## ABSTRACT

THE EXPERIMENTAL RESULTS OF A SERIES OF HYPERVELOCITY IMPACT FIRINGS WITH BOROSILICATE GLASS PROJECTILES, IN SEVERAL SIZE RANGES FROM 20 TO 50 MICRONS IN DIAMETER, ON BOTH SEMI-INFINITE AND THIN SHEET TARGETS ARE REPORTED. THE DATA ALLOWS THE DETERMINATION OF THE THRESHOLD VELOCITY FOR PERFORATION FOR THE THIN SHEET TARGETS AS WELL AS THE VARIATION OF DEPTH OF PENETRATION WITH VELOCITIES IN THE SEMI-INFINITE TARGETS. AMONG THE THIN SHEETS IMPACTED WAS THE 0.0015" THICK CAPACITOR SENSOR PANEL OF THE PEGASUS SATELLITE MICROMETEOROID DETECTION SYSTEM. THE EXPERIMENTS COVER THE RANGE OF 18,900 FEET PER SECOND TO 65,000 FEET PER SECOND.

SID 67-251

## INTRODUCTION

The experimental program described in this report had two objectives. The first was, by a series of hypervelocity impacts, the determination of the threshold velocity for perforation of specific materials impacted by artificial micrometeoroids. The threshold velocity for perforation is customarily referred to as the ballistic limit or the minimum velocity at which a specific projectile is capable of producing a perforation in a particular thin target. The materials of interest in this program were those employed in previous micrometeoroid measurement satellite experiments. The second objective was the determination of the projectile diameter to impact crater depth ratio for craters produced in semi-infinite targets of the same material composition and physical properties as the thin sheet targets studied in the first objective over a range of velocities encompassing the threshold perforation velocity for the thin sheet experiments.

## TARGET MATERIALS

The target materials were supplied by the George C. Marshall Space Flight Center and consist of Type 302 corrosion resistant steel in the half-hard condition in thickness of 0.001" and 0.002" and a nominal 0.0015" capacitor from the perforation sensor layer of a Pegasus micrometeoroid perforation detection satellite panel. In addition 2" x 3" x 0.375" of Type 302 CRES, reportedly in the same heat treat condition as the thin sheet material and 1.5" x 1.5" x 0.105" Type 1100-0 aluminum.

## EXPERIMENTAL TECHNIQUES

The firing experiments were conducted in North American Aviation's Mark IV Electrothermal Gun System in its Space Sciences Department, Space and Information Systems Division, Downey, California. The gun system which accelerates spherical silicate projectiles with a diameter range of 20 to 90 microns by aerodynamic drag forces produced by a dense flowing plasma, has been described in a series of previous reports. The most complete description appears in the Proceedings of the Seventh Hypervelocity Impact Symposium.

The method for determining the threshold perforation velocity was to provide a series of impacts over a wide range of velocities in sufficient number as to clearly define the minimum velocity projectile capable of producing a perforation. In order to determine the threshold velocity, the targets were mounted within the hypervelocity range target chamber with two viewing photomultiplier tubes. The field of view of the first photomultiplier tube was restricted to the front surface of the target material and detected the luminous impact flash. The impact flash signal was recorded on one channel of a two-beam oscilloscope,

SID 67-251

Tektronix Type 551 with Type K pre-amplifier. The field of view of the second photomultiplier was restricted to the rear surface of the target and, in event that a perforation took place, a luminous flash from the rear surface was detected and recorded on the second channel of the two-beam oscilloscope. Coincidences of impact flash and rear surface flash was evidence that the incident projectile has produced a perforation. All other range instrumentation techniques have been described in the referenced source.

It was a restriction in the statement of work that the projectile diameters be such that the threshold perforation velocity was in excess of 10 Km/sec (32,800 feet per second). For this reason each of the thin sheet target materials were subjected to impacts by borosilicate glass spherical projectiles (density 2.23) over a range of velocities in order to determine which projectile diameters would be used for the acquisition of impact data for the perforation experiments. The projectile diameters chosen for principle experiments were 22.9 microns (0.0009"), 33.0 microns (0.0013") and 51.4 microns (0.00202"). Standard deviation from the mean diameter was 2.5%.

The thin sheet Type 302 CRES was used in the "as received" condition. Precision measurements of received material indicated an actual thickness of 0.0018" for the nominal 0.002" CRES and 0.0009" for the nominal 0.001". The Pegasus sensor material was received in the form of a flight type 20" x 40" double surface panel. The full-scale panel was cut into two-inch squares and the plastic foam backing removed from the capacitor. The adhesive bonding material used to join the capacitor to the plastic foam panel remained on the capacitor surface. The target sheet therefore consisted of a multi-layered structure of 0.0015" aluminum, a bonded Mylar layer, a vapor deposited copper layer, and a layer of adhesive. The overall average thickness was 0.0019". This fact is significant in the interpretation of the perforation threshold data.

#### PERFORATION THRESHOLDS

Based upon the determination of the projectile diameters whose impacts lead to perforations at velocities above 32,800 feet per second, a series of firings were conducted for each of three specific thin sheet targets.

The results of the perforation experiments for 0.0013" diameter spheres on 0.0015" Pegasus detector panels is summarized in Table 1. A total of 30 perforations were obtained over a range of velocities from 57,300 feet per second down to 39,400 feet per second. No perforations were obtained at any velocities below 39,400 feet per second, and this value may be considered as the threshold velocity for perforations for this specific combination of projectile and target materials. The summary of perforation experiments for 0.0009" diameter projectiles on 0.001" 302 CRES is summarized in Table 2. A total of 35 perforations were obtained over the velocity range from 65,000 feet per second down to 38,800 feet per second. No perforations were obtained with any impacts below the lower limit. Table 3 summarizes the perforation

SID 67-251

experiments with 0.0013" diameter projectiles on 302 CRES where a total of 30 perforations were obtained over the velocity range from 60,200 feet per second down to 40,100 feet per second.

#### SEMI-INFINITE TARGET IMPACTS

It is the objective of this particular task to determine the ratio of crater depth to projectile diameter for each of the target materials and for each of the combinations of projectile diameters and target materials at the penetration threshold velocity for the thin sheet targets. To accomplish this end, a series of firings were conducted with appropriately sized projectiles on each of the target materials and the crater depth to projectile diameter ratio determined for each impact for which there was range indication that the impact was produced by an intact projectile. Table 4 summarizes the values of  $p/d$  for each of 31 craters obtained over an impact velocity range of 49,800 feet per second down to 15,400 feet per second for 0.0013" diameter projectiles on 1100 aluminum. Table 5 summarizes similar measurements for the 32 impact craters produced by 0.0009" diameter projectiles on 302 CRES over the velocity range from 54,300 feet per second to 24,900 feet per second. Similarly, Table 6 gives equivalent data for the 31 craters produced by 0.0013" diameter spheres on 302 CRES of 56,800 feet per second down to 24,900 feet per second.

#### MISCELLANEOUS FIRINGS

During the first portion of the effort, which consisted of a series of impact experiments on thin sheet targets for the purpose of determining the appropriate diameter of projectiles to be employed for the main body of firings, certain data points were obtained using different combinations of projectile diameters and targets than those employed in the main program. While the results of these firings indicated that the projectile diameter was such that the penetration threshold was below the desired value of 32,800 feet per second, the data is considered to have some value for the interpretation of both the laboratory experiments and the behavior of certain materials under space meteoroid impact. The results of these firings are summarized in Tables 7, 8 and 9.

#### SUMMARY

The  $p/d$  values for those impacts obtained at the penetration threshold velocity for each combination of projectile and target materials may be determined by drawing a smooth curve through the individual  $p/d$  values over the full velocity ranges indicated in Tables 4, 5 and 6. An anomalous result is noticed in the case of the 0.0015" Pegasus capacitor target. At the threshold perforation velocity of 39,400 feet per second, the corresponding  $p/d$  in the semi-infinite material is 2.04. If one assumes that the target material

SID 67-251

is basically 0.0015" aluminum, this would lead to a ratio of the thickness of the thin target material to the depth of penetration in the semi-infinite material of 0.56. This result cannot be accepted as having any significance. It should be remembered that the capacitor target was a composite target of four different materials, three of which have appreciable thickness. The influence of the adhesive bonding material used to provide adherence of the capacitor structure to the one-inch thick plastic foam is not negligible and appears to significantly increase the resistance to perforation by projectiles of the diameter used in the experiments.

SID 67-251

Table 7. Impact Velocities Leading to Perforation of 0.0015" Pegasus  
Detector Panels by 0.0009" diameter  
Borosilicate Glass Spheres

No perforations were obtained with any impacts between 14,000 and 60,000  
feet per second.

Table 8. Impact Velocities Leading to Perforation of 0.001" Half-hard  
302 CRES by 0.0013" Diameter  
Borosilicate Glass Spheres

| <u>Velocity,<br/>Feet Per Second</u> | <u>Firing Reference<br/>No.</u> |
