

NASA TECH BRIEF

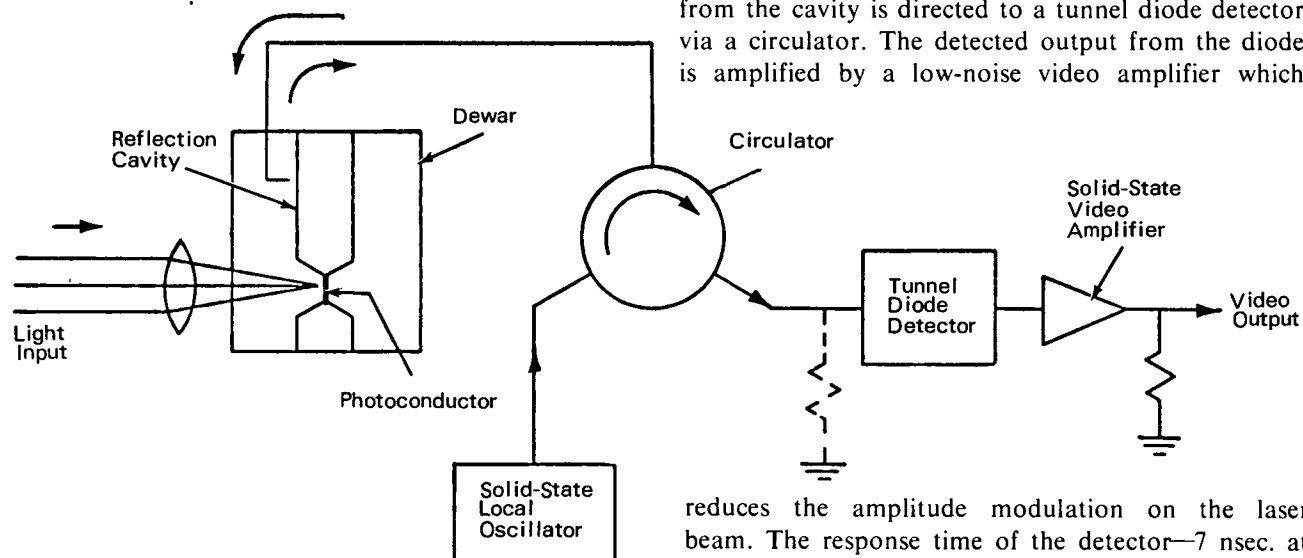

Goddard Space Flight Center

NASA Tech Briefs announce new technology derived from the U.S. space program. They are issued to encourage commercial application. Tech Briefs are available on a subscription basis from the National Technical Information Service, Springfield, Virginia 22151. Requests for individual copies or questions relating to the Tech Brief program may be directed to the Technology Utilization Office, NASA, Code KT, Washington, D.C. 20546.

Microwave Biasing Improves Detector Response in the Infrared Region

A detection system, which incorporates the advantages of microwave biasing, measures the output of a CO₂ laser at 10.6 microns with a

factor of 10^3 improvement in sensitivity. Recent theoretical and experimental studies on biasing photoconductive detectors by microwave energy demonstrated the advantages of this technique over conventional dc methods.

The biasing technique consists of mounting the photoconductive sample, mercury-doped germanium, in a microwave cavity and detecting the microwave power absorption that occurs when the conductivity of the sample is increased by the laser beam. In the experimental arrangement shown in the figure, the microwave power from an X-band Gunn-effect oscillator is directed to a coaxial re-entrant cavity

containing the detector. The cavity is mounted in a liquid-helium dewar which has a window transparent to laser radiation. The power reflected from the cavity is directed to a tunnel diode detector via a circulator. The detected output from the diode is amplified by a low-noise video amplifier which

reduces the amplitude modulation on the laser beam. The response time of the detector—7 nsec. at 10.6 microns—is limited by the lifetime of the material rather than by the external circuitry. A direct comparison of the experimental data indicates that, with an extrinsic photoconductor, the sensitivity is improved by a factor of 10^3 for wideband envelope detection.
