What is Image Registration …

• Definition

“Exact pixel-to-pixel matching of two different images or matching of one image to a map”

• Navigation or Model-Based Systematic Correction
  – Orbital, Attitude, Platform/Sensor Geometric Relationship, Sensor Characteristics, Earth Model, etc.

• Image Registration/Feature-Based Precision Correction
  – Navigation within a Few Pixels Accuracy
  – Image Registration Using Selected Features (or Control Points) to Refine Geo-Location Accuracy

• Image Registration as a Post-Processing or as a Feedback to Navigation Model
What is Data Integration and Fusion …

• **Definition “Data Integration”**

  “Data integration means combining data coming from different sources and providing users with a unified view of these data”
  
  – It usually does not refer to the extraction of relevant information, but rather to combination and/or concatenation of data (e.g. for a GIS or data assimilation or within a model)

• **Definition “Data Fusion”**

  “Data fusion is a formal framework in which are expressed the means and tools for the alliance of data originating from different sources. Data fusion aims at obtaining information of greater quality; the exact definition of 'greater quality' will depend upon the application.” (Wald, 1999)
The Role of Image Registration and Fusion in the Processing of Remotely Sensed Data

- Essential for spatial and radiometric calibration of multitemporal measurements for creating long-term phenomenon tracking data

- Used for accurate change detection and land cover/land use assessment

- Basis for extrapolating data throughout several scales for multi-scale phenomena (distinguish between natural and human-induced)
Impact of Misregistration

• (Towsnhend et al, 1992) and (Dai & Khorram, 1998): small error in registration may have a large impact on global change measurements accuracy
• e.g., 1 pixel misregistration error => 50% error in Vegetation Index (NDVI) computation (using 250m MODIS data)

Human-induced land cover changes observed by Landsat-5 in Bolivia in 1984 and 1998 (Courtesy: Compton J. Tucker and the Landsat Project, NASA Goddard Space Flight Center)

• Influence of image registration on products validation
• Impact of misregistration on legal, economic and sociopolitical (e.g., resource management), etc.
Image Registration and Fusion Applications

- **Multimodal registration and fusion**, for integrating complementary information from multiple sensors
  - Example: LIDAR and optical data for precision landing

- **Multitemporal registration and integration**, for change detection and Earth resource surveying
  - Example: Landsat Program, Landsat-4/5, Landsat-7 and Landsat-8

- **Viewpoint registration and fusion**, for landmark navigation, formation flying (sensor web) and planet exploration
  - Example: Landsat-7, EO-1 and MODIS for disaster management

- **Template registration and integration**, for content-based searching or map updating
  - Example: Finding flux towers in MODIS or EO-1 data
Challenges in Image Registration for Remote Sensing

• Remote Sensing vs. Medical or Other Imagery (“Big Data”)
  – Variety in the types of sensor data and the conditions of data acquisition
  – Size of the data
  – Lack of a known image model
  – Lack of well-distributed “fiducial points”

• Navigation Error (or varying “Initial Conditions”)
  – Historical satellites (e.g., Landsat-5 compared to Landsat-7)
  – Following a maneuver (e.g., star tracking)

• Needs:
  – Sub-pixel accuracy
  – Robustness to recurring use
  – Speed and High-Level of Autonomy (Near- or Near-real time applications, e.g., disaster management)
  – On-the-ground or On-Board Processing
Challenges in Image Integration and Fusion for Remote Sensing

• Same challenges than registration:
  – Various spectral and spatial resolutions
  – Acquired at different times, under different conditions
  – For example: Time series over a large number of years involving multiple programs and/or instruments

• Misregistration error

• Difficulty in quality assessment because of the lack of reference against which one may compare properties of the fused image; validation often done by the end-application not at the time of the fusion
  – Objective function often missing
  – Measures such as correlation, entropy, etc.
Challenges with Atmospheric and Cloud Interactions

*Baja Peninsula, California; 4 different times of the day (GOES-8)*
Challenges with Multitemporal Effects

Mississippi and Ohio Rivers before & after Flood of Spring 2002 (Terra/MODIS)
Challenges with Relief Effect

SAR and Landsat-TM Data of Lopé Area, Gabon, Africa
Challenges with Relief Effect (2)

Use Digital Terrain Models (DEM) => Taking terrain into account in matching
Theoretical vs. Operational Approaches for Image Registration

- Many promising theoretical approaches with good results on specific datasets, but no gold standard algorithm for operational use
- Every instrument has a working operational approach, often solved the same way (e.g., with Normalized Cross Correlation)
- Operational Team Requirements:
  - Know models of sensor/platform/etc.
  - Have access to complete data set
  - Have continuing demands/responsibility
  - Are registering same plots of land again and again – can invest effort in data preparation
  - Can’t take big risks on not fully proven methods
- Do not need one magic method – need toolbox of many approaches
Challenges with
Institutional Challenges

• Different communities/literature/requirements
  – Photogrammetry
  – Computer vision/image processing
  – Operational teams
  – Remote sensing/Earth scientists/end users

• Demanding/varying mission requirements
  – Caution in system design, new methods

• Difficulty to share data or models between instruments

• Understanding the requirements
  – Know what data is used for
  – Have to fuse many data sets
  – Have access to ancillary data
  – Know cultural and historical data
Precision Correction in Operational Systems

Some Examples - Highlights

- **AVHRR**: AUTONAV algorithm computes attitude corrections using Maximum Cross-Correlation (MCC) method between sequential images
- **GOES/METEOSAT**: CPs and NOAA Shoreline database (GSHHS) used to match edges extracted from meteorological images
- **LANDSAT**: CP image chips (1m orthorectified) using Gaussian pyramid, automatic Moravec window extraction and NCC or Mutual Information
- **MISR**: Database of 120 GCPs (each a collection of nine geolocated image patches of a well-defined and easily identifiable ground features, from Landsat, terrain-corrected, data) & ray casting simulation software
- **MODIS**: Biases and trends in the sensor orientation determined from automated control point (CP) matching and removed by updating models of the spacecraft and instrument orientation; finer CGPs from Landsat TM and ETM aggregated using PSFs and correlated with NCC
- **SEAWIFS**: Reference catalog of islands GCPs and matching using spectral classification and clustering of data, “nearest neighbor” and pattern matching techniques
- **SPOT**: Reference3D™ using DEM ortho-rectified simulated reference image in focal plane geometry, matching of input image to simulated using NCC and resampling into a cartographic reference frame
- **VEGETATION**: Database of CPs from SPOT for VEGETATION1 and VEGETATION1 for VEGETATION2; Matching by NCC
Precision Correction in Operational Systems (2)

- **Operational Environment**
  - Platform/sensor models integrated
  - Historical data available for statistics/modeling
  - Robustness and consistency over time is a requirement

- **General Characteristics**
  - Use database of Ground Control Points (GCP) or Chips
  - Normalized Cross-Correlation (NCC) is the most common similarity measure
  - Digital Elevation Model (DEM) is rarely integrated in the registration process
  - Cloud masking usually integrated
  - Errors in the \([0.15-0.5]\) range

- **Various approaches. No gold standard approach:**
  - Create framework to validate new image registration components and algorithms
  - For each algorithm, define “region of convergence” and “region of divergence”
  - Provide guidance/recommendations for utilization of algorithms and their components
  - Provide fast algorithms for real-time/near-real-time and on-board applications
Section 1b
Brief survey of registration, integration and fusion methods
Brief Image Registration Survey
Image Registration Frameworks

- **Mathematical Framework**
  - $I_1(x,y)$ and $I_2(x,y)$: images or image/map
  - find the mapping ($f, g$) which transforms $I_1$ into $I_2$:
    $$I_2(x,y) = g(I_1(f_x(x,y), f_y(x,y)) + n(x,y)$$
    - $f$: spatial mapping
    - $g$: radiometric mapping
    - $n$: sensor and other imaging noise
  - Spatial Transformations “$f$”
    - Translation, Rigid, Affine, Projective, Perspective, Polynomial, …
  - Radiometric Transformations “$g$” (Resampling)
    - Nearest Neighbor, Bilinear, Cubic Convolution, …

- **Algorithmic Framework (Brown, 1992)**
  1. Feature Extraction
  2. Feature Matching (Similarity Metrics & Matching Strategy)
  3. Image Resampling (if needed)
Image Registration Components

0  Pre-Processing
   • Cloud Detection, Region of Interest Masking, ...

1  Feature Extraction ("Control Points")
   • Gray Levels, Salient Points (e.g., Edges, Edge-like such as Wavelet Coefficients, Corners), Lines, Contours, Regions, Scale Invariant Feature Transform (SIFT), etc.

2  Feature Matching
   • Choice of Spatial Transformation (\textbf{function f}: a-priori knowledge)
   • Choice of Search Strategy :
     – Global vs Local, Multi-Resolution, Optimization, ...
   • Choice of Similarity Metrics
     – L2-Norm, Normalized Cross-Correlation, Mutual Information, Hausdorff Distance, ...

3  Remapping/Resampling (\textbf{function g}: if necessary)
General Approaches to Registration

1. Manual Registration
2. Correlation-Based Methods
3. Fourier-Domain and Other-Transform Based Approaches
4. Mutual Information and Distribution-Based Approaches
5. Feature-Point Methods
6. Contour- and Region-Based Approaches
Feature Extraction

• Gray levels
• Salient points
  – Edge-like, wavelet coefficients (Simoncelli and Freeman ‘95)
  – Corners (Kearny et al. ‘87, Harris and Stephens ’88, Shi and Tomasi ‘94)
• Lines
• Contours, regions (Govindu et al. ‘99)
• Scale invariant feature transform (SIFT), Lowe ‘04
Similarity Metrics

- **$L_2$-norm:**
  - Minimize the sum of squared errors (SSD) over overlapping subimage
  \[
  SSD(x, y) = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} [I_1(m, n) - I_2(m - x, n - y)]^2
  \]

- **Cross-correlation**
  - Maximize *cross-correlation* over image overlap
  \[
  I_1(x, y) \circ I_2(x, y) = \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} I_1(m, n)I_2(x + m, y + n)
  \]

- **Normalized cross-correlation (NCC)**
  \[
  NCC_{I_1, I_2}(x, y) = \frac{\sum_{m=0}^{M-1} \sum_{n=0}^{N-1} [I_1(m, n) - \bar{I}_1][I_2(x + m, y + n) - \bar{I}_2]}{\sqrt{\sum_{m=0}^{M-1} \sum_{n=0}^{N-1} [I_1(m, n) - \bar{I}_1]^2} \cdot \sqrt{\sum_{m=0}^{M-1} \sum_{n=0}^{N-1} [I_2(x + m, y + n) - \bar{I}_2]^2}}
  \]
**Similarity Metrics (2)**

- **Mutual information (MI):**
  Maximizes the degree of statistical dependence between the images

\[
MI(I_1, I_2) = \sum_{g_1} \sum_{g_2} p_{I_1,I_2}(g_1, g_2) \cdot \log \left( \frac{p_{I_1,I_2}(g_1, g_2)}{p_{I_1}(g_1) \cdot p_{I_2}(g_2)} \right),
\]

or using histograms, maximizes

\[
MI(I_1, I_2) = \frac{1}{M} \sum_{g_1} \sum_{g_2} h_{I_1,I_2}(g_1, g_2) \cdot \log \left( \frac{Mh_{I_1,I_2}(g_1, g_2)}{h_{I_1}(g_1) \cdot h_{I_2}(g_2)} \right)
\]

where \( M \) is the sum of all histogram entries, i.e., number of pixels (in overlapping subimage)
• Partial Hausdorff distance (PHD):

\[ H_K(I_1, I_2) = \min_{p_1 \in I_1} \min_{p_2 \in I_2} \text{dist}(p_1, p_2), \]

where \( 1 \leq K \leq |I_1| \) (Huttenlocher et al. ‘93, Mount et al. ‘99)
Similarity Metrics (4)

- Discrete Gaussian mismatch (DGM):

\[ w_\sigma(a) = \exp\left(- \frac{\text{dist}(a, I_2)^2}{2\sigma^2}\right) \]

where \( w_\sigma(a) \) denotes the weight of point \( a \), and

\[ \text{DGM}_\sigma(I_1, I_2) = 1 - \frac{\sum_{a \in I_1} w_\sigma(a)}{|I_1|} \]

is similarity measure ranging between 0 and 1
Transformation Functions

- Translation-only, rigid
- Rotation, scale, and translation (RST)
- Affine (6 degrees of freedom)

\[
\begin{align*}
  x' &= s \cos \theta \cdot x - s \sin \theta \cdot y + t_x \\
  y' &= s \sin \theta \cdot x + s \cos \theta \cdot y + t_y
\end{align*}
\]

\[
T_p = \begin{pmatrix}
  s \cos \theta & -s \sin \theta & t_x \\
  s \sin \theta & s \cos \theta & t_y \\
  0 & 0 & 1
\end{pmatrix}
\]

- Projective/homography (e.g., for perspective effects in image mosaicing); 8 parameters
Transformation Functions (2)

- Weighted linear transformation; adaptive transformation, continuous and smooth, applied to multiview images with local geometric differences, and maps an entire image to another

  - Interpolating surface is a weighted sum of planar patches, each of which passes through a control point and provides a desired gradient, i.e.,

    \[
    f(x, y) = \frac{\sum_{i=1}^{n} R_i(x, y)L_i(x, y)}{\sum_{i=1}^{n} R_i(x, y)}
    \]

    for monotonically decreasing weight \( R_i(x, y) = \left[ (x - x_i)^2 + (y - y_i)^2 \right]^{1/2} \)

    and \( L_i(x, y) = a_i(x - x_i) + b_i(y - y_i) + F_i \)
Matching Strategies

- Exhaustive search (exponential in dimensionality of space)
- Fast Fourier transform (FFT)
- Numerical optimization (e.g., *steepest gradient descent* wrt SSD, NCC, and MI (Thévenaz, Ruttimann, and Unser (TRU) ‘98; Spall ’92)
- Robust transformation estimate (e.g., RANSAC, LMS) if (most) correspondences are known (via SIFT-like)
- “Correspondenceless”, e.g., correlation of descriptor distribution/feature consensus (Govindu *et al.* ‘99)
- Robust feature matching (RFM), e.g., efficient subdivision and pruning of transformation space; Huttenlocher *et al.* ‘93, Mount *et al.* ’99, Netanyahu *et al.* ‘04
Matching Strategies (2)

- **Frequency domain-based approach**
  - Efficient computation of correlation as inverse of $F_1^*(u, v)F_2(u, v)$
  - Practical implementation (extension to NCC, masking invalid pixels, optimized computation)
  - Finding (small) rotational and scale differences (by matching chips)
  - Subpixel registration for translation-only using *phase* estimate (also in case of image aliasing)
  - Rotation and scale estimate by casting to *log-polar* coordinates
Matching Strategies (3)

- **Matched filtering**
  - Maximize SNR (using theory of linear systems)
  - Apply *phase-only* and *symmetric phase-only* matched filters for translation-only IR

\[
\text{Phase product} = \frac{F_1^*(u,v)}{|F_1(u,v)|} \frac{F_2(u,v)}{|F_2(u,v)|} = e^{-j(ut_x + vt_y)}
\]

- Apply *Fourier-Mellin transform* for rotation and scale changes; transform represents these parameters as translational shifts in log-polar coordinates of magnitude of Fourier spectrum, i.e., first estimate rotation and scale, followed by translation estimate
Matching Strategies (4)

- **Numerical optimization**
  - Powel’s, Brent’s (1-D), simplex, etc.

- **Steepest descent/ascent variants**
  - Standard
    \[ p_{k+1} = p_k - \lambda_k g_k \]
  - Newton-Raphson
    \[ p_{k+1} = p_k - \lambda_k H_k^{-1} g_k \]
  - Levenberg-Marquardt
    \[ p_{k+1} = p_k - (H_k + \lambda_k \text{diag}[H_k])^{-1} g_k \]

  - Apply to various similarity metrics, e.g., SSD (Eastman and Le Moigne ‘01), Mutual Information, etc.
    » Explicit computation of gradient (and Jacobian/Hessian), e.g., Thévenaz and Unser ‘00
    » Stochastic approx. (Spall ‘92; Cole-Rhodes et al. ’03)
Matching Strategies (5)

- **Alignment via local geometric distributions**

  Rotated contours

  Slope angle distributions and their correlation
Matching Strategies (6)

• Robust feature matching (RFM)
  – Space of affine transformations: 6-D space
  – *Subdivide*: Quadtree or kd-tree. Each cell $T$ represents a set of transformations; $T$ is *active* if it may contain $t_{opt}$; o/w, it is *killed*
  – *Uncertainty regions* (UR’s): Rectangular approximation to the possible images $\tau(a)$ for all $\tau \in T, a \in I_1$
  – *Bounds*: Compute *upper bound* (on optimum similarity) by sampling a transformation and *lower bound* by computing nearest neighbors to each UR
  – *Prune*: If lower bound exceeds best upper bound, then kill the cell; o/w, split it
Matching Strategies (7)

• Computational efficiency
  – “Culling” feature points via, e.g., condition theory
  – Efficient numerical or discrete algorithmic procedures
  – Hierarchical pyramid-like (wavelet) decomposition
  – Use landmark chip database (instead of a large scene) or alternatively, extract automatically corresponding regions of interest using mathematical morphology (Plaza et al ‘07)
Brief Image Fusion Survey
Methods of Image Fusion

• **Prerequisite to Image Fusion:** Very accurate registration
• **Various Approaches** [Blum and Liu, 2005]:
  – Multiscale-Decomposition-Based Fusion Methods

1. Multiscale representations: Pyramid Transform (e.g., Laplacian), Discrete Wavelet Transform (DWT) and Discrete Wavelet Frame (DWF)
2. Activity-level measurement
3. Coefficient Grouping Method
4. Coefficient Combining Method
5. Consistency Verification
Methods of Image Fusion (2)

– NonMultiscale-Decomposition-Based Methods
  • Pixel-Level Weighted Averaging
    – e.g., PCA
  • Non-Linear Method
    – e.g., separate images into low-pass (LP) and high-pass (HP); then modify and fuse LP and HP
  • Estimation Theory Based Methods
    – e.g. using Maximum A Priori (MAP) and Maximum Likelihood (ML) estimates or Markov Random Field (MRF) distributions
  • Color Composite Fusion
    – Combines input images in color space => false color representation
    – Often used with another method, e.g., PCA or Neural Network
  • Artificial Neural Networks
    – e.g., trained to superimpose objects of interest on background
Performance Evaluation of Fusion Algorithms

- **Objective Evaluation using a Reference Image**
  - **Root Mean Square Error (RMSE)**
    \[
    RMSE = \sqrt{\frac{1}{NM} \sum_{i=1}^{N} \sum_{j=1}^{M} |R(i, j) - F(i, j)|^2}
    \]
    Where \( R \) is the reference image, \( F \) the fused image, and \( NxM \) the size of the image
  - **Correlation**
  - **Peak Signal to Noise Ratio (PSNR)**
    \[
    PSNR = 10 \log_{10} \left( \frac{L^2}{\frac{1}{NM} \sum_{i=1}^{N} \sum_{j=1}^{M} |R(i, j) - F(i, j)|^2} \right)
    \]
    Where \( L \) is the number of gray levels in the image
Performance Evaluation of Fusion Algorithms (2)

- Objective Evaluation using a Reference Image (cont.)
  - Mutual Information (MI)
  - Universal Quality Index (QI) (Wang and Bovik, 2002)

\[
Q = \frac{4\sigma_{xy} \bar{x} \bar{y}}{(\sigma_x^2 + \sigma_y^2)[(\bar{x})^2 + (\bar{y})^2]}
\]

» Where \( \bar{x} \) and \( \bar{y} \) represent the average of all pixels in the reference and the fused images, respectively,

» \( \sigma_x^2 \) and \( \sigma_y^2 \) represent the respective variances and \( \sigma_{xy} \) represents the co-variance between the 2 images

- Other indexes derived from QI, (e.g., (Piella et al, 2003) where index based on the local saliencies of the input images)
Performance Evaluation of Fusion Algorithms (3)

- **Objective Evaluation without a Reference Image**
  - Standard Deviation (SD)
  - Entropy (H)
  - Overall Cross Entropy of the source images \(X, Y\) and the fused image \(F\)

\[
CE(X,Y;F) = \frac{CE(X;F)+CE(Y;F)}{2}
\]

with

\[
CE(X;F) = \sum_{i=0}^{L} h_x(i) \log_2 \left( \frac{h_x(i)}{h_F(i)} \right)
\]

» Where \(h\) is the normalized histogram of the image

Section 2c
Wavelets and Redundant Representations for Image Registration
Why Wavelets and Redundant Representations for Image Registration

- Representations such as the multiresolution wavelets utilized for the new compression standard JPEG-2000 can bring multisensor/multiresolution data to the same spatial resolution without losing significant information and without blurring the higher resolution data.

- At the lower resolutions, the process preserves important global features such as rivers, lakes and mountain ridges as well as roads and other man-made structures, while at the same time eliminating weak higher resolution features often considered as "noise or "spurious pixels." Of course, some of the important finer features will be lost at the lowest resolutions but, if needed, they can be retrieved in the iterative higher levels of decomposition.

- The multiresolution iterative search focuses progressively toward the final transformation with a decreasing search interval and an increasing accuracy at each iteration. Hence, this type of strategy achieves higher accuracies with higher speeds than a full search at the full resolution.

- Wavelet decomposition and multiresolution iterative search are very well-suited for fine-grained parallelization, thus speeding up the computations even more.
Wavelets for Image Registration

- 1994: First results on the utilization of orthogonal Daubechies wavelets for image registration
Rotation and Translation Invariance Issues

• Orthogonal wavelets, feature information changes within or across subbands with subsampling => Study for Shift Sensitivity:
  – low-pass subband relatively insensitive to translation, if features are twice the size of wavelet filters
  – high-pass subband more sensitive but can still be used.

*Correlate Wavelets of Two Pulses*
Translation Sensitivity – Low-Pass Level 3
Translation Sensitivity – High-Pass Level 3

Correlation Minima vs Pulse width

Correlation Averages vs Pulse width
Rotation- and Translation-Invariant Representations

- **Spline Wavelets** [Battle & Lemarié; Unser et al]
  
  $$V_i^n = \{ g_i^n(x) = \sum_{k=-\infty}^{\infty} c_i(k) \varphi^n(2^{-i} x - k), x \in \mathbb{R}, c_i \in l_2 \}$$
  
  with scaling function
  
  $$\varphi^n(x) = \sum_{k=-\infty}^{\infty} p(k) \beta^n(x - k)$$
  
  $p$ arbitrary invertible convolution operator or filter, and $\beta^n(x)$ is a $B$-spline of order $n$ (can be constructed by repeated convolution of $B$-Spline of order 0)

  ![Example of B-Spline Scaling Function and Associated Wavelet](image)

- **Simoncelli et al**
  - Relax critical sampling condition of wavelet transforms
  - Provides an overcomplete representation by $4k/3$
Framework for Evaluation of Image Registration Components

Features
- Gray levels
- Orthogonal Wavelets, Spline or Simoncelli Low-Pass Features
- Orthogonal Wavelet or Simoncelli Band-Pass Features

Similarity measure
- Correlation
- $L_2$-norm
- MI

Matching strategy
- Gradient descent
- FFT
- Gradient descent
- Robust feature matching
- Spall’s optimization
- Thévenaz, Ruttimann, Unser optimization

TARA (Toolbox for Automated Registration and Analysis)
Algorithm Testing Using … Synthetic Data

Transformation of Starting Scene:
- Scales in [0.8,1.2] (step = 0.05)
- Translations in [0,20] pixels (step = 0.5)
- Rotations in [0,20] degrees (step = 0.5)
- Gaussian noise in [-15, 20] dB (step = 1)
- Radiometric Transformation (PSF constructed from black 512x512 image with 5x5 white center)
Results Marquart Levenberg Optimization + L2 Similarity
Spline Wavelets and Simoncelli Features
Varying Noise – With or Without PSF [Zavorin et Le Moigne, 2005]

The shaded green regions in each plot correspond to those points in the parameter space for which the resulting global RMS registration error is larger than 1.0
Overall Main Findings

- Simoncelli-based methods outperform Spline pyramid-based methods
- Optimization based on Mutual Information does not perform better than L2-Norm
- Simoncelli/Low-Pass better than Simoncelli/Band-Pass for Low Noise and Same Radiometry and for Initial Guess Sensitivity

Sensitivity to Initial Guess [Le Moigne et al, 2004]
Registration using a Chip Database

1. Find Chips that correspond to the Incoming Scene
2. For Each Chip, Extract Window from input scene using UTM coordinates
3. Eliminate Windows with insufficient information
4. Smooth and Normalize gray values of both Chip and Window using a Median Filter
5. Register each (Chip,Window) Pair using a wavelet-based automatic registration: get a local transformation for each pair
6. Eliminate Outliers
7. Compute Global Rigid Transformation from all local ones
8. Compute Correct UTM of 4 Scene Corners of input scene
9. If desired, Resample the input scene according to the global transformation

Section 2f
Fusion using cokriging
Kriging and Cokriging …

• Kriging and cokriging are geostatistical techniques used for interpolation purposes, originally used in geo-statistics, mining, and petroleum engineering applications

• Both methods are generalized forms of univariate and multivariate linear regression models:
  – They are linear-weighted averaging methods, similar to other interpolation methods
  – Other methods use weights based on the distance of each control point (sample value) from the target location; controls points closer to the target receive the larger weights => not necessarily true if the data exhibit strong anisotropy
Kriging and Cokriging (2)

- Kriging and cokriging
  - Pioneered by Danie Krige, 1951; formalized by Georges Matheron in the 1960s
  - Ability to capture anisotropy of the underlying variables through the spatial covariance model:
    - Distant control points along the axis of maximum correlation should have greater influence on the interpolated value
    - Weights depend not only on distance, but also on the direction and orientation of the neighboring data to the unsampled

- Generalized version of kriging *(B.L.U.E)*:
  - *Best*: aims to minimize variance of the errors
  - *Linear*: estimates are weighted linear combination of the available data
  - *Unbiased*: tries to have mean residual, or error, equal to zero.
  - *Estimator*: \( \hat{\nu} = \sum_{j=1}^{n} w_j \cdot \nu \)
Cokriging ...

Interpolation using more than one type of variable to estimate an unknown value at a particular location.

Estimation error:

\[ \hat{u}_0 = \sum_{i=1}^{n} a_i u_i + \sum_{j=1}^{m} b_j v_j \]

\[ R = \hat{U}_0 - U_0 = w^T Z, \]

\[ w^T = (a_1, \ldots, a_n, b_1, \ldots, b_m, -1) \]

\[ Z^T = (U_1, \ldots, U_n, V_1, \ldots, V_m, U_0) \]

Goal of cokriging is to minimize variance of error subject to some constraints (to ensure unbiasedness of our estimate, here “ordinary cokriging”)

\[ Var(R) = w^T C_z w \]

\[ \sum_{i=1}^{n} a_i = 1, \sum_{j=1}^{m} b_j = 0 \]
Cokriging (2)

- Variance to minimize with 2 constraints:

\[ Var(R) = w^T C_z w \]

\[ = \sum_{i}^{n} \sum_{j}^{n} a_i a_j \text{Cov}(U_i U_j) + \sum_{i}^{m} \sum_{j}^{m} b_i b_j \text{Cov}(V_i V_j) \]

\[ + 2 \sum_{i}^{n} \sum_{j}^{m} a_i b_j \text{Cov}(U_i V_j) - 2 \sum_{i}^{n} a_i \text{Cov}(U_i U_0) \]

\[ - 2 \sum_{j}^{m} b_j \text{Cov}(V_j U_0) + \text{Cov}(U_0 U_0). \]

\[ Var(R) = w^T C_z w + 2 \mu_1 \left( \sum_{i=1}^{n} a_i - 1 \right) + 2 \mu_2 \left( \sum_{j=1}^{m} b_j \right). \]

Where \( m_1 \) and \( m_2 \) are 2 Lagrange multipliers.
Cokriging (3)

- The next step is taking partial derivatives of the above equation with respect to all \( n + m \) cokriging variables and the two Lagrange multipliers and setting them to zero. Then, we have the following \( n+m+2 \) equations to solve:

\[
\sum_{i=1}^{n} a_i \text{Cov}(U_i U_j) + \sum_{i=1}^{m} b_i \text{Cov}(V_i U_j) + \mu_1 = \text{Cov}(U_0 U_j), \quad \text{for } (j = 1 \ldots n)
\]

\[
\sum_{i=1}^{n} a_i \text{Cov}(U_i V_j) + \sum_{i=1}^{m} b_i \text{Cov}(V_i V_j) + \mu_2 = \text{Cov}(U_0 V_j), \quad \text{for } (j = 1 \ldots m)
\]

with \( \sum_{i=1}^{n} a_i = 1 \)

and \( \sum_{j=1}^{m} b_j = 0 \)
Experiments Cokriging – Spectral Dimension

• Spectral dimension
  – ALI: 9 multispectral bands
  – Hyperion: 220 hyperspectral bands
  – Increase spectral resolution of ALI where needed using Hyperion information

• One variable only

• Software used
  – UCL-FAO Agromet project
    (http://www.aigeostats.org/software/Geostats_software/agromet.htm)
  – C++
Results Cokriging – Spectral Dimension

Original 1 pixel plot for ALI and Hyperion
Fusion results on one pixel using cokriging by creating one band/value in center of each wavelength interval where ALI data is missing.
Fusion results on one pixel using cokriging by estimating up to 3 values in each wavelength interval where ALI data is missing.

Results Cokriging – Spectral Dimension (3)
Fusion results on one pixel using cokriging by estimating values at all Hyperion centers in each wavelength interval where ALI data is missing.
Experiments Cokriging – Fusion of Panchromatic and Multispectral

- Landsat 7 ETM data sets
  - Datasets provided by IEEE Data Fusion Committee
  - 8 Bands:
    - 7 multispectral at 30 m spatial resolution
    - 1 panchromatic at 15 m spatial resolution
- Objective
  - Pan sharpening of selected multispectral bands
- Comparative Methods
  - Cokriging
  - PCA
  - Wavelets

MS-7 | PC-7 | PC-7 | F7

PC Transform

Replace PC-1 with stretched PAN band

Inverse PC Transform

Stretch PAN band to match PC-1 in its mean and standard deviation.
Methods: Wavelet-Based Fusion – Fusion of Panchromatic and Multispectral

High Spatial Resolution Data: PAN

Low Spatial Resolution Data: MS

Decomposition

FUSED DATA

Improved Resolutions

Reconstruction
Evaluation Fusion Results – Fusion of Panchromatic and Multispectral

- Past Quality Metrics
  - Piella, etc.
  - Gray level only
  - No support for multi-spectral image

- Objective
  - Improved Classification
    - Performed k-means with k=7, max iterations 15 (for PCA and wavelets)
  - Needs ground truth

- Similarities
  - Spatial Quality: Entropy
  - Spectral quality: correlation

- Differences
  - Added Texture
  - Co-occurrence matrix for statistical texture properties (Haralick, 1973)
  - Variance image
Results Cokriging –
Fusion of Panchromatic and Multispectral

Landsat Pan-sharpened MS bands 2, 3, and 4
*Through Cokriging* with Pan band 8
Results PCA and Wavelets – Fusion of Panchromatic and Multispectral

Through PCA

Landsat Pan-sharpened MS bands 2, 3, and 4 with Pan band 8

Through Wavelets
Results Evaluation through Correlation – Fusion of Panchromatic and Multispectral

**Wavelet**
- Fuse pair of bands at a time
- Require various spatial resolution to differ by power of 2

**PCA**
- Fuse multiple bands at a time
- Require the same number of pixels (same image dimension) for all bands

**Cokriging**
- Fuse multiple bands at a time
- Fuse data with different spatial and spectral resolutions
- Fuse data of different natures
- Can handle scattered data
