CONTENTS

ABSTRACT

A FORTRAN IV Program for CDC 6400 is presented together with sample output illustrating the use of sequential linear discriminant analysis.

INTRODUCTION

In the standard text by Krumbein and Graybill (1965, p. 359 et seq.) the mathematical basis of linear discriminant functions is described. Numerous programs are available for this type of analysis. However, it has been found useful in many situations to examine the effectiveness of all, or many, combinations of measured variables for the samples to be segregated. Thus, in addition to discrimination on the basis of each individual measured variable used on its own, discrimination on the basis of each subset of two, three, four, or more, measured variables can also be calculated. Not infrequently, two variables that are poor discriminators when used individaully prove to be excellent discriminators when used together. Such results emphasize the value of scanning the output from a sequential regression program before the operator decides which subset of variables best serve his particular purposes.

This program has been used extensively in remote-sensing and petrological analyses at Northwestern University (e.g., Beckman and Whitten, 1966). However, in this report, the data set involving the physicochemical conditions and sedimentary textures in a lagoonal environment used by Krumbein and Graybill (1965, p. 363) is utilized; this has been done so that the reader can compare the results obtained with the present program with the worked example given by Krumbein and Graybill.

THE PROGRAM

Instructions for setting up the program are contained in the comment cards at the beginning of the FORTRAN listing. The data deck used for the

sample output is listed at the end of the FORTRAN listing. As written, every possible subset can be processed; alternatively, selected subsets can be called (as in the case illustrated). Selected sample output from the data deck illustrated is appended after the FORTRAN listing.
