1. INTRODUCTION

The purpose of this document is to present in handbook form a tabulation of station view periods and trajectory characteristics for Surveyor missions. Final trajectory selection for Surveyor missions for the launch periods contained in this report has not been completed, but changes which might occur are expected to be negligible, yielding data sufficiently accurate to be used for much of the preflight mission analysis. Used in conjunction with "Surveyor Direct Ascent Trajectory Characteristics," (see Section 8, References) this document should satisfy the need of the agencies supporting the Surveyor project.

BLANK

2. TRAJECTORY DESCRIPTION

THE ASCENT TRAJECTORY

The Surveyor spacecraft will be injected into an earth-moon transfer trajectory by the Atlas-Centaur launch vehicle. Two seconds after liftoff Atlas-Centaur begins a programmed roll that orients the vehicle into the proper flight azimuth. At 15 seconds, a pitchover program begins, tilting the vehicle to the required attitude for its particular mission. At approximately 144 seconds, the Atlas thrust structure and booster engines are jettisoned. The sustainer engine continues to provide thrust. After about 236 seconds, the Atlas phase of flight ends and the Centaur separates from the first stage. The Centaur is now traveling at approximately 10,000 mph at a height of about 80 miles. The Centaur engines ignite and propel the vehicle to a predetermined set of injection conditions. The spacecraft is separated from the Centaur about 1 minute after injection. To prevent later interference of the Centaur with the operation of the spacecraft Canopus sensor, the Centaur is turned 180 degrees and a retro maneuver is initiated about 4.5 minutes after injection.

THE POSTINJECTION TRAJECTORY

The Surveyor postinjection trajectories can, in general, be described by a geocentric ellipse. This earth-moon transfer ellipse can be thought of as rotating with the earth and containing the launch site until the time of liftoff. At liftoff time the ellipse is fixed in geocentric inertial coordinates. The plane containing the transfer ellipse can be considered to contain the launch site at launch time and the moon at touchdown. To compensate for the earth's rotation the launch azimuth is adjusted to maintain the required geometry. After the trajectory plane has been chosen, the trajectory is completed by specifying the central angle between launch and lunar impact.

The Surveyor lunar trajectories have flight times of approximately 64 hours. The flight time results in a central angle of approximately 170 degrees from injection to lunar encounter. Direct ascent trajectories require a boost arc close to 28 degrees in length, depending on the value of the flight-path angle (or true anomaly) at injection. Payload considerations limit the

injection flight-path angle to values between about -5.5 and +11 degrees. This restriction precludes arrivals at declinations more positive than -15 degrees for direct ascent trajectories.

NEAR EARTH CONIC PROGRAM

A detailed description of the conic program used to generate the information contained in this document is presented in the "Parking Orbit and Direct Ascent Near Earth Conic User Guide," EPD-198 (Reference 2) and the "Near Earth Conic Computer Program," EPD-163 Revision 1 (Reference 6).

The Near Earth Conic Computer Program solves the geometrical problem of finding a geocentric transfer ellipse that contains the launch site at launch time and the moon at encounter time.

CONIC VIEW PERIOD PROGRAM

The trajectory parameters as determined in the preceding Near Earth Conic Program paragraphs are inputs to the Conic View Period Program. The Conic View Period Program approximates time-variant geocentric position and velocity vectors in order to derive the station view periods. This program in general can be described as follows:

1) The geocentric position of the postinjection trajectory is approximated by the conic elements determined by the Near Earth Conic Program.

2) The lunar encounter portion of the trajectory is approximated by a rectilinear hyperbola as determined by conditions near the moon's sphere of influence.

The program gives a continuous view period and trajectory information from injection to lunar encounter.

3. SCOPE

This document contains station view periods and trajectory characteristics for the trajectories shown in Table 3-1.

The launch day is arbitrarily determined by the day on which a launch azimuth of 108 degrees would occur. This point is of importance in cases where the firing window straddles midnight, i. e., where the firing window occupies portions of each of two days.

View periods are provided for the following Deep Space Instrumentation Facility (DSIF) tracking sites; Ascension Island, Canberra, Australia; Johannesburg, South Africa; Goldstone, California; and Madrid, Spain. Table 3-2 lists the station coordinates and identification numbers. Air Force Eastern Test Range (AFETR) station view periods are not included in this document. However, due to their close proximity, ETR 75 (Ascension) may use the data generated for DSIF 72 (Ascension), and ETR 76 (Pretoria) may use DSIF 51 (Johannesburg) data.

In addition to the station view periods, the tabular listing presented in Section 9 includes important mission events and the associated tracking station parameters for the stations viewing these occurrences. The events are defined in Section 5. The geocentric trajectory characteristics at these significant times are presented at the end of the view period tabulations.

TABLE 3-2. TRACKING SITE LOCATIONS

Station Number	Name	Geocentric Coordinates*		
		Latitude, degrees	Longitude, degrees	Radius, kilometers
72	Ascension	- 7.9042	345.6708	6378.295
51	Johannesburg	[illegible]	27.685181	6375.4980
11	Goldstone	35.20807	243.15082	6372.0341
42	Canberra	-35.219630	148.98028	6371.6686
61	Madrid	40.238	355.7505	6370.0868

*All coordinates except Ascension are from JPL Interoffice Memo 372.21/318 by J. F. Scott, 1 September 1964. Ascension coordinates were obtained from W. O'Neil of Jet Propulsion Laboratory.

4. HOUR-ANGLE AND ELEVATION-ANGLE CONSTRAINTS

The pointing restrictions for the view periods presented are shown in Table 4-1.

TABLE 4-1. POINTING RESTRICTIONS FOR VIEW PERIODS

Station	Hour-Angle Limits, degrees	Elevation Limits,* degrees
Goldstone	± 90	0
Johannesburg	± 90	0
Canberra	±105	0
Madrid	±105	0
Ascension	None	0

*Previous Surveyor view period documents have used 5 degrees for elevation limits. Although this is usually a good approximation to the land or air mask, some stations are able to communicate with the spacecraft at lower elevations. Using an elevation limit of zero degrees gives an optimistic view period that is never exceeded.

If the rise (or set) time at another elevation is desired, divide the new elevation by the elevation rate (DEL) and add (or subtract) this time to (or from) the rise (or set) time.

5. PRINTOUT FORMAT

The printout format for each trajectory (defined by a launch date and launch azimuth) is divided into three sections. The first section contains the orbit parameters of the transfer-orbit trajectory. Included are the initial conditions at transfer-orbit injection (hereafter referred to as injection). This information is generated by the Near Earth Conic Program.

The second section contains the view period and tracking information. At the occurrence of either a view period event or a mission event, the tracking parameters of the probe with respect to all stations viewing it at that instant are calculated and printed.

The third section is a tabular presentation of the position and velocity vectors of the probe at the occurrence of mission events.

6. TABULATED OUTPUT DESCRIPTION

ORBIT PARAMETERS

Line 1

Output Symbol	Description	Units
GHA	Greenwich hour angle of Vernal Equinox at zero hours GMT on the encounter date	degrees
EPS	Earth-probe-sun angle at encounter	degrees
LOM	Longitude of the moon at encounter	degrees

Line 2

SX, SY, SZ	Geocentric unit vector to Moon at encounter (Mean of date)	
DAO	Declination of outgoing asymptote	degrees
RAO	Right ascension of outgoing asymptote	degrees
RM	Distance to moon at encounter	kilometers
LAT	Latitude of launch site	degrees
LON	Longitude of launch site	degrees

Output Symbol	Description	Units

7. ACCURACY OF DATA

Typical values of injection errors resulting from the Near Earth Conic Program are:

Injection longitude	~ 0.1 degree
Injection latitude	~ 0.2 degree
Injection time	~ 200 seconds

It may be noted that these accuracies are somewhat improved relative to those realized in earlier issues of this document using the former Near Earth Conic Program (Reference 3).

The resulting view period events relative to injection are well within the initial acquisition capabilities of the DSIF stations (Reference 4).

Typical values of view period event errors are as follows:

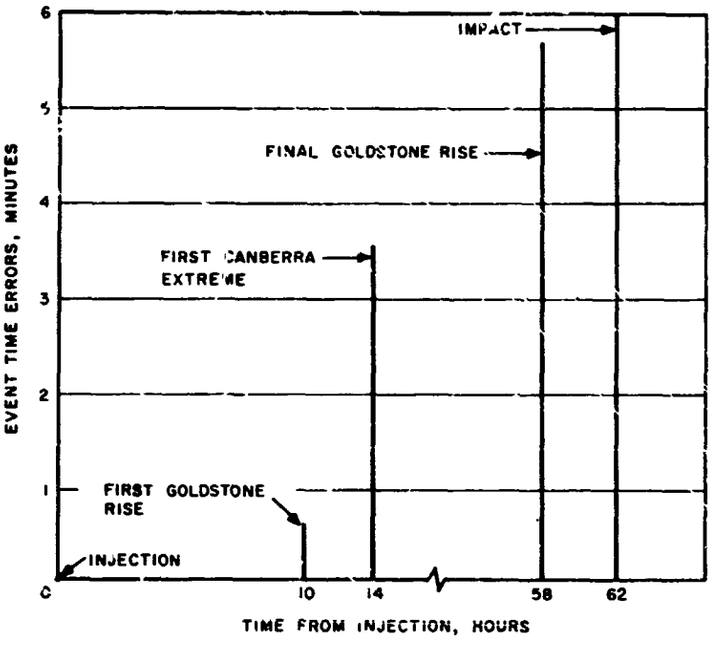
Range rate – 100 m/sec	This results in a frequency uncertainty of 0.71 kc. The expected frequency uncertainty is 15 kc (Reference 4).
Pointing angles (prior to 3 hours)	1.5 degree. S-band DSIF tracking capability is 16 degrees and the maximum expected uncertainty is approximately 8 degrees (Reference 4).
Event time	See below. (Typical event time error.)
Central angle pointing error	1.0 degree maximum

TYPICAL EVENT (RISE, SET, ETC.) TIME ERRORS

An integrating N-body trajectory program was used to check the accuracy of the Event times given in this document. To check these times, the program was run in two ways:

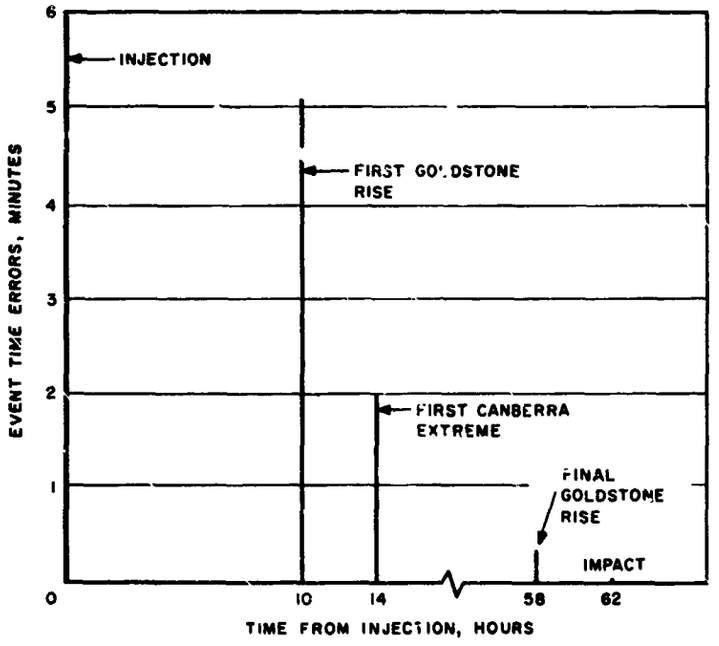
Case 1) Use the same injection time (as is given in this document) and determine subsequent event time errors.

Case 2) Use the same arrival time and determine the time errors for other events.



With case 1 it is obvious that event time errors in the vicinity of injection will be small. As the flight progresses, however, these errors increase to about 6 minutes at impact (Figure 7-1a).

From case 2, event time errors are small at impact and are at their maximum at injection (Figure 7-1b).



Therefore, in order to keep errors at a minimum when using this document, the following method should be employed:

1) Given a launch azimuth and injection (or launch) time, use columns 2 (or 3) of the data. These columns refer to the time from injection (or launch) and will yield very small event time errors in the vicinity of injection (injection + 10 hours). However, the GMT (column 4) in this neighborhood may be in error typically by 6 minutes.

2) Given an arrival time and a launch azimuth (and launch date), find the corresponding page in this document and determine the difference in the given arrival time and that which is printed out here. This difference may now be added to the GMT of the event times (column 4) in the vicinity of impact (impact -20 hours) and the event time errors will again be very small. Time from injection or launch (columns 2 or 3), however, may be in error by 6 minutes.

a) Case 1

b) Case 2

Figure 7-1. Typical Event Time Errors as Funtion of Time from Injection
