Some methods for improving cell peformance

- Smart termination
 - negative voltage slope, $\partial V/\partial t < 0$
 - rise in temperature, $\partial T/\partial t = Y$
- Charge current waveform changes
 - relaxation, I = 0
 - discharge burp, I < 0</p>

Areas of improvement remaining

- can break-in period to maximum capacity be accelerated?
- can discharge capacity be increased without compromising cycle life?
- can charge heat be reduced further?

Modifying the current waveform shown effective with NiCd cells

Methods to study effects of relaxation and burp discharge

	Charge	Termination Method		
	Waveform	∂T/∂t = X	∂ V/ ∂ t = - Y	$\partial^2 V / \partial t^2 = 0$
Galvanostatic	Constant current	X	X	
Pause	Constant current with short relaxation periods	X	X	X
Burp	Constant current with relaxation periods and discharge burps	X	X	X

Effects of interrupting the galvanostatic charge

- Lowers Ah input rate by 2.7%
- Total Ah input lowered by 4%, while Ah output unchanged
- Overvoltages essentially the same
- Charge heat rate, W, reduced throughout the charge *
- Total charge heat, J, lowered by 8% *
- Rise in cell temperature (T_{final} T_{init}) not affected *
- * evaluated at 425th cycle

-587-

Other Secondary Technologies Session

Effects of adding 5 ms discharge burps

- Reduces Ah input rate by 1.1%
- Increases total Ah input and output by 5%
- Lowers charge heat rate (e.g., by an additional 6% at midcharge point) *
- Lowers rise in cell temperature by ~1 °C, despite larger Ah input *
- Reduces overvoltage throughout charge (e.g., by ~50 mV near end of charge) *

Do differences between burp vs pause charging depend on cycle number?

break-in period shorter with pause

Is overvoltage reduction developed with cycle number?

* evaluated at 425th cycle

Do other NiMH cell designs exhibit similar behavior?

Performance dependent on charge method

- cycle life
- rise in cell temperature
- overvoltage
- break-in period
- etc.

Conclusions

Addition of "smart" termination to simple galvanostatic charge *

- prolongs cycle life
- lengthens break-in period

Addition short relaxation periods to "smart" galvanostatic charge *

- Iowers total Ah input without compromising discharge capacity
- shortens break-in period
- no effect on cycle life (to 400 cycles)
- Adding very short discharge burps to the relaxation periods *
 - increases total Ah input and output by same amount
 - lengthens break-in period
 - no effect on cycle life (to 400 cycles)

Burp charging improves cycle life with different NiMH cell designs

* Based on studies with 1 cell design

On-going Work

- Continue cycling comparison of galvanostatic, pause, and burp charging
- Compare morphology changes of electrodes
 - particle size distribution
 - porosity
- Compare burp heat effects with other cell designs
- Develop thermal model of NiMH cell based on obtained properties
 - heat capacity
 - thermoneutral potential
 - 9**E/**9**T**

Why does burping lower overvoltage?

Possible reasons;

- dislodges O₂ from cathode pores, preventing local current density rise
- increases or maintains electrode porosity, aiding ion transport
- results in less O₂ evolution, due to lower charge heat
- SEM analysis to date of electrodes after 400 cycles is unsupportive
 - particle size differences are small in negative electrode
 - porosity differences not yet discernable in positive electrode

In-situ analysis of positive electrode with 7x magnification fibroscope reveals

- bubbling activity increases with SOC during charging
- differences between charge techniques are not discernable

On-going Work

- Compare galvanostatic, pulse, and burp charging with 50x magnification
 - place electrode coil from NiMH cell into a transparent KOH beaker
 - place a reference electrode (Hg/HgO) between the electrodes
 - expose a portion of positive electrode for viewing
 - control waveform with an automated waveform generator
 - mark occurrance of pulses and burps with audio signal
 - record video and audio of bubbling activity on positive during charge

First Application - EMU Helmet Interchangeable Portable (EHIP) Lights

- Battery (P/N SED39130223)
 - 15 Sanyo NiMH cells arranged 3P-5S
 - strings connected in parallel to power 6W lights for 7 hours
 - bottom glide latches allow EVA replaceability from helmet
 - Raychem polyswitches limit current to 1.5 A/cell
 - weighs 1.04 kg
- Charger (P/N QC-1001)
 - charges 4 batteries in <4 hours independently and simultaneously
 - "burp" charge control achieved by 4 ICS-1702 chips
 - uses shuttle 28 \pm 4 Vdc input
 - strings connected in series (18V) during charging
 - thermistors in battery provide temperature input to charger
 - velcro mounted to mid-deck area
 - weighs 1.39 kg
- Charger has passed all certification tests
- New lights, battery, and charger first flight is STS-82 in Feb 97
