## INTRODUCTION

This final report consists of a section summarizing the past four years work and a section covering the new work, quantitative analysis of olivine in meteorites and other rocks.

The summary part consists of two earlier publications, "Disordered Pyroxene in Chondrites", and "Enstatite Produced by a Megabar Shock Event", an earlier semi-annual report showing the relationship between x-ray single-crystal photographs and shock in chondrites, two tables summarizing the occurrence of disordered pyroxene in mesosiderites, eucrites and howadites. The new work contains the % olivine and Mole % forsterite in 64 meteorites.

### Quantitative Analysis of Olivine

In Table I the chondrites are grouped according to the Von Schmus and Wood petrologic classification. There is some overlap, but in general, the L group chondrites have less olivine than the LL group and more than the H group. Knyahinya with an L group olivine composition has a much higher olivine content. Guarena and Selma also have higher olivine content than the other members of the H group. Most of the H group contains between 24 and 37% olivine. In the L group, most fall between 40 and 52% and in the LL group, between 45 and 61% olivine. The estimated probable error in the x-ray measurements is 5% of the olivine determination. The table below shows the average olivine content of the LL, L and H petrologic types. The olivine percentages in L4, L5 and L6 are almost

## Average % Olivine

|    | 3  | 4  | 5  | 6  |
|----|----|----|----|----|
| LL |    |    |    | 51 |
| L  |    | 46 | 46 | 45 |
| H  | 32 | 30 | 31 | 31 |

identical, and those in H3, H4, H5 and H6 are very similar. The uniform olivine composition within these groups suggests that the mineralogy within the L and H groups has always been the same.

Total quantitative mineralogical analysis of the chondrites should show more definitely whether or not they have changed since crystallization. The differences in mineralogy within the H and L groups probably are due to variations in temperature pressure or composition at the time of chondrite or chondrite formation.

Table II lists the olivine content of some terrestrial and oceanic rocks.
