously variable stress levels simulating a thermodynamic power generation cycle; and (4) Differential thermal analysis of unstressed samples for the complete transition temperature range during repeated cooling and heating cycles. Several engineering models demonstrating different applications of Nitinol were designed, fabricated, and tested. Descriptions of the physical properties characterized in the tests and of the various models and devices are presented in the report. Author

THE METALLURGY, BEHAVIOR, AND APPLICATION OF THE 18-PERCENT NICKEL MARAGING STEELS A Survey

A. M. Hall and C. J. Slunder 1968 143 p refs Prepared by Battelle Mem. Inst., Columbus, Ohio

(NASA-SP-5051) Avail: SOD $1.50; CFSTI CSCL 11F

A comprehensive view is presented on the technical status of 18% nickel maraging steels and on the outlook for the future of these materials. Research and development efforts are reviewed in production, mechanical and physical properties, corrosion behavior, physical metallurgy, as well as in forming, joining, and heat treating. Patterns of usage, methods of producing a broad range of mill products, and other applications and uses are also discussed. The purpose of the survey was to provide the research worker, the materials engineer, the process engineer, the designer, and other interested persons information to assist in the selection of these steels for appropriate application and to serve as a point of departure for further study and evaluation of the maraging steels. The majority of the steels reviewed contained additions of cobalt, molybdenum, and titanium. B.P.

REVIEW OF DUCTILIZING OF GROUP VIA ELEMENTS BY RHENIUM AND OTHER SOLUTES

William D. Klopp Washington Dec. 1968 36 p refs

(NASA-TN-D-4955) Avail: CFSTI CSCL 11F

The ductility of Group 6A alloys containing rhenium and other solutes from Groups 7A and 8A was reviewed. The rhenium ductilizing effect, found in Group 6A alloys containing 25 to 35 at. %Re, is promoted by other solutes from Group 7A and the early portions of Group 8A. The hardness minimums and lowered ductile-brittle transition temperatures observed in dilute Mo-Re and W-Re alloys are attributed to solution softening. This phenomenon occurs at low temperatures and is common to many dilute body-centered-cubic alloys containing substitutional solutes. Author

STRAIN RATE SENSITIVITY OF THREE TITANIUM ALLOY SHEET MATERIALS AFTER PROLONGED EXPOSURE AT 550°F (561°K)

Robert M. Baucom Washington Jan. 1969 33 p refs

(NASA-TN-D-4981) Avail: CFSTI CSCL 11F

Results are presented of an investigation of the effects of strain rate on three titanium-alloy sheet materials before and after prolonged exposure without stress at 550°F (561°K). The strain-rate sensitivity of the three alloys, Ti–8Al–1Mo–1V, Ti–4Al–3Mo–1V, and Ti–6Al–4V, was determined from the results of tensile tests performed at three strain rates on smooth and V-notched specimens. Little change in the tensile properties of smooth and V-notched specimens was observed at any given strain rate during accumulated exposure times up to 22,000 hours. This result indicates that the alloys under investigation are apparently stable for the exposures noted. The effect of an increase in strain rate on the tensile properties was generally a moderate increase in strength for each of the alloys. The sensitivity of Ti–8Al–1Mo–1V and Ti–4Al–3Mo–1V to sharp notches tended to decrease with an increase in strain rate. Author

HIGH TEMPERATURE MECHANICAL PROPERTIES OF POLYCRYSTALLINE HAFNIUM CARBIDE AND HAFNIUM CARBIDE CONTAINING 13-VOLUME-PERCENT HAFNIUM DIBORIDE

William A. Sanders and Hubert B. Probst Washington Jan. 1969 23 p refs

(NASA-TN-D-5008) Avail: CFSTI CSCL 11F

Hot pressed, single phase HfC and HfC containing 13-vol % HfB_2 were tested in three point transverse rupture to temperatures as high as 4755°F. Hot hardness tests were also run to 3200°F. Separate effects on the transverse rupture behavior of HfC due to the HfB_2 second phase and due to a grain size difference are discussed on the basis of strength, deformation, and metallographic results. The probable mechanisms responsible for deformation are also discussed. In hot hardness tests of HfC containing 13 vol % HfB_2 second phase, a change in the temperature dependency of hot hardness at 2600°F is discussed and related to the degree of cracking around indentations. ANALYTICAL STUDY OF FLOW REDUCTION DUE TO OXIDATION OF WIRE-FORM POROUS SHEET FOR TRANSPIRATION COOLED TURBINE BLADES
Albert Kaufman Washington Jan. 1969 23 p refs
(NASA-TN-D-5001) Avail: CFSTI CSCL 11F

Cyclic and static oxidation data for wires of N155, Driver-Harris 242, TD nickel-chromium, and Hastelloy X from 1400°F to 2000°F were used to determine flow reduction effects for pore diameters from 10 to 100 micrometers and exposure times up to 600 hours. Analytical results were compared with experimental flow reduction data for oxidized wire-form porous sheets from other investigators. Conclusions were drawn as to the suitability of these materials for transpiration cooling with a metal temperature of 1800°F. Author

HOT-SALT STRESS-CORROSION OF TITANIUM ALLOYS: GENERATION OF HYDROGEN AND ITS EMBRITTLING EFFECT
Hugh R. Gary Washington Jan. 1969 20 p refs
(NASA-TN-D-5000) Avail: CFSTI CSCL 11F

Alloy specimens of Ti-8Al-1Mo-1V were salt coated and exposed to conditions conducive to hot salt stress corrosion. Subsequent tensile tests revealed that ductility was strain-rate and temperature sensitive. Embrittlement was more pronounced at slow crosshead speeds in the vicinity of ambient temperature. After salt exposure, ductility was restored by vacuum annealing. Substantial increases in hydrogen content were measured in embrittled specimens. These results demonstrate that hydrogen can be generated during elevated temperature exposure to salt and that the subsequent embrittlement is a manifestation of the phenomenon of slow-strain-rate hydrogen embrittlement. EXAMINATION OF OXIDE SCALES ON HEAT RESISTING ALLOYS
Salvatore J. Grisaffe and Carl E. Lowell Washington Feb. 1969 44 p refs
(NASA-TN-D-5019) Avail: CFSTI

Twelve iron, nickel, and cobalt heat resisting alloys were cyclic furnace oxidation tested at from 1400° to 2200°F (1033 to 1478 K) for from 4 to 600 hours. Retained oxide scales and spall were identified using X-ray diffraction combined with X-ray fluorescence analyses. Metallography clarified scale growth sequences. After 600 hours at 2000°F (1366 K), the condition most studied, the best oxidation resistance, as reflected by weight change and spall weight, was exhibited by alloys forming single oxide scales of Al_2O_3 or Cr_2O_3. For alloys that developed multioxide scales, spinel constituent composition or lattice parameter did not correlate with oxidation resistance. Author

PROPERTIES OF HIGH EMITTANCE MATERIALS
R. E. Cleary, R. Emanuelson, W. Luoma, and C. Ammann Washington NASA Feb. 1969 139 p refs
(Contract NAS3-4174)
(NASA-CR-1278) Avail: CFSTI CSCL 11F

Results of a four year program to determine the suitability of selected high emittance materials for use as coatings on beryllium, Nb–1Zr, and AISI-310 stainless steels used in space power plant radiators are presented. Materials coated on beryllium included calcium, iron, and zirconium titanate, anodized beryllium, and aluminum oxide–aluminum titanate. Specimens were aged in vacuum at 800°, 1200°, and 1400°F for periods up to 1000 hours. The first three titanates were found to be compatible with beryllium for at least 1000 hours up to 1200°F, but the latter two coatings did not perform well. Long term emittance tests were conducted on calcium and iron titanate coated AISA-310 stainless steel, iron titanate coated Nb–1Zr, and Nb–1Zr coated with aluminum oxide–aluminum titanate. The stainless steel specimens were heated in vacuum to 1350°F for 20,000 hours, and the Nb–1Zr specimens were vacuum tested at 1700°F for 10,000 hours; all were thermally cycled to room temperature once a week. Varying degrees of stable emittance, bond strength, coating structure, and diffusion of coating constituents were found in the specimens as a function of hours tested, temperatures used, and thermal cycling. EXPLORATORY STUDY OF MECHANICAL PROPERTIES AND HEAT TREATMENT OF MOLYBDENUM-HAFNIUM-CARBON ALLOYS
Peter L. Raffo Washington Feb. 1969 44 p refs
(NASA-TN-D-5025) Avail: CFSTI CSCL 11F

A preliminary study was made of the structure and properties of Mo – Hf – C alloys. The compositions of the alloys ranged from 0.09 to 1.83 atomic percent Hf and 0.29 to 1.07 atomic percent C. The mechanical properties of these alloys were measured in the as-swaged, recrystallized, solution-treated, and aged conditions at room temperature and 1500° to 3000°F (1088 to 1922°K). The mechanical properties were compared with data on other molybdenum alloys the literature, and two commercial molybdenum alloys that were evaluated during this program. The Mo – Hf – C alloys show a strength advantage over the other alloys in creep-rupture tests at 2400°F (1588°K) and short-time tensile tests at 3000°F (1922°K). Author

TENSILE PROPERTIES AND CREEP STRENGTH OF THREE ALUMINUM ALLOYS EXPOSED UP TO 25000 HOURS AT 200 DEG TO 400 DEG F (370 DEG TO 480 DEG K)
Dick M. Royster Washington Jan. 1969 44 p refs
(NASA-TN-D-5010) Avail: CFSTI CSCL 11F

The tensile properties and creep strength of three aluminum-alloy sheet materials exposed up to 25000 hours at 200° to 400° F were investigated. The materials investigated were clad 2024–T81, X2020–T6, and clad RR–58 aluminum alloys. These alloys are representative of the types considered for a supersonic transport operating in the Mach 2 speed range. The effect of longtime, elevated-temperature exposures was determined from changes in tensile and notch properties at room temperature. The short-time, elevated-temperature tensile properties as well as the tensile stress required to produce 0.1-percent creep were determined. Metallurgical studies were made to determine micro-structural changes in the alloys due to exposure. With the exception of the X2020–T6 alloy, the material tensile properties were not severely affected by longtime unstressed exposure. The X2020–T6 alloy also exhibited poor notch toughness. Low creep strength in the aluminum alloys at temperatures above 300° F may limit their use for longtime exposures. Author

A METHOD FOR CHARACTERIZING THE SURFACE CLEANLINESS DURING ADHESION TESTING
James H. Bradford, Jr. Washington Mar. 1969 45 p refs
(NASA-TN-D-5055) Avail: CFSTI CSCL 11F

It has been shown that the degree of adhesion of metals depends upon the surface cleanliness. The paper presents a method

that was used to characterize the surface cleanliness of nickel during an adhesion experiment. The change in the work function of the surface as the metal was cleaned was used to indicate the degree of cleanliness. The point at which the work function was stable with additional cleaning was used as the cleanest surface. The cleaning technique was an argon-ion bombardment and heating process. Measurements showed that the maximum adhesion forces occurred when the surfaces were the cleanest. The cleaned surfaces were recontaminated with oxygen and the adhesion force decreased to zero. SOLUBILITY AND DIFFUSION OF OXYGEN IN TANTALUM
M. Parkman, R. Pape, R. McRae, D. Brayton, and L. Reed Washington NASA Feb. 1969 155 p refs
(Contract NAS3-7626)
(NASA-CR-1276; APO-68-1101) Avail: CFSTI CSCL 11F

The solubility of oxygen in tantalum between 600° and 900°C was determined by using a resistivity technique. Carefully reproduced pulses of oxygen were admitted to a high vacuum quartz tube furnace containing a tantalum wire. During each pulse, oxygen was maintained in contact with the specimen for a standard reproduced time after which the oxygen was pumped out and the resistance measured. A plot of change in resistance from the starting value versus number of oxygen charges resulted in a linear curve followed by one or more parabolic curves. The end of the linear section was interpreted to be the phase boundary. Specimens were analyzed by neutron activation to relate change in resistance to oxygen content. Changes in slope of the resistance versus temperature curve for Ta containing between 0.007% and 0.12% oxygen were found at about 450° and 750°C. An anomoly in the curve of resistance versus temperature for oxygen-doped Ta was found at about 900°C. Both of these effects were found in the 2-phase region and appear to be associated with the oxides. Preliminary solubility data were obtained with columbium and Ta–10W alloy. A trial run was made to test a proposed method of measuring diffusion of oxygen in refractory metals. Author

COMPATIBILITY TESTS OF MOLTEN URANIUM WITH TUNGSTEN AND TUNGSTEN—1.5 PERCENT HAFNIUM
Philip D. Takkunen Washington Mar. 1969 32 p refs
(NASA-TN-D-5076) Avail: CFSTI CSCL 11F

Isothermal compatibility tests were conducted on sealed tungsten (W) and tungsten–1.5-weight-percent hafnium (W–1.5Hf) capsules containing uranium (U) for 10 to 200 hours at 1200° and 1500° C. Extensive intergranular attack was observed in wrought W rod and in vapor deposited W. Hafnium appeared to offer some promise in reducing intergranular attack on W. Single crystal W appeared to be compatible with molten U although some evidence of mass transfer attack was found. In addition, U climbed up the sides of the single crystal capsules and attacked grain boundaries in the closure weld. Cracks were formed in all the capsule walls during cooling after U had solidified. Author

SOLUBILITIES OF VANADIUM, TITANIUM, AND ZIRCONIUM IN LIQUID POTASSIUM
Stephan Stecura Washington Mar. 1969 21 p refs
(NASA-TN-D-5093) Avail: CFSTI CSCL 07D

The solubility of vanadium in liquid potassium containing less than 20 wt ppm of oxygen between 1012 and 1341 K is about 6 to 70 wt ppm, respectively. The heat of solution for the vanadium solubility is 21 ± 4 kilocalories per mole (87.9 kJ/mole). Titanium and zirconium solubilities in liquid potassium between 1020 and 1341 K are less than 4 and 10 wt ppm, respectively. Vanadium, titanium, and zirconium solubilities were studied in potassium doped with potassium nitrate (KNO_3). The data suggest that KNO_3 is not a good doping agent for determining the effect of oxygen on the solubilities of transition metals in liquid potassium. Author

FABRICATION OF CERMETS OF URANIUM NITRIDE AND TUNGSTEN OR MOLYBDENUM FROM MIXED POWDERS AND FROM COATED PARTICLES
Philip D. Takkunen Washington Apr. 1969 35 p refs
(NASA-TN-D-5136) Avail: CFSTI CSCL 11B

Cermets containing uranium nitride particles dispersed in a matrix of tungsten or molybdenum were fabricated by cold-pressing and sintering mixed powders and by hot isostatic compaction of metal-coated UN particles. The effects of powder particle size and sintering conditions (time, temperature, and atmosphere) on the microstructure and density of cermets containing 50 volume percent UN were studied. Some sintered cermets were further densified by hot pneumatic impaction. Spherical UN particles coated with W or Mo were consolidated by hot isostatic compaction to produce dense cermets containing from 50 to 70 volume percent UN. Author

DYNAMIC STRAIN AGING DURING THE CREEP AND TENSILE TESTING OF A MOLYBDENUM-TITANIUM-CARBON ALLOY
Peter L. Raffo Washington Apr. 1969 26 p refs
(NASA-TN-D-5169) Avail: CFSTI CSCL 11F

A study was made of the creep and tensile properties of a Mo–0.82 Ti–0.20 C (at. %) alloy in the temperature range 1800° to 3200°F. A peak in the flow stress–temperature curve was noted for this alloy at 1800°F. The strain rate sensitivity of the flow stress was negative in the temperature range 1500° to 2200°F. The creep rate of this alloy above 2400°F has a stress and temperature dependence equal to that of unalloyed molybdenum. At temperatures below about 2400°F, the creep rate at a given stress depends not only on the stress and temperature, but on the entire preloading history. Precipitation occurs on dislocations in specimens crept at 1800°F. It was deduced that the strengthening effects noted during the creep and short time tests are directly related to carbide precipitation during plastic deformation. Precipitation during deformation has two main effects. The first is associated with the decrease in the mobile dislocation density which leads to a greatly decreased creep rate in a constant stress creep test and an increased work hardening rate in a constant strain rate tensile test. Secondly, precipitation during deformation may decrease the rate of recovery. Author

EXPLORATORY STUDY OF SILICIDE, ALUMINIDE, AND BORIDE COATINGS FOR NITRIDATION–OXIDATION PROTECTION OF CHROMIUM ALLOYS
Joseph R. Stephens and William D. Klopp Washington Apr. 1969 28 p refs
(NASA-TN-D-5157) Avail: CFSTI CSCL 11F

Chromium alloys were coated with silicon, aluminum, and boron by pack cementation. None of these simple coatings provided adequate nitridation-oxidation protection for a chromium +0.17 wt % yttrium alloy substrate as shown by a substantial increase in the ductile-brittle transition temperature after air exposure for 100 hr at 2100°F (1420°K). Iron modified silicide coatings afforded good protection, holding the transition temperature of air exposed specimens to 350°F (450°K) compared to 200°F (370°K) for recrystallized uncoated specimens. Additional attractive modifying elements included iron-molybdenum, iron-molybdenum-tungsten, iron-molybdenum-tungsten-titanium, and vanadium-molybdenum-tungsten-titanium. Author

SIGMA PHASE FORMATION AND ITS EFFECT ON STRESS-RUPTURE PROPERTIES OF IN-100
Robert L. Dreshfield and Richard L. Ashbrook Washington Apr. 1969 26 p refs
(NASA-TN-D-5185) Avail: CFSTI CSCL 11F

Three IN-100 compositions, sigma free to very sigma prone, were made by adding aluminum and titanium to one master heat. At 1550°F (843°C), the sigma free alloy had no sigma after 5000 hours; the very sigma prone alloy formed sigma in less than 24 hours. Sigma prone alloys had rupture lives as low as 10 percent of that expected for sigma free alloys in sigma forming, temperature–time realms. Sigma phase had no discernible effect on rupture ductility. The use of time–temperature parameters in sigma forming alloys was analyzed. Author

CREEP-RUPTURE DATA FOR WELDED N-155 TUBES
Richard E. Morris Washington May 1969 31 p refs
(NASA-TN-D-5195) Avail: CFSTI CSCL 11F

Creep rupture pressure tests were conducted to obtain creep deformation and lifetime data for use in the design of a helium-to-air heat exchanger with a 10,000 hour life for nuclear airplane application. Design curves are presented for 2 percent strain, 5 percent strain, and rupture in a graph of stress against Larson-Miller parameter. Creep strength of the tubes was about 2/3 of the sheet strengths given in handbooks. Tube strength was limited by the strength of the weld. Thermally cycled specimens had approximately 10 percent lower strength and higher average equivalent bore strains than specimens tested at constant temperature. Author

LEED STUDIES OF ADHESION TO A RHENIUM SURFACE
Donald H. Buckley Washington May 1969 19 p refs
(NASA-TN-D-5229) Avail: CFSTI CSCL 11A

Adhesion studies were conducted in a LEED apparatus with a quartz fiber contacting a rhenium $(10\bar{1}0)$ plane. Forces applied to the fiber in contact with the surface as well as those required to separate the solid surfaces were measured. LEED patterns were obtained before and after adhesive contact for both clean surfaces and surfaces with an oxygen layer. Adhesion of the quartz to rhenium occurred in the presence of, as well as the absence of, the oxygen layer. On surface separation, brittle fracture of quartz was observed to occur. Two structures were seen to develop with the admission of oxygen to the $(10\bar{1}0)$ surface of rhenium, a near (2×2) structure and also a (1×3) structure. Author

EVALUATION OF TWO NICKEL-BASE ALLOYS, ALLOY 713C AND NASA TAZ-8A, PRODUCED BY EXTRUSION OF PREALLOYED POWDERS
John C. Freche, William J. Waters, and Richard L. Ashbrook Washington May 1969 33 p refs
(NASA-TN-D-5248) Avail: CFSTI CSCL 11F

Prealloyed powders of Alloy 713C and TAZ-8A were made by inert gas atomization and extruded. The powder products were evaluated by tensile and stress rupture tests in the as-extruded and heat-treated conditions. Significant improvements in room temperature and 1200°F (649°C) strength were obtained over the as-cast condition, but lower strengths and superplastic behavior were observed for the extruded powder alloys in the 1800° to 2000°F (982° to 1094°C) temperature range. It was possible to hot form the TAZ-8A powder product at low strain rates and low applied loads. Heat treatments eliminated superplasticity. Author

LEED STUDY OF THE ADHESION OF VARIOUS MATERIALS TO THE (111) SURFACE OF NICKEL
Donald H. Buckley Washington May 1969 23 p refs
(NASA-TN-D-5247) Avail: CFSTI CSCL 11F

Adhesion studies were made with copper, tungsten, oxidized tungsten, and quartz contacting a nickel (111) surface. The copper, tungsten, oxidized tungsten, and quartz were in the form of 1 mm diameter flat ended fibers. Loads of 20 to 150 mg were employed with surface contact times of 10 to 300 sec. The nickel (111) surface was examined before and after adhesion contact with LEED. With clean metals, fracture in tension occurred in the lower cohesive strength material. When copper contacted nickel, a surface alloy formed. The contacting of clean nickel with an oxidized

tungsten surface resulted in oxygen transfer from tungsten to nickel with surface rearrangement. Quartz adhered to nickel with fracture occurring in the quartz on separation of the surfaces. Author

FATIGUE STRENGTH OF ELECTROLYTICALLY BORATED STEEL IN RELATION TO THE CHARACTER OF DISTRIBUTION OF INTERNAL STRESSES

B. G. Gurevich et al 29 Oct. 1968 10 p refs Transl. into ENGLISH from Fiz.-Khim. Mekhan. Materialov, Akad. Nauk Ukr. SSF (Kiev), v. 3, no. 6, 1967 p 693–699

(AD-683990; FTD-MT-24-380-68) Avail: CFSTI CSCL 11/6

Electrolytic coating of steel with boron, which is accompanied by the formation of high-hardness borides in the surface layer of steel, is employed to enhance the wear resistance of machine parts performing under conditions of abrasive wear. Since such machine parts often are exposed to cyclic loads, it was of interest to elucidate the effect of electrolytic boronizing on the fatigue strength of steels. Accordingly, the results of fatigue tests of electrolytically boronized specimens of 38KhS steel are presented. The decrease in fatigue strength after boronizing is due to the boronizing-induced compressive stresses in the boronized layer; these are balanced by high tensile stresses which are chiefly located in an extremely thin layer directly underneath the boronized layer. A PROPOSED MODEL FOR THE EFFECT OF OXIDATION ON THE HIGH-TEMPERATURE DEFORMATION OF NICKEL

James S. Wolf Washington Jun. 1969 71 p refs

(NASA-TN-D-5266) Avail: CFSTI CSCL 11F

The high-temperature deformation of unalloyed nickel is strongly affected by the presence of surface scale layers formed when creep tests are conducted in oxygen. Under applied stresses of 6.90 to 13.79 MN/m^2 (1000 to 2000 psi), the deformation rate of specimens at 1000°C is initially enhanced and later retarded upon their contact with oxygen gas. A phenomenological model of the transient creep process is proposed which accounts for these observations in terms of the self-pressurization and barrier qualities of the scale. A generalization of this model to other materials and to other environments is considered. Author

HIGH TEMPERATURE STRENGTH OF MATERIALS

G. S. Pisarenko, ed., et al, 1969 639 p refs Transl. into ENGLISH of the Book "Prochnost' Materialov Pri Vysokikh Temperaturakh" Kiev, Izd. Naukova Dumka, 1966 Published for NASA and NSF /ts IPST Cat. No. 5141

(NASA-TT-F-508; TT-68-50308) Copyright. Avail: CFSTI CSCL 11F

The results of investigations of the high temperature strength of materials and machine parts are presented. Emphasis is placed on the methods of investigating the physical and mechanical strength and ductility characteristics of a large class of heat resistant materials (mostly high melting) in a wide temperature range (up to 3500°k), under the action of constant and variable thermal and mechanical loads, inducing simple and compound states of stress. The apparatus, machines, stands, and instruments designed for this purpose are also described. The strength characteristics of different materials subjected to static (short and long time), as well as to vibrational loads, are discussed, together with thermal fatigue and thermal shock, including the cyclic action of high temperature gas flow. Elasticity characteristics and the load carrying capacity of machine parts are examined. The problem of measurement accuracy and reiability and the methods of processing test results with the aid of statistical mathematics are considered. Author

EFFECT OF TEMPERATURE AND PRESSURE ON CAVITATION DAMAGE TO A COBALT BASE ALLOY IN SODIUM

Stanley G. Young and James R. Johnston Washington Jun. 1969 22 p refs

(NASA-TN-D-5273) Avail: CFSTI CSCL 11F

A vibratory apparatus was used to subject the cobalt base alloy, L-605, to cavitation damage in sodium at 400°, 800°, and 1200°F. Cover gas pressures were varied from 1 to 4 atmospheres (10 to 40 N/cm^2) at each temperature. Increasing pressure increased the cavitation damage at each test temperature. Damage was greatest at the 800°F test temperature for all pressures. A volume-loss-rate contour diagram was constructed to show cavitation damage in terms of the combined temperature and pressure of the sodium. Author

CORROSION IN A COBALT ALLOY, TWO-PHASE MERCURY LOOP

Alex Vary, Coulson M. Scheuermann, Louis Rosenblum, and Warren H. Lowdermilk Washington Jul. 1969 36 p refs

(NASA-TN-D-5326) Avail: CFSTI CSCL 11F

A two-phase mercury corrosion loop was operated for 1147 hr at a peak liquid temperature of 1075° F (858 K). The loop was constructed of the cobalt-base alloy HS-25 (L-605). The maximum corrosion occurred in the boiler inlet near the point where two-phase flow began and the liquid temperature peaked. The loop results were compared with corrosion capsule tests and other loops of the same alloy. The corrosion markedly exceeded that found in either the reflux capsules or flow-velocity loops operated at the same temperature. Author

A NICKEL BASE ALLOY, WAZ-20, WITH IMPROVED STRENGTH IN THE 2000 DEG TO 2200 DEG F RANGE

William J. Waters and John C. Freche Washington Aug. 1969 23 p refs

(NASA-TN-D-5352) Avail: CFSTI CSCL 11F

A nickel-base alloy based on the nickel–aluminum–tungsten system was developed with high strength in the 2000° to 2200°F (1094° to 1205°C) range. It has a tensile strength of 20,000 psi (137.9 MN/m^2) at 2200°F (1205°C). Application of directional solidification techniques increased intermediate temperature tensile strength and generally increased ductility and stress rupture life. The combination of properties of the alloy suggest that it may have potential for application to stator vanes of advanced gas turbine engines. Author

DYNAMIC STRAIN AGING IN CARBIDE STRENGTHENED MOLYBDENUM ALLOYS
Peter L. Raffo Washington Jul. 1969 19 p refs
(NASA-TN-D-5355) Avail: CFSTI CSCL 11F

A study was made of the dynamic strain aging processes in carbide strengthened molybdenum alloys. Strengthening due to dynamic strain aging was observed in the temperature range 1500° to 2400°F (1088 to 1588 K). The strengthening is believed to arise from the pinning of mobile dislocations by metal-carbon pairs or clusters and/or carbide precipitates. This immobilization of the dislocations led to a high work-hardening rate and the observed strengthening. Author

BURST TESTING OF TUNGSTEN TUBING AT TEMPERATURES FROM 3000 DEG TO 4500 DEG F (1650 DEG TO 2480 DEG C)
Charles A. Gyorgak Washington Jul. 1969 20 p refs
(NASA-TM-X-1843) Avail: CFSTI CSCL 11F

Thin-walled tungsten tubing, 3/8 inch (9.5 mm) or 1/2 inch (12.7 mm) in diameter, produced by three extrusion techniques, by two vapor-deposition processes, or by electroforming in a molten fluoride bath were internally pressurized to failure at temperatures from 3000° to 4500° F (1650° to 2480°C). The burst strength of the majority of the tungsten tubes was equal to or greater than the ultimate tensile strength of wrought tungsten. Test results showed that the tungsten hexachloride vapor-deposition process is capable of producing tubing as strong as wrought tungsten tubing. The failure propagation was intergranular in all tungsten tubes tested. Author

SOLAR ABSORPTANCES AND SPECTRAL REFLECTANCES OF 12 METALS FOR TEMPERATURES RANGING FROM 300 to 500 K
Ernie W. Spisz, Albert J. Weigand, Robert L. Bowman, and John R. Jack Washington Aug. 1969 22 p refs
(NASA-TN-D-5353) Avail: CFSTI CSCL 11F

The solar absorptance of 12 metals (Al, Cu, Au, Mo, Ni, Pt, Ag, stainless steel 304, Ta, Sn, Ti, and V) were determined over the temperature range from 250 to 550 K by two different experimental methods. Direct measurements of solar absorptance were made with a cyclic radiation method using a high intensity carbon arc solar simulator. Indirect measurements of solar absorptance were obtained from spectral reflectance measurements obtained from an integrating sphere reflectometer over the wavelength range from 0.33 to 2.16 μm. The solar absorptance data as obtained from the two different methods as well as the spectral reflectance data are presented for the 12 metals. Author

MECHANICAL PROPERTIES OF ARC-MELTED TUNGSTEN-RHENIUM-HAFNIUM-CARBON ALLOYS
William D. Klopp and Walter R. Witzke Washington Jul. 1969 38 p refs
(NASA-TN-D-5348) Avail: CFSTI CSCL 11F

A study was conducted on the effect of 4 atomic percent rhenium on the mechanical properties of hafnium carbide strengthened tungsten-base alloys. The high temperature strengthening from HfC and improved low temperature bend ductility from the rhenium addition could be combined without detrimental interaction. Maximum strength alloys contained 0.3 to 0.4 mol percent hafnium carbide. The highest tensile strength observed at 3500°F (1927°C) was 75.4 ksi (520 MN/m^2) in the solution annealed and aged condition, while the mean 4t bend transition temperature noted was 200°F (93°C) for as-rolled sheet. EFFECT OF OUTDOOR EXPOSURE AT ELEVATED TEMPERATURE ON THE FATIGUE LIFE OF Ti-8Al-1Mo-1V TITANIUM ALLOY AND AM 350 STAINLESS STEEL SHEET
Edward P. Phillips Washington Jul. 1969 27 p refs
(NASA-TN-D-5362) Avail: CFSTI CSCL 11F

Constant-amplitude bending fatigue tests were conducted outdoors on central-hole (stress concentration factor of 1.6) and fusion-welded sheet specimens of duplex-annealed Ti-8Al-1Mo-1V titanium alloy and cold-rolled and tempered AM 350 stainless steel. The specimens were maintained at 550°F (561°K) during most of the exposure period to approximate the operating environment of a Mach 3 transport aircraft. The heating was interrupted when cyclic loads were applied, any time rain or snow was falling, and for a 4-hour period each night to allow dew to form. A static load was applied continuously for the duration of the tests. For comparison, tests were also conducted indoors at room temperature at the same stress levels. The results indicate that the outdoor test environment reduced the fatigue life of all materials tested. Based on the number of load cycles to produce the first failures, outdoor life was never reduced to less than 1/2 the indoor life; but the median outdoor life of the central-hole AM 350 specimen was reduced to 1/5 the median indoor life. OXIDATION AND THERMAL FATIGUE CRACKING OF NICKEL- AND COBALT-BASE ALLOYS IN A HIGH VELOCITY GAS STREAM
James R. Johnston and Richard L. Ashbrook Washington Aug. 1969 50 p refs
(NASA-TN-D-5376) Avail: CFSTI CSCL 11F

The superalloys IN-100, B-1900, Mar M-200, TAZ8A, Hastelloy X, TD-NiCr, L-605, X-40, Mar M-509A, and WI-52 were cyclically tested for resistance to oxidation in high velocity gas streams for 100 cycles between room temperature and temperatures up to 2000°F. Conventionally cast nickel base alloys were more resistant to weight loss than cast cobalt base alloys, but cast cobalt base alloys were more resistant to thermal fatigue cracking. However, Hastelloy X and directionally solidified and single grain Mar M-200 did not crack even after 100 cycles to 2000°F. Simulated steady state conditions reduced weight loss and incidence of cracking of the six alloys so tested. Author

EFFECT OF STRESS RATIO ON FATIGUE-CRACK GROWTH IN 7075-T6 AND 2024-T3 ALUMINUM-ALLOY SPECIMENS
C. Michael Hudson Washington Aug. 1969 31 p refs
(NASA-TN-D-5390) Avail: CFSTI CSCL 11F

Axial load fatigue crack growth tests were conducted on 12 inch-wide sheet specimens made of 7075-T6 and 2024-T3 aluminum alloy. These tests were made at stress ratios R (ratio of the minimum stress to the maximum stress) ranging from -1.0 to 0.8 and at maximum stress levels ranging from 5 to 50 ksi to study the effects of stress ratio on fatigue crack growth. The experimental results were analyzed by using the stress intensity method. For a given positive stress ratio, the fatigue crack growth rate was a single valued function of the stress intensity range for both 7075-R6 and 2024-T3 aluminum alloys. For $R \geq 0$ the crack growth rates varied systematically with R for both materials; the

higher stress ratios produced higher rates of fatigue crack growth for a given stress intensity range. Fatigue cracks in the 7075-T6 aluminum alloy grew at the same rates in all tests with $R \leq 0$ when the same maximum stress intensity factor was applied. In contrast, fatigue cracks in the 2024-T3 aluminum alloy grew faster in the tests with $R = -1$ than in the tests with $R = 0$ when the same maximum stress intensity factor was applied. Empirical equations previously developed by various investigators were fitted to the experimental data. In general, good correlation was obtained. Author

THE INFLUENCE OF CRACK LENGTH AND THICKNESS IN PLANE STRAIN FRACTURE TOUGHNESS TESTS

Melvin H. Jones and William F. Brown, Jr. Washington Aug. 1969 30 p refs

(NASA-TM-X-1860) Avail: CFSTI CSCL 11F

It is shown that K_{Ic} values determined in accordance with the present ASTM E-24 proposed test method for plane strain fracture toughness of metallic materials can vary moderately within the specimen size and geometric limitations imposed by the test method. The magnitude of these variations will depend on the material properties and would be increased by relaxation of the size requirements. The possibility of employing subsized specimens for screening materials regarding their plane strain fracture toughness was explored as well as several methods for relating these values to unaxial tensile data. TESTING OF HIGH-EMITTANCE COATINGS

R. E. Cleary and C. Ammann Washington NASA Aug. 1969 113 p refs

(Contract NAS3-10609)

(NASA-CR-1413) Avail: CFSTI CSCL 11F

Three coatings were applied to the platinum -20 wt.% rhodium alloy substrate by plasma spraying at a temperature of 1000±50° F. These coatings were hafnium oxide, cerium oxide, and iron titanate. The hafnium oxide was also applied chemically by the vapor deposition process. Initially, emittance testing of the plasma-sprayed coatings for 200 hours at 2100° F in a vacuum of 1×10^{7} torr or better disclosed these values for total hemispherical emittance:hafnium oxide, 0.51 to 0.64, cerium oxide, 0.87 to 0.91; iron titanate, 0.94. The emittance of the chemically vapor deposited hafnia was 0.63 to 0.71. The coatings were aged in air for 1500 hours at 1100°F. They were subsequently tested in vacuum at temperature of about 2100°F. The emittance was cerium oxide, 0.86 to 0.91; iron titanate, 0.90; hafnium oxide, 0.74 to 0.75. The cerium oxide coating was also tested for 2000 hours at 2100° F in a vacuum of 1×10^{-7} torr or better with an emittance of 0.85 to 0.93. Author

CRYOGENIC FRACTURE PROPERTIES OF THIN AISI 301 60-PERCENT COLD-REDUCED SHEET AT VARIOUS ANGLES TO THE ROLLING DIRECTION

Frederick D. Calfo Washington Sep. 1969 25 p refs

(NASA-TN-D-5413) Avail: CFSTI CSCL 11F

Fracture properties at various angles to the rolling direction in 0.022-in (0.056-cm-) thick AISI 301 60-percent cold-reduced stainless-steel sheet were determined. Specimens 3, 6, and 12 in. (7, 6, 15, 2, and 30.5 cm) wide were tested at -423° -320°, and 70°F. A gradual increase in yield and ultimate strengths was noted at all test temperatures as specimen orientation approached the transverse direction. Net fracture strength reductions of as much as 34 percent of the room temperature values were noted at cryogenic temperatures as the orientation of the cracked specimens approached the transverse direction. RECENT DEVELOPMENTS IN CHROMIUM AND CHROMIUM ALLOYS

William D. Klopp Washington Sep. 1969 28 p refs

(NASA-TM-X-1867) Avail: CFSTI CSCL 11F

Recent developments in chromium pertinent to its potential use in advanced jet engines are reviewed. Although chromium has a strength-to-density advantage over nickel, its inherent brittleness and furthe embrittlement by nitrogen during high temperature exposure are serious limitations to its use. Twelve chromium alloys are currently under development, the strongest showing a potential 150° F (83 K) service temperature advantage over nickel-base superalloys. However, a better balance between solution strengthening and precipitate strengthening must be achieved in order to improve the low temperature ductility of these alloys. Improved coatings for protection against nitrogen embrittlement must be developed. Author

HIGH TEMPERATURE OXIDATION PROTECTION OF TUNGSTEN

V. Ye. Ivanov et al Washington NASA Aug. 1969 132 p refs Transl. into ENGLISH of the book "Zashchita Volframa ot Okisleniya pri Vysokikh Temperaturakh" Moscow, "Atom" Press, 1968

(Contract NASw-1692)

(NASA-TT-F-583) Avail: CFSTI CSCL 11F

This book is intended for specialists in the field of high-temperature materials and protective coatings. The book reviews achievements in the field of protection of tungsten and its alloys from high-temperature gaseous corrosion. Particular attention is paid to corrosion- and heat-resisting coatings. The behavior of various coatings, the materials and methods used for their production, as well as the physicochemical mechanism of their formation and protective action are examined. The authors also analyze the possible utilization of tungsten as a high-temperature structural material, the oxidation of tungsten at high temperatures, and recent achievements in the development of refractory and corrosion-resistant tungsten-base alloys. HOT-SALT-STRESS-CORROSION CRACKING AND ITS EFFECT ON TENSILE AND STRESS-RUPTURE PROPERTIES OF Ti-6Al-4V TITANIUM-ALLOY SHEET

Dick M. Royster Washington Sep. 1969 36 p refs

(NASA-TN-D-5417) Avail: CFSTI CSCL 11F

Self-stressed, tensile, and stress-rupture specimens were made from 0.040-inch-thick (1.0 mm) annealed sheet. The self-stressed specimens, with stresses of 25 and 50 ksi (170 and 340 MN/m^2), were sprayed with a 3.4-percent sodium chloride solution and exposed at temperatures from 500° F to 600° F (530 K to 590 K) up to 10,000 hours. Cracking was obtained after approximately 20 hours at 600° F for the 50 ksi stress, but no cracking was noted at 500° F for up to 10,000 hours at either stress. The tensile specimens were salt coated in the same manner as the self-stressed specimens and exposed up to 1600 hours at temperatures from 550° F to 650° F (560 K to 620 K) and 50 ksi stress to develop and grow hot-salt-stress-corrosion cracks. When tested at room temperature, the presence of stress-corrosion cracks resulted in a large reduction in elongation. There was also a large decrease in tensile strength for the specimens exposed at 650° F. The salt-coated stress-rupture specimens were exposed at temperatures from 600° F to 700° F (590 K to 650 K) for stresses of 50 to 100 ksi (340 to 690 MN/m^2) until rupture occurred. A time-temperature parameter analysis was made of both the crack-initiation and stress-rupture data. A difference between the time for crack initiation and the time for stress rupture by a factor on the order of 300 was indicated. Author

STATISTICAL ANALYSIS OF HIGH-TEMPERATURE CREEP-RATE DATA FOR ALLOYS OF TANTALUM, MOLYBDENUM, AND COLUMBIUM
William L. Maag and William F. Mattson Washington Sep. 1969 23 p refs
(NASA-TN-D-5424) Avail: CFSTI CSCL 11F

Empirical creep-rate equations are presented for the refractory-metal alloys T-111, T-222, TZM, TZC, D-43, and Cb-1Zr. These metals are considered potential structural materials for space power systems. The method of least suqares was used to statistically analyze experimental creep data reported by other investigators. The form of the correlating equations is based on the theory that creep rate is a function of material temperature, stress, and structure. The equations cover a temperature range of 1256 to 1922 K (1800° to 3000° F) and a stress range of 3.4×10^6 to 5.5×10^8 Nm^{-2} (500 to 80,000 psi). The variability associated with each correlating equation is expressed in terms of its standard deviation. Author

EVALUATION OF META-BENZENEDISULFONIC ACID AS A STRESS-REDUCING ADDITIVE IN A WATTS NICKEL ELECTROPLATING BATH
J. A. Munford and C. E. Whitfield Washington Sep. 1969 9 p refs
(NASA-TN-D-5188) Avail: CFSTI CSCL 11F

The determination of the internal stress level and deposit hardness of nickel electrodeposited for a Watts-type bath containing controlled quantities of meta-benzenedisulfonic acid are described. The internal stress level was found to be highly sensitive to current density at low concentrations of the additive. As the additive concentration was increased, the stress level increased substantially, passed through a maximum, and then decreased at high concentrations. Deposit hardness was found to be more sensitive to current density than to stress level; no predictable relationship between stress and deposit hardness was observed. Author

EMISSIVITY COATINGS FOR LOW-TEMPERATURE SPACE RADIATORS
G. R. Cunnington, J. R. Grammer, and F. J. Smith Washington NASA Sep. 1969 refs
(Contract NAS3-7630)
(NASA-CR-1420) Avail: CFSTI CSCL 11C

Studies were made on the effects of simulated solar ultraviolet radiation, temperature, and vacuum on the stability of solar absorptance and total hemispherical emittance of seven potential low temperature space power system radiator coatings. A calorimetric in situ technique was used to measure broadband spectral and total absorptance and total hemispherical emittance as a function of time of exposure to an ultraviolet source (xenon lamp) at a 1-sun level. Exposures were for durations varying from 500 to 10,000 hr and a temperatures from 300°K to 533°K. The coatings investigated were titanium dioxide and zinc oxide pigments in methyl silicone binders; zinc oxide, zirconium silicate, and aluminum silicate in potassium silicate binders; and the optical solar relfector. The optical solar reflector was the most stable coating at 150°F; no change in its solar absorptance or total hemispherical emittance was observed during testing. Zinc oxide in potassium silicate showed the greatest stability for the paint type coatings; total hemispherical emittance remained constant and solar absorptance increased 0.06 during 10,000 hr of exposure at 422°K. MECHANICAL BEHAVIOR OF TANTALUM-BASE T-111 ALLOY AT ELEVATED TEMPERATURE
K. D. Sheffler, J. C. Sawyer, and E. A. Steigerwald Washington NASA Sep. 1969 27 p refs
(Contract NAS3-9439)
(NASA-CR-1436; ER-7365) Avail: CFSTI CSCL 11F

The tantalum-base alloy T-111 has been creep tested in an ultrahigh vacuum environment at temperatures and stresses chosen to provide approximately 1 percent creep in times up to 15,000 hours. Design data from five different heats are presented in the form of a Larson Miller plot for 1 percent creep life. Elevated temperature tension test data show a strain aging reaction in the 1400° to 2200° F range which produces unusual transient creep behavior. Values of activation energy and stress exponent suggest that steady state creep of T-111 is governed by a diffusion controlled microcreep mechanism rather than by nonconservative dislocation motion. AN EVALUATION OF THREE OXIDATION-RESISTANT ALLOY CLADDINGS FOR IN 100 AND WI 52 SUPERALLOYS
Michael A. Gedwill Washington Oct. 1969
(NASA-TN-D-5483; E-5011) Avail: CFSTI CSCL 11F

This study demonstrated the feasibility of protecting typical turbine alloys from cyclic furnace oxidation by cladding them with oxidation resistant alloy foils. Foils of Ni-30Cr-1.4Si, Ni-20Cr-4Al-1.2Si, and Fe-25Cr-4Al-1Y were bonded to IN 100 (Ni base) and WI 52 (Co base). Cyclic oxidation exposure to 200 hours was conducted at 1900° and 2000° F (1310 and 1360 K). At 1900° F (1310 K), gravimetric, metallographic, and inter-diffusion analyses showed all three claddings capable of providing excellent protection for both substrates. At 2000°F (1360 K), Ni-30Cr-1.4Si and Fe-25Cr-4Al-1Y provided excellent protection for WI 52, while Ni-20Cr-4Al-1.2Si afforded good protection for IN 100. Author

DISLOCATION STRUCTURES IN SINGLE CRYSTAL TUNGSTEN AND TUNGSTEN ALLOYS
Joseph R. Stevens Washington Oct. 1969 Washington Oct. 1969 21 p refs
(NASA-TN-D-5493; E-5098) Avail: CFSTI CSCL 11F

Deformation of tungsten single crystals as a function of strain, temperature, and alloying was studied by transmission electron microscopy. Unalloyed tungsten, W-1 and 3 percent Re, and W-1 and 3 percent Ta single crystals oriented for (101) [111] slip were deformed in compression at 150°, 300°, and 590°K. Transmission microscopy revealed that the substructure in unalloyed tungsten is similar to substructures in other refractory metals when compared on the basis of homologous temperature. The primary effect of rhenium additions is to produce edge dipolskl homologous temperature. The primary effect of rhenium additions is to produce edge dipoles in the wake of screw dislocations. Tantalum has a lesser effect on dislocation substructure. Author

SOLUBILITIES OF MOLYBDENUM AND TUNGSTEN IN LIQUID POTASSIUM
Stephan Stecura Washington Oct. 1969 14 p refs
(NASA-TN-D-5504) Avail: CFSTI CSCL 11F

A study was made of the solubilities of molybdenum and tungsten in liquid potassium containing less than 15 ppm by weight of oxygen. The solubility of molybdenum at 1040° and 1316°K is about 6 and 13 ppm by weight and that of tungsten at 1055° and 1328°K is about 20 and 130 ppm by weight, respectively. The apparent heats of solutions for molybdenum and tungsten solubilities in liquid potassium are 6.7 ±0.8 and 17.6 ±1.2 kcal/mole (28.0 and 73.7 kJ/mole), respectively. The solubility data for molybdenum are either the true solubility data, or relatively close to the true solubility data, for molybdenum in liquid potassium between 1040° and 1316°K. The solubility data for tungsten in liquid potassium between 1055° and 1328°K suggest that the solubility values might have been influenced by interstitial impurities, particularly by oxygen. Author

RESEARCH ON METALLURGICAL CHARACTERISTICS AND PERFORMANCE OF MATERIALS USED FOR SLIDING ELECTRICAL CONTACTS Summary Report, 1 May 1968 – 30 Apr. 1969
W. H. Abbott and E. S. Bartlett Washington NASA Oct. 1969 61 p refs
(Contract NAS12-657)
(NASA-CR-1447) Avail: CFSTI CSCL 11F

Studies of the friction, wear, and contact resistance stability of nine wrought gold alloys and three electroplated gold systems were made in both N_2-20 O_2 and high vacuum. Sliding durations were 100 cycles in N_2-20 O_2 and 500 cycles in vacuum. Environmental tests were made on each materials system. These consisted of exposure to flowers of sulfur at 30°C, and 1000-hour storage in N_2-20 O_2 at 200°C. Wear test and control specimens exposed in this manner were analyzed by contact resistance measurements and analysis of surface films. All of the wrought gold alloys showed high friction (μ_k = 1.2-2.0) and wear rates in both air and vacuum. No correlation was apparent between wear rates, wear mechanism, and mechanical properties. Differences in wear and friction were attributed almost entirely to differences in surface chemistry or surface energy of the alloy. Contact resistance stability was shown to be closely related to wear mechanism and resistivity. High resistivity and fine wear particles always produced static contact resistance instability and high noise levels. Author

HOT-SALT STRESS-CORROSION OF A TITANIUM ALLOY UNDER A SIMULATED TURBINE-ENGINE COMPRESSOR ENVIRONMENT
Hugh R. Gray and James R. Johnston Washington Oct. 1969 35 p refs
(NASA-TN-D-5510) Avail: CFSTI CSCL 11F

Threshold curves for hot-salt stress-corrosion of the Ti-8Al-1Mo-1V alloy were determined for a variety of exposure conditions that simulated the environment found in a compressor of a gas turbine engine. Specimen surface condition was the most influential variable. Specimens in the as-machined condition exhibited higher threshold stresses than did stress-relieved specimens. High velocity airflow and high air pressure raised the threshold curves for embrittlement slightly, but did not eliminate embrittlement entirely. Salt concentration, air dewpoint, and salt deposition temperature did not significantly shift threshold curves. Longer exposure times lowered threshold stresses. Author

A SURVEY OF THE PHOTODEGRADATION OF ORGANIC POLYMERS EXPOSED TO ULTRAVIOLET RADIATION.

Ronald F. Reinisch and Hermilo R. Gloria (NASA, Ames Research Center, Moffett Field, Calif.).

Solar Energy, vol. 12, Sept. 1968, p. 75-84. 17 refs.

Examination of some of the variables involved in the photodegradation of organic polymers, with special emphasis given to research on the photochemistry of polyvinyl chloride. Attention is focused on those variables that are critical to the successful UV stabilization of polymers, and on a discussion of the nature of the UV absorbing grouping, the wavelength dependence of the photochemical reaction, and the rate-enhancing effect of polychromatic radiation. EFFECT OF GAMMA RADIATION IN VACUUM ON THE TENSILE PROPERTIES OF POLYMER FILMS.

H. L. Price (NASA, Langley Research Center, Hampton, Va.). American Society of Mechanical Engineers, Winter Annual Meeting and Energy Systems Exposition, New York, N. Y., Dec. 1-5, 1968, Paper 68-WA/RP-6. 8 p. 15 refs.

Members, $0.75; nonmembers, $1.50.

The tensile properties of polymer films have been measured in air after the films were exposed to gamma radiation in vacuum. The dose rate was approximately 1.6 Mrads per hour for doses to 2000 Mrads at a pressure of 10^{-6} torr. Four 0.001-in.-thick films were tested: poly(ethylene terephthalate) or PETP; poly(cyclohexylenedimethylene terephthalate) or PCTP; poly(vinylidene fluoride) or PVF_2; and a polyimide or PI. The yield strength, tangent modulus, tensile and elongation at break were obtained from the tensile tests. The average value and standard deviation of each property are given, based on the results of 25 tests at each dose. The data show the effect on the tensile properties of chain scission and cross linking and indicate the useful dose range of the films subjected to ionizing radiation. (Author)

NASA-sponsored research.

The paper includes a review of the cryogenic behavior on several adhesive materials encountered in the fabrication of NASA's liquid hydrogen-liquid oxygen powered Saturn S-IVB stage built by Douglas. It describes some of the materials and techniques known to improve joint strength in cryogenic applications. The results of a recent Douglas cryogenic structural adhesive evaluation program are presented. The ability of the resin system to absorb energy, the inclusion of a selected glass mat in the cured bond line, and the use of ambifunctional silane primers for the improvement of cryogenic joint strengths are discussed. Preliminary results of an evaluation of boron and graphite filaments as possible reinforcements for cryogenic propellant tanks. The composite tensile strength characteristics of glass, boron, and graphite at 297, 77, and 20 K are determined. The composite interlaminar shear strength of these materials and the single-filament strengths of boron are determined at 297 and 77 K. Cyclic tests are performed at 77 and 20 K on cylinders having aluminum foil liners to determine the cyclic life and mode of linear failure of these cylinders. Z.W.

New York, Marcel Dekker, Inc., 1968, p. 73-86. 10 refs.

The effects of stretch temperature, heat-set temperature, and heat-set time on the cryogenic mechanical properties of PET film were studied by using a two-level factorial experiment. Squares of amorphous PET sheet were given a simultaneous biaxial 3X stretch in a laboratory film stretcher at either 85 or 95°C. The levels of heat-set temperature and time investigated were 190 and 210°C and 15 and 120 sec, respectively. Crystallinities of the films were determined by the density-gradient technique. Tensile properties were measured in liquid nitrogen (77 K) and liquid hydrogen (20 K). Biaxial burst properties were obtained in liquid nitrogen. It was found that processing variables significantly affect the stress-strain properties of PET film at cryogenic temperatures. These results and encouraging values of flexibility offer leads for possible use of specially processed PET films for cryogenic space applications. (Author)

New York, Marcel Dekker, Inc., 1968, p. 87-117. 8 refs.
Contract No. NAS 3-6287.

The mechanical properties of four modified-epoxy resin systems were investigated. Tensile properties (including strength, modulus, and elongation), notch toughness, impact strength, the coefficient of linear thermal contraction, and thermal-shock resistance were determined for cast-resin specimens at 75, -320, and -423°F. Interlaminar shear strengths (Naval Ordnance Laboratory horizontal shear and short-span shear) were obtained for glass-filament-wound-composite specimens at the three temperatures. The two systems with the best cryogenic properties were a hybrid-epoxy/polyurethane (resin 4A) and a highly modified bisphenol-A epoxy (resin 2). In choosing the optimum system, the same tests (except for notch toughness, impact strength, and short-span shear) were performed on filament-wound-composite specimens at the three temperatures. In these tests the performance of resin 4A was better than, or at least comparable to, that of resin 2. (Author)

MECHANICAL RELAXATION OF POLY-4-METHYL-PENTENE-1 AT CRYOGENIC TEMPERATURES.
Motowo Takayanagi and Nobuhiro Kawasaki (Kyushu University, Faculty of Engineering, Fukuoka, Japan).
IN: CRYOGENIC PROPERTIES OF POLYMERS; PROCEEDINGS OF THE NASA-CASE CONFERENCE ON THE PROPERTIES OF POLYMERS AT CRYOGENIC TEMPERATURES, NASA LEWIS RESEARCH CENTER AND CASE-WESTERN-RESERVE UNIVERSITY, CLEVELAND, OHIO, APRIL 25-27, 1967. [A69-16485 05-18]
Edited by T. T. Serafini and J. L. Koenig.
New York, Marcel Dekker, Inc., 1968, p. 119-136. 12 refs.

Observation, in the temperature dispersion curve of poly-4-methyl-pentene-1 (P4MP1), of the secondary absorption associated with thermal motion of side chains (β_{sc}). The absorption can be observed as a doublet at about -150 to -160°C (110 cps). By inspecting the absorptions of the various kinds of samples with different crystallinity, including bulk-crystallized and solution-grown crystals, the low-temperature secondary absorption can be separated into the β_{sc}-A absorption associated with the frozen amorphous chains and the β_{sc}-C absorption associated with the defect region within the crystal phase. The effect of crystal transformation, γ-ray irradiation, and annealing of single crystals upon the β absorption was also considered. F.R.L.

IN: CRYOGENIC PROPERTIES OF POLYMERS; PROCEEDINGS OF THE NASA-CASE CONFERENCE ON THE PROPERTIES OF POLYMERS AT CRYOGENIC TEMPERATURES, NASA LEWIS RESEARCH CENTER AND CASE-WESTERN-RESERVE UNIVERSITY, CLEVELAND, OHIO, APRIL 25-27, 1967. [A69-16485 05-18]
Edited by T. T. Serafini and J. L. Koenig.
New York, Marcel Dekker, Inc., 1968, p. 155-169. 32 refs.

The mechanical behavior of poly(ethylene terephthalate) (PET) was studied at temperatures from 4 to 300 K with a free oscillating torsion pendulum and an Instron tester. Torsion pendulum data show the presence of relaxation maxima below 80 K. Noncrystalline specimens show a small peak at 48 K (δ) and a shoulder at 8 to 12 K (ϵ). A peak at 20 K is observed in crystalline samples, both oriented and unoriented. In addition drawn specimens show a pronounced peak at 48 K and the asymmetric maximum in the 100 to 240-K region is split into two peaks. The logarithmic decrement in the β-loss region decreases with increasing crystallinity and orientation, while the cryogenic loss peaks increase in intensity. Tensile tests with biaxially oriented and heat-set films show a twofold increase in elastic modulus and a tenfold increase in toughness at cryogenic temperatures when compared with "amorphous" PET. Contract No. NASr-49(15).

The results of a comprehensive NASA-sponsored ablation test program, which was managed by Stanford Research Institute and monitored by Ames Research Center, NASA, are presented. Detailed measurements of mass loss rates (total and pyrolysis) and temperature (surface and internal) were obtained for a number of ablation materials in twelve arc-heated wind tunnels over a wide range in convective heating rate (50 to 3300 Btu/ft^2 sec), stagnation point pressure (0.004 to 30 atm), and stream enthalpy (1700 to 34,000 Btu/lb). The materials evaluated, which are considered to be representative of current heat shield formulations, included Teflon, phenolic-nylon (one high-density and two low-density versions), two formulations of silicone elastomer, and an epoxy-novolac in a fiberglass honeycomb. Test stream centerline calibration data are compared for the participating facilities, and some radial profiles of heating rate are shown to illustrate the uniformity of the air environments. Correlations of the mass loss and temperature measurements, in terms of measured environmental parameters, are suggested by dimensional analysis and evaluated by a regression program. The influence of model scale, heating rate, and pressure level are considered and comparisons are made with existing data. Delineation and discussion of the differences in the ablative response of the various materials are emphasized. (Author)

Compression molding processes for three molecular forms of Pyrrone salt-like intermediate molding powders. Three different procedures were investigated to compression mold the Pyrrones. The one-pressure procedure, in which a pressure of 6,500 psi was applied at room temperature and a 450°F curve temperature was used, was not satisfactory. A modified one-pressure procedure, in which the die was charged with previously heated powder and the pressure was applied at 500°F, permitted small moldings to be made at 700°F. A two-pressure molding procedure was used successfully to mold both small and large disks. The results of this investigation show that the critical factor in molding the Pyrrones is the elimination of volatiles. G.R.

Description of a program initiated to evaluate the high-melting-point, high-density, ceramic oxides as white thermal control coating pigments. A new testing facility was available for the program, and

efforts were made concurrent with coating studies to identify better methods of conducting environmental tests. In the coating studies, a major effort was undertaken to characterize the pigments in terms of purity, particle size, and microstructure. During the early ultraviolet exposure test, new information was obtained that indicated important influence of impurities lower than 20 ppm. The activity in environmental testing was to more nearly simulate the solar wind outside the earth's magnetosphere. To this end, thermal electrons were added to the proton beam, thereby evaluating equal number and combinations of protons and electrons. The paper documents the material characterization, environmental influence of neutral beams, measurement of UV damage using X-ray diffraction, theoretical influences of impurities in UV stability, and the results of synthesis and evaluation activities. IN: MATERIALS AND PROCESSES FOR THE 70'S; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBITION, 15TH, LOS ANGELES, CALIF., APRIL 29-MAY 1, 1969, PROCEEDINGS. (A69-35501 19-15)
North Hollywood, Western Periodicals Co.; Azusa, Calif., Society of Aerospace Material and Process Engineers (Science of Advanced Materials and Process Engineering Proceedings. Volume 15), 1969, p. 249-256. 7 refs.

Graphite fibers were fabricated into NOL rings and biaxial-wound cylinders. Filament tensile strengths of NOL rings were determined at 75, -320, and -423 deg F. Comparisons were made of ambient temperature fiber tensile strengths as obtained from NOL rings, strand tests, and biaxially wound cylinders. Fatigue characteristics of internally pressurized cylinders were determined at 75 and -320 deg F. Fatigue comparisons are made of graphite and glass filament-wound cylinders on the basis of specific strength. (Author)

RADIATION STABILITY OF UNFILLED PYRRONE MOLDINGS.
Howard L. Price and Vernon L. Bell (NASA, Langley Research Center, Hampton, Va.).
IN: MATERIALS AND PROCESSES FOR THE 70'S; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBITION, 15TH, LOS ANGELES, CALIF., APRIL 29-MAY 1, 1969, PROCEEDINGS. (A69-35501 19-15)
North Hollywood, Western Periodicals Co.; Azusa, Calif., Society of Aerospace Material and Process Engineers (Science of Advanced Materials and Process Engineering Proceedings. Volume 15), 1969, p. 335-347. 9 refs.

An investigation has been made of the stability of unfilled pyrrone moldings to electron irradiation in air. Previous radiation data have shown that pyrrone films made with pyromellitic dianhydride retained their mechanical properties after doses up to 50,000 Mrads. The present investigation included preparing the molding powder from benzophenone tetracarboxylic acid dianhydride and diaminobenzidine in either dimethylacetamide or ethylene glycol. A workable (but not necessarily optimum) molding procedure was developed to form the powder into parts suitable for mechanical testing. The molded parts were cut into test specimens for flexural tests at elevated temperatures to 600 deg F (582 deg K) and, after exposure to electron radiation in air, to doses of 50,000 Mrads (5×10^{10} rad). ABLATIVE THERMAL PROTECTION AT LOW HEATING RATES.
Ronald B. Pope, Salvatore R. Riccitiello, Howard E. Goldstein, and John A. Parker (NASA, Ames Research Center, Moffett Field, Calif.).
IN: MATERIALS AND PROCESSES FOR THE 70'S; SOCIETY OF AEROSPACE MATERIAL AND PROCESS ENGINEERS, NATIONAL SYMPOSIUM AND EXHIBITION, 15TH, LOS ANGELES, CALIF., APRIL 29-MAY 1, 1969, PROCEEDINGS. (A69-35501 19-15)
North Hollywood, Western Periodicals Co.; Azusa, Calif., Society of Aerospace Material and Process Engineers (Science of Advanced Materials and Process Engineering Proceedings. Volume 15), 1969, p. 421-434. 12 refs.

Evaluation of ablative materials for thermal protection at low heating rates is discussed. Initially, 21 different materials with densities between 225 and 2200 kg/cu m were evaluated by performing convective heating tests in arc-heated nitrogen streams and observing the backface temperature rise and surface recession. Modified polyurethane foam composite with a density of 54 kg/cu m, which has characteristics desirable for ablative thermal protection, was developed. The ablative performance of the foam was evaluated, and excellent insulative performance was demonstrated. Ablative performance of the foam materials is compared with the performance of state-of-the-art materials and with analytical predictions. (Author)

DETECTION AND MINIMIZATION OF CHEMICALLY INDUCED IGNITION HAZARDS OF GLYCOL FLUIDS.
W. R. Downs (NASA, Manned Spacecraft Center, Houston, Tex.) and David B. Boies (IIT Research Institute, Chicago, Ill.).
IN: ANNALS OF ASSURANCE SCIENCES; PROCEEDINGS OF THE EIGHTH RELIABILITY AND MAINTAINABILITY CONFERENCE, DENVER, COLO., JULY 7-9, 1969. (A69-35999 19-15)
Conference sponsored by the American Institute of Aeronautics and Astronautics, the Society of Automotive Engineers, and the American Society of Mechanical Engineers.
New York, Gordon and Breach, Science Publishers, Inc., 1969, p. 316-324. 6 refs.

Electrical circuits of spacecraft, military aircraft, and naval vessels generally contain silver or silver-clad conductors. A spillage or seepage of a glycol/water solution on silver-clad wires or defectively insulated components carrying direct current creates a flammability hazard by the reaction of the silver anode in contact with glycol solution. The effects of the chemical reactions leading to ignition produce radio-frequency disturbances (detectable on an AM receiver) and induce rapid fluctuations of current as a function of contact time. When spillages of glycol/water occur on electrical equipment, the circuit elements must be washed and the parts tested for freedom from contamination before the system can be qualified as hazard-free. Techniques for flushing electrical circuitry as a part of quality assurance procedures are described. The results of a study of pinhole leaks in aluminum tubing of a glycol loop system disclosed that pinhole leaks do not develop rapidly from corrosion and that confidence in a tubing system is verified if no leakages develop as a result of hydrostatic pressure qualification tests. STATIC OXIDATION AND COMPATIBILITY OF BORON NITRIDE AND BORON NITRIDE COMPOSITE TO 2000°C.
John D. Buckley (NASA, Langley Research Center, Flight Vehicles and Systems Div., Spacecraft Equipment Section; George Washington University, Hampton, Va.).
(American Ceramic Society, Annual Meeting, 70th, Chicago, Ill., Apr. 20-25, 1968.)
American Ceramic Society Bulletin, vol. 48, July 1969, p. 711-715. 13 refs.

Two grades of boron nitride and a boron nitride composite were subjected to temperatures up to 1500 deg C in air and up to 2000

deg C in a vacuum for various periods of time. The results showed that composition influences thermal shock and oxidation resistance of boron nitride bodies. Compatibility tests were made with four refractory oxides, JTA graphite composite, and five refractory metals at temperatures up to 1800 deg C. Little or no reaction occurred between the boron nitride compositions and the refractory ceramics up to 1500 deg C and the refractory metals up to 1000 deg C.

THE DEVELOPMENT OF POLYBENZIMIDAZOLE COMPOSITES AS ABLATIVE HEAT SHIELDS.
Robert R. Dickey, John H. Lundell, and John A. Parker (NASA, Ames Research Center, Moffett Field, Calif.).
Journal of Macromolecular Science, Series A—Chemistry, vol. 3, July 1969, p. 573-584. 16 refs.
Contract No. NAS 7-340.

Description of the formulation of several new low-density polybenzimidazole (PBI) composites. The proposed structure of the basic linear PBI prepolymer and of several highly cross-linked PBI polymers are presented. The cross-linked PBI's were obtained either thermally (by postcuring to a high temperature) or chemically (by the use of either preoxidized polyfunctional amines or triphenyl trimeasate as a comonomer in the polymerization). Both the linear and the cross-linked PBI composite materials were tested in an arc-heated wind tunnel at a stagnation-point heating rate of 800 W per sq cm and a surface pressure of 2.5 atm. For comparison, a standard phenolic-nylon material of approximately the same density was also tested. The test results show that the linear PBI composite had a lower mass-loss rate than the phenolic-nylon material. The results also indicate that the ablation performance of PBI composites can be substantially improved by cross-linking. The improvement is particularly noticeable in regions of high surface shear. SINTERING KINETICS OF ULTRA FINE CALCIA STABILIZED ZIRCONIA
David Griffith Wirth, Jr. (Ph.D. Thesis) 1967 104 p
Avail: Univ. Microfilms: HC $5.20/Microfilm $3.00 Order No. 68-1887

Kinetics for the initial, intermediate, and final stages of sintering of ultrafine calcia stabilized zirconia were determined. Initial stage kinetics as determined by isothermal shrinkage measurements indicated a grain boundary mechanism of material transport was operative. The activation energy for sintering in this stage agreed quite closely with that for oxygen ion diffusion indicating that this species was rate controlling. This indicated that overall cation diffusion was enhanced. The results of intermediate stage kinetics as determined by isothermal porosity determination also indicated that oxygen ion was still the rate controlling diffusing species. The material transport mechanism was postulated to still be grain boundary diffusion based on the high grain boundary volume to bulk volume ratio as indicated by the small crystallite size and high activation energy for crystallite growth. Final stage kinetics as determined by isothermal grain growth studies indicated that rate control had been transferred to the cation species in the bulk. Dissert. Abstr.

A STUDY TO DETERMINE THE PRESENCE OF VOLTAGE BREAKDOWN DUE TO PROTON IRRADIATION IN POLYMERIC MATERIALS
Herbert D. Hendricks and William E. Miller Washington Nov. 1968 21 p refs
(NASA-TM-X-1688) Avail: CFSTI CSCL 11I

A study was made to determine proton induced voltage breakdowns in a series of polymeric materials: Kapton (H-film), Teflon (TFE), Pyrrone, Mylar, and polyethylene. Proton energy was varied from 0.40 to 3.25 MeV with a flux of 10^9, 10^{10}, 10^{11}, or 2×10^{11} protons/cm^2-sec. Samples were irradiated to a fluence of 10^{13} to 5×10^{14} protons/cm^2 for each test. Sample temperatures were 27°C and -134°C. No charge storage or induced voltage breakdown effects were observed. This observation is in sharp contrast to the numerous induced voltage breakdowns observed for electron irradiation of similar types of polymeric samples. A theory developed by Nichols and van Lint predicts that a behavior of this type should be less prevalent because of proton rather than electron irradiation. Author

CRYSTALLOGRAPHIC DATA ON SELECTED ARTIFICIAL GRAPHITES WITH COMMENTS ON THE ROLE OF THE DEGREE OF CRYSTAL DEVELOPMENT IN OXIDATION
Howard G. Maahs Washington Nov. 1968 18 p refs
(NASA-TN-D-4888) Avail: CFSTI CSCL 11I

Crystallographic parameters have been measured by X ray diffraction on 40 grades of commercially available, nonpyrolytic, artificial graphite (that is, industrially manufactured graphite consisting of filler and binder). The parameters measured are the lattice dimensions (a and d_c), and the crystallite diameter and height. Since artificial graphite is composed of a mixture of two or more graphite carbons, the measured crystallographic parameters are apparent only and are truly representative of neither the filler nor the binder. However, the measured interlayer spacing of artificial graphite is a good approximation of that of the filler. A survey of the literature indicates that the less graphitic a carbon, the less resistant the carbon is to oxidation. For this reason the binder in artificial graphite should be locally more reactive than the filler. Therefore, the aerodynamic erosion resistance of artificial graphite may be largely dependent on the binder, particularly in high-shear environments in which filler particles may be mechanically removed because of preferential oxidation of the binder matrix. MAGNETIC AND ELECTRICAL MATERIALS CAPABLE OF OPERATING IN THE 800° TO 1600°F TEMPERATURE RANGE
R. E. Stapleton Washington NASA Dec. 1968 129 p refs
(Contract NAS3-6465)
(NASA-CR-1213; WAED-67-24E) Avail: CFSTI CSCL 09A

Four candidate high-purity dielectric materials were fabricated into thin wafer, test capacitors and their electrical properties were measured in vacuum at temperatures up to 1100°F. These materials included: pyrolytic boron nitride, single crystal Al_2O_3, hot-pressed BeO, and polycrystalline Al_2O_3. The data shows that pyrolytic boron nitride (PBN) has superior electrical properties over the temperature range and can be fabricated into very thin (<0.001 inch) large area capacitor wafers. A number of multi-layer capacitors (pyrolytic boron nitride dielectric) have been designed and evaluated at temperatures up to 1100°F. Sputtered, thin film electrodes were used on all devices. The feasibility of interconnecting these electrodes without supplementary metal foil tabs has been demonstrated. An extended life test was successfully completed on a five wafer pyrolytic boron nitride (PBN) capacitor at 1100°F in vacuum. Author

FORCE-PENETRATION CHARACTERISTICS OF A SAND HORIZONTALLY PENETRATED BY PLATES, CONES, AND SPHERICAL SEGMENTS
Paul A. Hustad and William R. Cox Washington NASA Jan. 1969 217 p refs
(Grant NsG-604)
(NASA-CR-1252) Avail: CFSTI CSCL 08M

The influence of time upon the force-penetration characteristics of sand was determined by varying the velocity at which the models penetrated into the backfills. Three separate phases of laboratory testing were included. The first consisted of designing a test setup and performing pilot tests that simulated the classical plane-strain earth-pressure problem. The second phase utilized much the same type of loading apparatus as that used in Phase I. Two heights of walls, 1 ft and 1.5 ft, were penetrated at various constant velocities into loose and dense backfills. For the range of velocities that were utilized, the observations showed that the time effects were negligible. The third phase utilized two sizes of right-circular cones and spherical segments which were penetrated into backfills horizontally supported by polyethylene membranes. The rate and vertical depth below the soil surface at which the models penetrated the loose and dense backfills were varied. The same general range of velocities as in Phase II were utilized, and it was found that the time effects were negligible. Equations are presented that provide a means of predicting the maximum horizontal and vertical soil reactions. Author

MECHANICAL BEHAVIOR OF BORON-EPOXY AND GLASS-EPOXY FILAMENT-WOUND CYLINDERS UNDER VARIOUS LOADS
Harvey W. Herring, Robert M. Baucom, and Richard A. Pride Washington Mar. 1969 66 p refs
(NASA-TN-D-5050) Avail: CFSTI CSCL 11D

A study was made to determine the mechanical behavior of boron-epoxy and S-glass–epoxy filament-wound cylinders under tensile, compressive, torsional, and pressure loads. These cylinders were fabricted in either an orthotropic winding pattern or an isotropic pattern. Conventional theory used to predict the elastic behavior of glass-epoxy filament-wound cylinders was discovered to be equally adequate for the boron-epoxy cylinders. Since Young's modulus for a boron filament is much greater than that for a glass filament, the boron-epoxy cylinders were considerably stiffer than those of glass-epoxy. Attempts to correlate cylinder failure strengths calculated from existing state-of-the-art theories with experimental failure strengths met with varying success. Thus, additional research is necessary before failure characteristics of filament-wound composite cylinders, either glass- or boron-reinforced, can be accurately predicted. Author

TENSILE BEHAVIOR OF BORON FILAMENT REINFORCED EPOXY RINGS AND BELTS
Robert M. Baucom Washington Mar. 1969 31 p refs
(NASA-TN-D-5053) Avail: CFSTI CSCL 11D

The room-temperature tensile characteristics of boron-filament epoxy-resin composites have been determined. The effect of low to elevated temperatures on rings and cyclic loading on belts was also investigated. An analysis of the tensile strength of the monofilaments used for the fabrication of the composite specimens is included. In addition, a theoretical analysis of the bending stresses inherent in ring tensile testing is presented. The average strength of the boron monofilaments before winding into the rings and belts was about 406 ksi (2800 MN/m^2). The average room temperature strength of the composites ranged from 90 ksi (620 MN/m^2) for the rings to 66 ksi (455 MN/m^2) for the belts. These low composite strengths are the result of two principal factors: low filament-volume fraction in the composite, and bending stresses induced by the ring test fixtures. With these two factors considered, the filament strength in the composite ring was 85% of the average monofilament strength. Author

LOW-DENSITY FOAM FOR INSULATING LIQUID–HYDROGEN TANKS
Irving E. Summer Washington Mar. 1969 52 p refs
(NASA-TN-D-5114) Avail: CFSTI CSCL 11I

A lightweight polyurethane foam insulation for liquid hydrogen tanks of space vehicles was developed that (1) could be foamed in place, (2) did not crack when chilled to liquid hydrogen temperature, and (3) had a thermal conductivity of 0.0137 W/(m)(K) (0.0079 Btu/(hr)(ft)(°R) at a mean temperature of 136 K (243° R). The foaming-in-place technique in which the foam constituents were poured directly on the tank, coupled with the specific foam formulation, produced a 34.4-kg/m^3–(2.14-lb/ft^3) density foam that remained structurally intact during all simulated ground-hold, vibration, and space-hold tests conducted. Thermophysical properties of the foam were determined, and thermal stress profiles throughout a layer of insulation were calculated. Author

(Contract NAS1-6287)
(NASA-CR-1310; P68-148) Avail: CFSTI CSCL 07C

This report describes the development and processing of polymers formed from the condensation reaction of aromatic dianhydrides with aromatic tetraamines in various solvents. In Phase I, the primary efforts involved the synthesis and characterization of the polymer formed from the condensation of pyromellitic dianhydride (PMDA) with diaminobenzidine (DAB) in polar solvents and the subsequent preparation and testing of fabricated articles. In Phase II, primary efforts included the synthesis, characterization, and subsequent fabrication of the polymer formed from the condensation of benzophenone tetracarboxylic dianhydride (BTDA) with diaminobenzidine (DAB) in the esterifying solvent ethylene glycol (EG). Phase III of the program was directed toward laminates fabricated from the polymer formed from the condensation of BTDA with DAB in the esterifying solvent ethanol (EtOH) had flexural strength above 70,000 psi and moduli above 3×10^6 psi, but more important, the thermal stability was greatly improved. The most promising resin system of the three investigated, from the standpoint of both mechanical strength and thermal stability, is the polymer formed from BTDA and DAB in ethanol. Author

OUTGASSING CHARACTERISTICS OF AN EXPOXY-IMPREGNATED MAGNET COIL
Ronald J. Schertler Washington Jun. 1969 12 p refs
(NASA-TM-X-1813) Avail: CFSTI CSCL 11I

Outgassing tests a function of temperature were conducted using an epoxy-impregnated magnet coil. Glass tape impregnated with epoxy resin provided the electrical insulation between the conductors. Outgassing data were taken by measuring the rate of pressure rise due to the magnet coil heating in a closed vacuum system. The outgassing rate increased exponentially from 3.05×10^{-8} torr-liter per square centimeter-second at an epoxy temperature of 24° C to 9.0×10^{-7} torr-liter per square centimeter-second at 53°C. The coil assembly had a higher outgassing rate at temperatures above 30°C than small disk-shaped samples of the same epoxy. Author

EFFECTS OF CYCLIC HEATING AND THERMAL SHOCK ON HAFNIA STABILIZED WITH CALCIA, MAGNESIA, and YTTRIA
John D. Buckley and David R. Wilder (Iowa State Univ., Ames) Washington Aug. 1969 43 p refs
(NASA-TN-D-5279) Avail: CFSTI CSCL 1/C

Solid solutions of HfO_2-CaO, HfO_2-Y_2O_3, and HfO_2-MgO were studied for: (1) temperature effects on stabilization (the process of eliminating or limiting the monoclinictatragonal crystallographic inversion common in hafnia at ≈1700°C); (2) effects of cyclic heating on the crystal lattice stability; and (3) thermal shock effects on partially and fully stabilized hafnia. Calcia-stabilized hafnia exhibited similar solubility when sintered at 2000° and at 1800°C. Yttria-stabilized hafnia indicated that sintering at 2000°C and at times over 9 were necessary to obtain near-maximum solution. The high vapor pressure of magnesia limits sintering temperatures for magnesia-stabilized specimens to 1800°C. Yttria-stabilized hafnia maintains its stability whereas magnesia- and calcia-stabilized specimens destabilize when subjected to a single heat cycle (25° to 1750°C). Reheating to 1925° C for 30 min under 10^{-5} torr did not produce restabilization. Hafnia stabilized with calcia or yttria maintained original stability when subjected to 25 cycles between 1040° and 1730°C in air at ambient pressure. Magnesia-stabilized hafnia was stable when removed from the furnace at 1730°C and cooled in ambient air, but was unstable

when removed at 1040°C and cooled under the same conditions. Overall thermal-shock resistance yttria-stabilized hafnia quickly cooled in ambient air from temperatures up to 2000°C was superior to the others. K.W.

AN INVESTIGATION OF THE BASIC PROPERTIES OF IRRADIATED POLYETHYLENE MEMORY MATERIALS

Preston Keusch, Donald Greer, and John Rozembersky Washington NASA Sep. 1969 122 p refs

(Contract NAS1-7335)

(NASA-CR-1384; RAI-397) Avail: CFSTI CSCL 11H

Described are the properties, work, and conclusions reached on irradiated polyethylene memory materials. The properties affecting crosslinking, the main memory factor which determines the memory in the materials were investigated using different commercial polyethylene materials. These properties include: molecular weight, molecular weight distribution, and the degree of branching. It was found that the molecular weight distribution was the main factor that influenced the crosslinking efficiency. The conditions at which crosslinking occurs- temperature, oxygen environment, and the radiation dose were investigated. Memory studies were performed on the commercial materials to see if they completely restored after being deformed. The mechanical properties of the superior memory material tested, Poly-Eth 5555 film, were also presented. Low temperature tests, tensile tests, and modulus of elasticity were determined for all of the materials. It was concluded that the material with the best crosslinking properties had the best memory characteristics. Author

NUMERICAL SOLUTION OF SYMMETRIC POSITIVE DIFFERENTIAL EQUATIONS.

Theodore Katsanis (NASA, Lewis Research Center, Cleveland, Ohio).

Mathematics of Computation, vol. 22, Oct. 1968, p. 763-783. 8 refs.

A finite-difference method for the solution of symmetric positive linear differential equations is developed. The method is applicable to any region with piecewise smooth boundaries. Methods for solution of the finite-difference equations are discussed. The finite-difference solutions are shown to converge at essentially the rate $O(h^{1/2})$ as $h \to 0$, h being the maximum distance between adjacent mesh-points. An alternate finite-difference method is given with the advantage that the finite-difference equations can be solved iteratively. However, there are strong limitations on the mesh arrangements which can be used with this method. (Author)

HIGH ACCURACY GAMMA FUNCTION VALUES FOR SOME RATIONAL ARGUMENTS.

D. C. Galant and P. F. Byrd (NASA, Ames Research Center, Moffett Field, Calif.).

Mathematics of Computation, vol. 22, Oct. 1968, p. 885-887.

Tabulation of high-accuracy gamma-function values for some rational arguments. During the course of determining accurate Gaussian quadrature formulas for certain nonclassical weight functions, it was necessary to compute $\Gamma(p/q)$ to 60D to obtain moments to high accuracy. In particular, $\Gamma(p/q)$ was needed for $p = 1, 2, \ldots, q - 1$, $2p \neq q$, and $q = 3, 4, 5, 8, 10$. The quantities $\Gamma(p/q)$, which for special cases also arise in the computation of Bessel functions of fractional order or of the Airy functions, were calculated using an interpretive routine that treated floating-point numbers of 70 significant figures. RECURSIVE FORMULAS FOR THE EVALUATION OF THE CONVOLUTION INTEGRAL.

H. H. Trauboth (NASA, Marshall Space Flight Center, Huntsville, Ala.).

Association for Computing Machinery, Journal, vol. 16, Jan. 1969, p. 63-72.

Derivation of recursive formulas for the numerical evaluation of the real convolution integral which is a valuable mathematical tool for simulating control systems and electrical networks on a digital computer. The formulas are derived for the case where the impulse response is given analytically. These formulas require considerably less computation time and memory space than the general time series formulas, and can be effectively applied for digital simulation of continuous physical systems. M.G.

ANALYTIC CONTINUATION OF APPELL'S HYPERGEOMETRIC SERIES F_2 TO THE VICINITY OF THE SINGULAR POINT x = 1, y = 1.

G. E. Hahne (NASA, Ames Research Center, Moffett Field, Calif.)

Journal of Mathematical Physics, vol. 10, Mar. 1969, p. 524-531. 18 refs.

The infinite series, absolutely convergent if $|x| + |y| < 1$, for Appell's $F_2(\alpha, \beta, \beta', \gamma, \gamma'; x, y)$ is analytically continued into a linear combination of four infinite series in powers of $(x - 1)$ and $(y - 1)$; each of the latter four series is absolutely convergent if $|x - 1| + |y - 1| < 1$. The analytic continuation is carried out by manipulation of the Mellin-Barnes integral representations for the hypergeometric functions appearing in the course of the calculation. (Author)

A COMPARISON OF GRADIENT DEPENDENT TECHNIQUES FOR THE MINIMIZATION OF AN UNCONSTRAINED FUNCTION OF SEVERAL VARIABLES.

Terry A. Straeter (NASA, Langley Research Center, Hampton, Va.).

American Institute of Aeronautics and Astronautics, Aerospace Computer Systems Conference, Los Angeles, Calif., Sept. 8-10, 1969, Paper 69-951. 6 p. 14 refs.

Members, $1.00; nonmembers, $1.50.

Use of a simplified aerospace problem and Rosenbrock's parabolic valley function as a basis for comparison with respect to ease of implementation and speed of convergence in terms of number of function evaluations. The problem is a two-dimensional minimum time-to-intercept problem with constant thrust in free space. The Armstrong-Marquardt method, a minimization algorithm for a sum-of-squares-type function arising in boundary-value problems in optimal control, is applied. Tables summarizing the results are given. F.R.L.

PERIODIC SMALL-AMPLITUDE SOLUTIONS TO VOLTERRA'S PROBLEM OF TWO CONFLICTING POPULATIONS AND THEIR APPLICATION TO THE PLASMA CONTINUITY EQUATIONS.

J. Reece Roth (NASA, Lewis Research Center, Cleveland, Ohio).

Journal of Mathematical Physics, vol. 10, Aug. 1969, p. 1412-1414. 15 refs.

Solution of the coupled set of first-order nonlinear differential equations describing a generalized form of Volterra's problem of two conflicting populations, using an approximate method. The solutions obtained in this analysis are relevant to special cases of the classical problem of predator and prey, and also to certain low-frequency oscillations in partially ionized plasmas that arise from periodic solutions to the neutral and charged-particle continuity equations. (Author)

NUMERICAL SOLUTION OF TRICOMI EQUATION USING THEORY OF SYMMETRIC POSITIVE DIFFERENTIAL EQUATIONS.

Theodore Katsanis (NASA, Lewis Research Center, Cleveland, Ohio).

SIAM Journal on Numerical Analysis, vol. 6, June 1969, p. 236-253. 9 refs.

The Tricomi equation can be expressed in symmetric positive form. Admissible boundary conditions assure existence and uniqueness of solutions. It is shown that boundary conditions are admissible for the Tricomi equation for any region with piecewise smooth boundaries. A wide choice of boundary conditions is possible. A Tricomi equation with a known analytical solution is solved by a finite difference scheme for symmetric positive equations as an illustration of the numerical results which can be obtained. There is

strong convergence to the analytical solutions, but pointwise divergence. Smoothing of the solution reduces the divergence, however, and satisfactory numerical results are obtained. (Author)

VARIABLE MESH METHODS FOR DIFFERENTIAL EQUATIONS
R. Van Wyk Washington NASA Nov. 1968 40 p refs
(Contract NAS7-470)
(NASA-CR-1247; REPT-R-7491) Avail: CFSTI CSCL 12A

A multistep predictor-corrector method for the numerical solution of ordinary differential equations is developed. The difference equations employed are generalizations, for the case of variable mesh spacing, of previous formulas requiring fixed step size. In addition to retaining the high local accuracy and convergence properties of the earlier methods, the variable mesh method is developed in a form conductive to the generation of effective criteria for the selection of subsequent step sizes in the step by step solution of differential equations. These criteria are based on considerations of truncation error, convergence of corrector iterations, and an extensive treatment of relative numerical stability. The algorithm has been tested extensively and compared with other methods. The results of the comparison favor the new method. Also discussed are an extension of the variable mesh multistep method for the case of stiff equations and application of the variable mesh approach to partial differential equations. Author

REGRESSION ANALYSIS PROCEDURES FOR THE EVALUATION OF TRACKING SYSTEM MEASUREMENT ERRORS
Bobby G. Junkin Washington Dec. 1968 141 p refs
(NASA-TN-D-4826) Avail: CFSTI CSCL 17I

A regression analysis method for Tracking System Error Model Studies (TEMS) is presented for evaluating systematic errors in measurements obtained from various tracking systems. The mathematical procedures include a rigorous least squares adjustment of error model parameters with constraints, using a priori values for these parameters and their variances. Truncated tracker error models for representing the systematic errors are established using the TEMS method in conjunction with a stepwise regression procedure. This procedure involves examining at every step the variables incorporated in the error model in previous steps. A specific variable is deleted from or entered into the model by using the Gaussian Elimination Method for solving the linear system of normal equations in the regression. Although C-band radar error models are used, the procedures can be adapted to other types of tracking systems. Results from application to the Apollo-Saturn 501 (AS-501) flight test data are presented and indicate generally acceptable truncated C-band radar error models. Author

A GENERALIZED AVERAGING METHOD FOR LINEAR DIFFERENTIAL EQUATIONS WITH ALMOST PERIODIC COEFFICIENTS
Thomas J. Coakley Washington Apr. 1969 17 p refs
(NASA-TN-D-5167) Avail: CFSTI CSCL 12A

A new method for analyzing linear differential equations with almost periodic coefficients is described and discussed. The

method is essentially a generalization of the classical Floquet theory developed for linear periodic systems. By use of the method, it is shown that an almost periodic system with rapidly varying coefficients can always be reduced or transformed to a corresponding system with either constant or slowly varying coefficients. An example is discussed which illustrates the method and indicates how the reduced system is frequently more easily analyzed than the original system. Author

THE USE OF INTEGRAL TRANSFORMS IN THE ESTIMATION OF TIME VARIABLE PARAMETERS
Henry C. Lessing and D. Francis Crane Washington May 1969 47 p refs
(NASA-TN-D-5194) Avail: CFSTI CSCL 12A

A study was made of the concept of integral transformations applied to the differential form of the system equations and the use of these equations in parameter estimation. The two principal results of the study are given: the extension of the transformation equations to explicitly account for time variability of the system parameters, and an extension of the application of the concept to the output error formulation of the parameter estimation problem. It is shown that, as a result, the output error formulation acquires stability properties that were impossible previously. Experimental results are presented to illustrate the theoretical developments. These results show the ability of the new formulations to estimate parameters that are highly variable with time. Author

APPROXIMATING PROPERTIES OF LINEAR MODELS FOR INPUT–OUTPUT DESCRIPTIONS
Ernest Gunther Holzmann Washington NASA May 1969 153 p refs
(Grant NGR-020-073)
(NASA-CR-1319) Avail: CFSTI CSCL 12A

B. L. Ho's existence theorem states necessary and sufficient conditions for strict realizability that are satisfied only in ideal situations. Mathematical proof is given that good dynamical simulation is possible with linear models which represent partial, rather than minimal, realizations. The restrictions of B.L. Ho's theorem do not apply to partial realizations, and the class of partially realizable input–output descriptions is large enough for practical purposes. For any normal sequence of scalar Markov parameters, the transfer function of each partial realization is shown to lie on the diagonal of the E-array corresponding to the given sequence. The proof is based on the classical theory of the Padé approximation. Relevant parts of this theory are reviewed and developed in the report, including a new, stronger form of Padé's representation theorem. As a by-product of this research, a sharpened, computationally more efficient version of B. L. Ho's minimal realization algorithm was derived. Author

N69-28196*# Arizona Univ., Tucson.
COMPUTATION OF REGIONS OF CONSTRAINED STABILITY FOR NONLINEAR CONTROL SYSTEMS
Demosthenes P. Gelopulos and Donald R. Schultz Washington NASA Jun. 1969 143 p refs
(Grant NsG-490)
(NASA-CR-1328) Avail: CFSTI CSCL 12A

The classical control system stability criterion is revised, and methods are devised for determining the region of stability. Excursion stability is defined in such a way that the practical constraints on the system are incorporated into the stability measure. Computational algorithms are devised which are used to determine the region of excursion stability. Two distinct algorithms evolve which are compared on the basis of computational efficiency. The revision of the stability criterion ties stability analysis to the physical system and thereby makes stability analysis useful for engineering purposes. A key feature of the algorithms, which may be used for evaluating the stability of nonlinear systems, is the fact that it is not necessary to select any state functions on any intuitive or semi-intuitive bases. Therefore, the algorithms are not inherently limited to low order systems. Author

STABILITY THEORY OF NONLINEAR OPERATIONAL DIFFERENTIAL EQUATIONS IN HILBERT SPACE
Chia-Ven Pao Washington NASA. May 1969 177 p refs
(Grant NGR-39-011-039)
(NASA-CR-1356) Avail: CFSTI CSCL 12A

The object of this research is to establish some criteria for the existence, uniqueness, stability, asymptotic stability and stability region of a solution of the linear or nonlinear, time-invariant or time-varying operational differential equations (i.e., equations of evolution) in Banach spaces and in Hilbert spaces, from which criteria for the same results regarding a solution of the corresponding type of partial or ordinary differential equations can be deduced. In the linear case, semi-scalar product on a Banach space and linear semi-group theory are used; in the nonlinear case, equivalent inner product on a Hilbert space and the concept of nonlinear semi-group are introduced. A FORMALIZATION OF MEASUREMENT SCALE FORMS
Wayne A. Lea Washington Jun. 1969 44 p refs
(NASA-TN-D-5277) Avail: CFSTI CSCL 12A

A mathematical model of measurement and specific scale forms is developed, using the minimum mathematical structure

necessary to define each scale type. Measurement is defined, and a series of restrictions are applied to measurements to yield a precisely specified hierarchy of measurement scale forms including nominal, ordinal, interval, and ratio scales, as well as several others. Equivalences are mathematically defined for each scale form, and theorems are presented specifying the sets of transformations under which equivalence is preserved, thus yielding the scale form invariances. The hiearchy of measurement scale forms is summarized in a pictorial 'spectrum' diagram. Author

THE DESIGN OF LINEAR MULTIVARIABLE CONTROL SYSTEMS USING MODERN CONTROL THEORY (WITH APPLICATIONS TO COUPLED CORE REACTOR CONTROL)
Charles R. Slivinsky, Donald G. Schultz, and Lynn E. Weaver Washington NASA Jun. 1969 184 p refs
(Grant NGL-03-002-006)
(NASA-CR-1345) Avail: CFSTI CSCL 12A

Both conventional, frequency-domain techniques and modern, combined frequency-domain, time-domain procedures are considered. Two basic design requirements are noninteraction and that specified subsystem transfer functions be achieved. Conventional methods are shown to have the disadvantage of complexity, both in carrying out the design calculations and in the physical implementation of the compensation. The attention centers on the state variable feedback design of multivariable systems, including procedures for identifying the fixed zeroes of the subsystems and the number of subsystem poles controlled by state variable feedback. By treating each subsystem individually, previously developed knowledge of state variable feedback design of single-input, single-output systems can be applied. Three methods for adding dynamics to the multivariable system before state variable feedback is applied are proposed for improving the system response. A coupled-core nuclear reactor with a three-core linear model is examined as an example of the application of state variable feedback design. K. W.

LOW-ORDER CLASSICAL RUNGE-KUTTA FORMULAS WITH STEPSIZE CONTROL AND THEIR APPLICATION TO SOME HEAT TRANSFER PROBLEMS
Erwin Fehlberg Washington Jul. 1969 46 p refs
(NASA-TR-R-315) Avail: CFSTI CSCL 12A

In an earlier report, the author derived fifth-to eighth-order Runge–Kutta formulas with stepsize control. In this paper, similar first- to fourth-order formulas are developed. Such low-order formulas are of interest in some heat transfer problems. It is well-known that the parabolic partial differential equations of such problems can be reduced to ordinary differential equations. However, it is also well-known that the application of Runge–Kutta methods to such problems is often very time-consuming. Higher-order formulas do not offer advantages in this respect, since stability considerations, resulting from the exponential character of the solution, exclude an increase of the integration stepsize that would make such high-order formulas meaningful. Therefore, low-order Runge–Kutta formulas can be expected to solve such problems more efficiently than any high-order formula. For the efficiency of Runge–Kutta formulas, it is essential that their truncation errors be as small as possible. Author

DESIGN OF EXPERIMENTS AS DOUBLY TELESCOPING SEQUENCES OF BLOCKS WITH APPLICATION TO A NUCLEAR REACTOR EXPERIMENT
Arthur G. Holms and Steven M. Sidik Washington Aug. 1969 41 p refs
(NASA-TN-D-5369) Avail: CFSTI CSCL 12A

A blocked two-level factorial experiment was designed to measure the radiolysis of water. Effects of controlled variables are biased by changes in radiation with time and by equipment changes between fuel cycles; the experiment is therefore doubly confounded. Experimenting is subject to unplanned curtailments with respect to the first bias, and might be expanded with respect to the second. So that the more important parameters can be estimated free of biases ordinarily resulting from the indefinite size of the experiment, the rationale is given for arranging the blocks of the experiment in a doubly telescoping (orthogonally blocked) sequence. MANIPULATION ERRORS IN FINITE ELEMENT ANALYSIS OF STRUCTURES

R. J. Melosh and E. L. Palacol Washington NASA Aug. 1969 145 p refs
(Contract NAS5-10369)
(NASA-CR-1385) Avail: CFSTI CSCL 12A

These errors for the displacement and force methods of structural analysis for systems of finite elements in series and in parallel are examined. The principal manipulation error involves distortion of the mantissa of the floating decimal representation of the number. This error depends upon the selection of number base, number of places carried, arithmetic mode, and manipulation mode. These characteristics are fixed by the selection of computer hardware and software. The manipulation error is also influenced by problem scale, structural idealization, the sequencing of joints and elements, selection of coordinate axes, element representations used, choice between the force or displacement method, and the algorithm selected for solving the load-deflection relationships for the structure. Errors are studied in the input–output, generation, and elimination phases of calculation. The input–output phase involves that part of the problem in which the data is introduced into the computer and results are output for analyst interpretation. Input errors are not significant. Author

A NEW MATRIX THEOREM AND ITS APPLICATION FOR ESTABLISHING INDEPENDENT COORDINATES FOR COMPLEX DYNAMICAL SYSTEMS WITH CONSTRAINTS

William C. Walton, Jr. and Earl C. Steeves Washington Oct. 1969 28 p refs
(NASA-TR-R-326; L-6052) Avail: CFSTI CSCL 12A

A method is presented by which equations of motion of a linear mechanical system can be derived in terms of independent coordinates when the system is described in terms of coordinates which are not independent but instead are governed by linear homogeneous equations of constraint. There is a discussion of the origin in practical vibrations analysis of dynamical systems involving equations of constraint. Methods previously used for handling such systems are discussed and the method is demonstrated to have the following advantages: (1) For the most general constraint equations, solution of the equations is reduced in substance to computing the eigenvalues and eigenvectors of a symmetric matrix. (2) The method is applicable when there are redundancies in the equations of constraint. Author

APPLICATION OF MODERN NETWORK THEORY TO ANALYSIS OF COMPLEX SYSTEMS

John C. Faken Washington Oct. 1969 46 p refs
(NASA-TN-D-5511) Avail: CFSTI CSCL 12A

Present day systems have grown to exceed the intuitive grasp of systems analysts, thus negating the value of techniques which depend upon intuition as a substitute for mathematical rigor. A methodology based on the Modern Network Theory of electrical engineering is presented which, when considered in the light of digital computer technology, shows up as a capable and powerful tool for the analysis of complex systems. The examples presented to demonstrate the various techniques show that Modern Network Theory is not limited to electrical systems but appears to be applicable to systems in general. Author

ATMOSPHERIC STRUCTURE RESEARCH FOR LONG-TERM FORECASTING.
William Nordberg (NASA, Goddard Space Flight Center, Laboratory for Atmospheric and Biological Sciences, Greenbelt, Md.).
United Nations, Conference on the Exploration and Peaceful Uses of Outer Space, Vienna, Austria, Aug. 14-27, 1968, Paper 68-95397. 21 p. 14 refs.

Discussion of the feasibility of deriving meteorological parameters relating to the temperature, density, moisture, and energy structure of the atmosphere using satellite observations. The development of mathematical models that simulate the planetary and cyclone scale structure of the atmosphere is seen as important in long-term forecasting by satellite. The need for global atmospheric observations, for a period of a few months to a year, which will provide adequate data input for such models, is stressed. The various methods of making and interpreting satellite observations of atmospheric structure are described. Since the major spacecraft and onboard remote sensing devices for the required observations are so complex and expensive, international cooperation in the launching and operation of such weather satellites is considered imperative. P.G.M.

INTERNATIONAL EXPERIMENTATION WITH COMMUNICATIONS SATELLITES.
Leonard Jaffe (NASA, Office of Space Science and Applications, Washington, D.C.).
United Nations, Conference on the Exploration and Peaceful Uses of Outer Space, Vienna, Austria, Aug. 14-27, 1968, Paper 68-95421. 22 p.

Summary of the international experimentation with U.S. satellites during the last ten years. Fourteen experimental communications satellites have been launched by the U.S. since December 1958. Two of these were passive reflecting satellites, Echo 1 and Echo 2; seven were medium-altitude active satellites: Score, Courier, Telstar 1 and 2, Relay 1 and 2, and ATS 2. Five satellites were synchronous altitude satellites, and three of these five were geostationary satellites. The UK and France participated in experiments with the first passive satellite, Echo 1. As the program went on, additional countries became involved, including the Federal Republic of Germany, Brazil, Italy, the USSR, Japan, Canada, the Scandinavian countries, Spain, and India. Still other countries were involved from time to time. Each participating nation followed its own theories in the mechanical and electrical design, and all participants exchanged technical information with other participants without restraint. P.v.T.

WEATHER RESEARCH SATELLITES.
Morris Tepper (NASA, Office of Space Science and Applications, Washington, D.C.).
United Nations, Conference on the Exploration and Peaceful Uses of Outer Space, Vienna, Austria, Aug. 14-27, 1968, Paper 68-95350. 19 p.

Description of a broad program of meteorological satellite research, including specific plans for unmanned satellites, and of future possibilities with a meteorologist on board a manned spacecraft. An outline is given of the program, starting with the first satellite efforts concerned with observation systems designed to provide global cloud cover information, and improvements introduced into the satellites, instruments, and techniques. A discussion is given of the extrapolation of observational data to provide information on the future positions of such atmospheric phenomena as fronts, hurricanes, jet streams, and cloud complexes. The current program is reviewed. It has three objectives: (1) to provide global and local observations of cloud cover both day and night, (2) to provide "continuous" observation of the earth's cloud cover, and (3) to provide measurements of the vertical structure of the atmosphere. The possible contributions to meteorology by a man in space are considered. I.P.

CHARACTERISTICS OF TURBULENCE OBSERVED AT THE NASA 150-M METEOROLOGICAL TOWER.
George H. Fichtl (NASA, Marshall Space Flight Center, Huntsville, Ala.).
Journal of Applied Meteorology, vol. 7, Oct. 1968, p. 838-844. 12 refs.

Recent observations of turbulence obtained at the NASA 150-m meteorological tower located at Kennedy Space Center, Fla., are presented. The wind data were obtained at the 18-, 30-, 60-, 90-, 120-, and 150-m levels, while temperature data were obtained at the 3-, 18-, 60-, 120-, and 150-m levels. Most of the tests were made during the daylight hours, and the duration time of each test ranged between 30 and 60 min. A survey of the surface roughness length associated with the tower site is presented. Estimates of the roughness length were calculated with wind profile laws consistent with the Monin-Obukhov similarity hypothesis. In the case of those wind directions θ in the ranges $0^\circ \leqq \theta < 150^\circ$, $180^\circ \leqq \theta < 240^\circ$, and $300^\circ \leqq \theta < 360^\circ$ the roughness length is 0.23 m, while for those wind directions in the ranges $150^\circ \leqq \theta < 180^\circ$ and $240^\circ \leqq \theta < 300^\circ$, the roughness length has the values 0.51 and 0.65 m, respectively. Longitudinal turbulence spectra calculated from recent observations are also presented. It is shown that the nondimensional frequency nz/u, associated with the peak of the logarithmic spectrum, is proportional to $z^{4/5}$, where u is the wind speed at height z and n is the frequency. Based on an analysis of the logarithmic spectrum in the inertial subrange, it is implied that the local mechanical production of turbulent energy is balanced by the local viscous dissipation at the 18-m level. ATMOSPHERIC MEASUREMENTS FROM SATELLITES.
Robert M. Rados (NASA, Goddard Space Flight Center, Greenbelt, Md.).
American Institute of Aeronautics and Astronautics, Aerospace Sciences Meeting, 7th, New York, N.Y., Jan. 20-22, 1969, Paper 69-158. 10 p.
Members, $1.00; nonmembers, $1.50.

Brief survey of atmospheric measurements from satellites. A chronology of satellites which have provided atmospheric measurements and the specific sensors which were flown, a listing of planned satellites with their atmospheric sensors, and some vital statistics on the sensors which have been flown or which are under development, are tabulated. It is noted that recent exploration of the ATS-1 images of cloud cover on an hourly basis has demonstrated the potential of defining winds in the tropical areas and the movement of vorticity patterns from the Southern to the Northern Hemisphere. The use of WEFAX through the ATS 1 and 2 satellites has demonstrated the practicality of transmitting data collected

and analyzed to a central location to users in remote or distant locations which either cannot provide facilities of their own or cannot obtain these analyses more efficiently. Satellites can also be used to measure sferics and sea state through the use of microwave radiometers, lasers, etc. M.M.

WIND MEASUREMENTS IN NOCTILUCENT CLOUDS.
J. S. Theon, W. S. Smith, and W. E. McGovern (NASA, Goddard Space Flight Center, Aeronomy Branch, Greenbelt, Md.).
Science, vol. 164, May 9, 1969, p. 715, 716. 5 refs.

The results of eight soundings conducted from sites at high latitude during the summers of 1963 through 1965 suggest that a relation exists between the winds at the mesopause and the occurrence of noctilucent clouds. These measurements indicate that situations in which noctilucent clouds are present are associated with lower wind speeds than is the case where there are no clouds. (Author)

SATELLITE MAPPING OF THE PACIFIC TROPICAL CLOUDINESS.
Jacob Bjerknes (California, University, Los Angeles, Calif.), Lewis J. Allison, Guenter Warnecke (NASA, Goddard Space Flight Center, Greenbelt, Md.), Earl R. Kreins (USAF, Environmental Technical Applications Center, Washington, D.C.), and Frederic A. Godshall (ESSA, Silver Spring, Md.).
American Meteorological Society, Bulletin, vol. 50, May 1969, p. 313-322. 17 refs.

Sampling survey of a six-year period of satellite-observed tropical Pacific cloudiness. The variable position of the boundary between the west Pacific equatorial rain clouds over warm water and the east Pacific aridity along the equator over cool upwelling water is considered. Features of the geographic cloudiness distribution not generally observable are discussed, and the generally held assumption that the bulk of tropical rain over the oceans is generated when the sea is warmer than the air is verified. DETAILED WIND AND TEMPERATURE PROFILES.
G. H. Fichtl, D. W. Camp, and W. W. Vaughan (NASA, Marshall Space Flight Center, Huntsville, Ala.).
IN: CLEAR AIR TURBULENCE AND ITS DETECTION; BOEING COMPANY, SYMPOSIUM, SEATTLE, WASH., AUGUST 14-16, 1968, PROCEEDINGS. [A69-33732 17-20]
Edited by Yih-Ho Pao and Arnold Goldburg.
New York, Plenum Press, 1969, p. 308-333. 19 refs.
NASA-supported research.

Analysis of three detailed temperature profiles and the associated wind profiles obtained with the aid of the Jimsphere/FPS-16 radar wind sensing system during October 1967 at Cape Kennedy. The analysis is based on a consideration of structure functions, which represent the vertical mean square difference in the temperature and wind spread fluctuations about the mean profiles over the vertical length scale. It is shown that the wind-temperature sensing data thus obtained could be of considerable importance in assessing the output from remote clear air turbulence detectors, whether ground-based or mounted on board aircraft. ON A STEADY STATE THEORY OF GLOBAL MONSOONS.
M. Sankar-Rao (NASA, Goddard Space Flight Center, Goddard Institute for Space Studies, New York, N.Y.) and Barry Saltzman (Travelers Research Center, Inc., Hartford, Conn.).
Tellus, vol. 21, no. 3, 1969, p. 308-330. 30 refs.
ESSA Contract No. E 22-137-67N.

Steady-state solution of the quasi-geostrophic perturbation equations for the forced response of the atmosphere to a parametized form of heating which is proportional to the difference between the mean low-level air temperature and the prescribed ground surface temperature. The solutions, obtained as a sum of spherical harmonic components, are shown to be sensitive to the form of the vertical variation of the heating, as well as to the horizontal scale. This is due to the possibility of a "matching" of the vertical variation of the internal forcing with the vertical variation of the solution for the "quasi-resonant" horizontal mode. For a particular vertical variation of the heating which is removed from this point of magnified quasi-resonance, the composite solutions up to the fifteenth degree, for January and July conditions in the Northern Hemisphere, show a fair amount of agreement with observed normal maps. The main errors are a tendency for the computed features to be displaced to the east of the observations at both upper and lower levels, and an overly weak response over Asia and the Pacific. Some possibilities for improving the model are discussed. (Author)

CLOUD HEIGHT CONTOURING FROM APOLLO 6 PHOTOGRAPHY.
Victor S. Whitehead, Ivan D. Browne, and Joe G. Garcia (NASA, Manned Spacecraft Center, Houston, Tex.).
American Meteorological Society, Bulletin, vol. 50, July 1969, p. 522-528.

Analysis of selected photographs taken during the unmanned Apollo 6 mission in which they were subjected to stereoscopic photogrammetry to determine the heights of cloud bases and the tops of convective clouds. Examples of how these calculated heights may be used to infer the physical characteristics of the ambient atmosphere are shown. The detail within the photographs permits contouring of cloud-top heights within mesoscale systems. Accuracies of height determination are estimated to be plus or minus 250 m. (Author)

STATISTICAL SPECIFICATION OF THE 500-MB HEIGHT FIELDS USING SMOOTHED MEDIUM-RESOLUTION RADIOMETRIC FIELDS OF NIMBUS II.
Frank L. Martin (NASA, Goddard Space Flight Center, Greenbelt, Md.; U.S. Naval Postgraduate School, Monterey, Calif.).
Journal of Applied Meteorology, vol. 8, Aug. 1969, p. 668-686. 13 refs.
Navy-supported research.

Over an area spanning the North American Continent from tropical to polar latitudes, and between 40 and 135 deg W longitude, four consecutive days of the Nimbus 2 Medium Resolution Infrared five-channel equivalent blackbody temperatures and of 1000-mb geopotential fields were used to specify the 500-mb field of geopotential. Three of the four days were reserved for dependent data, the fourth day being reserved for independent test-case data. The data samples were stratified into "extratropical" and subtropical-tropical areas, and then pooled three-day stepwise, with screening regression equations being developed by areas. In the lower latitude stratifications, the 500-mb regression equations were only of marginal significance, but in the extratropical zone (latitudes 32-64 deg N), the regressions have 500-mb height specifications with multiple correlation coefficients of 0.95. Moreover, in the independent-data test case, no shrinkage of explained variances occurred in these extratropical latitudes. Here the most important predictors for $Z_5(I, J)$ were the equivalent blackbody temperatures in the 14-16 micron and 10-11 micron channels, the 1000-mb geopotential, and finally an effective blackbody temperature associated with the solar-reflectance channel. (Author)

TESTS OF THE EFFECT OF GRID RESOLUTION IN A GLOBAL PREDICTION MODEL.
M. Sankar Rao (NASA, Goddard Space Flight Center, Goddard Institute for Space Studies, New York, N.Y.) and Ludwig Umscheid, Jr. (Computer Applications, Inc., New York, N.Y.).
Monthly Weather Review, vol. 97, Sept. 1969, p. 659-664. 7 refs.

Assessment of the results of tests of an integration scheme proposed by Kurihara and Holloway (1967) which has a variable angular grid spacing and offers advantages in problems of geophysical fluid dynamics by rigorously conserving mass and energy. In order to examine the errors produced by the expanded angular grid spacing near the poles, an attempt was made to investigate the accuracy of this scheme by numerical experiments involving various grid resolutions. The results show that, in order to achieve a solution with acceptable accuracy, the grid spacing near the pole has to be decreased by a factor of 9. O.H.

ATMOSPHERIC LIMITS ON THE OBSERVATIONAL CAPABILITIES OF AEROSPACECRAFT

John C. Evvard Washington Dec. 1968 23 p refs

(NASA-TN-D-4940) Avail: CFSTI CSCL 04B

Atmospheric turbulence decreases the ground observational capability of an aerospacecraft. Most of the effect arises from transient distortions of the light path near the surface (up to 15 or 20 km) where the air density is high. Hence, the viewing accuracy of a satellite observer looking at the ground is generally much higher than for a ground observer viewing a satellite. Estimates of the atmospheric resolving power error for both the ground and the aerospacecraft observer have been made. The estimated uncertainty of viewing a point on the ground directly beneath an aerospacecraft need be no larger than 12 centimeters. Expressions are derived for the altitude and angular dependency of the uncertainty. Author

A STUDY OF JIMSPHERE WIND PROFILES AS RELATED TO SPACE VEHICLE DESIGN AND OPERATIONS

S. I. Adelfang, E. V. Ashburn, and A. Court Washington NASA Nov. 1968 116 p refs

(Contract NAS8-20747)

(NASA-CR-1204; LR-21588) Avail: CFSTI CSCL 04B

During the period December 1964 through April 1967, Jimsphere wind sensors were used to obtain 1194 profiles in the altitude range 1 km to 20 km over Cape Kennedy. This report consists of an analysis of the winds and wind shears derived from the Jimsphere data. The zonal and meridional components of the wind were found to have a distribution that is significantly closer to a normal distribution that the distribution of the components determined for the winds measured by conventional radiosonde methods. Extreme ($\geq$ 95%) Jimsphere wind speeds at 7 km through 15 km are not independent of the extreme wind speeds at 12 km altitude. Mean shears at 8, 12, and 16 km are a function of a power of the shear layer thickness, Δz for $\Delta z \leq 1$ km. The power is 1 for mean zonal and scalar shears, not clearly defined for mean meridional shears, and 2/3 for mean vector shears. The standard deviation and the 95% scalar, vector, zonal, and meridional shears are also a function of the altitude interval Δz to the 2/3 power. Given that the shear is extreme at 12 km altitude the simultaneous occurrence of non-overlapping extreme vector and zonal shears measured over altitude layers of 50 to 1000 meters, is a low probability event. Definitions of steady state wind and gusts are discussed in terms of filtering the wind data for the relevant frequency ranges and in terms of space vehicle characteristics. Author

EXAMETNET DATA REPORT SERIES: ANNUAL REPORT, 1967

Washington 1969 188 p refs Prepared by Texas Univ., Shellenger Research Labs., El Paso

(NASA-SP-176) Avail: CFSTI CSCL 04B

Exametnet meteorological rocket launchings and data dissemination are conducted synoptically from launch sites at Chamical, Argentina; Natal, Brazil; and Wallops Island, Virginia, U.S.A. The reduced data from the launchings for each quarter are checked, further reduced, compiled, and published in the Exametnet Data Report Series. These network data reports, after being reviewed and edited by all participants of the Exametnet, are then compiled into the annual publication for broad dissemination. This annual publication contains, for the year 1967, the meteorological rocket observational data acquired by each participant. Appendixes concerning related activities of the Exametnet are also included in the annual reports. The appendixes for this report describe the data

and some of the technical and scientific activities of Exametnet participants and in addition, list all Exametnet and related publications. Author

RESPONSE CHARACTERISTICS OF METEOROLOGICAL ROCKET WIND REDUCTION TECHNIQUES
Alvin J. Miller (ESSA, Hillcrest Heights, Md.) Aug. 1969 14 p refs
(NASA-TM-X-1850) Avail: CFSTI CSCL 04B

By use of analytical expressions for position and time as functions of height the response characteristics of the height-based and time-based manual wind reduction techniques for meteorological rocketsondes are deduced. It is shown that the height-based method is more consistent in depicting medium-scale perturbations than is the time-based method. This is accomplished, however, at the expense of the simplicity of the time-based system. Author

INFERENCE OF STRATOSPHERIC TEMPERATURE AND MOISTURE PROFILES FROM OBSERVATIONS OF THE INFRARED HORIZON Final Report
Frederick B. House and George Ohring Washington NASA Aug. 1969 62 p refs
(Contract NAS1-7572)
(NASA-CR-1419; GCA-TR-69-5-N) Avail: CFSTI CSCL 04B

The feasibility of inferring temperature and moisture profiles in the stratosphere from horizon radiances in the 15 micron CO_2 band and the H_2O rotational band was studied. Investigations are performed of inversion techniques, absorption band structures, error analyses and problems related to instrument design. A relatively simple inference method termed the instant inversion technique is developed and applied successfully to both theoretical radiance profiles and observed orison radiances from Project Scanner. A detailed analysis of these inversion results leads to a recommended measurement and data reduction technique to determine both temperature and moisture profiles in the stratosphere and lower mesosphere. INVESTIGATION OF THE TURBULENT WIND FIELD BELOW 150-METER ALTITUDE AT THE EASTERN TEST RANGE
Alfred K. Blackadar, John A. Dutton, H. A. Panofsky, and Anton Chaplin Washington NASA Aug. 1969 105 p refs
(Contract NAS8-21140)
(NASA-CR-1410) Avail: CFSTI CSCL 04B

The development of suitable analytical and empirical models for studying the characteristics of wind near the ground as a source of aerodynamic loads imposed on vehicles during launch operations is discussed. Factors affecting the structure of the wind, wind shear, and associated turbulence so as to permit predictions about the statistical effects of wind on space vehicles, both on the launch pad and during the first few moments of flight are also investigated. Statistical models of the turbulent environment constructed on the basis of the climatology of the relevant parameters are presented. Author

500-mb geopotential data over Antarctica, averaged for a five-year period (1958–1962), revealed one climatic cyclone with the center located inside the triangle formed by stations Vostok, Amundsen-Scott and McMurdo. Periodicities in the atmospheric circulation are described. Stratospheric warmings occur during periods of increased cyclonic activity, and appear to be preceded by a small temperature increase in the troposphere and the lower stratosphere up to the 100-mb and 50-mb levels. In the lower stratosphere the circumpolar vortex over Antarctica does not break down into two centers during stratospheric warming periods as is usually observed over the Arctic, where the powerful cyclonic systems in the northern hemisphere can reach central Arctic areas. QUADRATURE VARIATIONS IN DISCRETE-ORDINATES CALCULATIONS
Robert E. Sullivan Washington Sep. 1969 19 p refs
(NASA-TM-X-1887) Avail: CFSTI CSCL 12A

Techniques to reduce computer time required to solve the Boltzmann transport equation in the discrete ordinates (S_n) approximation were studied. These techniques are based on initial use of low-order angular quadrature or spatial mesh to generate preliminary neutron flux distributions which are then converged in the high-order detail required of the final calculation. Results indicate that these modifications to the standard S_n method can decrease problem execution times and yield results which are as accurate as those obtained with the standard method. Author

THE GENERAL UTILITY AND CHARACTER OF PROSPECTIVE NAVIGATION SERVICES SATELLITE SYSTEMS.
Eugene Ehrlich (NASA, Office of Space Science and Applications, Washington, D.C.).
United Nations, Conference on the Exploration and Peaceful Uses of Outer Space, Vienna, Austria, Aug. 14-27, 1968, Paper 68-95363. 18 p.

Discussion of a navigation satellite - a spacecraft system whose mission is to provide "useful" services during movements of manned terrestrial-based vehicles from one point to another. These services are those that will make travel more economical, safer, and more comfortable, and include position determination service, communications service, and telemetry service for ships, aircraft, etc. Three satellite concepts, two conceived by Westinghouse Corporation and by Philco Corporation, and the TRW navigation satellite concept are discussed. The character of the satellite, orbits, and user equipment are considered in detail. I.P.

AN APPROACH TO AUTONOMOUS ORBITAL NAVIGATION.
Saul Moskowitz (NASA, Electronics Research Center, Guidance Laboratory, Cambridge, Mass.).
(International Federation of Automatic Control, Symposium on Automatic Control in Space, 2nd, Vienna, Austria, Sept. 4-8, 1967, Paper.)
IEEE Transactions on Aerospace and Electronic Systems, vol. AES-4, Sept. 1968, p. 736-751. 6 refs.

Suggestion of a particular autonomous solution to the orbital navigation problem. The solution, although probably nonoptimal, is practical, and many aspects of it have been proven feasible through both analysis and actual spaceflight evaluation. The formulation of the orbital parameters problem in terms of geometric and orientation plays a significant role in the realization of the proposed approach. The scheme yields a direct measure of orbital parameters through several alternate approaches, rather than one which measures and corrects for deviations from a reference trajectory. M.M.

APPROACH GUIDANCE PLANET TRACKER.
Murray K. Cohen (Kollsman Instrument Corp., Elmhurst, N.Y.) and Mark Gorstein (NASA, Electronics Research Center, Cambridge, Mass.).
IN: EASCON '68; INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, ELECTRONICS AND AEROSPACE SYSTEMS CONVENTION, WASHINGTON, D.C., SEPTEMBER 9-11, 1968, RECORD. [A69-13176 03-07]
New York, Institute of Electrical and Electronics Engineers, Inc., 1968, p. 279-289.

Demonstration of a working breadboard model of a planet tracker which can acquire and track over a wide range of planet size and phase illumination. The approach taken is that of a no-moving-part tracker using an image dissector as the sensor. An image of the planet is focused on the dissector cathode. A circular scan with a superimposed radial dither scans the outline of the electron image. Error signals are generated when there is lack of coincidence between the planet and scan centers. A hardware description and the results of a preliminary test evaluation are given. A closed-loop tracking-error analysis which accounts for signal-to-noise effects derived from planet photometric data is also presented. I.P.

ITERATIVE GUIDANCE APPLIED TO GENERALIZED MISSIONS.
Helmut J. Horn (NASA, Marshall Space Flight Center, Dynamics and Flight Mechanics Div., Aero-Astrodynamics Laboratory, Huntsville, Ala.), Doris C. Chandler (NASA, Marshall Space Flight Center, Dynamics and Flight Mechanics Div., Guidance Branch, Huntsville, Ala.), and Volis L. Buckelew (NASA, Marshall Space Flight Center, Dynamics and Flight Mechanics Div., Guidance Branch, Guidance Application Section, Huntsville, Ala.).
(American Institute of Aeronautics and Astronautics, Guidance, Control and Flight Dynamics Conference, Huntsville, Ala., Aug. 14-16, 1967, Paper 67-620.)
Journal of Spacecraft and Rockets, vol. 6, Jan. 1969, p. 4-8. 7 refs.

The iterative guidance mode (IGM) was developed to satisfy the launch vehicle requirements of the Saturn-Apollo flights. Improvements in the formulation of the guidance equations extend the application of the IGM to more general missions: (1) a more sophisticated prediction of the "effective" gravity vector which permits use of the guidance scheme for extended trajectory arcs without deterioration of the optimization characteristics; (2) development of equations which permit the use of total energy as an additional end constraint, reducing or entirely eliminating the need of precomputation and curve fitting for a major group of missions; and (3) the reduction of sensitivity to noise in the acceleration measurement, which is achieved by computing and filtering a fictitious thrust, the product of measure acceleration, and computed mass. The effectiveness of these modifications, which are presented against the background of a short derivation of the basic equations, is numerically evaluated for selected trajectories. (Author)

Edited by Michał Łunc.
Oxford, Pergamon Press, Ltd.; Warsaw, Państwowe Wydawnictwo Naukowe, 1968, p. 393-404.

Discussion of the guidance systems used for U.S. manned space flights, involving a combination of onboard and ground-based systems. Because of the greater storage capacity and speed of the ground computers and the greater ground display capacity, more precise solutions to complicated guidance problems, such as in-flight mission planning, can be achieved. Onboard systems, on the other hand, are better suited for such guidance functions as terminal phase guidance and closed-loop, powered-flight steering. Both the Gemini and Apollo programs utilize guidance systems which rely heavily on both onboard and ground functions. The best qualities of both systems are combined to optimize the safety and success of the mission. P.v.T.

THE DESIGN OF A LARGE ANGLE THREE-AXIS ATTITUDE SERVOMECHANISM FOR SPACECRAFT.
G. Meyer (NASA, Ames Research Center, Moffett Field, Calif.).
IN: INTERNATIONAL ASTRONAUTICAL FEDERATION, INTERNATIONAL ASTRONAUTICAL CONGRESS, 18TH, BELGRADE, YUGOSLAVIA, SEPTEMBER 24-30, 1967, PROCEEDINGS. VOLUME 1 - ASTRODYNAMICS, GUIDANCE AND CONTROL, MISCELLANEA. [A69-17560 06-30]
Edited by Michał Łunc.
Oxford, Pergamon Press, Ltd.; Warsaw, Państwowe Wydawnictwo Naukowe, 1968, p. 499-505.

Definition of an attitude servo as a control system which adjusts the attitude and angular velocity of the spacecraft so as to follow the reference which may be varying in time. Such systems are multidimensional, multivariable, nonlinear, and nonautonomous with infinite sets of forcing functions and initial conditions. A procedure for designing such systems for spacecraft which are controlled by means of an arbitrary angular momentum exchange and storage device is presented. The discussion is restricted neither to small-angle motion nor to single-axis motion of the spacecraft. Indeed, the nonlinear effects arising from kinematics and gyroscopic action, the presence of bounds on angular momentum exchange rate and storage capacity of the controlling device, and variations in system parameters are taken into account. The proposed control scheme forces the spacecraft into the desired attitude by generating torque about all three axes simultaneously. P.v.T.

IRRADIATION AND MANUAL NAVIGATION.
Richard F. Haines and William H. Allen (NASA, Ames Research Center, Moffett Field, Calif.).
(Institute of Navigation, Annual Meeting, 24th, Monterey, Calif., June 19-21, 1968.)
Navigation, vol. 15, Winter 1968-1969, p. 355-365. 45 refs.

Description of the results of a series of investigations of the minimal angle of resolution (MAR) between a point and an extended circular source and between a point source and a simulated horizon. A total of 11 highly trained male observers took part in the experiments. All had 20:20 distance acuity. Each observer moved a point source along various frontal plane meridians behind an extended source in order to determine at what position it became invisible due to the effects of irradiation. The results indicate that: (1) the apparent edge of high-luminance targets can be displaced as much as 15' from the target's actual edge under some viewing conditions; (2) the MAR is a function of both the contrast ratio between the target and background and the luminance of the point source; and (3) the detrimental effects of irradiation are not reduced by using optical filters across the entire field of view to reduce the luminance of the extended source. The findings are related to certain aspects of manual navigation currently in use. M.M.

RECENT PROGRESS IN NAVIGATION SATELLITES.
L. M. Keane (NASA, Electronics Research Center, Cambridge, Mass.).
(INSTITUTE OF NAVIGATION, NATIONAL AIR MEETING ON SUPERSONIC NAVIGATION, SEATTLE, WASH., NOVEMBER 15, 16, 1967, PROCEEDINGS, p. 226-241.)
Navigation, vol. 15, Winter 1968-1969, p. 415-423.

Examination of studies of navigation by satellite which emphasize designing the satellite system so that a user may navigate without the requirement for an onboard transmitter. Compared to a totally active or transponding system, this approach offers the advantages of increased numbers of potential users and increased resistance to interference. Independent measurements of position for North Atlantic ATC can be made simultaneously by incorporating transmitters into aircraft and relaying the position-measurement data on ground command. The results of recent studies of hyperbolic ranging systems and long-baseline interferometer approaches are presented. Spectrum occupancy, satellite power, lane ambiguities, and computational procedures are discussed. Modes of operation which show promise for improving SST operation are described. F. R. L.

A CONCEPT OF MIDCOURSE AND TERMINAL GUIDANCE WITH SINGLE POSITION FIXES OBTAINED FROM ONBOARD OPTICAL MEASUREMENTS.

Harold A. Hamer (NASA, Langley Research Center, Hampton, Va.).

IN: INSTITUTE OF NAVIGATION, ION NATIONAL SPACE MEETING ON SPACE NAVIGATION—PRESENT AND FUTURE, HOUSTON, TEX., APRIL 22-24, 1969, PROCEEDINGS. (A69-35789 19-21)

Washington, D.C., Institute of Navigation, 1969, p. 31-55.

Description of manual procedures developed for midcourse and terminal guidance. Requiring only simple onboard calculations, these procedures lead to guidance predictions sufficiently accurate for emergency backup guidance, rapid onboard navigation and guidance checks, and so forth. The methods have been studied in detail for earth-to-moon trajectories, and are being studied further for application to interplanetary trajectories. They are being considered also with regard to controlling entry angle on moon-to-earth trajectories. The terminal procedure appears to be especially promising for interplanetary missions because the target-planet ephemeris error limits the reliability of earth-based radar measurements. (Author)

GUIDANCE AND CONTROL CONSIDERATIONS FOR ADVANCED MANNED SPACE MISSIONS.

R. A. Gardiner and G. Xenakis (NASA, Manned Spacecraft Center, Houston, Tex.).

IN: INSTITUTE OF NAVIGATION, ION NATIONAL SPACE MEETING ON SPACE NAVIGATION—PRESENT AND FUTURE, HOUSTON, TEX., APRIL 22-24, 1969, PROCEEDINGS. (A69-35789 19-21)

Washington, D.C., Institute of Navigation, 1969, p. 243-262. 19 refs.

Discussion of the directions that future manned navigation, guidance, and control developments are likely to take. The scope of these future developments is shown to be encompassed by the types of space transportation systems to be used and the objectives of the exploration bases to be developed. The requirements for an earth orbital exploration base and its supporting logistics shuttle are considered in the context of past experience and the unique requirements of the future. It is shown that there will be a transition from programs that are principally developmental in nature, to programs which are more operationally conditioned. This fact, coupled with the resulting longer duration missions, indicates a need for a reconsideration of the manned navigation, guidance, and control system approaches. The mechanization challenge for the future will not be in meeting discrete performance requirements. It will result from the need to meet stringent reliability goals that will, more than ever before, be intimately associated with program costs. (Author)

EVALUATION OF STRAPDOWN GUIDANCE SYSTEMS ON INTERPLANETARY MISSIONS.

Ellis F. Hitt (Battelle Memorial Institute, Columbus Laboratories, Systems and Electronics Dept., Columbus, Ohio) and Edmund J. Koenke (NASA, Electronics Research Center, Guidance Laboratory, Cambridge, Mass.).

(American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Dynamics Conference, Pasadena, Calif., Aug. 12-14, 1968, Paper 68-828.)

Journal of Spacecraft and Rockets, vol. 6, May 1969, p. 623-626.

Contract No. NAS 12-550.

Techniques developed for evaluation of strapdown guidance systems designed for automated interplanetary missions are discussed. Cost effectiveness is defined with cost equal to the guidance system weight and effectiveness equal to the probability that the guidance system operates correctly. System weight is the sum of the inertial sensing unit, computer, midcourse correction system, and energy source weights. The effectiveness probability is the appropriate combination of the probabilities related to failures due to component unreliability, insufficient midcourse fuel, and excessive target miss. Using this model, penalty functions relating parameters describing weight, accuracy, reliability, and power requirements of candidate systems are presented. Techniques for estimating these parameters and features of the computer programs implementing the work are discussed. Results for an interplanetary trajectory to Jupiter are presented and point to areas requiring development to improve strapdown guidance systems for automated interplanetary missions. (Author)

A PRECISION AUTOCOLLIMATING SOLAR SENSOR.

R. K. Melugin (NASA, Ames Research Center, Moffett Field, Calif.), J. M. Hall, and D. F. Johnson (Exotech, Inc., Rockville, Md.).

American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-858. 6 p.

Members, $1.00; nonmembers, $1.50.

Contract No. NAS 2-4050.

Alignment changes in attitude sensors and spacecraft structure

that usually occur during launch and space environments cause degradation in attitude control accuracy. A new sensor concept is described which utilizes a miniature, integral electronic autocollimator to measure arc second alignment changes of a high-accuracy solar attitude sensor relative to a reference surface. Although the concept is implemented in a solar sensor, it is applicable to other instruments where high angular measurement accuracy is required. Design features include solid quartz optics to minimize thermal deformation, an optical bandpass filter to minimize detector thermal drift, and signal processing electronics to permit arc second telemetry resolution. Flight data described include an in-flight solar cell detector calibration and a summary of sensor performance on a sounding rocket flight. The sensor solar attitude measurement uncertainty was less than 2.0 arc seconds root sum square. (Author)

GROUND-BASED GUIDANCE FOR LAND-LANDING MANNED SPACECRAFT EQUIPPED WITH LOW-VELOCITY DESCENT SYSTEMS.
Donald J. Bourque (NASA, Manned Spacecraft Center, Houston, Tex.).
American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-864. 7 p.
Members, $1.00; nonmembers, $1.50.

Results of an extensive series of flight tests of a 400-lb spacecraft model, equipped with a 20-ft single-keel parawing in conjunction with an experimental ground-based guidance system called the terminal landing system. The tests were conducted to identify flight-operations requirements and to support test and development of low-velocity descent systems. Three basic approach and landing procedures were designed, tested, and analyzed: (1) high-altitude glide path intercept, (2) low-altitude glide path intercept, and (3) spiral. Analyses of test data indicate that the high-altitude glide path intercept approach is usually best under normal landing conditions but that the low-altitude glide path intercept approach provides the best chance of correcting contingency situations brought about by changes in system performance or predicted winds. It is concluded that the terminal landing system concept is workable as an operational ground-based guidance system. (Author)

Description of an advanced laser tracking technique for future space guidance systems utilizing single mode diffraction limited GaAs lasers, precision laser beam deflectors, and an ultralinear image dissector. A 0.1-deg laser beam and a 0.1-deg instantaneous field of view are scanned synchronously over a 30 by 30-deg acquisition field. Once acquired, a target will be illuminated and tracked anywhere within the 30 by 30-deg field. The particular setup described is directed toward cooperative rendezvous, docking, and stationkeeping applications. Z.W.

GUIDANCE AND CONTROL PARAMETERS OF A PLANETARY CARTOGRAPHIC PROBE.
Saul Moskowitz (NASA, Electronics Research Center, Computer and Guidance Technology Div., Cambridge, Mass.).
American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-879. 15 p. 10 refs.
Members, $1.00; nonmembers, $1.50.

Study of the guidance and control requirements for a planetary orbiting cartographic spacecraft. Mapping scales of $1:10^6$ and $1:5(10^6)$ were selected for the parametric study of lunar, Martian, and Jovian cartography. Relations are derived connecting camera pointing angle, field of view, and imaging resolution in terms of planetary physical characteristics and mapping scale. From these, orbit selection rules are formulated. The choice of an image overlap of 10 per cent leads to spacecraft attitude control requirements. The resulting overall guidance and control parameters are described in terms of possible instrumentation subsystems. (Author)

AUTONOMOUS NAVIGATION IN LONG-DURATION, HIGHLY ECCENTRIC ORBITS ABOUT MARS.
Flora Byars Lowes (NASA, Manned Spacecraft Center, Houston, Tex.).
American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-880. 9 p. 8 refs.
Members, $1.00; nonmembers, $1.50.

Study of the problem of effective autonomous navigation for a manned spacecraft in long-duration, highly eccentric orbits. A statistical error analysis using star-horizon, unknown-landmark, and surface-beacon measurements is presented for a 300-day orbital stay time about Mars. The data are processed with a Kalman filter, and the methods are evaluated for their applicability and effectiveness in minimizing estimated state errors and in producing reasonable measurement schedules. Results of the study indicate that the two optical angle-measurement methods, although constrained by the orbital geometry, can be optimally combined and used for only 4 hours during each day to produce an accuracy of less than 1 n mi. The estimated error in the spacecraft position obtained by continuous onboard-radar tracking of surface beacons is larger than that obtained with the optical navigation techniques. However, this result is dependent on the beacon location errors and was found to improve as knowledge of the locations increased. (Author)

Investigation of the influence of navigation state-vector update on lunar mission completion capability for Saturn V. Midcourse correction budget exceedance rates are compared for unupdated and updated navigation with the expected navigation hardware and scheme errors. Accelerometer failure cases produce large navigation errors and are therefore analyzed extensively. The amount of midcourse correction budget strongly affects the number of exceedances due to navigation hardware, but influences accelerometer failure cases only slightly. The same is true of the effect of launch date, flight azimuth, and opportunity. Vehicle performance dispersions have a large influence on accelerometer-failure cases but do not affect navigation error cases. The expected navigation update accuracy is adequate. For the severe portion of the launch window, the number of times per million flights that mission objectives are compromised through proposed budget exceedance is reduced from 15,400 to 3,360 by navigation update. A NEW MODEL PERFORMANCE INDEX FOR THE ENGINEERING DESIGN OF FLIGHT CONTROL SYSTEMS.
Herman A. Rediess (NASA, Flight Research Center, Edwards, Calif.) and H. Philip Whitaker (Massachusetts Institute of Technology, Cambridge, Mass.).
American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-885. 12 p. 12 refs.
Members, $1.00; nonmembers, $1.50.
Grant No. NGR-22-009-229.

Description of the theory and application of a new performance index, the Model PI, that brings engineering design specifications into the analytical design process. A parameter optimization design procedure is established that starts with practical engineering specifications and uses the Model PI as a synthesis tool to obtain a satisfactory design. The Model PI represents a new criterion for approximating one dynamical system by another, based on a novel geometrical representation of linear autonomous systems. It is shown to be an effective performance index in designing practical systems and to be substantially more efficient than a comparable model-referenced integral squared error performance index. The design procedure is demonstrated by designing a lateral-directional stability augmentation system for the X-15 aircraft. (Author)

FLIGHT TEST REPORT OF EXPERIMENTS IN INERTIAL NAVIGATION SYSTEM UPDATING.
R. J. Madigan and J. Canniff (NASA, Electronics Research Center, Cambridge, Mass.).
American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Mechanics Conference, Princeton, N.J., Aug. 18-20, 1969, Paper 69-842. 8 p.
Members, $1.00; nonmembers, $1.50.

Results of guidance and navigation flight tests, demonstrating some of the improvements that may be achieved in navigation system performance by having an onboard inertial system in communication with an external navigation aid. Aided-inertial system performance and the determination of inertial system flight readiness are discussed. Attention is given to system configuration, aided system performance as a function of controlled degradation of the inertial measurement unit, aided system performance in the position/velocity update mode, and stationary (fixed position) navigation as a technique for evaluating system performance prior to flight commitment. OPTIMUM INTERPLANETARY MIDCOURSE VELOCITY-CORRECTION SCHEDULES.
Thomas B. Murtagh (NASA, Manned Spacecraft Center, Houston, Tex.).
IN: GUIDANCE AND CONTROL IN SPACE; INTERNATIONAL FEDERATION OF AUTOMATIC CONTROL, CONGRESS, 4TH, WARSAW, POLAND, JUNE 16-21, 1969, PROCEEDINGS. (A69-39644 21-21)
Warsaw, Wydawnictwa Czasopism Technicznych NOT (Technical Session 43), 1969, p. 19-38. 11 refs.

Analysis of a theoretical basis for the optimization of interplanetary midcourse velocity-correction schedules as set forth in published literature. Cicolani's results (1966) are discussed, and suggestions are made as to how the limitations involved could be eliminated by reforming his optimal timing equations. Another set of equations is developed for predicting the optimal timing of a sequence of variable-time-of-arrival velocity corrections, using Cicolani's assumptions with regard to the accuracy of the navigation system and the statistical model of the guidance system. The analytical results for individual and combined optimal velocity correction strategies are compared with the results of a simulation program using an earth-based radar and an onboard sextant with a Kalman filter tracking data for two typical interplanetary missions. Good agreement is obtained between the theoretical results and the simulation results, especially when the amount of earth-based radar is increased. V.Z.

A PASSIVE METHOD FOR SCANNING THE CELESTIAL SPHERE.
Albert J. Fleig, Jr. (NASA, Goddard Space Flight Center, Stabilization and Control Branch, Greenbelt, Md.).
(American Institute of Aeronautics and Astronautics, Guidance, Control and Flight Dynamics Conference, Pasadena, Calif., Aug.

12-14, 1968, Paper 68-854.)
Journal of Spacecraft and Rockets, vol. 7, July 1969, p. 846, 847.

A passive method for scanning the celestial sphere which is applicable to missions requiring long lifetime and moderate pointing accuracies is described. The spacecraft is spin-stabilized, and it is the spin axis which is caused to follow the scan pattern. The scan is obtained by combining the gravity gradient-induced precession of the spacecraft's spin axis about its orbit pole with the oblateness-induced precession of the orbit pole. The parameters directly affecting a particular mission are the orbit altitude, inclination, and eccentricity and the body spin rate, cone angle, and inertia difference. Design curves which can be used for parameter tradeoff studies of these factors are included. (Author)

A SIMPLIFIED KALMAN ESTIMATOR FOR AN AIRCRAFT LANDING DISPLAY.
Robert B. Merrick (NASA, Ames Research Center, Theoretical Guidance and Control Branch, Moffett Field, Calif.).
American Institute of Aeronautics and Astronautics, Aerospace Computer Systems Conference, Los Angeles, Calif., Sept. 8-10, 1969, Paper 69-944. 9 p.
Members, $1.00; nonmembers, $1.50.

Description of the application of Kalman filter simulation for estimating the position and velocity of an aircraft from data given by an airborne digital computer in a zero-zero landing system. The on-board estimator must operate within very limited allowances of computation time (70 milliseconds) and computer storage (600 words). The pertinent observation equations are linearized around the current estimated trajectory. The first mechanization of the Kalman filter approach drastically exceeded the on-board computer constraints. Several substantial simplifications were made to meet these constraints, and the results show that equivalent performance is obtainable with a much simpler system. Z.W.

SATELLITE ATTITUDE CONTROL USING A TORQUED, 2-AXIS-GIMBALED BOOM AS THE ACTUATOR.
James A. Gatlin (NASA, Goddard Space Flight Center, Greenbelt, Md.), A. G. Buckingham, and W. H. Pleasants (Westinghouse Electric Corp., Defense and Space Center, Baltimore, Md.).
(American Institute of Aeronautics and Astronautics, Guidance, Control, and Flight Dynamics Conference, Pasadena, Calif., Aug. 12-14, 1968, Paper 68-857.)
Journal of Spacecraft and Rockets, vol. 6, Sept. 1969, p. 1013-1018.

Description of a commandable gravity-gradient boom for satellite precision attitude control. Each of the two boom gimbal axes is equipped with a torquer and a shaft encoder. Satellite attitude control is maintained, using an active attitude reference and torquing against the inertia of the boom. Gravity-gradient torques keep the boom "anchored" in the gravity field, and small momentum wheels damp the boom librations. Yaw-axis momentum control utilizes the orbital coupling of the roll/yaw axes. Results of linear analyses, computer simulations, and some hardware tests exemplify the performance of this commandable gravity gradient system and demonstrate its feasibility. The system can be expected to statically point to any spot on the earth to within $\pm 0.1^{\circ}$ and to track low-altitude satellites to within $\pm 0.5^{\circ}$. P.v.T.

INFLUENCE OF ANGLE OF GLIDE SLOPE ON THE ACCURACY OF PERFORMING INSTRUMENT APPROACHES IN A SIMULATOR
Lindsay J. Lina and George C. Canavos Washington Nov. 1968 44 p refs
(NASA-TN-D-4835) Avail: CFSTI CSCL 17G

A simulator study was made to determine the effect of glide slope angle on the accuracy of performing a landing approach and a go around. Statistical evaluation of the data indicates that the angle of glide slope had no appreciable effect on the accuracy of approach but had an influence on the minimum altitude in the missed approach maneuver. The probability of completing a landing without excessive maneuvering in the last few seconds of flare is reduced by a varying cross wind. Author

COMPARISON OF INFORMATION DISPLAY CONCEPTS FOR LANDING OF VTOL AIRCRAFT
William Gracey Washington Nov. 1968 44 p refs
(NASA-TN-D-4861) Avail: CFSTI CSCL 17G

A variety of instrument displays for the landing of VTOL aircraft are described. The displays are classified in terms of basic concepts for the presentation of attitude and guidance information. The concepts range from the simple display of vertical- and horizontal-situation information to the more complex combination of attitude and guidance information in perspective form. The information elements of the displays are presented either in abstract form or with varying degrees of realism. Guidance information is combined as flight-director commands in some displays and as pictorial presentations in others. Tests of those displays that have been evaluated either in simulators or in flight are discussed. The review of these tests shows that the only display with which VTOL landings have been achieved in flight (under simulated zero–zero conditions) is the real-world display of a closed circuit television system. A televised display of a simulated real-world landing site is therefore suggested as a possible form of display for achieving VTOL landings under zero–zero conditions. Author

ANALYTIC APPROXIMATIONS FOR APPLICATION TO SPACECRAFT OPTICAL NAVIGATION ON SHORT DATA ARCS
Alton P. Mayo and William M. Adams, Jr. Washington Nov. 1968 32 p refs
(NASA-TN-D-4863) Avail: CFSTI CSCL 17G

The standard least squares orbit determination procedures are simplified for application to a navigation system where position fixes are taken over a short trajectory arc. Basic assumptions used are as follows: (1) for small perturbations in spacecraft state, velocity deviations remain constant and position deviations increase linearly with time and (2) the sensitivity of the measurements to small spacecraft position changes remains constant over the trajectory arc. Simple analytic expressions are then derived for estimating the accuracy of the spacecraft position and velocity as a function of the number of fixes and the time span over which the fixes are made, or inversely the number of fixes and the time span over which they must be made for a prescribed position and velocity accuracy. For a large number of measurements the standard deviation of the position error was shown to vary inversely as the square root of the number of measurements, as expected, and the standard deviation of the velocity error was shown to vary inversely as the product of the square root of the number of measurements and the time span over which the measurements are made. Simplified equations are also derived for determining the orbit (state) of the spacecraft. Author

SEXTANT SIGHTING MEASUREMENTS FROM ON BOARD THE GEMINI 12 SPACECRAFT
Donald W. Smith and Bedford A. Lampkin Washington Dec. 1968 30 p refs
(NASA-TN-D-4952) Avail: CFSTI CSCL 17G

21 NAVIGATION

The capability of a spacecraft navigator to make in-flight navigation measurements from on board the spacecraft using a hand-held sextant has been studied extensively. Tests on board the orbiting Gemini 12 spacecraft were designed to determine the effect of the actual spaceflight environment on navigator performance. The results show that: (1) hand-held sextant measurement performance is excellent providing a standard deviation of measurement error less than 10 arc seconds; (2) spacecraft rotational motion and the actual spacecraft environment had little effect on the navigator performance; and (3) window-induced measurement errors in the Gemini 12 spacecraft were small and predictable. The optical hand-held sextant appears to have application to on-board navigation for future manned space flights. Author

INFRARED HORIZON PROFILES FOR WINTER CONDITIONS FROM PROJECT SCANNER

Ruth I. Whitman, Thomas B. Mc Kee and Richard E. Davis Washington Dec. 1968 127 p refs

(NASA-TN-D-4905) Avail: CFSTI CSCL 17G

Measured horizon radiance profiles in spectral bands of 615 cm^{-1} to 715 cm^{-1} (carbon dioxide) and 315 cm^{-1} to 475 cm^{-1} (rotational water vapor) from the Project Scanner flight of December 10, 1966 are shown. Data cover a latitude range from 13° North to 61° North. Excellent agreement between the measured and independently predicted radiance profiles in the CO_2 band where horizontal temperature gradients are small verifies the analytical technique. When the horizontal temperature gradients are large, the computational model used is inadequate for predicting radiance profiles. Seasonal and latitudinal variations in radiance profiles are shown to be primarily a function of the variations in temperature structures. In the 315 cm^{-1} to 475 cm^{-1} (H_2O) region, mixing ratios of water vapor were deduced at low latitudes from the radiance measurements. Under both summer and winter meteorological conditions, the same trends in the mixing ratio above the tropopause are evident, that is, a region of relatively constant mixing ratio followed by a region of increasing mixing ratio. SIMULATION STUDIES OF THE SUPERSONIC TRANSPORT IN FUTURE AIR TRAFFIC CONTROL SYSTEMS

Richard H. Sawyer, Norman S. Silsby, and Milton D. Mc Laughlin Washington Dec. 1968 90 p refs

(NASA-TN-D-4944) Avail: CFSTI CSCL 17G

The problems anticipated for the supersonic transport (SST) in operations in simulated Air Traffic Control (ATC) systems were studied in real time by using an SST aircraft flight simulator and the Federal Aviation Administration ATC simulation facilities. Airline crews operated the SST flight simulator, and experienced air-traffic controllers operated at ATC simulation facilities. Design-study configurations of the SST were used in the tests. The test program consisted of departures and arrivals under weather conditions which required operations by FAA Instrument Flight Rules in the New York, Los Angeles, San Francisco, and London terminal areas. For the future ATC system concepts investigated, substantial changes in course (up to nearly 50°) at supersonic speeds were required in many instances on the airway routes and to effect transition to and from the high-altitude track systems. Such changes were detrimental to SST performance and increased the workload for the crew. Further, substantial amounts of maneuver fuel were required for complying with ATC flight-path restrictions and for following indirect routings along the airways and to and from the high-altitude track systems. MINIMUM THRUST FOR CORRECTING KEPLERIAN ORBITS WITH APPLICATION TO INTERPLANETARY GUIDANCE

Frederick W. Boltz Washington Dec. 1968 69 p refs

(NASA-TN-D-4945) Avail: CFSTI CSCL 22C

The first-order thrust requirements obtained in the analysis are presented in terms of the optimum thrust angle and the minimum derivative of thrust-produced velocity impulse with respect to the particular orbital parameter to be corrected. Minimum thrust requirements are found for correction at a given point along an orbit of the semimajor axis, the eccentricity, and the true anomaly or orientation of the line of apsides (argument of pericenter) within the orbital plane. Minimum thrust requirements are also found for correcting the orbital radius at an arbitrary point and the elapsed flight time to arrive at that point. In addition, thrust requirements are obtained for correction at a given point along an orbit of the elapsed flight time to a second arbitrary point having a fixed value of orbital radius. A general formulation of the thrust requirements for simultaneous correction of any pair of the orbital parameters that define the in-plane motion is presented in terms of the minimum thrust requirements for correction of each of the parameters separately. PLANETARY PROBE GUIDANCE ACCURACY INFLUENCE FACTORS FOR CONJUNCTION-CLASS MISSIONS

Thomas B. Murtagh Washington Jan. 1969 42 p refs

(NASA-TN-D-4852) Avail: CFSTI CSCL 22C

The influence of spacecraft onboard radar data type and accuracy, of nominal entry trajectory parameters, and of planet radius uncertainty for unmanned planetary probe guidance is presented for a typical conjunction-class mission. The results of the analysis indicate that a probe guidance corridor on the order of 24 nautical miles can be obtained for a total midcourse velocity requirement less than 100 fps. The corridor results were more sensitive to variations in the nominal entry trajectory parameters than to variations in the assumed error in the radius of the target planet. Author

SECOND ORDER ERRORS IN LINEARIZED VELOCITY CORRECTIONS AND THEIR EFFECTS ON THE RATE OF CONVERGENCE OF ITERATIVE SOLUTIONS

John D. McLean Washington Feb. 1969 37 p refs

(NASA-TN-D-5037) Avail: CFSTI CSCL 17G

Two methods of computing linearized corrections are considered. The first, referred to as the linear method, computes the velocity correction as a linear function of position and velocity deviations at the time of the correction. The second method, referred to as the half-linear method, computes the trajectory ahead to the terminal time and then determines velocity correction as a linear function of the actual terminal error. The linear and half-linear guidance laws are presented together with formulas for predicting the errors in them caused by nonlinearity. These formulas are based on the assumption that the errors are adequately represented by second-order terms. Second-order errors are presented for both guidance methods on conic trajectories with eccentricities of 0.2, 0.98, and 2.0, and the errors for the two guidance methods are compared. A simulated lunar mission is used as an example to show how the data from the conic trajectories can be used to give a qualitative idea of the relative performance of the linear and half-linear methods on an n-body trajectory. The relative advantage of using the linear or half-linear method to compute the first velocity correction when iteration is used to reduce the residual error is investigated. Also, the effect of neglecting perturbing forces in calculating the state transition matrix is considered. Author

AIRCRAFT NAVIGATION
S. S. Fedchin et al Feb. 1969 570 p Transl. into ENGLISH of the book "Samoletovozhdeniye" Moscow, Transp., 1966
(NASA-TT-F-524) Avail: CFSTI CSCL 17G

The theory and practice of aircraft navigation at the modern level of aviation technology are summarized in this book; the most important practical problems of the utilization of general, radio engineering, and astronomical means of aircraft navigation are set forth; the procedure of the pilot's preparation for flight, the means of calculating the distance and duration of a flight, and the carrying out of prelanding maneuvering and landing of the aircraft under complex meteorological conditions during the day or at night are elucidated. The basic material of the book, sufficient for the practical mastery of the means and methods of aircraft navigation, is presented with the application of mathematics within the limits of a secondary school course. The problems which are necessary for a deeper study of the material are discussed in terms of principles of higher mathematics. The book is intended for pilots and navigators. It can be used as a textbook for students of civil aviation educational institutions. Author
