TIME-OPTIMAL CONTROL OF GRAVITY GRADIENT SATELLITES WITH DISTURBANCES*

ABSTRACT

The optimal control of spacecraft with gravity gradient coarse stabilization and active libration damping for precision pointing represents a promising approach for advanced experiments, e.g. laser communications, where angular position within .001° must be achieved and maintained in the presence of disturbances. This paper deals with the time optimal control for this case. A suboptimal (i.e. nearly optimal) control law for the general gravity gradient satellite (GGS) is obtained by a two-step approximation: first the general GGS is approximated by a dumbbell satellite (DS) and secondly a small angle approximation is derived. The optimal control law for this case is calculated and applied to two representative examples of a 24 hour synchronous GGS. The practical results are shown and discussed. It can be seen how the optimal control law derived for the DS works for the general GGS as a suboptimal control law. The Maximum Principle, which is used in this paper, is also extended to cover operating conditions with disturbances. It is shown that disturbances change the optimal control law significantly, a result that is very important for practical applications of the maximum principle.

*The work for this paper was accomplished while the author held a National Research Council Postdoctoral Resident Research Associateship supported by the National Aeronautics and Space Administration, Goddard Space Flight Center. The author is very much obliged to Mr. W. Isley and Mr. D. Endres for their valuable suggestions.
NOMENCLATURE

The center of all coordinate systems are at the center of mass (c.m.) of the spacecraft. All coordinate systems are right handed.

\( a, a, a \) - gravity gradient coefficient for pitch, roll and yaw respectively

\( C_i \) - linear viscous damping coefficient of the damper rod

\( C_2 \) - linear spring coefficient of the damper rod

\( d \) - reduced disturbance torque \( = \frac{T_{di}}{I_{ii}}, i = x, y, z \)

DS - Dumbbell Satellite

GG - Gravity Gradient

GGS - Gravity Gradient Satellite

\( H_{ib} \) - inertial angular momentum of the main body of the spacecraft, measured in body-fixed coordinates, \( i = x, y, z \)

\( I \) - moment of inertia of the damper rod about its axis of rotation

\( I_{ii} \) - inertia tensor of the main spacecraft body

\( r \) - distance from the center of the earth to the c.m. of the spacecraft

\( t \) - time

\( T_{ci} \) - control torques, \( i = x, y, z \)

\( T_{di} \) - disturbance torques, \( i = x, y, z \)

\( U_i \) - reduced control torques \( i = \frac{T_{ci}}{I_{ii}}, i = x, y, z \)

\( \vec{v} \) - inertial velocity of the spacecraft

\( x, y, z \) - attitude reference system (\( x \) has the direction from the center of the earth to the c.m. of the spacecraft, \( y \) lies normal to \( x \) and in the orbital plane such that the component of \( \vec{v} \) in the \( y \) direction is greater than zero)
coordinate system fixed to the main body of the spacecraft (xₜ, yaw axis, yₜ, roll axis, zₜ, pitch axis)

coordinate system fixed to the damper rod

pitch angle

set value of pitch angle

earth gravitational constant

orbital angular rate, i.e., rotation of the xₜ, yₜ, zₜ system in inertial space, measured in the xₜ, yₜ, zₜ system, i = x, y, z

angles of the damper rod relative to the body-fixed coordinate system

time consumed for damping of initial librations

roll angle

set value of roll angle

yaw angle

angular inertial velocity of the main body of the spacecraft, measured in the xₜ, yₜ, zₜ system, i = x, y, z

orbital angular rate for a circular orbit (\( \omega = \sqrt{\frac{1}{r^3}} \))
1. INTRODUCTION

The development of control policies for highly precise fine pointing of spacecraft is a necessary condition for a number of advanced experiments, e.g. laser communications. The gravity gradient technique offers a good approach for long term coarse stabilization of a spacecraft. However, precise pointing to certain angles is required for some experiments, and it may be desirable to accomplish this in minimum time. Also for these experiments, disturbances such as the solar torque acting on the spacecraft must be counteracted by proper control.

The overall optimal control policy must meet two basic objectives: (1) acquisition of the precision pointing mode in minimum time starting from a coarse GG mode, and (2) extended term precision pointing by counteraction of disturbance torques. This paper will treat only the acquisition requirement. The optimal control law as developed herein is applied to two representative examples of a synchronous equatorial 24 hour earth spacecraft. The method employed for active libration damping is the use of a reaction jet device operating in the micro-pound thrust level regime, which can be an ion engine, resistojet, or pulsed plasma system. It is envisioned that any use of the ion engine would require special consideration of control actuations. The main difficulty with the ion engine is that it cannot be readily turned on and off for thrusting purposes. One possibility is to combine libration damping with orbit corrections. Another possibility is to
provide a balanced couple which cancels out the orbital effects. The resistojet has already been studied as a means of optimal large angle maneuvering for a synchronous spacecraft. Pulsed plasma systems appear to offer high promise for use in both acquisition and holding modes due to their precision impulse bit capability and relatively high specific impulse. It is assumed that a minimum of six thrust directions is provided on the spacecraft to provide control in pitch, roll, and yaw axes.

The procedure used to develop these control laws is as follows:

1. The general rotational equations of motion for a GGS including a damping mechanism is formulated.

2. These equations are linearized for a DS in a circular equatorial orbit with small vibrations.

3. The optimal control laws are developed for this DS. To check the validity of these control laws for a more general synchronous GGS, the control laws are applied to the simulation of the complete GGS.

2. EQUATIONS OF MOTION FOR A GRAVITY GRADIENT SATELLITE

For development of an optimal control law, a GGS which has four rigid GG booms and a rigid damper rod is assumed.

The damper rod will be assumed to rotate in a plane fixed with respect to the main body. The spacecraft-damper rod system therefore represents a seven degree of freedom system. For pointing the axes of the spacecraft to given angles only the equations of rotational motion are of interest for circular orbits. These are
\[
\begin{bmatrix}
\dot{x}_b \\
\dot{y}_b \\
\dot{z}_b
\end{bmatrix}
= I
\begin{bmatrix}
\dot{x}_b \\
\dot{y}_b \\
\dot{z}_b
\end{bmatrix}
\left[
\begin{bmatrix}
\ddot{x}_b \\
\ddot{y}_b \\
\ddot{z}_b
\end{bmatrix}
\right] (1)
\]

where
\[
\begin{align*}
\dot{x}_b &= M_{xb} \cdot M_{xd} \cdot \sin \cdot 2 \cdot M_{zd} \cdot \cos \cdot 2 - (\dot{z}_b H_{zb} - \dot{z}_b H_{yb}) \cdot P \cdot \cos \cdot 2 \cdot T_{cx} - T_{da}, \\
\dot{y}_b &= M_{yb} \cdot M_{xd} \cdot \cos \cdot 2 \cdot \sin \cdot 1 - M_{zd} \cdot \sin \cdot 2 \cdot \cos \cdot 1 - (\dot{z}_b H_{xb} - \dot{z}_b H_{zb}) \\
&\cdot P \cdot \sin \cdot 2 \cdot \cos \cdot 1 \cdot T_{cy} - T_{dy}
\end{align*}
\]

and
\[
\begin{align*}
\dot{z}_b &= M_{zb} \cdot M_{xd} \cdot \cos \cdot 2 \cdot \sin \cdot 1 - M_{zd} \cdot \sin \cdot 2 \cdot \sin \cdot 1 - (\dot{z}_b H_{yb} - \dot{z}_b H_{xb}) \\
&\cdot P \cdot \sin \cdot 2 \cdot \cos \cdot 1 \cdot T_{cz} - T_{dz}
\end{align*}
\]

The torques \( M_{tb} \) and \( M_{nd} \) caused by the gravity gradient effect are, for the main body of the spacecraft

\[
\begin{align*}
M_{xb} &= \frac{3}{r^3} \left( I_{yy} - I_{zz} \right) a_2 a_3 - I_{xy} a_1 a_3 - I_{xz} a_1 a_2 + I_{yz} \left( a_1^2 - a_2^2 \right), \\
M_{yb} &= \frac{3}{r^3} \left( I_{zx} - I_{xy} \right) a_3 a_2 - I_{zy} a_1 a_3 + I_{zx} \left( a_1^2 - a_3^2 \right) + I_{zy} a_1 a_2 \\
\text{and} \\
M_{zb} &= \frac{3}{r^3} \left( I_{xx} - I_{yy} \right) a_1 a_2 + I_{zx} \left( a_2^2 - a_3^2 \right) + I_{xz} a_2 a_3 - I_{yz} a_1 a_3
\end{align*}
\]

and for the damper rod

\[
\begin{align*}
M_{xd} &= 0, \\
M_{yd} &= \frac{3 \mu}{r^3} I_j b_1 b_2 \\
\text{and} \\
M_{zd} &= \frac{3 \mu}{r^3} I_j b_1 b_3
\end{align*}
\]
P and $M_{sd}$ used in (2) are given by:

$$\begin{align*}
\begin{bmatrix}
P \\
I_x \chi_d (\gamma_d - \theta_d)
\end{bmatrix}
\begin{bmatrix}
P \\
\gamma_d - \theta_d
\end{bmatrix}
\end{align*}$$

and

$$M_{sd} = C_1 \theta_2 - C_2 \theta_2$$

where the latter term is the restoring torque exerted on the damper rod by the spring-damper mechanism.

The $a_i$ ($i = 1, 2, 3$) and $b_i$ ($i = 1, 2, 3$) used in (3), which give the relations of the GG torques to the angular positions, are:

$$\begin{align*}
a_1 &= \cos \theta_1 \\
a_2 &= \cos \theta_1 \sin \gamma_1 \\
a_3 &= \cos \theta_1 \sin \gamma_1 \sin \theta_1 \\
b_1 &= a_1 \sin \theta_1 - a_2 \cos \theta_1 \cos \gamma_1 - a_3 \cos \theta_1 \sin \gamma_1 \\
b_2 &= a_2 \sin \theta_1 + a_3 \cos \theta_1 \\
b_3 &= a_1 \cos \theta_1 - a_2 \sin \gamma_1 \cos \theta_1 - a_3 \sin \gamma_1 \sin \theta_1
\end{align*}$$

The equation of motion for the damper rod is

$$\ddot{\gamma}_2 = -\dot{\gamma}_b \sin \gamma_1 + \dot{\gamma}_b \cos \gamma_1 - \dot{\omega}_d \dot{\theta}_d - \frac{M_{yd} + M_{sd}}{I_y}$$

Integration of (1) and (6) furnishes $\dot{\omega}_b$, $\dot{\gamma}_b$, $\dot{\theta}_b$, and $\ddot{\gamma}_2$.

The pitch, roll, and yaw angles, which are the Euler angles between the body-fixed and the attitude reference system, will be used throughout this report. These can be obtained by subtracting $\dot{\omega}_b$, the orbital rate which is the rate at which the attitude reference system rotates in the inertial system, from $\dot{\omega}_b$. 

4
This gives

\[ I \begin{pmatrix} v_b \\ \cos \left( \frac{\theta}{2} \right) \sin \left( \frac{\theta}{2} \right) \\ \sin \left( \frac{\theta}{2} \right) \cos \left( \frac{\theta}{2} \right) \end{pmatrix} \]  \hspace{1cm} (7)

and

\[ v_c = v_b \sin \left( \frac{\theta}{2} \right) \sin \left( \frac{\theta}{2} \right) \]

A digital program was written which allows the calculation of \(\ldots\) and \(\ldots\) according to Equations (1) through (7). This program also pays attention to elastic collision processes of the damper rod against its stops, which limit the rotation of the damper rod in the \(x_1 - z_1\) plane.

3. APPROXIMATION OF GRAVITY GRADIENT SATELLITES BY A DUMBBELL SATELLITE

In this section the equations of motion for a DS will be derived from the equations developed in the previous section for that of the more general gravity gradient satellite (GGS). Thus it will be assumed that no damper rod exists, that \(I_{yy}\) and \(I_{zz}\) are the same order of magnitude, and that

\[ I_{yy} = I_{zz} = I_{xx} \]  \hspace{1cm} (8)

Eq. (1) and (2) now yield:

\[ I_{xx} = \frac{1}{2} \left( I_{yy} - I_{xx} \right) \begin{pmatrix} v_b \\ -T_{cx} - T_{dx} - M_{sb} \end{pmatrix} \hspace{1cm} (a) \]

\[ I_{yy} = \frac{1}{2} \left( I_{zz} - I_{xx} \right) \begin{pmatrix} v_b \\ -T_{cy} - T_{dy} - M_{yb} \end{pmatrix} \hspace{1cm} (b) \]

and

\[ I_{zz} = \frac{1}{2} \left( I_{xx} - I_{yy} \right) \begin{pmatrix} v_b \\ -T_{cx} - T_{dz} - M_{sb} \end{pmatrix} \hspace{1cm} (c) \]

5
Equation (3) becomes:

\[
\begin{align*}
\mathbf{m}_{eh} &= \frac{3}{r^3} (I_{yy} - I_{xx}) \mathbf{a}_2 \mathbf{a}_3, \\
\mathbf{m}_{yh} &= \frac{3}{r^3} (I_{zz} - I_{xx}) \mathbf{a}_1 \mathbf{a}_3, \\
\mathbf{m}_{zh} &= \frac{3}{r^3} (I_{xx} - I_{yy}) \mathbf{a}_1 \mathbf{a}_2 \\
\end{align*}
\]

(10)

and

\[\mathbf{m}_{hd} = \mathbf{m}_{yd} - \mathbf{m}_{zd} = 0.\]

For small angles Equations (9) and (10) can be approximated by:

\[
\begin{align*}
\omega &= \frac{3}{2} \frac{I_{zz} - I_{yy}}{I_{xx}} - \frac{I_{zz} - I_{yy} - I_{xx}}{I_{yy}} \frac{T_{cz} + T_{dz}}{I_{xx}} \quad (a) \\
\omega &= \frac{3}{4} \frac{I_{zz} - I_{xx}}{I_{yy}} - \frac{I_{zz} - I_{xx} - I_{yy}}{I_{yy}} \frac{T_{cy} + T_{dy}}{I_{yy}} \quad (b)
\end{align*}
\]

(11)

and

\[
\omega = \frac{3}{2} \frac{I_{yy} - I_{xx}}{I_{zz}} = \frac{T_{cx} + T_{dx}}{I_{xx}} \quad (c)
\]

where \( \omega = \omega / r^3 \) and \( \omega_{eh} = \omega_{zh} = 0 \) for nearly circular equatorial orbit.

The sign on the right side of Equation (11b) is changed with respect to Equation (9b); this only means that torques about the y axis are considered negative. This approach leads to a more convenient form for the derivation of the following optimal control concepts.

It is now assumed that

\[I_{zz} - I_{yy} - I_{xx}.\]
as is true, e.g. for the ATS-D and ATS-E spacecraft. Thus Eq. (11) become

\[ \ddot{a}_1 = u_1 - d_1 \]

(13)

\[ \ddot{a}_2 = u_2 - d_2 \]

(14)

and

\[ \ddot{a}_3 = u_3 - d_3 \]

(15)

where

\[ a_2 = 2 \frac{I_{zz} - I_{yy}}{I_{xx}} \]

\[ a_3 = 4 \frac{I_{zz} - I_{yy}}{I_{yy}} \]

\[ a_4 = 3 \frac{I_{yy} - I_{xx}}{I_{zz}} \]

\[ u_x \frac{T_{xx}}{I_{xx}} + u_y \frac{T_{yy}}{I_{yy}} + u_z \frac{T_{zz}}{I_{zz}} \]

\[ d_1 \frac{T_{dx}}{I_{xx}} + d_2 \frac{T_{dy}}{I_{yy}} + d_3 \frac{T_{dz}}{I_{zz}} \]

When \( d_1 = d_2 = d_3 = 0 \) and \( u_x, u_y, u_z \) are constant each of the Equations (13) to (15) obviously gives circles for each of the phase plane plots \((\cdot, \cdot), (\cdot, \cdot)\) or \((\cdot, \cdot)\) respectively. Simulations of the GCS under the same conditions result in circles for the phase plane plots (trajectories) for angles up to 10°. This also proves the applicability of the approximations used to obtain these equations.

4. OPTIMAL CONTROL FOR THE DUMBELL SATELLITE

Equations (13), (14), and (15) give a set of decoupled equations for pitch, yaw and roll angles of a D.S. These equations make the derivation of an optimal
control law using Pontryagin's Maximum Principle practically feasible. It is assumed that the reduced control torques $u_1$, $u_2$, and $u_3$ are bounded in magnitude, i.e.

$$
\begin{align*}
-K_1 \leq u_1 \leq K_1 \\
-K_2 \leq u_2 \leq K_2 \\
-K_3 \leq u_3 \leq K_3
\end{align*}
$$

and

$$
K \leq u \leq K
$$

(16)

4.1 Optimal Control Laws for Pitch $(\beta)$ with no Disturbance Torques

Let

$$
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= 0
\end{align*}
$$

(17)

Thus (14) becomes

$$
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= ax_1 - u_3
\end{align*}
$$

(18)

when $\theta_4 = 0$.

The theory of optimal control shows that a vector

$$
\vec{p} = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix}
$$

is used to calculate the dot product

$$
H = \vec{p} \cdot \vec{x}
$$

(19)
where

\[
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2
\end{bmatrix}
\]

Next (19) must be maximized by a proper choice of \(u_a\).

Eq. (19) yields

\[ H = p_1 x_2 - p_2 \left( -a_2 x_1 - u_2 \right). \]

which is maximized by

\[ u_a = K_o \text{ sign } p_2. \]

The theory of optimal control shows further, that

\[ \frac{dp_i}{dt} = H_{x_i}, \text{ } i = 1, 2, \]

which yields

\[
\begin{bmatrix}
\dot{p}_1 \\
\dot{p}_2
\end{bmatrix} = \begin{bmatrix}
a_2 p_2 \\
p_1
\end{bmatrix}. \tag{21}
\]

Solving (21) gives

\[
\begin{bmatrix}
\ddot{p}_1 \\
\ddot{p}_2
\end{bmatrix} = \begin{bmatrix}
-A \sqrt{a} \cos \left( \sqrt{a} t - \phi \right) \\
A \sin \left( \sqrt{a} t - \phi \right)
\end{bmatrix}. \tag{22}
\]

where \(A, \phi > 0\) are integration-constants. Eq. (20) can now be written as:
\[ u_a = K_a \operatorname{sgn}(\sin(\frac{\sqrt{a_a} t}{a_a} - \gamma)). \]  

(23)

The solution of (18) is then:

\[
\begin{aligned}
x_1(t) &= \frac{\pm K_a}{a_a} \left( x_{10} - \frac{\pm K_a}{a_a} \right) \cos \frac{\sqrt{a_a} t}{\sqrt{a_a}} - x_{20} \sin \frac{\sqrt{a_a} t}{\sqrt{a_a}} \\
x_2(t) &= -\left( x_{10} - \frac{\pm K_a}{a_a} \right) \sin \frac{\sqrt{a_a} t}{\sqrt{a_a}} - x_{20} \cos \frac{\sqrt{a_a} t}{\sqrt{a_a}}.
\end{aligned}
\]

(24)

and

\[
x_1(t) = x_{10} - x_{10}(t = 0) \\
x_2(t) = x_{20} - x_{20}(t = 0) - x_1(t = 0).
\]

It can be seen that \( x_1(t) \) and \( x_2(t)/\sqrt{a_a} \) form a circle in the \( x_1(t) - x_2(t)/\sqrt{a_a} \) plane.

The center of this circle lies at

\[ x = \frac{K_a}{a_a} \text{ for } u_a = K_a, \]

and at

\[ x = -\frac{K_a}{a_a} \text{ for } u_a = -K_a. \]

To find the optimum switching law we first consider initial conditions \( x_{10}, x_{20} \), which lie on a circle which passes through the origin. Comparing Eq. (23) and (24), it is clear that optimal trajectories cannot stay longer than for an
angle $\sqrt{\frac{a}{a}} t = \pi$ on a specific circle. Therefore one can obtain the geometric locus of all points with initial conditions $(x_0, x_1 / \sqrt{a_2} = 0)$, which can be transferred immediately into the origin, to be the two semi-circles shown in Fig. 2.

Now assume initial conditions which require at least two switching points according to Eq. (23). Also assume the last trajectory will lie on $S_{-1}$. Eq. (23) and (24) show that the next to the last state with $u = + K_a$ must last for

$$t = \frac{\pi}{\sqrt{a_2}}$$

It can be seen further, that this state is represented by a semicircle with its origin at $K_a / a_2$, with its endpoint on $S_{-1}$ and its starting point at a semicircle with its origin at $3 K_a / a_2$ and a radius of $K_a / a_2$ (see Fig. 3 and Ref. 5 and 6).

When we apply this procedure for all such states leading to $S_{-1}$, we see that the switching circle for switching from $- K_a$ to $+ K_a$ is given by another semicircle with its center at $3 K_a / a_2$ and a radius of $K_a / a_2$. When we continue this procedure for all initial conditions in the $x_1 - x_2 / \sqrt{a_2}$ plane, we see that the switching circles are located as in Fig. 3.

Therefore the centers of the switching circles are located at

$$K_a \left(2n - 1 \right) \frac{a_2}{a}, \ldots, 2, 1, 0, 1, 2, \ldots$$

(25)

where $n$ is the number of the switching circle.
4.2 Optimal Control Laws for Roll (\(\dot{\phi}\)) and Yaw (\(\dot{\psi}\)) with no Disturbance Torques

When Eq. (13), (14), and (15) are compared, no difference in their form is noted as long as \(a_0 \neq 0\), \(a_z \neq 0\), and \(a_z \neq 0\). This is valid for a spacecraft with different principal moments of inertia. Therefore for this case the same optimal control law can be applied to Roll and Yaw as is derived for Pitch in Section 4.1. This is obtained by substituting \((a_z . \varphi)\) by \((a_z . \varphi)\) or \((a_z . \varphi)\) respectively.

However, another control law must be derived, when two or three of the principle moments of inertia are equal. This will be done in the next section for yaw, when \(I_{yy} = I_{zz}\).

The flow chart of a digital program for the control laws developed in this section and section 4.1 is given in Fig. 4. In this program a deadband is defined as

\[
\sqrt{x_1^2 + \left(\frac{x_2}{\sqrt{a_1}}\right)^2}
\]

with \(a_1 = a_0, a_z\) or \(a\), respectively.

Control is switched off completely, when the state of the system is inside this deadband (loop 1). Disturbances or later the application of the exact GGS – program can drive the system out of the deadband again (loop 2).

4.3 Optimal Control Law for Yaw (\(\dot{\psi}\)) for \(I_{yy} = I_{zz}\) with no Disturbance Torques

For a symmetrical spacecraft \(I_{yy} = I_{zz} \gg I_{xx}\) and hence \(a_\psi\) becomes 0. For this case another optimal control law must be derived for yaw (\(\dot{\psi}\)).
Let
\[
\begin{align*}
&x_1 = \cdot 1 \\
&x_2 = \cdot 1
\end{align*}
\]
(26)
and then (12) becomes
\[
\begin{align*}
&x_1 = x_2 \\
&x_2 = u_y
\end{align*}
\]
(27)
Using (19) and (26) the Hamiltonian becomes \( H = p_1 x_2 + p_2 u_y \), which is maximized by
\[
u_y = K_y \ sgn \ p_2.
\]
Applying
\[
\frac{dp_i}{dt} = - \frac{\partial H}{\partial x_i} \ (i = 1, 2)
\]
again gives
\[
\begin{align*}
&p_1 = 0 \\
&p_2 = - p_1
\end{align*}
\]
(28)
which results in
\[
\begin{align*}
&p_1 = B \\
&p_2 = - Bt + C
\end{align*}
\]
(29)
From Eq. (27) and (29) one obtains
\[
\begin{align*}
&x_1 = K_y \frac{t^2}{2} \ sgn \ (C - Bt) + Dt + E \\
&x_2 = K_y t \ sgn \ (C - Bt) - D
\end{align*}
\]
(30)
Thus all trajectories are parabolas. From (29) it is evident, that $p_2$ can change sign at most once. Therefore the complete optimal trajectory from a given initial condition in the $x_1 - x_2$ plane consists of one or two segments of a parabola, where the second parabola leads to the origin. It is evident, that the parabolas leading to the origin are also the switching lines (see Fig. 5 and Ref. 5 and 6).

For initial conditions with $x_{20} = 0$ the time consumed for reaching the origin can be calculated to be

$$2\sqrt{x_{20}}$$

Figure 6 shows the flow chart for a digital program of this control law.

4.4 Consideration of Different Reference Values

The optimal control laws in the above sections lead $\alpha$, $\beta$, and $\psi$ to the origin. We will now consider the case for reference values (set values) $x_0$, $y_0$, $z_0 \neq 0$. Considering Eq. (13) through (15) with $a_x$, $a_y$, $a_z \neq 0$ one sees that the following new equations can be written, which contain an additional control term of thrust to balance the gravity gradient torque at the set value:

$$\ddot{\psi} + a_\psi \psi = \pm K_\psi + a_\psi \psi_s$$
$$\ddot{\phi} + a_\phi \phi = \pm K_\phi + a_\phi \phi_s$$

(31)

and

$$\ddot{\alpha} + a_\alpha \alpha = \pm K_\alpha + a_\alpha \alpha_s$$

But Eq. (31) also can be written as

$$\ddot{\psi}_1 + a_\psi \psi_1 = \pm K_\psi$$
$$\ddot{\phi}_1 + a_\phi \phi_1 = \pm K_\phi$$
and

\[ z_1 - a_\alpha = z_s + K_s, \]

where

\[ z_1 = \bar{z} - z_s, \]

\[ z_1 = z - z_s, \]

and

\[ z_1 = z - z_s. \]

Therefore Eq. (17) - (24) can be applied as before, now leading \( \psi, \dot{x}, \) and \( a_\alpha \) to 0 and therefore \( \psi, \dot{x} \) and \( a_\alpha \) to the desired setpoints. In Fig. 3 the switching lines will shift and also the optimal trajectories. This results in Fig. 7.

A similar approach is valid for yaw (\( \omega \)) when \( a_\omega = 0 \). The switching lines of Fig. 5 must simply be shifted so that they lead to \( \omega_s \).

4.5 Consideration of Disturbances

The spacecraft usually is subjected to various disturbances, which are different in magnitude and time history. However, there are two typical kinds of disturbances, which should be considered: a constant bias torque and a disturbance torque with a 24 hour period. A constant disturbance torque can be caused e.g., by attitude thruster misalignments: station keeping thrusters can introduce disturbance torques where the thrust vector is not aligned through the center of mass. A disturbance torque with a 24 hr. period is caused, e.g., by solar pressure acting on the synchronous spacecraft.

First a constant disturbance torque will be considered. Eq. (15) now is

\[ \ddot{z} + a_\alpha \alpha = u_\alpha + d_\alpha. \]
where \( d_a \) is the constant disturbance torque divided by \( I_{zz} \). There are two approaches to solve this problem theoretically. First \( d_a \) could be measured by observing the shift of the trajectories and then counteracted by a control torque of the same magnitude. The total reduced control torque would be now:

\[
T_u = \frac{T_{zz}}{I_{zz}} = K_a - d_a.
\]  

(33)

This would lead to the same switching lines for optimal control as in Fig. 2, 3 and 7. However the practical hardware constraints show that control torques according to Eq. (33) are much more difficult to implement than control torques of the form

\[
T_u = -K_a.
\]

Therefore a modification of the switching lines of Fig. 2, 3 and 7 is found as follows:

From (32) one proceeds as was done for (17) - (22):

\[
x_1 = x_2,
\]

\[
x_2 = a_x x_1 + u_a + d_a
\]

and

\[
H = p_1 x_2 - p_2 ( -a_x x_1 + u_a + d_a )
\]

which again results in condition (23).
Substituting $\pm k_1$ by $\pm k_1 + d_1$ in Equation (24) shows that all trajectories are shifted by $d_1/a_1$ in the direction of the $x_1$-axis and that the radii change. Similar considerations which led to Figure 2 and 3 give Fig. 9 for the optimal switching lines.

Similar considerations hold for optimal control of . when $a = 0$. We only have to substitute $\pm k_1$ by $\pm k_1 + d_1$ in Eq. (30). The equations for the switching lines read now:

\begin{align*}
&x_1 = \sqrt{2\left( \frac{K_1 - d_1}{a_1} \right) x_1} \quad \text{for } x_1 < 0, \\
&x_2 = \sqrt{2\left( \frac{K_1 + d_1}{a_1} \right) x_1} \quad \text{for } x_1 > 0
\end{align*}

(34)

It is obvious that the above calculations are only valid for $K_1 + d_1$ for $i = 1, 2, 3$.

For slowly changing disturbances optimal control could be implemented by changing the switching lines according to Fig. 9 and according to the momentary value of $d_i$. The interactions of changing disturbances and changing of switching lines bring up serious problems of identification of disturbances and problems of stability, which are presently under investigation. Two approaches to optimal control while the disturbance torque is varying are shown in Fig. 9. It is assumed that the optimal trajectory starts without disturbance at $x_{10}, x_{20}/y_0$ and reaches $S_1$ and $P_1$, and follows $S_2$ (after switching control from $-K$ to $+K$) until a disturbance $d$ occurs at the instant the state is at $P_2$. The trajectory now changes from that of $S_2$ to $S_{4*}$, where $S_{4*}$ depends upon the disturbance. The $S_{4*}$ trajectories are circles with their origin shifted by $d/a$ in direction of $x$. Two procedures now exist:

* $S_1$ replaces $S_3$, $S_2$ replaces $S_{-1}$ in section § 1.
a. Retention of +K at P, thereby following trajectory R, to P and there
switching to -K. When S is reached at P, control is switched back to +K and
S, followed to the origin, or

b. After occurrence of the disturbance d at P, control is switched immediately
to -K, until S is reached at P'. S then is followed to the origin by changing
the control back to +K.

However, for the further investigations of the optimal control law in this
paper it is assumed, that \( T_d > -K \) for all three axes. Thus, it is not necessary
to apply the refined control law given in Fig. 8 and 9. The approach to the origin
in presence of small disturbances can be seen from Fig. 10.

It can be seen from Fig. 10, that the positive \( x_1 \) axis may serve as an ad-
ditional switching line when the trajectory intersects from the negative \( x_2 \) direc-
tion. The negative \( x_1 \) axis forms the additional switching line in the case when
the trajectory intersects coming from positive \( x_2 \) values. A more sophisticated
control law in the presence of disturbances is suggested for future work in this
area as follows: switching from +K to -K or vice versa shall be implemented,
when the distance from the set point (here \( \text{the origin} \) starts to increase. This
should at least give stable performance under all working conditions.

5. APPLICATION OF THE DS-OPTIMAL-CONTROL TO THE GRAVITY
GRADIENT SATELLITE

This section will discuss the results of applying the DS control to the GGS
computer simulation. Two GGS – configurations are used. The first, which will
be called GGS 1, is characterized by \( I_{yy} = I_{zz} > I_{xx} \) and no damping mechanism,
the second (GGS 2) is characterized by the moments of inertia of the ATS-D satellite.
5.1 Data of the GGS

a. For the symmetric case (GGS 1)

\[
\begin{bmatrix}
1000 & 0 & 0 \\
0 & 48000 & 0 \\
0 & 0 & 48000
\end{bmatrix}
\] (in slug ft^2).

\[I_1 = 0\text{ and } C_1 = C_2 = 0.\]

b. For the unsymmetric case (GGS 2)

\[
\begin{bmatrix}
3180 & 0 & 0 \\
0 & 13500 & 261 \\
0 & 261 & 16700
\end{bmatrix}
\] (in slug ft^2).

\[I_1 = 540 \text{ slug ft}^2.\]

\[\theta = 53.4^\circ.\]

\[C_1 = 1.322 \text{ slug ft}^2/\text{sec}\]

and

\[C_2 = 4.7 \times 10^{-2} \text{ slug ft}^2/\text{sec}^2.\]

5.2 Choice of Control Torques

In order to choose the proper magnitude of control torque it should be noted, that a necessary condition for controllability of a gravity gradient satellite is, that in the whole pointing region for each axis

\[T_c \geq T_{ss} - T_d \quad (35)\]
where $T_c$ is the control torque exerted by the ion thruster, $T_{sg}$ is the restoring torque due to the gravity gradient effect for a particular set of value and $T_d$ is the disturbance torque. To point in a particular direction, a certain $T_{sg}$ has to be counteracted; this torque can be calculated by Eq. (10). Since $T_{sg}$ changes only when the set values of $\ldots, k, \ldots$ are changed and therefore much less often than $T_c$, counteraction of $T_{sg}$ by a control torque of the same magnitude can be assumed. Pointing is desired to every point on the earth disc as seen from a synchronous spacecraft. Therefore $-8.5^\circ \leq \gamma \leq 8.5^\circ$ is valid, and a maximum gravity gradient torque in this region for the pitch ($\gamma$) axis of the asymmetric spacecraft is given by

$$T_{sg,max} = 2.5 \times 10^{-5} \text{ ft lb}.$$ 

A disturbance torque is assumed to be caused by solar pressure with a peak value of $10^{-5} \text{ ft lb}$. Eq. (35) now yields

$$T_{ca} = 35 \times 10^{-6} \text{ ft lb}.$$ 

To give the same $T_c/I$ ratios on the other axes of the asymmetric spacecraft and on all axes of the symmetric spacecraft, the following torques are chosen for the asymmetric spacecraft:

$$T_{ca} = 28.5 \times 10^{-6} \text{ ft lb}$$

and

$$T_{cg} = 6.6 \times 10^{-6} \text{ ft lb}.$$ 

and for the symmetric spacecraft:

$$T_{ca} = 10^{-4} \text{ ft lb}$$

$$T_{cg} = 10^{-4} \text{ ft lb}$$
and

\[ T = 2.09 \times 10^{-4} \text{ ft lb} \]

5.3 Comparison of Time Consumed for Damping Librations to \\
= \theta = 0^\circ \text{ for GG Satellites and DS}

The optimal switching lines given in Fig. 3, 5 and 7 are applied to all three axes simultaneously. To compare the results obtained for a GGS with the ideal case of a DS, the time consumed for reaching an angle of 0° after a certain initial condition is plotted in Fig. 11 and 12. For Fig. 11 the time consumed for a DS is calculated by applying the optimal control law derived in Section 4 to the equation

\[ \dot{x} + ax = u \text{ where } a = a_z \text{ and } u = \pm K_z. \]

Two different \( a_z \), called \( a_{z1} \) and \( a_{z2} \) are used for GGS 1 and GGS 2, respectively. Therefore two different DS must be used for comparison. DS 1 uses \( a_{z1} \), whereas DS 2 uses \( a_{z2} \). The lower time consumed by a GGS for higher initial conditions can be explained as follows: the coupling of all three axes transfers some of the energy of the pitch axis to roll and yaw axes where optimal control is also being applied. Therefore energy is taken out of the whole system faster than for the uncoupled case of a DS. The region of \( \theta^\circ \) between 15° and 60° for GGS 2 shows on the other hand, that this effect is outweighed by the less exact approximation of an asymmetric GGS by a DS. Therefore a slightly higher time is consumed for this region than is predicted.

Figure 12 shows the equivalent comparisons for initial conditions \( \neq 0 \) only on roll \((\theta_0)\). Approximately the same \( a_z \) is used for both GGS 1 and GGS 2. Therefore approximately the same equivalent DS is valid for comparison of both GGS. Similar explanations for the shape of the plot hold as for pitch.
Since the yaw angle is not significant for pointing to certain points on the surface of the earth, plotting of the graphs for $y = v$ equivalent to Fig. 11 and 12 are not given here. It is just mentioned, however, that for GGS 1 consistency with predicted values is achieved, whereas for GGS 2 some deviations of predicted values are observed. An exact explanation of this problem would involve a discussion of the exact equations (1) to (7) and goes beyond the scope of this paper.

5.4 Investigations of the Influence on the Settling Time of Initial Conditions not Equal to Zero on all Three Axes

To show the influence on of other initial conditions than in Section 5.3 $z_0 = \dot{z}_0 = \ddot{z}_0 \neq 0$ and $\dot{z}_0 - \dot{z}_0 = \ddot{z}_0 = 0$ are chosen. Fig. 13 shows for pitch for GGS 1 and GGS 2 in comparison to the DS. Fig. 15 presents the graphs for roll. For yaw the same remarks are valid as in Section 5.3.

5.5 Pointing to Directions Other Than $\theta = \gamma = 0^\circ$

In the previous investigations, it always was assumed the pointing should lead to $\gamma = \gamma = 0^\circ$. Now pointing to $\gamma$, $\gamma$, with $-8.5^\circ \leq \gamma, \gamma \leq 8.5^\circ$ is considered. The simulations show that application of the control law derived in Section 4.4 for reference values $\neq 0$ gives no difference in when pointed to set values $\gamma, \gamma$. $\gamma$, other than $\gamma = \gamma = 0^\circ$. This assumes that $\dot{\gamma}_0 - \dot{\gamma}_0$ or $\ddot{\gamma}_0 - \ddot{\gamma}_0$ now has the same value as $\dot{\gamma}_0$ or $\ddot{\gamma}_0$ respectively in Sections 5.3 and 5.4. This assumes further that the same control torque $T_c$ is still available and the torque necessary to counteract the gravity gradient torque $T_{gg}$ at the set value is supplied in addition to $T_c$. $\gamma$ is increased if counteracting of $T_{gg}$ is provided by control thrust while decreasing the thrust $T_c$ available for actual control purposes. Fig. 15 gives for the DS as a function of $K = T_c / \gamma$. The parameter $\Theta$ is the difference between initial condition and the set value.
5.6 Influence of Disturbances on the Time Consumed (\( \cdot \)) for Damping of Librations

Investigations concerning control under the influence of a sinusoidal disturbance torque with a 24 hour period were carried out. The peak value of \( T_o \) is assumed to be \( 10^{-3} \) ft lb. \( \cdot \) is plotted in Fig. 16 for pitch \((\phi_0 \neq 0, \phi_0 = \phi_0 = 0)\) and in Fig. 17 for roll \((\phi_0 \neq 0, \phi_0 = \phi_0 = 0)\) with \( \psi_0 = \psi_0 \psi_0 = 0 \) in both cases.

Two phases for the disturbance torque are chosen, the first is \( 0^\circ \) and the second is \( 180^\circ \) relative to the starting point of control application.

It can be seen that under favorable phases of the disturbance torque the effect on control action nets in no increase of \( \cdot \). One can also consider cases, where \( \cdot \) could be decreased; whereas it can be seen from Fig. 16 and 17, that under unfavorable circumstances \( \cdot \) is increased by 50%.

6. CLOSING REMARKS

It has been shown, that the time-optimal control law for a dumbbell satellite can be applied to a gravity gradient satellite as suboptimal control.

The next major consideration must be development of a control policy for the extended term precision pointing mode. Of special interest is the formulation of an adaptive disturbance torque computer for operation in a scallop mode limit cycle. It is also intended to expand the performance index for the acquisition mode to include both time and fuel weighting factors. Methods of state determination will also be assessed during follow-on application studies.
