ABSTRACT

15400

The ultraviolet spectrum of a planet is produced by the following physical processes: (1) dayglow, the scattering of solar photons by atoms and molecules in the upper atmosphere of the planet; (2) daylight, the combination of rayleigh scattering of solar radiation and absorption by atmospheric constituents that produces the planetary albedo in the ultraviolet; and (3) electron excitation, the excitation of atoms and molecules in the upper atmosphere by auroral electrons and by photoelectrons.

A quantitative description of each of these processes is given. The atoms and molecules that are prominent in planetary ultraviolet spectra are listed. Calculations are given of planetary molecular emission spectra that are the result of optically thin and optically thick fluorescent scattering and of excitation by auroral bombardment and by photoelectrons. Rocket measurements of the dayglow spectrum of the Earth are given for the spectral region between 2000 and 4000 Å. The main spectral features are the nitric oxide gamma bands, the ionized molecular nitrogen first negative bands, and the nitrogen second positive bands. A rocket measurement of the Earth's ultraviolet albedo between 1900 and 3200 Å is also given. This spectrum shows the absorption produced by ozone in the Earth's atmosphere.

*Author***I. INTRODUCTION**

The ultraviolet spectroscopy of a planetary atmosphere is concerned with the phenomena that occur when the atmosphere is subjected to radiation from the Sun. Atoms that are in the upper atmosphere may undergo resonance reradiation when the solar radiation contains resonance lines of the same atoms. Upper atmosphere molecules may fluoresce when the solar continuum at appropriate wavelengths penetrates to the level in the atmosphere where the molecules are present. The molecules absorb energy at several wavelengths and then re-

radiate at either the same or longer wavelengths. Solar radiation at all wavelengths in the ultraviolet undergoes rayleigh scattering by the molecules in the atmosphere. The resulting spectrum contains spectral features of the incident solar radiation as well as absorption features that are produced by molecules in the planetary atmosphere. The ionization of atmospheric molecules by extreme ultraviolet solar radiation produces fast photoelectrons in the upper atmosphere. These photoelectrons may strike other atmospheric atoms or molecules and cause them to radiate.

Radiation from the Sun, in the broader definition including charged particles and magnetohydrodynamic plasma waves, directly or indirectly causes the upper atmosphere to be subjected to charged particle bombardment at large geomagnetic latitudes. This electron bombardment during an aurora causes the atoms and molecules of the upper atmosphere to radiate.

The dayglow consists of the upper atmosphere emissions that occur when the atmosphere is directly illuminated by the Sun. The phenomena producing these discrete spectral features include resonance reradiation, fluorescence, photoelectron excitation, and chemical and ionic reactions. Rayleigh scattering in the atmosphere produces daylight, and this term may be applied in the ultraviolet even when the spectrum includes absorption

features. When viewed from outside the atmosphere, this phenomenon may also be called the planetary ultraviolet albedo. The spectral emissions of the aurora are produced by charged particle bombardment while the aurora itself is controlled in some way by the geomagnetic field. Historically, it has been observed at night when the daylight is absent; however, auroral emissions may be present during the day, as well. The nightglow is produced by chemical and ionic reactions in the upper atmosphere and does not require the direct presence of solar radiation. The Sun is responsible, however, for the energy that appears in the nightglow spectral emissions. Finally, the twilight glow contains phenomena of both the dayglow and nightglow. It is the time when the lower atmosphere is in the shadow and both the fluorescence of the dayglow and the luminescence of the nightglow are present.

II. THEORY

The theory of the twilight and day airglow is treated by Chamberlain (Ref. 1). The following discussion is adapted from this work.

A. Atoms, Single-Scattering

The equation that describes the single-scattering of a photon by an atom is as follows:

$$4\pi \mathcal{J}_\lambda = \pi \mathcal{F}_\lambda \frac{\pi e^2}{mc^2} \lambda^2 f \tilde{\omega} \frac{\mathcal{N}}{\mu} \quad (1)$$

where $4\pi \mathcal{J}_\lambda$, which is a function of wavelength λ (Å), is the emission rate, given in photon-cm⁻²-sec⁻¹ Å⁻¹ (1 rayleigh equals 10⁶ photon-cm⁻²-sec⁻¹); $\pi \mathcal{F}_\lambda$ is the solar flux, also a function of wavelength, given in photons cm⁻²-sec⁻¹ Å⁻¹; $\pi e^2/mc^2$ is a combination of physical constants, equal to 8.829×10^{-21} cm²-Å, which permits the solar flux to be

expressed per wavelength interval; f is the f -value or oscillator strength of the line or multiplet; $\tilde{\omega}$ is the albedo for single-scattering and is equal to $A_j / \sum_j A_j$ for a line where A is the Einstein transition probability; $\mathcal{N}$ is the number of atoms in the column being observed, given in atom-cm⁻², and is equal to $\int_h^\infty n dz$ when an atmosphere is viewed upward in a vertical direction, where n is the volume density of atoms in atom-cm⁻³ at height h in the atmosphere; $\mu = \cos \theta$, where θ is the angle of emergence of the scattered photon from a plane-parallel atmosphere. The emission rate $4\pi \mathcal{J}$ is usually integrated over wavelength for the line or multiplet. Chamberlain (Ref. 1) has found it convenient to define a quantity g , the number of photons scattered/sec/atom.

$$g = \pi \mathcal{F}_\lambda \frac{\pi e^2}{mc^2} \lambda^2 f \tilde{\omega} \quad (2)$$

which is convenient because emission rates may be directly converted into column densities of atoms by the following expression:

$$4\pi \mathcal{J} = g \frac{\mathcal{N}}{\mu} \quad (3)$$

B. Molecules, Single-Scattering

The single-scattering theory for atoms may readily be adapted for use with diatomic molecules. Because of the presence of vibrational band systems in molecules, particular attention must be paid to fluorescence in the formalism. Using v' to designate the vibrational level of the upper electronic state and v'' of the lower, Eq. (1) may be written for a molecular band in fluorescence as follows:

$$4\pi \mathcal{J}_{v',v''} = \pi \mathcal{F}_{0v'} \frac{\pi e^2}{mc^2} \lambda_{0v'}^2 f_{0v'} \tilde{\omega}_{v',v''} \frac{\mathcal{N}_0}{\mu} \quad (4)$$

The emission rate and albedo are written with the subscripts in the order $v'v''$ to emphasize that they are concerned with the fluorescent band in emission. The solar flux and oscillator strength have the subscripts $0v'$ to emphasize that they are concerned with the absorption band from the lowest vibrational level of the ground electronic state. The molecule column density has the subscript 0 to indicate that it pertains to the number of molecules in the lowest vibrational level of the ground state. The albedo for single-scattering of the fluorescent band is as follows:

$$\tilde{\omega}_{v',v''} = \frac{A_{v',v''}}{\sum_{v''} A_{v',v''}} \quad (5)$$

where the A 's are the transition probabilities and the summation is over a v'' progression. The transition probability of a molecular band is related to the band strength through the following equation:

$$A_{v',v''} = \frac{64\pi^4}{3hc^3} \frac{\nu_{v',v''}^3}{d_{v'}} S_{v',v''} \quad (6)$$

where $S_{v',v''}$ is the band strength, $\nu_{v',v''}$ is the frequency of the band and $d_{v'}$ is the degeneracy of the upper level. The band strength is equal to the square of the electronic-vibrational matrix element for the band. When the square of the average value of the electronic transition moment R_e^2 does not vary with internuclear distance, the band strength may be written

$$S_{v',v''} = \bar{R}_e^2 q_{v',v''} \quad (7)$$

where $q_{v',v''}$ is the square of the overlap integral of the vibrational wave-functions and is called the Franck-Condon factor. When measured values of band strengths

are not available and when calculated values of Franck-Condon factors are available, if the assumption is made that R_e^2 is constant, the albedo for single-scattering may be calculated from the Franck-Condon factors from the following expression:

$$\tilde{\omega}_{v',v''} = \frac{\nu_{v',v''}^3 q_{v',v''}}{\sum_{v''} \nu_{v',v''}^3 q_{v',v''}} \quad (8)$$

The emission rate factor $g_{v',v''}$ for a molecular band is then

$$g_{v',v''} = \pi \mathcal{F}_{0v'} \frac{\pi e^2}{mc^2} \lambda_{0v'}^2 f_{0v'} \tilde{\omega}_{v',v''} \quad (9)$$

so that the emission rate may be related to the number of molecules in the oblique column through

$$4\pi \mathcal{J}_{v',v''} = g_{v',v''} \frac{\mathcal{N}_0}{\mu} \quad (10)$$

Ideally, the oscillator strength $f_{0v'}$ should be available from laboratory measurements for each absorption band under consideration. When this is not possible, the concept of an oscillator strength for the entire band system may be used by asserting that $f_{XX} = \sum_{v'} f_{0v'}$, where f_{XX} is the oscillator strength for the electronic transition from a ground state X to an excited state N . The band oscillator strength may then be obtained from the band system oscillator strength through the use of the Franck-Condon factors.

$$f_{0v'} = f_{XX} q_{0v'} \quad (11)$$

(See Ref. 2 for a discussion of the various assumptions made in this procedure.) The emission rate factor then may be written

$$g_{v',v''} = \pi \mathcal{F}_{0v'} \frac{\pi e^2}{mc^2} \lambda_{0v'}^2 f_{XX} q_{0v'} \tilde{\omega}_{v',v''} \quad (12)$$

When even a measure of the band oscillator strength is not available, it still may be useful to calculate the relative intensities of fluorescent bands. Here, the quantity $g'_{v',v''}$ is introduced as equal to

$$g'_{v',v''} = \pi \mathcal{F}_{0v'} \frac{\pi e^2}{mc^2} \lambda_{0v'}^2 q_{0v'} \tilde{\omega}_{v',v''} \quad (13)$$

where formally $g_{v',v''} = g'_{v',v''} f_{XX}$. Finally, it is useful to have a concept of the relative strength of fluorescent bands that is free from the influence of the spectral variation in solar flux. The quantity "band fluorescent cross section" $\sigma_{v',v''}$ is introduced here to be equal to

$$\sigma_{v',v''} = \frac{\pi e^2}{mc^2} \lambda_{0v'}^2 q_{0v'} \tilde{\omega}_{v',v''} \quad (14)$$

The units of this quantity are $\text{cm}^2\text{-}\text{\AA}$, and it is the product of a cross section and a wavelength interval. The electronic band system oscillator strength is not included in the band fluorescent cross section.

C. Multiple-Scattering, Optically Thin

The theory for resonance and fluorescent scattering for the case of multiple-scattering has been summarized by Chamberlain and Sobouti (Ref. 3). The following discussion is adapted from this work.

The emission rate for reflection from a plane-parallel planetary atmosphere for reradiation of the resonance band is

$$4\pi \mathcal{J}_{v'v''} = \frac{\pi \mathcal{F}_{0v'}}{\mu} \sqrt{2} \lambda_D' \tilde{\omega}_{v'0} \frac{\mu \mu_0}{\mu + \mu_0} \times [X(\mu) X(\mu_0) - Y(\mu) Y(\mu_0)] \quad (15)$$

where the X 's and Y 's are Chandrasekhar's radiative transfer functions (Ref. 4). Here they are functions of $\tau_c/\sqrt{2}$, where τ_c is the optical depth at the center of the spectral line.

The optical depth is equal to the product of the absorption cross section and the column density of molecules. Because the absorption cross section is obtained from the f -value of the band, the optical depth may be expressed as follows:

$$\tau_c = \frac{\pi e^2}{mc^2} \frac{\lambda_{0v'}^2}{\lambda_D'} f_{0v'} \mathcal{N}_0 \quad (16)$$

The quantity λ_D' is related to the doppler line width λ_D by

$$\lambda_D' = \sqrt{\pi} \lambda_D = \sqrt{\pi} \frac{\lambda_c}{c} \sqrt{\frac{2kT}{M}} \quad (17)$$

where λ_c is the wavelength in the center of the line, c is the velocity of light, and $\sqrt{2kT/M}$ is the most probable velocity. For τ_c very small, Eq. (15) reduces to

$$4\pi \mathcal{J}_{v'0} = \frac{\pi \mathcal{F}_{0v'}}{\mu} \sqrt{2} \lambda_D' \tilde{\omega}_{v'0} \frac{\tau_c}{\sqrt{2}} \quad (18)$$

which in turn reduces to Eq. (4).

The emission rate for a fluorescent band for an optically thin atmosphere in reflection is

$$4\pi \mathcal{J}_{v'v''} = \pi \mathcal{F}_{0v'} \sqrt{2} \lambda_D' \tilde{\omega}_{v'v''} \frac{\mu_0}{\mu} \times \left[\frac{1 - \frac{1}{2} \tilde{\omega}_{v'0} (\alpha^{(0)} + \beta^{(0)})}{1 - \tilde{\omega}_{v'0}} \right] [X(\mu_0) - Y(\mu_0)] \quad (19)$$

The $\alpha^{(0)}$'s and $\beta^{(0)}$'s are zero moments of the X 's and Y 's. The X 's and Y 's are again functions of $\tau_c/\sqrt{2}$ and $\tilde{\omega}_{v'0}$. The X and Y functions and their moments are tabulated by Sobouti (Ref. 5). For small values of $\omega_{v'0}$, Eq. (19) reduces to

$$4\pi \mathcal{J}_{v'v''} = \pi \mathcal{F}_{0v'} \sqrt{2} \lambda_D' \tilde{\omega}_{v'v''} \frac{\mu_0}{\mu} [X(\mu_0) - Y(\mu_0)] \quad (20)$$

For small values of τ_c , Eq. (20) also reduces to Eq. (4).

D. Multiple-Scattering, Optically Thick

The expression for emission rate for a resonance reradiation band in reflection from an optically thick plane-parallel planetary atmosphere is

$$4\pi \mathcal{J}_{v'0} = \pi \mathcal{F}_{0v'} \Delta \lambda \tilde{\omega}_{v'0} \frac{\mu_0}{\mu + \mu_0} H(\mu) H(\mu_0) \quad (21)$$

where the H 's are tabulated by Chandrasekhar (Ref. 4). The $\Delta \lambda$ is an effective line width. The judgment to be used in selecting this value is discussed by Chamberlain and Sobouti (Ref. 3).

The emission rate for a fluorescent band in reflection from an optically thick planetary atmosphere is

$$4\pi \mathcal{J}_{v'v''} = \pi \mathcal{F}_{0v'} \frac{\Delta \lambda \tilde{\omega}_{v'v''}}{\sqrt{1 - \tilde{\omega}_{v'0}}} \frac{\mu_0}{\mu} H(\mu_0) \quad (22)$$

The H 's are a function of $\tilde{\omega}_{v'0}$. For small $\omega_{v'0}$, Eq. (22) reduces to

$$4\pi \mathcal{J}_{v'v''} = \pi \mathcal{F}_{0v'} \Delta \lambda \tilde{\omega}_{v'v''} \frac{\mu_0}{\mu} H(\mu_0) \quad (23)$$

The relative intensities of both resonance and fluorescent bands from Eqs. (21) and (23) are proportional to the solar flux and the albedo for single-scattering,

$$4\pi \mathcal{J}_{v'v''} \sim \pi \mathcal{F}_{0v'} \omega_{v'v''} \quad (24)$$

The band oscillator strength is not involved because the solar flux penetrates into the optically thick atmosphere until all of the bands are saturated (Ref. 6).

E. Absorption and Rayleigh Scattering

All the molecules in the atmosphere produce rayleigh scattering of the solar radiation. In combination with ultraviolet absorption by certain of the molecules in the upper atmosphere, the rayleigh scattering produces the bulk of the planetary albedo in the middle ultraviolet. Singer (Ref. 7) first pointed out the important role played by ozone absorption in producing the Earth's albedo. This problem is treated extensively by Green (Ref. 8).

The expression for single-scattering by all the atmospheric constituents and with absorption by certain of the molecules is

$$4\pi \mathcal{J}_\lambda = \frac{\pi \tilde{\mathcal{F}}_\lambda}{\mu} \frac{3}{4} (1 + \cos^2 \psi) \int_h^\infty \sigma_R n_R \\ \times \exp \left[- \int_h^\infty \left(\frac{1}{\mu_0} + \frac{1}{\mu} \right) \sum_i \sigma_{A,i} n_{A,i} dz \right] dz \quad (25)$$

where σ_R is the cross section for rayleigh scattering, n_R is the number density of molecules contributing to the rayleigh scattering, $\sigma_{A,i}$ is the absorption cross section for atmospheric constituent i , $n_{A,i}$ is the number density of this absorber, and $3/4 (1 + \cos^2 \psi)$ is the rayleigh phase function. It is related to the zenith and azimuth angles of the incident and emerging radiation by

$$\cos \psi = \mu \mu_0 + (1 - \mu^2)^{1/2} (1 - \mu_0^2)^{1/2} \cos(\phi - \phi_0) \quad (26)$$

where $\mu = \cos \theta$, θ is the zenith angle, and ϕ the azimuth angle.

F. Electron Excitation

The theory of excitation of molecular bands by electron bombardment has been discussed in Refs. 2 and 9. The expression for the excitation of a vibrational band may be written

$$4\pi \mathcal{J}_{r',r''} = I_E \sigma_E q_{0v'} \tilde{\omega}_{r',r''} \frac{\mathcal{N}_0}{\mu} \quad (27)$$

where I is the particle flux in electrons $\text{cm}^{-2}\text{-sec}^{-1}$ and is a function of electron energy; σ_E , which is also a function of electron energy, is the cross section for the excitation of an electronic state; $q_{0v'}$ is the Franck-Condon factor for excitation of the vibrational levels of the excited electronic state from the lowest vibrational level of the ground electronic state; $\tilde{\omega}_{r',r''}$ is the albedo for single-scattering of the fluorescent vibrational band (it may or may not be a transition back to the ground state); and $\mathcal{N}_0/\mu$ is the number density of molecules in the oblique column. The use of Franck-Condon factors in the excitation probability as well as in the fluorescent albedo again implies that the electronic and vibrational transition moments may be separated and that the electronic transition moment does not vary with changing internuclear distance. Cross sections for electronic excitation of several atoms and molecules of atmospheric interest have been collected by Dalgarno (Ref. 10). Cross sections of most of the electronic excitations in molecular nitrogen are given by Green and Barth (Ref. 11). When the bombarding beam of electrons is not monoenergetic, it is necessary to perform an integration or summation of the $I_E \sigma_E$'s over electron energy.

III. ATOMS AND MOLECULES IN PLANETARY SPECTRA

Atoms that may play a role in producing spectra in the upper atmospheres of Venus, the Earth, and Mars are hydrogen, oxygen, nitrogen, argon, and carbon. The wavelengths of the resonance lines of these atoms are given in Table 1. The first four are present in the Earth's upper atmosphere, and free carbon could be present in the upper atmospheres of the other planets because of the greater abundance of carbon dioxide, especially on Venus. For an atom to produce a strong planetary emission line through resonance reradiation, it is necessary that the solar spectrum contain a strong emission of the same atom. The Lyman alpha line of atomic hydrogen at 1216 Å is a strong solar feature. The resonance lines of oxygen at 1304 Å, nitrogen at 1200 Å, and carbon at 1657 Å also appear in the solar spectrum. The argon line at 1048 Å may or may not be present in the spectrum of the Sun. However, the Sun does radiate as a black body at 5500°K at this wavelength (Ref. 12). Because photoelectron bombardment may also excite atomic spectra in planetary atmosphere, other lines of these atoms may appear as well.

Molecules that may be important in producing planetary emission spectra are nitrogen, oxygen, nitric oxide, carbon monoxide, the hydroxyl radical, the cyanogen radical, and the molecular ions of nitrogen, oxygen, nitric oxide, and carbon monoxide. Band systems of these molecules that are prominent in the ultraviolet are listed in Table 2. The wavelength of the 0-0 band of each system is listed as well. Where the resonance lines of the atoms lie in the far ultraviolet, the most prominent fluorescent bands of the molecules are in the middle ultraviolet where the solar continuum is sufficiently intense to excite them. The nitrogen-oxygen systems are important in the Earth's upper atmosphere; carbon systems may be important on Mars and Venus.

Table 1. Atoms that may undergo resonance reradiation in planetary atmospheres

Atom	Nomenclature	Wavelength, Å
Argon	Resonance line	1048
Nitrogen	$^1S_0 - ^1P_1 \begin{smallmatrix} 3/2 \\ 2, 2, 2 \end{smallmatrix}$	1200
Hydrogen	Lyman alpha	1216
Oxygen	$^3P_{2,1,0} - ^3S_1$	1302, 4, 6
Carbon	$^3P_{0,1,2} - ^3P_{0,1,2}$	1657

Molecules that may determine the spectral characteristics of the planetary ultraviolet albedo are ozone, oxygen, and carbon dioxide. The absorption bands and continua of these molecules determine the amount of solar radiation scattered into space by the planetary atmosphere. The wavelength regions of interest for these molecules are listed in Table 3. Ozone and oxygen are prominent in the Earth's atmosphere. Carbon dioxide may be important on the other planets.

Table 2. Molecules that may undergo fluorescence in planetary atmospheres

Molecule	Band system	Nomenclature	Wavelength, Å
Nitric oxide	Gamma	$A^2\Sigma^+ - X^2\Pi_r$	2262
	Delta	$C^2\Pi - X^2\Pi_r$	1909
	Beta	$B^2\Pi - X^2\Pi_r$	2198
Oxygen	Schumann-Runge	$B^3\Sigma_u^- - X^3\Sigma_g^-$	2026
	Herzberg	$A^3\Sigma_u^- - X^3\Sigma_g^-$	2885
Nitrogen	Vegard-Kaplan	$A^3\Sigma_u^+ - X^1\Sigma_g^+$	2010
	Lyman-Birge-Hopfield	$\sigma^1\Pi_g - X^1\Sigma_g^+$	1450
	Birge-Hopfield	$b^1\Pi_u - X^1\Sigma_g^+$	986
	Second positive	$C^3\Pi_u - B^3\Pi_g$	3370
Hydroxyl	Ultraviolet	$A^2\Sigma^+ - X^2\Pi_r$	3064
Cyanogen	Violet	$B^2\Sigma^+ - X^2\Sigma^+$	3876
Carbon monoxide	Cameron	$\sigma^3\Pi_u - X^1\Sigma^+$	2063
	Fourth positive	$A^1\Pi - X^1\Sigma^+$	1544
	Hopfield-Birge	$\sigma'^3\Sigma^+ - X^1\Sigma^+$	1804
Nitrogen ion	First negative	$B^2\Sigma_u^+ - X^2\Sigma_g^+$	3911
	Second negative	$C^2\Sigma_u^+ - X^2\Sigma_g^+$	1549
Nitric oxide ion	First negative	$A^1\Pi - X^1\Sigma^+$	1368
Oxygen ion	Second negative	$A^2\Pi_u - X^2\Pi_g$	2610
Carbon monoxide ion	First negative	$B^2\Sigma^+ - X^2\Sigma^+$	2191
	Comet tail	$A^2\Pi_u - X^2\Sigma^+$	4900

Table 3. Molecules that may undergo absorption in planetary atmospheres

Molecule	Nomenclature	Wavelength, Å
Ozone	O ₃	2000-3000
Oxygen	O ₂	1250-1750
Carbon dioxide	CO ₂	1250-2000

IV. CALCULATIONS OF PLANETARY MOLECULAR SPECTRA

Spectral emission factors have been calculated for the 20-band systems listed in Table 2 using the formalism described in Section II. The emission factors for the many bands in each of the systems may be used to obtain the relative spectral intensities of a band system as they may appear in a planetary atmosphere under various conditions of excitation. Synthetic spectra may be obtained from these calculations for excitation by fluorescence in both optically thin and optically thick atmospheres and for excitation by electron bombardment from either low-energy photoelectrons or higher-energy auroral electrons.

The planetary atmospheres emission factors for each band system are listed in the Appendix in the order given in Table 2. These calculations are the result of a computer output, and the nomenclature on the printout will be identified with the symbols used in the equations in this paper. The bands are arranged in v' progressions. The first column, marked $v-vv$, meaning $v'-v''$, lists the band number. The second column, marked *LAMBDA*, is the wavelength λ of the band origin in Å. These band origins were calculated from molecular constants given by Herzberg (Ref. 13) and Wallace (Ref. 14). The wavelengths listed by Wallace (Refs. 14, 15), which are based on experimental measurements, should be used for precise identifications and not the wavelengths listed in these calculations. The third column, marked *Q*, lists the Franck-Condon factors that are identified in the equations as $q_{v',v''}$. These factors are from the work of Nicholls (Refs. 9, 16-22) and they are based on a Morse potential. The fourth column, marked *OMEGA*, is the $\omega_{v',v''}$ given in the text, the albedo for single-scattering. It has been calculated according to Eq. (8). The fifth column, marked *Q. OMEGA*, is the $q_{0v'} \tilde{\omega}_{v',v''}$ of the text. It is described by Eq. (27) and is applicable to excitation by electron bombardment. The sixth column, marked *SIGMA*, is the $\sigma_{v',v''}$ given in Eq. (14). It is the band fluorescent cross section and is a function of the molecular properties and not of the exciting radiation. The seventh column, marked *FLUX*, is the solar flux $\pi \mathcal{F}_{0v'}$ in photon-cm²-sec⁻¹-Å⁻¹. The eighth column, marked *F-NUM*, is the quantity $f_{0v'}/q_{0v'}$ or the f -value for the band system as given by Eq. (11). For the spectral regions 880-1540 and 1770-2985 Å, the calculations of Brinkman et al. (Ref. 23) were used. These calculations have been taken from the experimental work of Tousey (Ref. 24), Malitson et al. (Ref. 25), and Wilson et al. (Ref. 26); they provide 10 Å averages every 1 Å. For the spectral interval between 1540 and 1770 Å the flux was calculated by considering the Sun as a black body at

4700°K. For the spectral range above 2985 Å the solar flux values listed by Johnson (Ref. 27) were used. These values are 50 Å averages given every 50 Å. The fluorescent emission factor calculations using these last solar flux values are much less realistic than the calculations that use the 10 Å averages. The ninth column, marked *G*, gives the calculations of $g_{v',v''}$, the emission rate factor of Eq. (9). This factor determines the spectral intensity distribution in an optically thin atmosphere. When the f -value for the band system is not available, the quantity g' of Eq. (13) is calculated. The column is then marked *G-PRIME*, and the *F-NUM* column does not appear. The last column, marked *FLUX. OMEGA*, is the product of solar flux $\pi \mathcal{F}_{0v'}$ and the albedo for single-scattering $\tilde{\omega}_{v',v''}$. As shown by Eq. (24), it determines the spectral intensity distribution for an optically thick atmosphere. For certain band systems all of these emission factors are not applicable; here the calculations are abbreviated.

A. Nitric Oxide

The three bands systems of nitric oxide that are of interest in planetary atmospheres are the gamma bands, $A^2\Sigma^+-X^2\Pi_r$, the delta bands, $C^2\Pi-X^2\Pi_r$, and the beta bands, $B^2\Pi_r-X^2\Pi_r$. The calculations of the molecular emission factors for these bands are given in Section I-III of the Appendix. The f -values are from Bethke (Ref. 28). (See Nicholls, Ref. 21.) Where the measurements are missing or blended, values have been interpolated or extrapolated from the existing data. The Franck-Condon factors used here are from Nicholls (Ref. 19). The values of g , the emission rate factor, are taken from Column 9 of the calculations and are plotted as synthetic spectra in Figs. 1, 2, and 3. These figures show that for a given amount of nitric oxide, the 1-0 gamma band at 2149 Å is the most intense emission feature in single-scattering fluorescence. The emission rate factor of 7.69×10^{-6} for this band means that a column density of 1.3×10^{14} molecule-cm⁻² is required to produce an emission rate of 1 kilorayleigh (see Eq. 10). This is the amount of nitric oxide above the 90-km level in the Earth's atmosphere. The optical depth of the 1-0 band for this amount of nitric oxide may be calculated with the use of the band fluorescent cross section of Column 6. The product of the band cross section and the f -value gives a cross section of 1.5×10^{-17} cm²-Å. The effective line width of the 1-0 band may be estimated as follows: The line width λ'_0 (Eq. 17) of a single rotational line is 4.0×10^{-3} Å for a nitric oxide molecule at 200°K. The number of lines in the band that are effective in the

Fig. 1. Synthetic spectrum of nitric oxide gamma bands in fluorescence in optically thin atmosphere

Fig. 2. Synthetic spectrum of nitric oxide delta bands in fluorescence in optically thin atmosphere

Fig. 3. Synthetic spectrum of nitric oxide beta bands in fluorescence in optically thin atmosphere

absorption of solar radiation may be estimated at 160 to give a total effective line width for the band of 6.4×10^{-1} Å. The effective cross section is then 2.3×10^{-17} cm², and the effective optical depth 3×10^{-3} . Thus, the fluorescent scattering in the Earth's atmosphere at 90 km is optically thin, and the *g* factors may be used to calculate the intensity of the fluorescence. Figure 1 gives the relative intensities of the most intense bands of the gamma system.

The *g* emission rate factors for the nitric oxide delta bands are plotted as a synthetic spectrum in Fig. 2. The most intense band in single-scattering is the 1-0 at 1826 Å. The emission rate factor of this band is approximately one order of magnitude less than the factor for the 1-0 gamma band. Thus, the amount of nitric oxide that will produce an emission rate of 1 kilorayleigh in the 1-0 gamma band will produce only 110 rayleighs in the 1-0 delta band. The nitric oxide beta bands are even weaker in fluorescence. The strongest beta band in fluorescence, the 10-0 at 1817 Å, will produce an emission rate of only 10 rayleighs for the same amount of nitric oxide considered for the gamma and delta bands. The emission rate factors of the beta bands are plotted in Fig. 3. Because *f*-numbers are available for all three of these band systems, it is possible to intercompare their relative intensities and conclude that the gamma bands are the most important spectral features in identifying nitric oxide in a planetary dayglow.

The nitric oxide gamma, delta, and beta bands illustrate different types of behavior of band systems in fluorescence. The upper electronic levels of both the gamma and delta bands have nearly the same equilibrium internuclear distance as the lower levels. Following the Franck-Condon principle, these bands reradiate most intensely at the wavelengths where they absorb the light and in relatively few bands. In contrast, the upper level of the beta bands is at a greater internuclear distance than the lower level. These bands reradiate at wavelengths longer than those where they absorb the energy; thus, the energy is spread out over many bands. Band systems with this characteristic are more difficult to detect because the available energy is spread out over a larger portion of the spectrum.

B. Oxygen

The ultraviolet band systems of molecular oxygen that are of interest in planetary atmospheres are the Schumann-

Runge system, $B^3\Sigma_u^- - X^3\Sigma_g^-$, and the Herzberg system, $A^3\Sigma_u^+ - X^3\Sigma_g^-$. The Schumann-Runge bands arise from an allowed transition, while the Herzberg bands are from a forbidden transition. The molecular emission factors for these bands are listed in Sections IV and V of the Appendix. The *f*-values for the Schumann-Runge bands are from the work of Bethke (Ref. 28). (See Nicholls, Ref. 21.) The band strengths for the Schumann-Runge system are from Nicholls (Refs. 16, 21), and the Franck-Condon factors for the Herzberg bands are from Nicholls (Ref. 22). Because of the large optical depth of these band systems in the Earth's atmosphere, synthetic spectra for optically thin and optically thick fluorescence and for electron excitation are plotted in Figs. 4-9 for both systems. A comparison may be made of optically thin and optically thick fluorescent scattering for the Schumann-Runge bands in Figs. 4 and 5. For optically thin fluorescence, the more intense bands lie at the shorter wavelengths, the most intense band being the 13-3 at 1942 Å. For optically thick fluorescence, where the solar radiation may penetrate into the atmosphere until all the vibrational levels are populated, the emission bands appear at longer wavelengths, the most intense band being the 0-13 at 3234 Å. The electron-excitation spectrum in Fig. 6 shows the emphasis on the shorter-wavelength bands. The most intense bands are the 21-1 and 21-2 at 1800 and 1851 Å, respectively.

The Herzberg bands show the same spectral characteristics as the Schumann-Runge bands for the various methods of excitation. Because the Herzberg bands arise from a forbidden transition, they would always be much less intense than the Schumann-Runge bands. Both band systems arise from transitions in which the upper level is at a greater internuclear distance than the lower. This causes the emission bands to be spread out over many wavelengths. Here, even when the absorption bands are optically thick, the fluorescence may be treated as single-scattering, because most of the energy is re-emitted at longer wavelengths. The approximation used in Eq. (24) is particularly valid under these circumstances.

The Herzberg bands that appear in the nightglow of the Earth are excited by a chemical reaction, and their relative spectral intensities are not to be compared with the excitation mechanisms used in calculating the synthetic spectra in Figs. 7-9.

Fig. 9. Synthetic spectrum of oxygen Herzberg bands as excited by electron bombardment

C. Nitrogen

The band systems of interest in molecular nitrogen are the Vegard-Kaplan bands, $A^2\Sigma_u^+-X^1\Sigma_g^+$, the Lyman-Birge-Hopfield bands, $a^1\Pi_g-X^1\Sigma_g^+$, the Birge-Hopfield bands, $b^1\Pi_u-X^1\Sigma_g^+$, and the second positive bands, $C^3\Pi_u-B^3\Pi_g$. The first two of these transitions are forbidden as electric dipole radiation, while the last two are allowed transitions. The first three of these band systems may occur in a planetary atmosphere as the result of optically thin or optically thick fluorescence or as the result of electron bombardment. The second positive bands may be excited by electron bombardment but not by the fluorescence of solar radiation, because the transition from the ground state of molecular nitrogen to the upper state of these bands is forbidden as an electric dipole transition. The molecular emission factors for these four band systems are given in Sections VI-IX of the Appendix. The Franck-Condon factors were taken from the work of Nicholls (Refs. 9, 17).

Synthetic spectra of these band systems of molecular nitrogen are plotted in Figs. 10-19. The Vegard-Kaplan (Figs. 10-12), the Lyman-Birge-Hopfield (Figs. 13-15), and the Birge-Hopfield bands (Figs. 16-18) have spectra plotted for optically thin fluorescence, optically thick fluorescence, and electron excitation. The second positive bands (Fig. 19) have only electron excitation spectra plotted. Electronic oscillator strengths were not used for the nitrogen band systems, and the optically thin case is represented by the quantity g' of Eq. (13). These three band systems show the spectral characteristics that have been previously noted for the other band systems. The optically thick spectra show the energy degraded more to the long-wavelength end of the spectrum as compared to the optically thin spectra. The electron excitation spectra show the greatest concentration of energy toward the short-wavelength end of the spectrum. The most intense

bands for electron bombardment of nitrogen for each of the systems are: the 10-0 Vegard-Kaplan band at 1592 Å, the 3-0 Lyman-Birge-Hopfield band at 1354 Å, the 5-0 Birge-Hopfield band at 953 Å, and the 0-0 second positive band at 3370 Å. All of these systems should appear in planetary auroral spectra and in the dayglow spectra that are excited by photoelectrons.

D. Radicals

Two free radicals that are of interest in planetary atmospheres have strong band systems in the ultraviolet: the ultraviolet system of the hydroxyl radical, $A^2\Sigma^+-X^2\Pi_i$, and the violet system of the cyanogen radical, $B^2\Sigma^+-X^2\Sigma^+$. In both of these systems, the upper and lower states are at nearly the same internuclear distance, which makes the 0-0 band of the system the strongest transition. The molecular emission factors are listed in Sections X and XI of the Appendix. For hydroxyl, the f -numbers and transition probabilities are from Nicholls (Ref. 20). (See Dalby, Ref. 29.) The f -number for cyanogen is from the review by Dalby (Ref. 29), and the Franck-Condon factors are from Nicholls (Ref. 18). The 0-0 band of hydroxyl at 3064 Å has a value of g , the emission rate factor, of 8.6×10^{-4} photon-molecule⁻¹-sec⁻¹. A 1-kilorayleigh emission rate would require a column density of 1.2×10^{12} molecule-cm⁻².

The 0-0 band of cyanogen at 3876 Å has an emission rate factor of 7.3×10^{-2} photon-molecule⁻¹-sec⁻¹. A column density of 1.4×10^{10} molecule-cm⁻² is required to produce a 1-kilorayleigh emission rate for cyanogen. Synthetic spectra for these two systems are not plotted because each time they would consist only of a single band.

The 0-0 bands of both hydroxyl and cyanogen appear in the fluorescent spectra of comets.

E. Carbon Monoxide

The molecular band systems of carbon monoxide that are of interest in planetary atmospheres are the Cameron bands, $a^3\Pi_u-X^1\Sigma^+$, the fourth positive bands, $A^1\Pi-X^1\Sigma^+$, and the Hopfield-Birge bands, $a'^3\Sigma^+-X'^1\Sigma^+$. The fourth positive bands arise from an allowed transition while the other two are from forbidden transitions. The molecular emission factors for these systems are listed in Sections XII-XIV of the Appendix. The Franck-Condon factors for these calculations were taken from Nicholls (Ref. 9).

Synthetic spectra of the carbon monoxide band systems are presented in Fig. 20-22 for optically thin fluorescence. The quantity g' of Eq. (13) is plotted. The most intense bands of each system are: the 0-1 at 2158 Å for the Cameron bands, the 1-0 at 1510 Å for the fourth positive,

and the 9-0 at 1526 Å for the Hopfield-Birge. The g' values for these last two bands are 2.2×10^{-6} and 1.0×10^{-6} , respectively. Because the fourth positive system is allowed, while the Hopfield-Birge system is forbidden, it is certain that the Hopfield-Birge will be less intense than the fourth positive in fluorescence. The g' value of the 0-1 Cameron band is 7.1×10^{-4} . The actual importance of this system compared with the fourth positive depends on how strongly the change of multiplicity required in the Cameron bands weakens the oscillator strength as compared with the fourth positive.

A recent measurement of the f -value of the fourth positive bands by Hesser and Dressler (Ref. 30) permits the calculation of g , the emission rate factor. The band oscillator strength $f_{v',v''}$ for the 1-0 is 2.02×10^{-2} , and $g_{1,0}$ be-

Fig. 20. Synthetic spectrum of carbon monoxide Cameron bands in fluorescence in optically thin atmosphere

Fig. 22. Synthetic spectrum of carbon monoxide Hopfield-Birge bands in fluorescence in optically thin atmosphere

comes 2.1×10^{-7} photon-molecule $^{-1}$ -sec $^{-1}$. A column density of 4.8×10^{15} molecule-cm $^{-2}$ is required to produce an emission rate of 1 kilorayleigh. The amount of carbon monoxide above the mesopause on Mars should be considerably greater than this amount (Chamberlain, Ref. 31).

The optical depth in the fourth positive band may be calculated with the aid of the band fluorescent cross section from Section XIII of the Appendix and the band f -value. The cross section is 1.2×10^{-16} cm 2 -Å. Using estimates for the band line width similar to those used earlier for the nitric oxide gamma bands, the effective cross section becomes approximately 1×10^{-16} cm 2 . The 1-0 band of the fourth positive system will be approximately unit optical depth when there are enough molecules in the column to produce an emission rate of 1 kilorayleigh.

F. Molecular Ions

A number of molecular ions that are of importance in planetary ionospheres have spectra in the ultraviolet part of the spectrum. The ones considered here are the first negative bands of molecular nitrogen, $B^2\Sigma_u^+ - X^2\Sigma_g^+$, the second negative bands of molecular nitrogen, $C^2\Sigma_u^+ - X^2\Sigma_g^+$, the first negative bands of nitric oxide, $A^1\Pi - X^1\Sigma^+$, the second negative bands of molecular oxygen, $A^2\Pi_u - X^2\Pi_g$, the first negative bands of carbon monoxide, $B^2\Sigma^+ - X^2\Sigma^+$, and the comet tail bands of carbon monoxide, $A^2\Pi_r - X^2\Sigma^+$. The molecular emission factors for these bands are given in Sections XV-XX of the Appendix. The Franck-Condon factors for the molecular nitrogen ions are from Nicholls (Refs. 9, 17); for the nitric oxide and oxygen ions, from Nicholls (unpublished); and for the carbon monoxide ions, from Nicholls (Ref. 9). All of these transitions are allowed by the rules of electric dipole radiation.

The g' values for these molecular ion band systems are plotted in Figs. 23-28 as synthetic spectra. The most intense band of the nitrogen first negative system (Fig. 23) is the 0-0 at 3911 Å (band head at 3914 Å) with a g' value of 1.4×10^0 . The most intense band of the second negative system (Fig. 24) is the 5-0 at 1337 Å with its g' value of 5.0×10^{-7} . This very small value for the second negative band is a reflection of the small amount of solar energy available at shorter wavelengths and of the fluorescent energy being spread out among a larger number of bands in this system than in the first negative system. Because the type of electronic transition for both band systems is the same, it is expected that the electronic oscillator strengths will be similar. Because of the large difference in g' values, it is unlikely that the second negative bands will play any important role in the dayglow if the wavelength region of the first negative bands is experimentally

available. A measurement of the intensity of the first negative bands will make it possible to calculate the expected intensity of the second negative. An electronic f -value of 3.5×10^{-2} is given by Dalby (Ref. 29) for the first negative bands. When it is combined with the g' value, the emission rate factor g becomes 4.9×10^{-2} photon-ion $^{-1}$ -sec $^{-1}$. A value that is now being used, 6×10^{-2} photon-ion $^{-1}$ -sec $^{-1}$ (Wallace and Nidey, Ref. 32), is probably more nearly correct, because this value was based on a detailed examination of the solar intensity across the band. As mentioned earlier, in the present work the solar spectrum is calculated in detail below 2985 Å, while at longer wavelengths 50-Å averages are used. This 6×10^{-2} value of g for the 0-0 first negative band indicates that a column density of 1.7×10^{10} ion-cm $^{-2}$ is needed to produce an emission rate of 1 kilorayleigh. Such a column density is present in the Earth's atmosphere.

The most intense band of the nitric oxide first negative system (Fig. 25) is the 6-0 at 1223 Å with a g' value of 6.5×10^{-7} . Even if the oscillator strength of this system were of the order of 10^{-1} , a column density of 10^{16} ion-cm $^{-2}$ would be necessary to produce a fluorescent emission rate of 1 kilorayleigh. Such a column density far exceeds the amount of ionized nitric oxide in the Earth's atmosphere. The reason for low value of the emission rate factor for this band system is again the low intensity of the solar radiation at such short wavelengths.

The most intense band of the second negative band of molecular oxygen (Fig. 26), the 11-1 at 2242 Å, has a g' value of 7.2×10^{-5} . Again, using an optimistic value for the electronic oscillator strength, a single band of this system would not produce an emission rate of more than 1 to 10 rayleighs in the Earth's atmosphere. However, for this system, the reason for the low value of the emission rate factor is that the fluorescent energy is spread among so many bands. The sum of all the radiation in this system may be detectable in the Earth's atmosphere, while it would be difficult to measure individual bands (Zipf, Ref. 33).

The most intense bands of the carbon monoxide first negative (Fig. 27) and comet tail bands (Fig. 28) are the 0-0 at 2191 Å and the 2-0 at 4264 Å, respectively. Their respective g' values are 7.8×10^{-3} and 5.8×10^{-1} . The band oscillator strength $f_{0,0}$, for the 0-0 first negative band is 8.2×10^{-3} (Lawrence, Ref. 34). The emission rate factor g for this band is then 1.2×10^{-4} photon-ion $^{-1}$ -sec $^{-1}$. The oscillator strength for the comet tail bands is 2.2×10^{-3} (Dalby, Ref. 29). The emission rate factor g for the 2-0 band is then 1.3×10^{-3} photon-ion $^{-1}$ -sec $^{-1}$. A column den-

sity of 7.7×10^{11} ion-cm⁻² is required to produce an emission rate of 1 kilorayleigh. As the name suggests, these bands have been observed in the tails of comets.

A summary of most intense bands of each system is given in Table 4. The band number and wavelength

are given for all the systems for optically thin fluorescence. When available, the emission rate factor g is given for these bands. The g' value is given for all systems that undergo fluorescence. Where appropriate, the band number and wavelength of the most intense bands are listed for optically thick fluorescence and electron excitation.

Table 4. Most intense bands

Band system	Optically thin		g photon- molecule ⁻¹ -sec ⁻¹	g'	Optically thick		Electron excitation	
	$v'-v''$	$\lambda, \text{\AA}$			$v'-v''$	$\lambda, \text{\AA}$	$v'-v''$	$\lambda, \text{\AA}$
Nitric oxide gamma	1-0	2149	7.7×10^{-6}	3.3×10^{-3}				
Nitric oxide delta	1-0	1826	8.6×10^{-7}	9.2×10^{-5}				
Nitric oxide beta	10-0	1817	7.2×10^{-5}	1.1×10^{-5}				
Oxygen Schumann-Runge	13-3	1942	2.9×10^{-9}	8.9×10^{-8}	0-13	3234	21-1	1800
Oxygen Herzberg	12-1	2528		1.0×10^{-4}	3-4	3234	12-1	2528

V. ULTRAVIOLET SPECTRA OF EARTH

Several examples of ultraviolet spectra of the Earth's upper atmosphere are given here. These examples include excitation of the spectra by optically thin fluorescence, photoelectron excitation, and the combination of absorption and rayleigh scattering. The nitric oxide gamma bands and the nitrogen first negative bands are produced in the Earth's dayglow by the fluorescence of incident solar radiation. Both systems are optically thin. The nitrogen second positive bands are present in the dayglow of the Earth as a result of the bombardment of atmospheric nitrogen by fast photoelectrons that, in turn, have been produced by the photoionization of the upper atmosphere by extreme ultraviolet solar radiation. Absorption by ozone determines the overall spectral characteristics of the Earth's ultraviolet albedo. The rayleigh scattering retains the detailed Fraunhofer features of the solar spectrum.

Ultraviolet spectra of the limb and disk of the Earth have been obtained in a series of flights of Aerobee rockets. These experiments used an attitude-control system to point the rocket and a scanning spectrometer at the limb and the disk of the planet. The results of three of these flights are shown in Figs. 29-31.

The dayglow spectrum of the Earth between 1730 and 2730 Å is shown in Fig. 29. The nitric oxide gamma bands in fluorescence are the most prominent spectral features. This spectrum was obtained at an altitude of 146 km while the scanning spectrometer was aimed at a zenith angle of 99 deg, which enabled it to look through the limb of the atmosphere (Barth, Ref. 35). The emissions originate in the 85- to 125-km region of the atmosphere. The lower spectrum is the flight record; the upper is a synthetic spectrum calculated from the emission rate factors $g_{v'v''}$ of Section I of the Appendix. The spectral sensitivity of the rocket spectrometer is sketched behind the two spectra.

Another spectrum of the dayglow of the Earth is shown in Fig. 30. It covers the wavelength range 2000-4000 Å with a different spectral sensitivity from the previous spectrum. This spectrum was obtained from an altitude of 165 km while the spectrometer was aimed at a zenith angle of 90 deg through the horizon (Barth and Pearce, Ref. 36). The spectrometer measured spectral emissions originating from 135 km and higher. The 0-0 band of the nitrogen first negative bands is the most intense feature at 3914 Å. A rocket spectrum of this band had previously been obtained by Wallace and Nidey (Ref. 32). The spectrum in Fig. 30 also shows the 1-0 band of the nitric oxide gamma bands at 2150 Å. Both the 3914 and 2150 Å bands are produced by fluorescence. The nitrogen second positive bands also appear in this dayglow spectrum. They are the result of excitation by photoelectron bombardment. The spectral sensitivity of the rocket spectrometer is sketched behind the flight spectrum.

The ultraviolet albedo of the Earth is shown in the wavelength range 1900-3200 Å in Fig. 31. This spectrum was obtained from an attitude-controlled rocket at an altitude of 168 km while the scanning spectrometer was aimed at a zenith angle of 180 deg, directly downward at the atmosphere (Ref. 37). The lower spectrum is the flight record of the Earth's albedo. It shows solar spectral features and the absorption produced by ozone in the Earth's atmosphere. The upper spectrum is a synthetic spectrum of the incident solar radiation. The detailed Fraunhofer features may be seen in both the incident solar spectrum and the scattered daylight. The spectral sensitivity of the rocket spectrometer is sketched behind the two spectra. The Earth's albedo is given in units of kilorayleigh $(10\text{Å})^{-1}$ as an apparent emission rate. The solar flux is in units of $\text{photon-cm}^{-2}\text{-sec}^{-1} (10\text{Å})^{-1}$.
