ABSTRACT

The results of a literature survey that was made of radiochemical cross sections below 425 MeV are given in tabular form. The cross-section data are tabulated for reactions involving incident protons, neutrons, and π mesons in the energy range from about 20 to 400 MeV interacting with nuclei ranging from lithium to the heaviest weight elements.

The results of a literature search for the experimental reaction cross sections usually measured by radiochemical techniques are presented in this report. Cross sections are tabulated for reactions involving incident protons, neutrons, and π mesons in the energy range from about 20 to 400 MeV interacting with nuclei ranging from lithium to the heaviest weight elements.

The earliest data included here are those tabulated in a comprehensive survey made by Bruninx[8,29*] for reactions below about 400 MeV, and the latest data include those published before July 1965 in the Physical Review or in articles abstracted in the May 1965 issue of Science Abstracts, Physics.

The experimental data were taken from tables and graphs in the references cited, with no attempt being made to evaluate the experiments. The errors listed are the published errors, and may reflect statistical errors or systematic errors or both. In a few cases the same data are tabulated under two different references: the original publication and another publication which cited the original material. We made no attempt to eliminate this overlap.

The bulk of the data that are tabulated pertain to reactions involving incident protons; the remaining few cases consist of neutron data and pion data. For each type of incident particle the data are listed according to increasing target mass number, and for each target the data are tabulated according to decreasing atomic number of the residual nucleus, decreasing mass number of the residual nucleus, and increasing incident-particle energy.

Target and residual nuclei are listed with the element symbol followed by the mass and atomic numbers in parentheses.

---

*See list of references preceding tables.

Omission of the mass number in the target nucleus reflects a similar omission in the published data, and we assumed that the element used in the experiment was in its naturally occurring state. In the combinations of isotopes in the residual nucleus for which the mass number was also omitted, the combinations are as follows: $^{34+38}_{17}Cl$, $^{43+44}_{21}Sc$, $^{81+82}_{37}Rb$, $^{83+84}_{39}Y$, $^{116+117}_{52}Te$, $^{120+121}_{53}I$, $^{171+172}_{71}Lu$, $^{176+180}_{73}Ta$, $^{191+193m}_{78}Pt$, $^{198+199}_{79}Au$, and $^{192+193+194}_{81}Tl$. Parentheses around a cross-section value indicate that the actual value of the cross section is less than that number. The designation E-2 or E-3 following a set of parentheses indicates that the value within the parentheses should be multiplied by 10^{-2} or 10^{-3}.

This literature search is a direct outgrowth of our attempts to evaluate the accuracy of our cascade-evaporation model[54] in predicting radiochemical cross sections. A report on the evaluation is in progress.[55]
