SUMMARY

A new variant of CPW which has been termed channelized CPW, CCPW, is presented. Measured and computed propagation characteristics are presented. Lumped equivalent circuit element values for a CCPW open circuit and right angle bend have been obtained. CCPW power divider junctions and a coax-to-CCPW in-phase, radial power divider are also presented.

INTRODUCTION

Coplanar waveguide, CPW, on a dielectric substrate consists of a center strip conductor with semi-infinite ground planes on either side (1). A variant of CPW is grounded coplanar waveguide, GCPW, which has an additional ground plane on the opposite side of the substrate to facilitate heat removal and packaging (2). These transmission lines have several advantages which make them ideally suited for microwave integrated circuits. The disadvantage of CPW and GCPW is that the structure can support spurious modes besides the CPW mode since the transverse dimensions may be several wavelengths.

This paper presents a new variant of CPW. The new structure has side walls which, together with the ground plane, constitutes a channel and hence is appropriately termed as channelized coplanar waveguide, CCPW. A shielding structure may be used to further confine the electromagnetic fields. This structure is shown in Fig. 1. The enclosure of the CPW transmission line eliminates radiation loss and spurious surface modes created at discontinuities. Also, because the basic transmission line structure is CPW, CCPW maintains the inherent advantages over microstrip for easy shunt as well as series mounting of active and passive components.

To maintain a single CPW mode of propagation, CCPW must be designed to suppress the dielectric filled rectangular waveguide mode, the microstrip mode, and the rectangular coax mode. The channel width, $2B$, is chosen such that the rectangular waveguide mode is cutoff. The microstrip and rectangular coax modes are suppressed by the proper selection of the slot width, W , the center strip

width, S , and the substrate thickness, D . The ratios W/D and S/D must be sufficiently small to suppress the microstrip mode. The ratio W/B must be small to suppress the rectangular coax mode.

This paper presents lumped element circuit models for several CCPW discontinuities, together with their element values as a function of frequency. The discontinuities characterized are an open circuit and a right angle bend. The measured frequency dependence of the effective dielectric constant, $\epsilon(\text{eff})$, and the unloaded quality factor, Q , are also presented for CCPW lines fabricated on $\epsilon(r) = 2.2 \pm 0.02$ RT/Duroid 5880, $\epsilon(r) = 6.0 \pm 0.15$ RT/Duroid 6006, and $\epsilon(r) = 10.2 \pm 0.25$ 3M Epsilam-iO substrates. This is followed by the design and characterization of a CCPW T-junction and 1-to-3 in-phase, matched power divider. Lastly, the performance of a novel Coax-to-CCPW in-phase, N-way radial power divider circuit is presented.

METHOD OF MEASUREMENTS

A resonator technique similar to that described by Richings (3) and Stephenson and Easter (4) was used. The $\lambda/4$ end coupled stubs could not be etched off as in the case of microstrip since this would alter the CCPW open end parameters. Hence, a four resonator set had to be fabricated for each frequency to determine the end effects. This will contribute some errors to the results because the resonator lengths and gaps will not be identical for the two $\lambda/2$ and λ resonators. The circuit dimensions were measured to ± 0.0002 in. The gaps were varied to maintain a coupling coefficient, β , less than 1. For most of the resonator sets $\beta \leq 0.3$. This is a sufficient condition to minimize the loading of the resonator for transmission lines with Q 's ≥ 100 as are reported in this paper. The Q was determined through a technique given in Ref. 5.

EFFECTIVE DIELECTRIC CONSTANT

The $\epsilon(\text{eff})$ was measured over the frequency range of 3 to 18 GHz for several unshielded CCPW lines and the results are shown in Fig. 2. The CCPW lines have been modeled using Cohn's technique (6) and the $\epsilon(\text{eff})$ is plotted for each CCPW line. $\epsilon(\text{eff})$ of grounded CPW calculated from the closed form expression of Ghone and Naldi (7) is also plotted for comparison.

Effect of Substrate Thickness

$\epsilon(\text{eff})$ was measured for unshielded CCPW lines fabricated on substrates with D in the range of 0.062 to 0.250 in. The CCPW parameters S , W , $2B$, and $\epsilon(r)$ were held fixed at 0.045, 0.010, 0.200, and 2.2 in. respectively. No variation in $\epsilon(\text{eff})$ was observed for the thicker substrates, $W/D \leq 1/12.5$. $\epsilon(\text{eff})$ of the thinner substrate, $W/D \approx 1/6$, was 0.7 percent higher than the other measured cases; this may be due to the microstrip mode.

Effect of Cover Height

$\epsilon(\text{eff})$ was measured for shielded CCPW lines with cover heights of $H = D$, $2D$, and $4D$. Resonators were tested with $\epsilon(r)$, D , S , and W equal to 2.2, 0.125, 0.045, and 0.010 in. respectively. Resonators were also fabricated on $D = 0.050$ in., $\epsilon(r) = 6$ and 10.2 substrates. In all the cases, the change in $\epsilon(\text{eff})$ from the unshielded case was negligible.

LOSS MEASUREMENTS

Figure 3 shows the measured Q for resonators of length λ as a function of S for a fixed frequency and $\epsilon(r)$. The Q of the unshielded resonators decreases with increasing S indicating an increase in radiation loss. The shielding enclosure eliminates the radiation loss as evidenced by the higher Q .

Figure 4 shows the measured Q over the frequency range of 3 to 18 GHz for λ resonators both with and without shielding. The reduction in Q with increasing frequency for the unshielded case is due to the increase in radiation loss. With shielding, the Q is observed to increase with frequency due to the reduction of radiation loss. A change in the cover height from $H = 2D$ to $H = D$ showed no measurable difference in Q . The effect of varying D in the range of 0.062 to 0.250 in. on Q was measured. No measurable variation in Q over the frequency range of 8 to 18 GHz was observed.

OPEN END LINE EXTENSION

When a CPW line is terminated in an open circuit, there is an excess fringing of the electromagnetic fields which gives rise to a capacitance, C_f (8). This capacitance is equivalent to a short length of a transmission line, L_o , terminated in a perfect open circuit. The open end line extension for the unshielded CCPW de-embedded from the resonator data is shown as a function of frequency in Fig. 5. There was no variation in L_o for resonators with a cover height of $H \geq 2D$.

RIGHT ANGLE BEND

A CCPW right angle bend and its equivalent circuit are shown in Fig. 6. The capacitance, C , is created by the accumulation of excess charge at the corners in the two slots and the resulting excess electric fields to the ground plane. The current flow interruption creates the excess

inductance which can be equated to a length of transmission line, L . Radiation from the corner is represented by the shunt resistance. The equivalent circuit parameters were found through resonator techniques and are shown in Table I.

CHANNELIZED CPW MATCHED T-JUNCTION

A CCPW matched T-junction was fabricated. At the T-junction, the characteristic impedance, Z_1 , of the two side arms are in parallel and the net impedance the input arm sees is $Z_1/2$. Therefore, for impedance matching, the characteristic impedance, Z_0 , of the feed line was set equal to $Z_1/2$. The insertion loss of the junction, including test fixture loss, is 0.5 dB and the return loss is greater than 10 dB from 3 to 6 GHz.

CHANNELIZED CPW MATCHED 1-TO-3 IN-PHASE POWER DIVIDER

A CCPW matched 1-to-3 in-phase power divider was fabricated. An important requirement for a power divider is that the signal emerging from the output ports is in phase. In order to achieve this, the path length between the side arms and the thru arm must be equalized. This is achieved by tapering the center conductors of the three output lines and the input line so they meet at a point. The taper also facilitates impedance matching of the input port to the output ports. For the octave bandwidth of 3 to 6 GHz, a maximum amplitude imbalance of 1 dB was measured. The isolation between output ports was 9 dB and the input return loss was greater than 10 dB.

COAX-TO-CHANNELIZED CPW IN-PHASE N-WAY RADIAL POWER DIVIDER

A coax-to-CCPW in-phase, four-way radial power divider is shown in Fig. 7. The junction is formed by the intersection of four CCPW lines. Power is coupled to this junction from a coaxial cable whose outer conductor is slotted along the \hat{z} direction to form four coupled transmission lines. The center pin of the coaxial line meets the intersecting CCPW center conductors while the four coupled outer conductors meet the CCPW ground planes. Therefore, the electric current at the open end of the coax is divided into the four CCPW lines as illustrated in Fig. 8. This arrangement has the advantage of holding ground planes at the same potential and exciting the four CPW lines in equal amplitude and phase. The amplitude and the phase balance for this circuit over a 2 to 18 GHz band are within 0.5 dB and 1° respectively; the isolation is 10 dB between the output ports.

CONCLUSIONS

This paper presents a new variant of CPW which has been termed CCPW. Measured propagation characteristics for CCPW are presented and compared with computed values. Equivalent circuit component values are presented for an open circuit and a right angle bend. CCPW power divider junctions and a novel coax-to-CCPW in-phase, radial power divider are also described.
