ABSTRACT

This report describes two computer programs developed for the investigation of legged planetary landers. Analytical methods incorporated in the programs, operating instructions, and examples of program utilization are described. One program developed is the Structural Analysis Program, containing a Center Body Option, which can be used to analyze a structure by utilizing a finite element idealization. It also contains a Landing Gear Option for determination of the energy absorption and load-stroke characteristics of either a cantilever or inverted tripod landing gear configuration. The second program is the Landing Loads and Motions Program, used to predict spatial landing dynamics of a legged lander containing up to five landing gears. This program also contains options for including the effects of a flexible center body and determining lander stability.

Several exemplary computer runs are discussed to aid in interpretation of the operating instructions and to illustrate various available program options. Analytical results for several of these cases are compared to test data obtained during model test programs conducted at NASA Langley Research Center.

1. INTRODUCTION

This report describes two computer programs developed by McDonnell Douglas Astronautics Company - East under NASA Contract NAS-1-8137(U) for investigation of legged type planetary landers. They are the Structural Analysis Program and the Landing Loads and Motions Program. The Structural Analysis Program contains options for the determination of internal center body load distributions, center body modal information, and the large displacement behavior of either an inverted tripod or a cantilever gear configuration. The Landing Loads and Motions Program can be employed for the determination of the spatial landing motions of a lander idealized either as a rigid body or as a flexible body. In addition, options are available for the determination of overall landing loads and lander stability boundaries.

Results of analyses conducted on typical legged lander configurations are presented and compared with test results obtained at NASA Langley Research Center. Test results were obtained using the Task Order Three Lander(Reference (1)) shown in Figure 1-1. These analyses demonstrate the capabilities of the developed computer programs.

The programs developed during Task Order Five provide the capability of conducting a complete design study on a legged lander beginning at the preliminary design phase and continuing through a final evaluation of the lander's structural configuration. A flow diagram of this capability is presented in Figure 1-2. Program options permit detailed analyses to be conducted at any point during the evolution of a legged lander. For example, analytical investigations for boiler plate models, scale models, or final lander configurations can be conducted.

During the preliminary design phase, various landing gear configurations are evaluated with the Landing Gear Option of the Structural Analysis Program. At the same time the landing loads and stability of a lander idealized with a rigid center body are investigated with the Landing Loads and Motions Program. Results of these analyses are used to select a final landing gear configuration. In addition, the predicted rigid body landing loads are used in conjunction with the Center Body Option of the Structural Analysis Program to determine internal load distributions in the center body structure. Based on

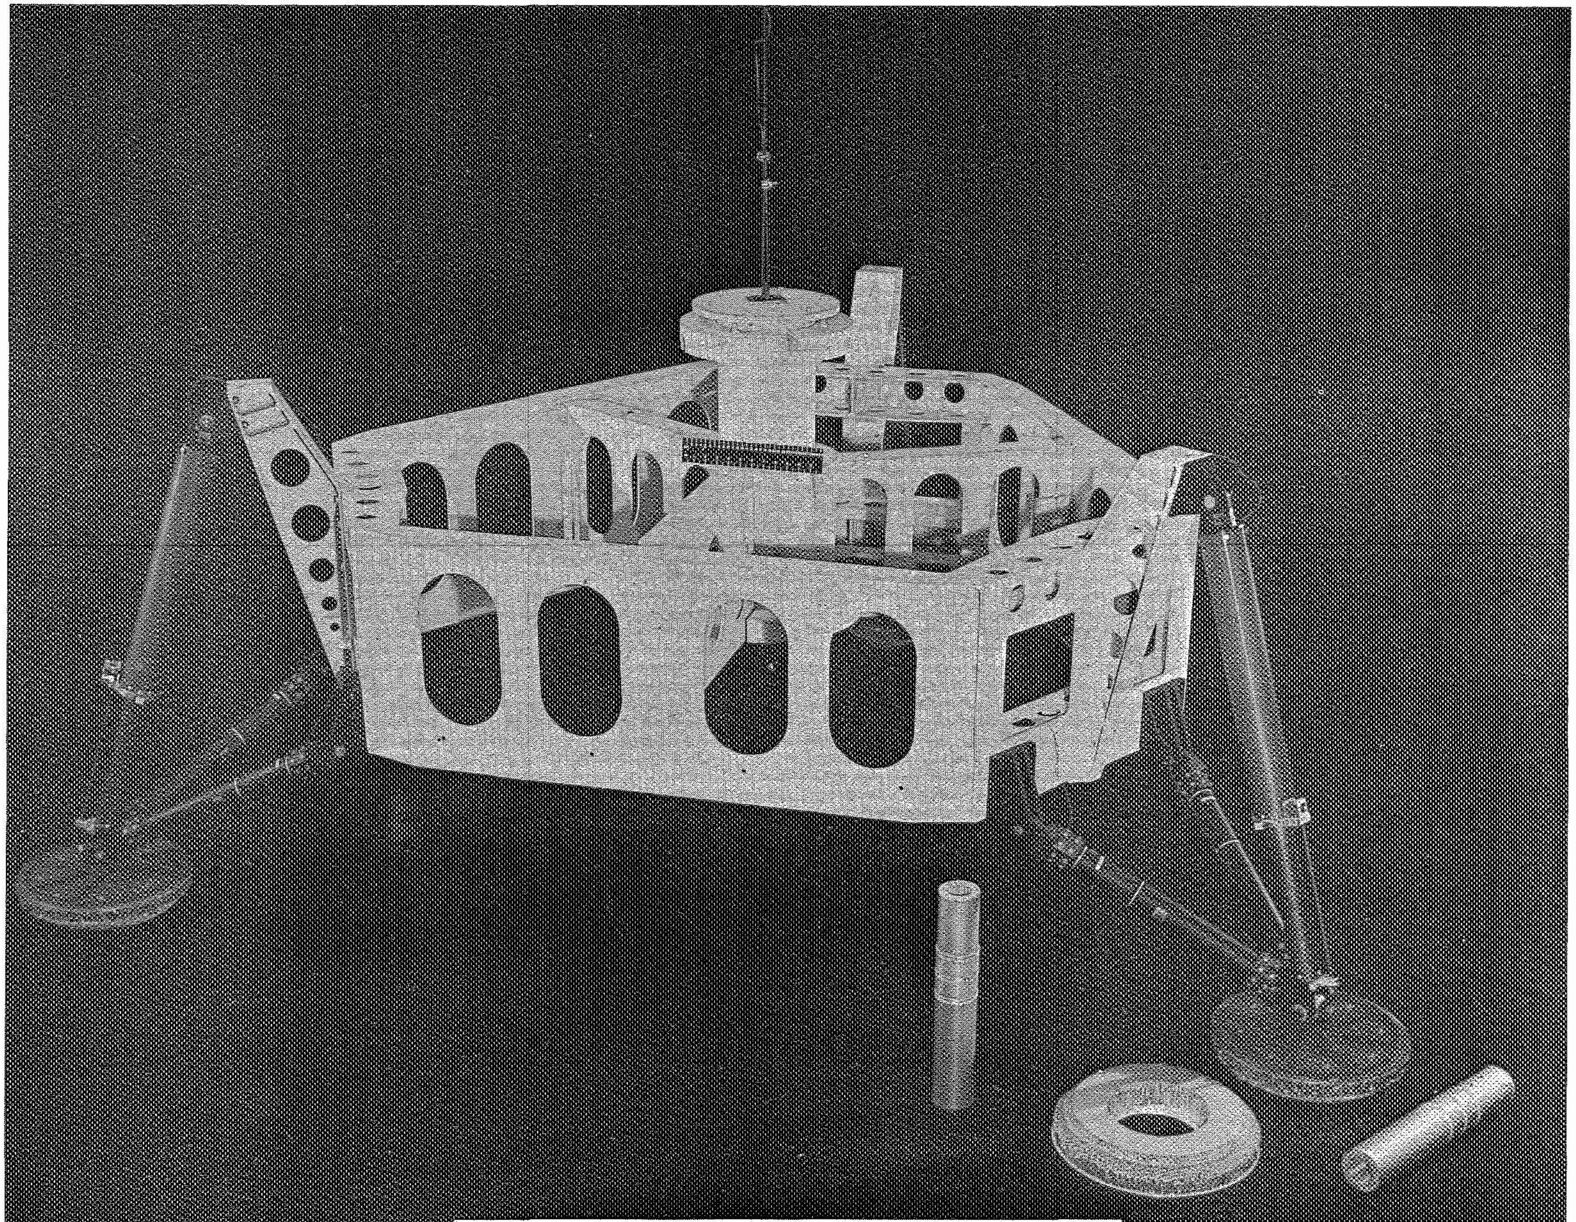

FIGURE 1–1 TASK ORDER THREE LANDER

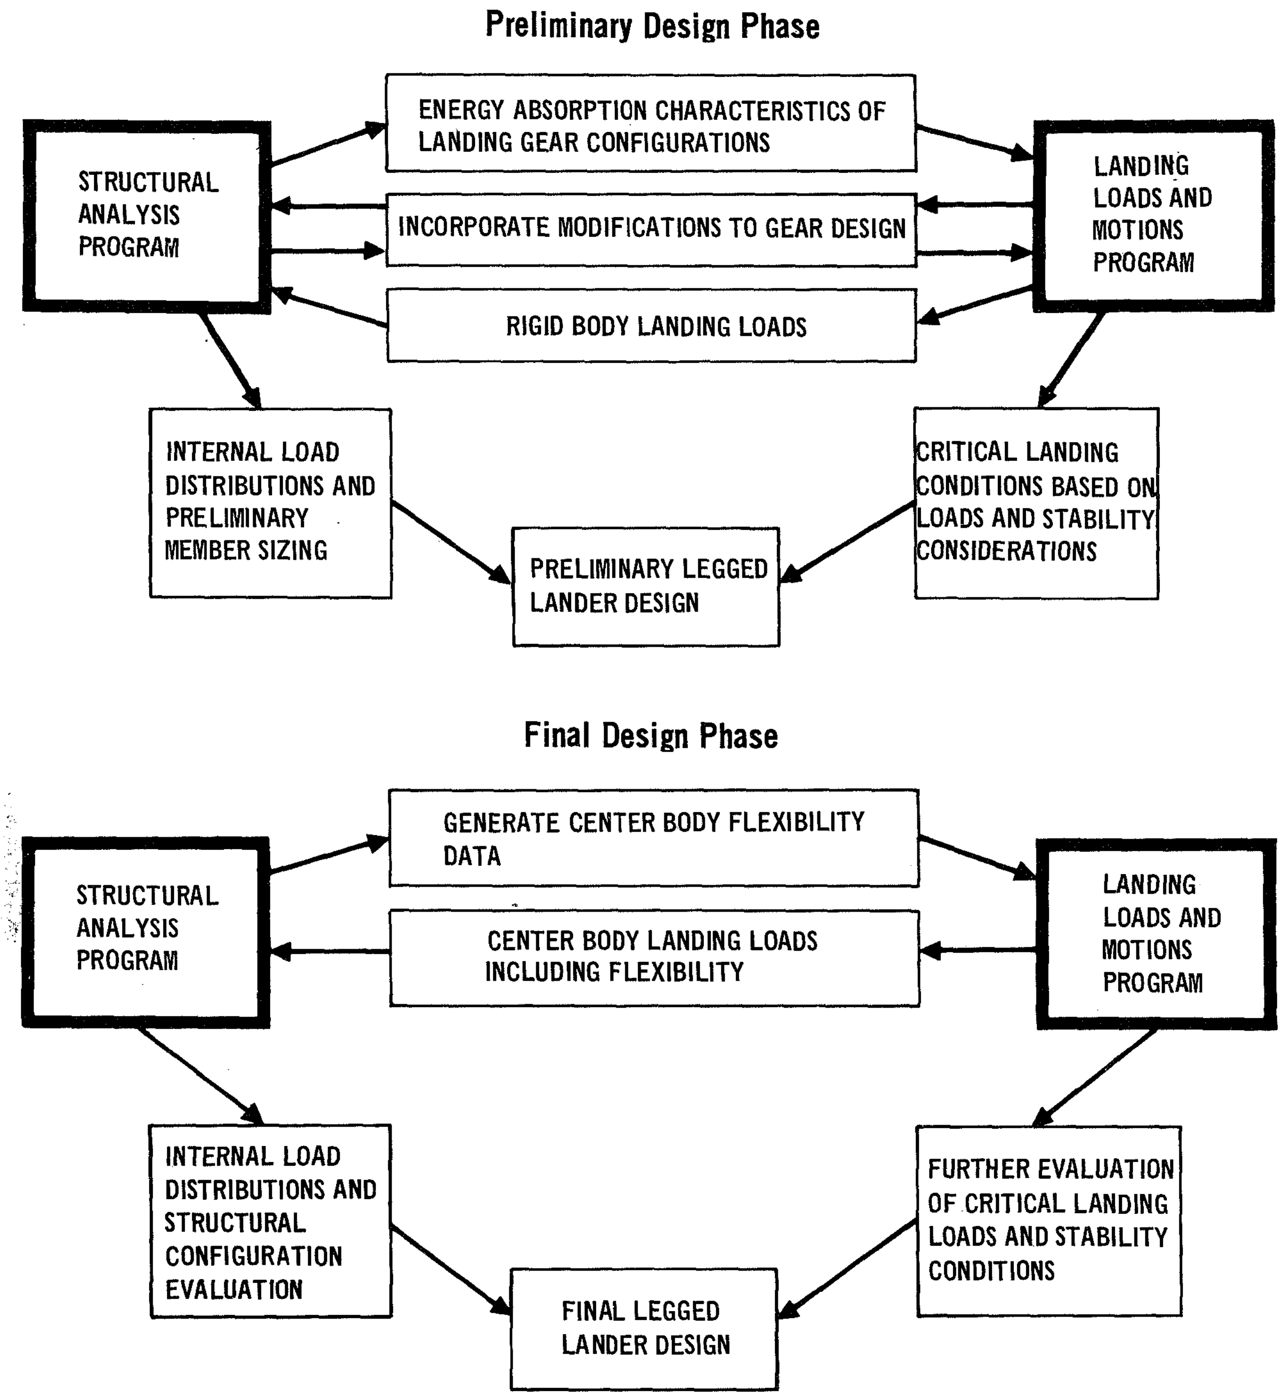

Preliminary Design Phase

Final Design Phase

FIGURE 1–2 TASK ORDER FIVE PROGRAM USAGE DIAGRAM the results of this preliminary design phase, the lander's structural arrangement is selected. At this time, the programs are used to determine center body flexibility information, landing loads, and stability conditions for the flexible lander, and internal load distributions for the final center body structural configuration.

2. COMPUTER PROGRAM CAPABILITIES

The two computer programs developed during Task Order Five contain many options which permit analyses of a wide variety of legged lander configurations. Legged lander configurations considered and the associated program capabilities and options are discussed in the following sections.

2.1 Legged Lander Description - The general arrangement of a typical legged lander configuration is shown in Figure 2-1. The legged lander is composed of three basic components: (1) center body, (2) payload and auxiliary equipment, and (3) landing gear. Items included in each component are shown in Figure 2-2.

The two landing gear configurations reflected in the analysis are shown in Figure 2-3. They are the inverted tripod gear and the cantilever gear. The main strut of both gears incorporates an energy absorption system. Drag struts may also include an energy absorption system or for the inverted tripod gear, they may simply be frame members stabilizing the main strut.

2.2 Structural Analysis Program - Two major options are available in the Structural Analysis Program. The first of these is the Center Body Option for the small displacement, finite element analysis of a legged lander center body structure. In formulating the Center Body Option, the Structural Analysis Program written for Task Order Two, Reference (2), was employed as a nucleus. During Task Order Five, many improvements and additions were made to this baseline program. In addition, a Landing Gear Option was developed for determining the large displacement stroking behavior of an individual landing gear. This is a major addition to the capabilities of the Task Order Two version of the Structural Analysis Program.

2.2.1 Center Body Option - The Center Body Option of the Structural Analysis Program is formulated for solution of redundant structures based on the small displacement finite element stiffness method and utilizing iterative methods of solution. The program can determine internal and external load distributions and deflection patterns for any system of forces or deflections impressed on a network of structural bar members and shear webs. behavior of support structure can be simulated with the program. The program also allows simulation of cables, or any support members with restricted load carrying capability in certain directions. Mode shapes and natural frequencies may be obtained using this program. For modal analysis, a routine is incorporated to allow reduction in the size of the stiffness matrix for large structures, thus permitting a reduction in the required computer storage requirements and run time.

New capabilities available in this option of the Structural Analysis Program over the Task Order Two version follow. An optional iterative technique, the Conjugate Gradient Method, was added to increase program efficiency for solution of nodal deflections. A more efficient data input routine was programmed reducing core size required by this routine. The maximum number of bars which can be used to idealize a structure was increased from 74 to 130. A rectangular shear web element was added to expand idealization capability. An additional 2500 words of storage was provided for storing nonzero terms of the stiffness matrix. An improved matrix reduction routine was developed to increase efficiency when employing the modal analysis routine. The maximum number of lowest natural frequencies and associated mode shapes (excluding rigid body modes) that can be requested from the modal analysis routine was increased from 5 to 95. In addition, the capability for handling multiple data cases was added. These capabilities result in a program whose core storage requirements at execution utilize the maximum allowable storage (70K) specified for computer programs by NASA Langley Research Center.

The iterative method programmed for solution of nodal deflections was selected to minimize computer core storage allocated to the solution routine. It also permits minimization of computer time for a preliminary design problem, since accuracy requirements can be specified.

Both straight bar members and rectangular shear webs are available for idealization of the center body structure. As explained in Section 4.1.1.2, the program internally replaces a shear web by two diagonal bar elements. Hence the bar element is the basic element of the Center Body Option.

Each bar element is capable of carrying axial load, shear in two directions, bending in two directions, and torsion. Bar properties are assumed to be constant between nodes (symmetry about one of the principal axes is assumed). The bar's longitudinal axis is assumed to pass through the centroidal axis and the bending neutral axes are assumed to align with centroidal axes. Torsional shear center of the bar is assumed to be on the bar's longitudinal axis.

Cables, which have one end attached to a support and the other to a structural joint, may be idealized by restricting the compression load carrying capability to zero, thus exercising the plastic analysis program logic.

Plastic behavior of support structure, such as crushable attenuators, may be simulated by inputting the force causing plastic deformation of each support member. An upper and lower limit must be input on the particular force or moment being constrained.

The program is based on small deflection theory with Hooke's Law applying, except with regard to the plastic support option of the program. Buckling of members is not considered, and coupling effects, such as occur with beam-columns, are neglected. Bars are assumed to be rigidly connected to each other, unless otherwise specified. Bars pinned at both ends may be simulated by setting the appropriate moments of inertia equal to zero. Bars pinned at one end and fixed at the other may be idealized through the use of special input indicators. Loads are applied to the joints as concentrated forces in global coordinates.

Computer core storage restrictions necessitated a number of limitations on the problem size which may be considered with the Center Body Option. As described in the operating instructions, this storage can be increased to accommodate larger problems. Within the current limitations, the allowable problem size is governed by the following considerations: up to 74 joints with six degrees of freedom at each joint, or a maximum assembled stiffness matrix 444 by 444; 130 bars maximum; 30 shear webs maximum, each of which reduces the allowable number of bars by two; 26 reference points maximum; 300 support constraints maximum; 88 plastic force constraints maximum (88 upper and 88 lower limits); and 88 nonzero input deflections maximum. Mode shapes and natural frequencies can be determined for a maximum assembled stiffness matrix size of 102 by 102 which corresponds to 17 joints with six degrees of freedom or many joints with fewer degrees of freedom. A reduction routine permits modal analysis of large, complex structures because the associated large stiffness matrix (444 x 444 maximum) may be reduced to the allowable size (102 by 102) by selectively eliminating degrees of freedom. The program utilizes the mode shapes of the reduced system to generate mode shapes for all degrees of freedom of the original large stiffness matrix. The number of lowest natural frequencies and associated mode shapes requested from the modal analysis routine for any structure with free-free support must be a multiple of five and less than the order of the reduced stiffness matrix minus six.

2.2.2 Landing Gear Option - The Landing Gear Option of the Structural Analysis Program provides the capability for investigating the large displacement stroking behavior, energy absorption characteristics, and internal load distribution in an inverted tripod or cantilever landing gear. These characteristics are obtained by solving the displacement equations of equilibrium at specified steps of applied footpad joint parameters. These parameters can be specified in either of two ways: (1) a displacement normal to an arbitrarily oriented landing surface and the friction coefficient of the surface can be specified or (2) all three orthogonal displacement components in the Surface Coordinate System can be specified. The number of steps to be used for investigating the displaced state must be specified. The landing surface can be arbitrarily oriented with respect to the lander by specifying three Euler angles which orient the Surface Coordinate System relative to the Lander Coordinate System. A least squares solution technique is employed to solve the equations of equilibrium for the displacements at each step. The gear geometry and strut properties are arbitrary input quantities.

The program determines the external forces and displacements at the node points of the gear in the Surface Coordinate System, the internal loads in all struts, and the total energy components absorbed by the gear in both the Surface and Lander Coordinate Systems. The energy associated with crushing of footpad attenuation material can also be included for a footpad with up to three honeycomb crush levels.

The inverted tripod landing gear is idealized in the program with four nodes and three pin-ended elements representing the main strut and two drag struts. These elements have only axial load-carrying capability and may contain attenuation material with up to five crush levels in both tension and compression.

The cantilever landing gear is idealized in the program with five nodes and four elements. The main strut is idealized with two elements both of which have bending and axial load-carrying capability. These members are assumed to be rigidly connected at the center junction of the main strut. The junctions of the main strut with the center body and the footpad are assumed to be pinned. The drag struts are pin-ended with axial load-carrying capability only. The drag struts and the lower element of the main strut contain attenuation material with up to five crush levels in both tension and compression.

For both the inverted tripod and cantilever gear idealizations, all element properties are assumed constant between nodes. None of the elements of either gear is assumed to be capable of carrying torsional loads. The bending moment of inertia about any axis normal to the longitudinal axis of the main strut of the cantilever gear is assumed to be constant and beam-column effects are not included. Each strut of either gear may be of a different material.

2.3 Landing Loads and Motions Program - The Landing Loads and Motions Program predicts the landing dynamics of a legged lander. The lander is idealized as a center body structure to which the landing gears are attached. A small footpad which contacts the landing surface is located at the base of each landing gear. Program options are available for obtaining landing motions, landing loads, and stability information for planar or spatial landings on many different types of landing surfaces.

The lander center body may be idealized as either a rigid body or the effects of a flexible structure may be included. For a rigid center body up to six rigid body degrees of freedom may be included in the analysis. To conserve computer run time, any combination of center body rigid degrees of freedom may be suppressed when running planar landing cases. The flexible center body is represented by the superposition of a number of free-free vibratory modes on the rigid body motion. From one to five modes may be included in the analysis. Flexible center body information may be obtained from either the Center Body Option of the Structural Analysis Program or some other eigenvalue program.

For a given legged lander configuration, up to five gears may be considered which may be either inverted tripod or cantilever gears. Each gear consists of a main strut and two drag struts which have pinned ends; thus, no moments or torques may be introduced at their ends. Both the main strut and drag struts are capable of carrying tension and compression loads and may possess velocity dependent force characteristics, elastic-plastic load-stroke characteristics, or a combination of the two. Five plastic load levels are available in both tension and compression for all of the landing gear struts. The load-stroke characteristics of all main struts in a given lander configuration are the same. Likewise, these characteristics for all the drag struts are the same, however, they may be different than the main struts. For a cantilever gear, the effect of main strut bending is included by modifying the elastic portion of the drag strut load-stroke relationship. Any combination of a constant magnitude Coulomb friction force, or a damping force dependent on the magnitude of the strut stroking velocity may be included in either the main struts, drag struts, or both. These friction forces are directed opposite to the strut stroking velocity. Relative motion between the center body and each footpad is employed in determining the magnitudes and directions of the landing gear strut loads.

Each footpad is represented as a single mass with three rigid body translational degrees of freedom. One degree of freedom is normal to the landing surface and the other two are in the plane of the landing surface. On an optional basis, a plastic load attenuation material, with up to three crush levels, may be located on the bottom of each footpad. For footpads whose equations of motion are not being integrated, the associated gears are assumed to be extensions of the center body structure and their inertia effects are included in the center body equations of motion.

Two soil mechanics routines are available for studying the footpad-soil interaction phenomenon. One method is similar to the footpad-soil interaction analysis developed during the Lunar Module Soil Mechanics Study. In this case, the soil is represented in terms of a number of semiempirical relationships. The second method determines the soil force through a simple elastic-plastic relationship between soil pressure and depth of soil penetration in conjunction with a coefficient of friction.

In addition to the standard program output defining the time histories of the footpad and center body motions and the load-stroke time histories in each landing gear strut, a number of additional output options are available. Accelerations at as many as ten points on the center body may be determined. This option allows the determination of landing accelerations for equipment items throughout the center body or correlation with test data obtained from accelerometers located at points other than the center of gravity.

The time history of the lander stability angle and pitching velocity of the lander in the direction of minimum stability may be obtained. This option, in conjunction with the spatial capabilities of the program and the two soil mechanics routines, allows a comprehensive study of the lander's stability characteristics to be made.

On an optional basis, all of the time history quantities required for defining the landing loads and acceleration patterns throughout the center body structure may be output on a magnetic tape. Points in time corresponding to possible high center body landing loads are determined by evaluating the printed output data obtained from the Landing Loads and Motions Program. The data on the magnetic tape may then be retrieved and the total landing load distribution throughout the center body structure determined at these specific time points of interest. The resulting loads are a combination of the inertia loads, gravity loads, and landing gear loads acting on the center body structure. These landing loads can then be input to the Center Body Option of the Structural Analysis Program and the internal loads in the individual structural members obtained.

Two numerical integration methods are incorporated in the program. These consist of a constant step Runge-Kutta method and a variable step Runge-Kutta method. The constant step method allows definite user control over integration step size. The variable step method often results in less computer time for long runs such as required for stability cases.

3. STRUCTURAL DESIGN CRITERIA

In the design of a legged lander configuration, specific constraints and criteria are imposed on the design dependent on the mission to be accomplished by the vehicle. Presented in the following sections are typical design constraints and factors of safety to be used during the design process of a legged lander. These were used as guidelines in determining the capabilities and options to be incorporated in the two computer programs developed during Task Order Five. However, it is emphasized that these do not represent limitations on the computer programs.

3.1 Design Constraints - The following factors must be considered in landing system and payload structure design: simplicity, reliability, stowability, structural compatibility, environmental compatibility, weight and sterilizability. Methods must be provided for accomplishing postlanding payload exposure to permit operations of experiments such as bioscience and imagery; measurements of wind velocity and direction, ambient pressure, temperature, and humidity; determination of soil composition; and operation of systems such as power, communication, and thermal control. In addition, the following is a typical list of specific constraints which should be considered.

(1) Mass of the landed vehicle shall be 584 kilograms.

(2) The landed vehicle (center body structure and landing gear structure) shall be compatible with an 3.35 meter base diameter, 120° blunted cone entry vehicle.

(3) Touchdown shall occur at a vertical velocity of 6.1 meters per second (relative to the gravity vector), and a maximum horizontal velocity of 3.7 meters per second.

(4) The total mass of the scientific payload shall be a minimum of 175 kilograms and the payload packing density shall not exceed a maximum of 943 dynes/cm^3.

(5) The landing vehicle shall not be restricted in orientation about the roll axis.

(6) Pitch and yaw attitudes at touchdown may vary as much as $\pm 10°$ from a plane normal to the gravity vector.

(7) The landing vehicle shall have as a goal the capability of successfully landing on slopes of 30° to the local horizontal.

(8) The landing system shall have the capability of performing satisfactorily when landing on surfaces containing particles varying in size from sand to 12.7 centimeter diameter rocks.

(9) The atmospheric pressure at the surface shall be assumed to be nine mb.

(10) The drag force on the footpad shall vary with penetration and applied normal forces.

(11) The landing surface shall be assumed to have an average crushing stress of 41×10^8 dynes/m^2 for penetrations to depths of 15.2 centimeters, a constant density of 1414 dynes/cm^3 for penetrations to depths of 15.2 centimeters and an angle of internal friction of 39 degrees.

(12) The coefficient of sliding friction between the surface and the footpad shall be assumed to be 0.3.

(13) Payload deceleration at any point in the payload shall be limited to a maximum of 20 earth g-units and landing deceleration of the footpads shall be limited to a maximum of 250 earth g-units.

(14) Methods shall be available for accomplishing post landing payload exposure to permit operation of experiments such as bioscience and imagery; measurements of wind velocity and direction, ambient pressure, temperature, and humidity; determination of soil composition; and operation of systems such as power, communication, and thermal control.

(15) Post landing orientation required by certain individual equipment items will be accomplished by aligning the item's positive X axis within ±5 degrees to an axis perpendicular to the local surface slope.

(16) Materials considered for use in the structures shall be compatible with space environment and a maximum temperature of 500°K and shall have minimum outgassing characteristics when exposed to a vacuum. Organic materials shall not be used in areas which may be subject to abrasion with the landing surface or to fragmentation with subsequent scattering of fragments on the landing surface.

(17) Surface gravitational acceleration shall be assumed to be 375 cm/sec^2.

3.2 Factors of Safety - The following factors shall be applied to the maximum loads (limit loads) encountered in planetary landing within the constraints specified above.

Energy Absorbing Material for Landing Gear Struts	1.00
All Other Structures	1.25

The load obtained by multiplying limit load by the appropriate factor of safety is the ultimate load used in sizing the structure.

The landing gear system shall have capability for stroke greater than that required for landings within constraints defined herein. This additional stroke shall be available to provide clearance between the bottom of the center body and a rock lying on the surface.

THIS PAGE INTENTIONALLY LEFT BLANK

4. STRUCTURAL ANALYSIS PROGRAM

The Structural Analysis Program contains a Center Body Option and a Landing Gear Option. The Center Body Option determines internal load distributions in the center body structure, and generates modal data for use in the Landing Loads and Motions Program. Energy absorption capability of a single landing gear undergoing large displacement stroking motion is investigated with the Landing Gear Option.

In the Center Body Option, internal and external load distributions and deflection patterns are determined for any system of forces or deflections impressed on an elastic network of structural bar members and rectangular shear webs. Problems for which the support structure behaves plastically can be solved. In addition, mode shapes and natural frequencies can be obtained for a center body with free-free support.

The Landing Gear Option of the program is used to analyze the large displacement stroking behavior of a single inverted tripod or cantilever landing gear. Energy absorption characteristics of the gear and internal strut loads are obtained for any number of applied footpad displacement steps. The footpad can be required to stroke a given distance along any arbitrarily oriented straight line, or a given distance normal to an arbitrarily oriented frictional plane. In the latter case, the coefficient of friction between the footpad and the frictional plane determines the sliding path of the footpad in the plane.

Analytical methods employed in the linear small displacement and nonlinear large displacement finite element portions of the Structural Analysis Program are presented in Section 4.1. A discussion of the normal mode method for obtaining modal data is also included in this section. Organization of the program is described in Section 4.2 and information necessary to operate the program is presented in Section 4.3. A listing of the program is contained in Appendix H.

4.1 Analytical Methods - The landing system and payload structures are highly redundant space frames consisting of a network of members possessing extensional, flexural, and torsional stiffness. Several methods for solving complex structural problems are in use today that effectively utilize the computer. Two methods considered for the Structural Analysis Program were the finite difference method and the finite element method. The finite element method was selected because of simplicity in dealing with nonhomogeneous, anisotropic structural applications. In addition, the elements can be changed easily in shape and size to follow complex boundary conditions or to allow for regions of rapid changes in stress or deflection.

A fundamental part of the finite element method is the technique used to obtain displacements at junctions of elements. Two approaches considered for the Structural Analysis Program were the force (flexibility) method and the stiffness (displacement) method. The stiffness method was selected primarily because the stiffness matrix developed may be used directly to generate the centerbody normal modes required to include centerbody flexibility in the Landing Loads and Motions Program. Also, the stiffness method lends itself readily to the large displacement technique necessary for landing gear analysis.

4.1.1 Center Body Option - The Center Body Option of the Structural Analysis Program can be used to analyze a structure idealized with an elastic network of structural bar elements and rectangular shear webs. The program internally replaces a rectangular shear web by two diagonal bar elements whose stiffness characteristics are equivalent to the shear web. Hence, the basic element of the program is the bar element.

4.1.1.1 Coordinate System - Two coordinate systems employed in the Center Body Option are the Local Coordinate System and the Global Coordinate System. Each bar member has its set of local coordinates as shown in Figure 4-1. Displacement notation of a general bar element capable of carrying axial load, shear in two directions, bending in two directions, and torsion is also indicated in Figure 4-1 for the Local Coordinate System. Subscript 1 refers to a displacement due to axial load, subscripts 2 and 3 are for displacement due to shear loads, subscript 4 is for a rotation due to torque, and subscripts 5 and 6 are for rotations due to moments. The Local Coordinate System origin for each bar is located at joint "p," with the X_ℓ axis aligned along the member axis. Positive X_ℓ is on the side of joint "p" towards joint "q." The Y_ℓ axis is perpendicular to X_ℓ and is located in the "pqr" plane. Positive Y_ℓ is on the side of X_ℓ towards point "r." The Z_ℓ

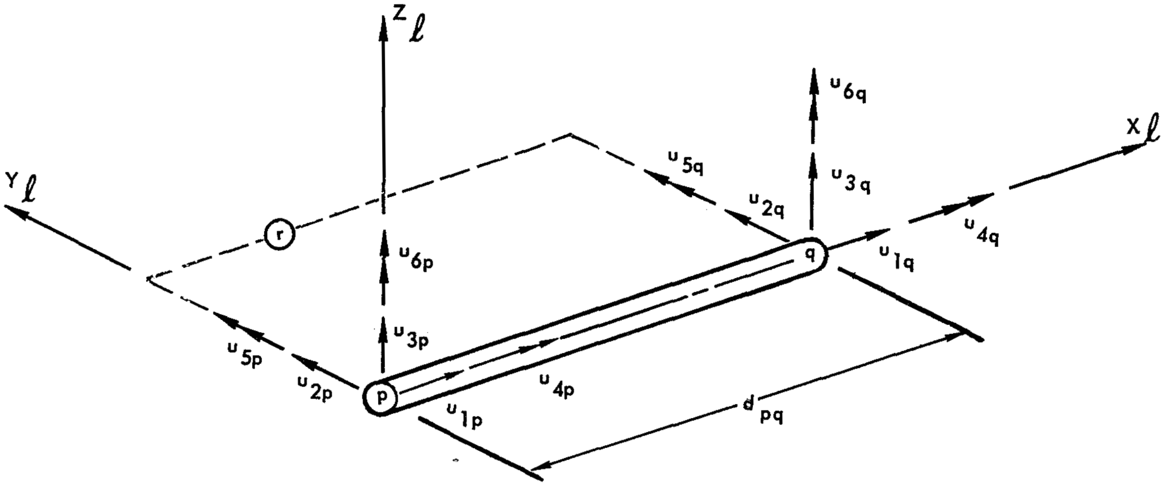

FIGURE 4–1 DISPLACEMENTS OF GENERAL BAR ELEMENT IN LOCAL COORDINATE SYSTEM

axis is then established using the right hand rule. Local Coordinate Systems are established by identifying each bar's origin (joint "p"), end (joint "q"), and orientation of the bending axis Y_ℓ (defined by joint "r"). Moment of inertia I_T about the Y_ℓ axis, moment of inertia I_N about the Z_ℓ axis, cross-sectional area A, torsional constant J, modulus of elasticity E, and shear modulus G are specified for each bar relative to its Local Coordinate System.

A common coordinate system (global) for all structural elements must be established so that element forces and displacements may be related to a common frame of reference. This Global Coordinate System may be any convenient orthogonal right hand system. Displacement notation of the bar element in the Global Coordinate System is shown in Figure 4-2. Joint locations, external load distributions, and joint deflections are all specified in the Global Coordinate System.

4.1.1.2 Stiffness Matrices - A stiffness matrix for each bar element is generated in its Local Coordinate System based on small deflection theory. This is done by applying a unit displacement or rotation to one end of the bar (while restraining all other rotations and displacements) and determining the induced forces and moments. Displacements and rotations are applied sequentially until all degrees of freedom at each end of the bar element have been included. Displacement notation of a general bar element capable of carrying axial load, shear in two directions, bending in two directions, and torsion was shown in Figure 4-1.

Force-displacement relationships for the three unit displacements and three unit rotations possible at each end of the bar element are shown in Figure 4-3. Forces and displacements in the Local Coordinate System are related in matrix form by

$$\{F\} = [K]\,\{\delta_L\} \tag{4-1}$$

In Equation (4-1), [K] is the matrix of stiffness coefficients; {F} is a column matrix of applied forces at the joints, and $\{\delta_L\}$ is the column matrix of joint displacements. Application of Maxwell's Reciprocal Law allows formulation of a symmetric stiffness matrix when an orthogonal coordinate system is employed. The element stiffness matrix for a general bar is given in

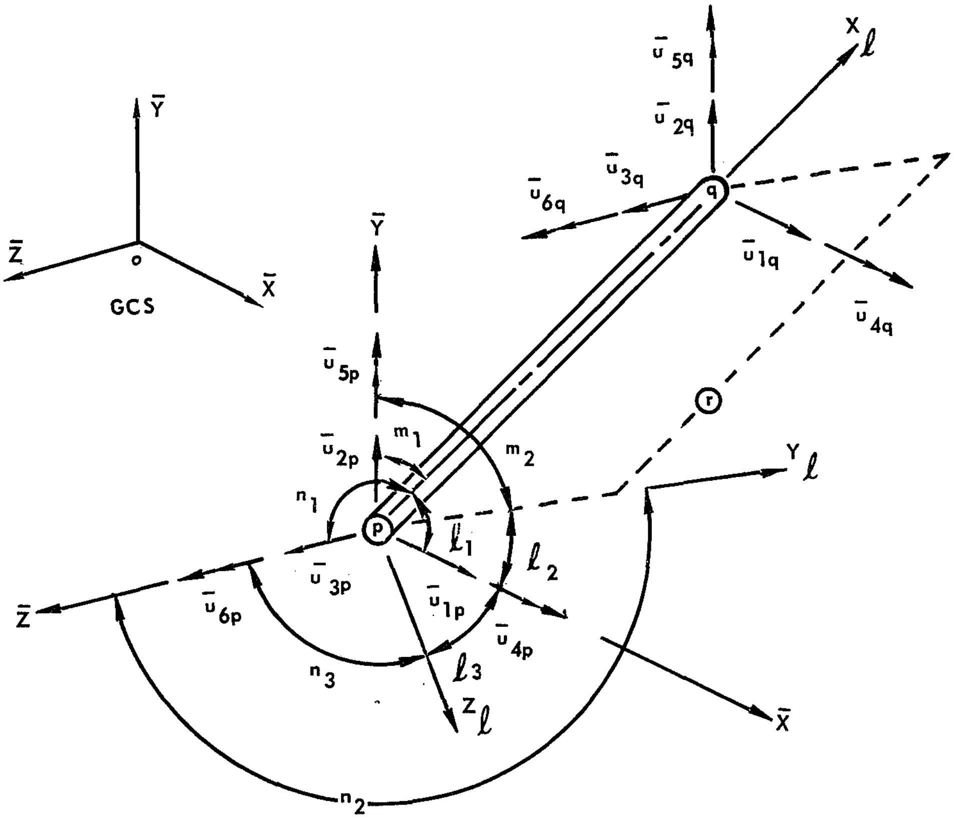

FIGURE 4–2 DISPLACEMENTS OF GENERAL BAR ELEMENT IN GLOBAL COORDINATE SYSTEM

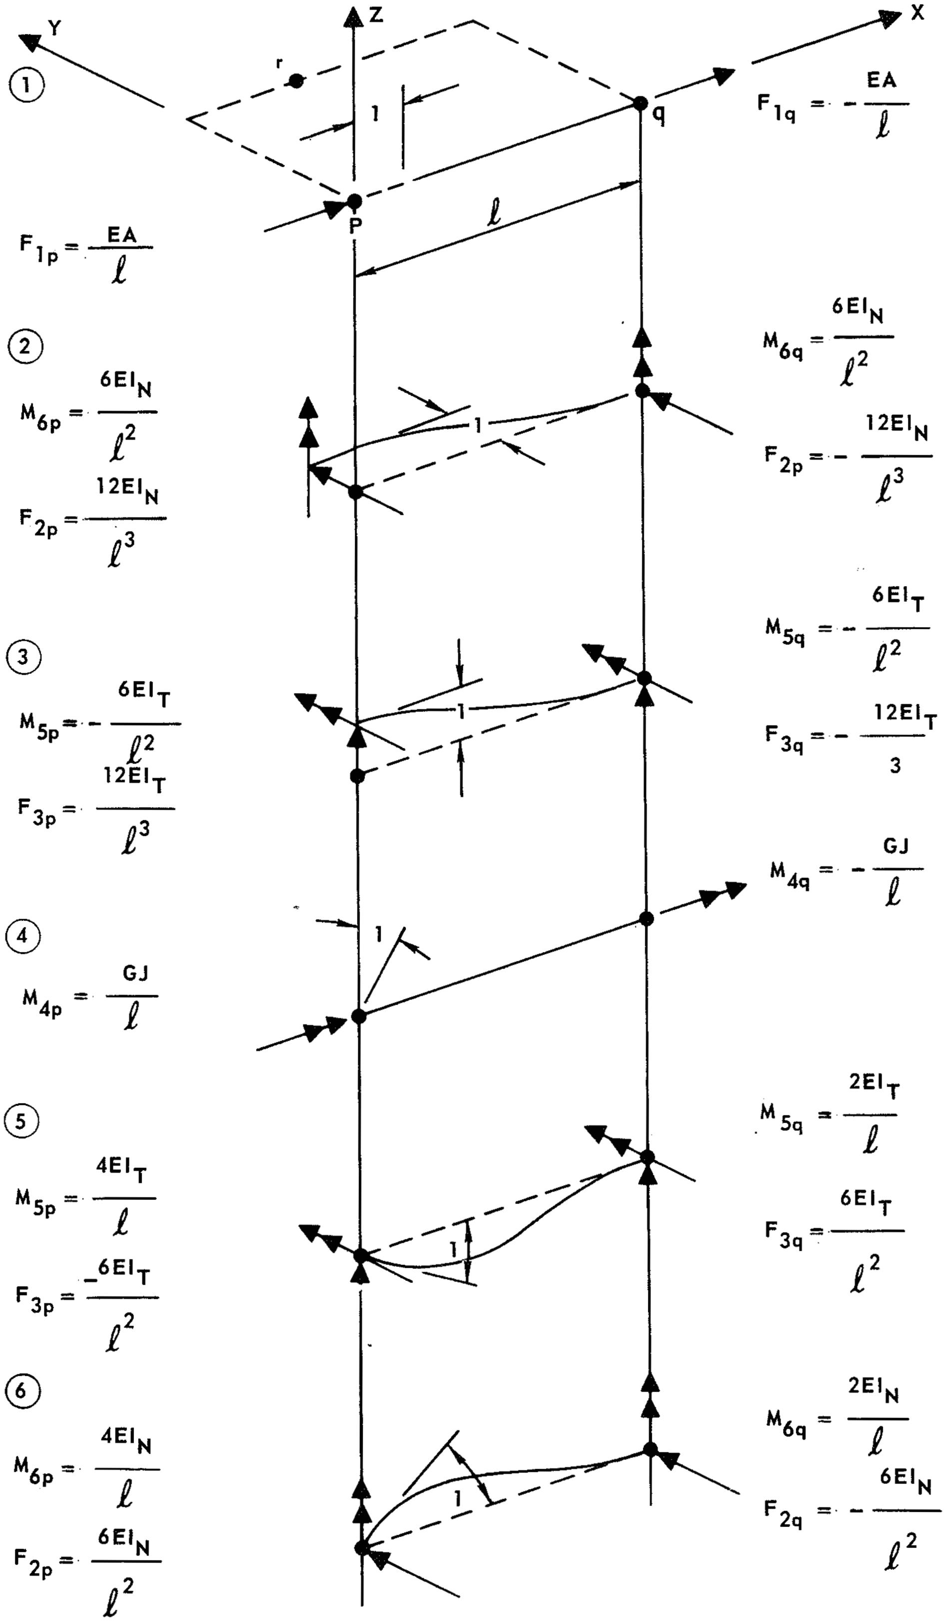

FIGURE 4–3 FORCE – DISPLACEMENT RELATIONS FOR GENERAL BAR ELEMENT

Figure 4-4. Terms in this matrix are the stiffness coefficients given in Figure 4-3.

If it is desired to include the effects of shearing strain on elemental beam deflection, the program applies the stiffness factors given in Figure 4-5 to the corresponding terms in Figure 4-4. Input shear form factors K_N and K_T are determined by dividing the total cross-sectional area of the bar by the area effective in carrying shear loads. The area used in determining K_N should be the area effective in carrying shear in the local Y_ℓ direction (bending about the Z_ℓ axis), while K_T is determined based on effective area for shear in the Z_ℓ direction. An example calculation of shear form factors K_N and K_T is given in Figure 4-6.

In addition, a rectangular shear web element is incorporated in the Center Body Option. The shear web idealization used by the program is indicated in Figure 4-7. Here the shear web is replaced by two diagonal bar elements whose stiffness characteristics are equivalent to the shear web. Cross-sectional properties of diagonals are derived by requiring equivalent strain energies in shear web and diagonals for statically equivalent internal loads.

Both ends of a member may be pinned (allowed to freely rotate) in a given direction by setting the appropriate moment of inertia equal to zero. If it is desired to pin one end of a member, while the other end remains fixed, the program utilizes the terms shown in Figures 4-8 through 4-11 in place of the corresponding terms in Figure 4-5. Terms used depend on the joint (p or q) pinned and the bending axis (Y_ℓ or Z_ℓ) about which the end is allowed to rotate. For example, if it is desired to pin the q end of a member with respect to bending about the Y_ℓ axis, terms in Figure 4-11 would be used in place of the corresponding terms in Figure 4-5.

To determine the stiffness matrix for the completely assembled structure, all element forces and displacements are related to the Global Coordinate System. Displacement notation of the bar element in Global Coordinate System is defined in Figure 4-2.

Transformation matrices are needed to change the frame of reference of each element from the Local to the Global Coordinate System. This transformation is expressed by the linear matrix equation

$$\{\delta_L\} = [\lambda]\{\delta_G\} \qquad (4\text{-}2)$$

$$K = \begin{array}{c|cccccccccccc|}

FIGURE 4–11 SUBSTITUTE FACTORS IN K_S MATRIX ALLOWING ELIMINATION OF ROTATIONAL RESTRAINT IN Y DIRECTION AT POINT Q where $[\lambda]$ is a matrix of direction cosines (cosines of angles between Local and Global Coordinate Systems) obtained by resolving global displacements in the direction of local coordinates. For the general bar, $[\lambda]$ is given in Equation (4-3).

$$\lambda = \begin{bmatrix} \bar{\lambda} & 0 & 0 & 0 \\ 0 & \bar{\lambda} & 0 & 0 \\ 0 & 0 & \bar{\lambda} & 0 \\ 0 & 0 & 0 & \bar{\lambda} \end{bmatrix} \qquad (4\text{-}3)$$

In Equation (4-3), each $\bar{\lambda}$ is a 3 by 3 matrix of the direction cosines of the local coordinate axes relative to the global system, as shown in Equation (4-4).

$$\bar{\lambda} = \begin{bmatrix} \ell_1 & m_1 & n_1 \\ \ell_2 & m_2 & n_2 \\ \ell_3 & m_3 & n_3 \end{bmatrix} \qquad (4\text{-}4)$$

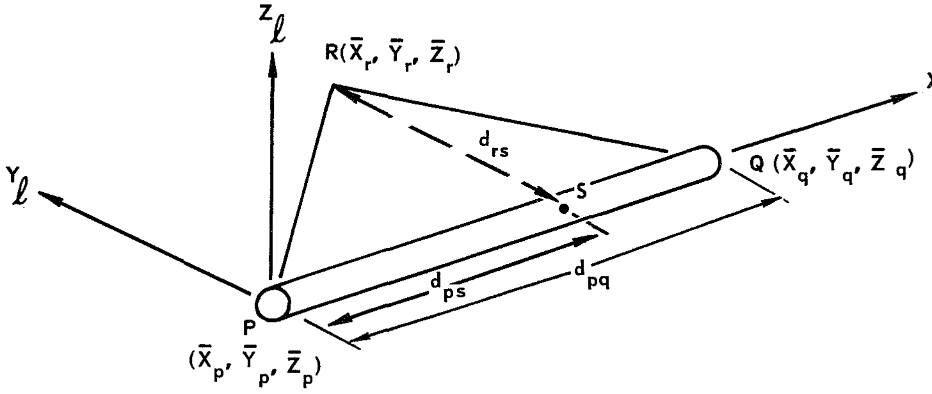
The row format of λ corresponds to the sequence of displacements in the Local Coordinate System specified for the stiffness matrix in Figure 4-4. The column format of λ corresponds to a similar sequence in the Global Coordinate System (i.e., $\bar{u}_{1_p}$, $\bar{u}_{2_p}$, $\ldots\bar{u}_{6_p}$). Values of the direction cosines relating the Local Coordinate System to the Global Coordinate System are determined as indicated in Figure 4-12.

Each element stiffness matrix is transformed from the Local to the Global Coordinate System by Equation (4-5)

$$[\bar{K}] = [\lambda]^T[K][\lambda] \qquad (4\text{-}5)$$

where $[\bar{K}]$ is the element stiffness matrix transformed to Global Coordinate System and $[\lambda]^T$ is the transpose of transformation matrix $[\lambda]$.

The total stiffness matrix (K_A) for the assembled structure (in the Global Coordinate System) as shown in Figure 4-13, is generated by systematically adding the transformed element stiffness matrices. Nodal points on



$$d_{pq} = \sqrt{(\bar{X}_q - \bar{X}_p)^2 + (\bar{Y}_q - \bar{Y}_p)^2 + (\bar{Z}_q - \bar{Z}_p)^2}$$

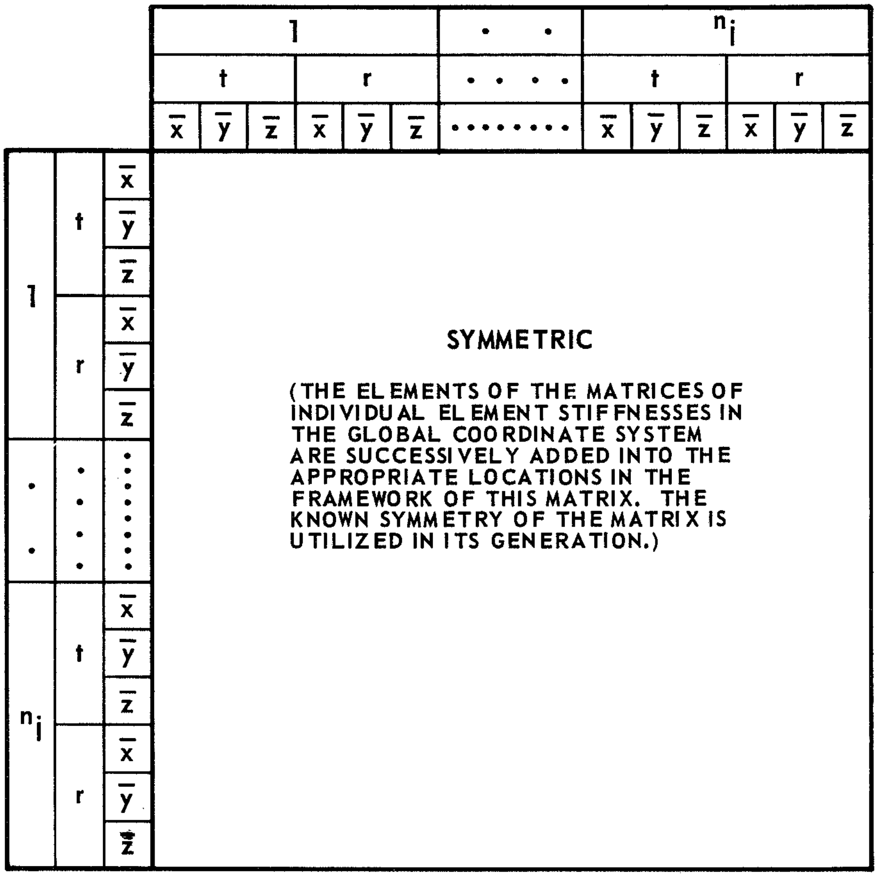
$$d_{rs} = \sqrt{(\bar{X}_r - \bar{X}_p)^2 + (\bar{Y}_r - \bar{Y}_p)^2 + \bar{Z}_r - \bar{Z}_p)^2 - d_{ps}^2}$$

$$d_{ps} = \ell_1 (\bar{X}_r - \bar{X}_p) + m_1 (\bar{Y}_r - \bar{Y}_p) + n_1 (\bar{Z}_r - \bar{Z}_p)$$

DIRECTION COSINE	COSINE OF ANGLE BETWEEN		EQUATION FOR DIRECTION COSINE
	LOCAL AXIS	GLOBAL AXIS	
ℓ_1	X_ℓ	$\bar{X}$	$(\bar{X}_q - \bar{X}_p)/d_{pq}$
m_1	X_ℓ	$\bar{Y}$	$(\bar{Y}_q - \bar{Y}_p)\ d_{pq}$
n_1	X_ℓ	$\bar{Z}$	$(\bar{Z}_q - \bar{Z}_p)\ d_{pq}$
ℓ_2	Y_ℓ	$\bar{X}$	$[(\bar{X}_r - \bar{X}_p) - \ell_1 d_{ps}]/d_{rs}$
m_2	Y_ℓ	$\bar{Y}$	$[(\bar{Y}_r - \bar{Y}_p) - m_1 d_{ps}]/d_{rs}$
n_2	Y_ℓ	$\bar{Z}$	$[(\bar{Z}_r - \bar{Z}_p) - n_1 d_{ps}]/d_{rs}$
ℓ_3	Z_ℓ	$\bar{X}$	$m_1 n_2 - m_2 n_1$
m_3	Z_ℓ	$\bar{Y}$	$-\ell_1 n_2 + \ell_2 n_1$
n_3	Z_ℓ	$\bar{Z}$	$\ell_1 m_2 - \ell_2 m_1$

NOTE: POINT r IS AN ARBITRARILY SELECTED POINT LYING IN THE $X\ell - Y\ell$ PLANE. IT IS USED TO IDENTIFY THE ORIENTATION OF MEMBER BENDING AXES $Z\ell$ AND $Y\ell$ RELATIVE TO THE GLOBAL COORDINATE SYSTEM. (I_N IS THE MOMENT OF INERTIA ABOUT THE $Z\ell$ AXIS AND I_T IS THE MOMENT OF INERTIA ABOUT THE $Y\ell$ AXIS.)

FIGURE 4-12 DIRECTION COSINES OF LOCAL COORDINATE SYSTEM RELATIVE TO GLOBAL COORDINATE SYSTEM



SYMMETRIC

(THE ELEMENTS OF THE MATRICES OF INDIVIDUAL ELEMENT STIFFNESSES IN THE GLOBAL COORDINATE SYSTEM ARE SUCCESSIVELY ADDED INTO THE APPROPRIATE LOCATIONS IN THE FRAMEWORK OF THIS MATRIX. THE KNOWN SYMMETRY OF THE MATRIX IS UTILIZED IN ITS GENERATION.)

SYMBOLS t AND r INDICATE TRANSLATIONAL AND ROTATIONAL DISPLACEMENTS RESPECTIVELY.

FIGURE 4–13 ASSEMBLED STIFFNESS MATRIX FORMAT the idealized structure are numbered consecutively from 1 to n_J. The stiffness matrix K_A is assembled with a row and column format corresponding to the three translational followed by the three rotational degrees of freedom in the global system at each node in sequence. In this general case, the size of the stiffness matrix is $6n_J \times 6n_J$.

4.1.1.3 Elastic Analysis - The assembled stiffness matrix $[K_A]$ is related to the column matrices of global forces and displacements at each node by Equation (4-6) which represents a combination of Equation (4-1) through (4-5). The word "forces" in this discussion implies both forces and moments, and the word "displacements" implies both deflections and rotations.

$$\{F\} = [K_A]\{\delta_G\} \tag{4-6}$$

The stiffness matrix is singular. That is, its determinant vanishes and its inverse does not exist. Boundary conditions (supports) must be defined to prevent rigid body motion. Once $[K_A]$ has been determined, a solution can be obtained for any set of support conditions.

As described in Reference (3), the unknown nodal displacements and support reactions are normally obtained by partitioning Equation (4-6) according to the location and orientation of supports as indicated in Equation (4-7).

$$\left\{\begin{array}{c} F_{(m-n)} \\ \hdashline F_n \end{array}\right\} = \left[\begin{array}{c:c} A_{(m-n) \times (m-n)} & B_{(m-n) \times n} \\ \hdashline B'_{n \times (m-n)} & D_{n \times n} \end{array}\right] \left\{\begin{array}{c} \delta_{(m-n)} \\ \hdashline \delta_n \end{array}\right\} \tag{4-7}$$

Subscripts n and m are

n = number of support boundary conditions (i.e., $\delta_n = 0$),

m = order of stiffness matrix.

This partitioning results in two sets of equations: Equation (4-8) relates unknown nodal displacements to known applied forces, and Equation (4-9) relates unknown support reactions to unknown nodal displacements.

$$\{F_{(m-n)}\} = [A]\{\delta_{(m-n)}\} \tag{4-8}$$

$$\{F_n\} = [B'] \{\delta_{(m-n)}\} \tag{4-9}$$

The inverse of matrix [A] in Equation (4-8) is the flexibility matrix of the structure. Equation (4-8) may be rewritten to give unknown nodal displacements in terms of the flexibility matrix and known applied forces as shown in Equation (4-10).

$$\{\delta_{(m-n)}\} = [A]^{-1} \{F_{(m-n)}\} \tag{4-10}$$

The unknown reactions may be obtained by combining Equations (4-9) and (4-10) as shown in Equation (4-11).

$$\{F_n\} = [B'] [A]^{-1} \{F_{m-n}\} \tag{4-11}$$

The preceding discussion outlines the method normally used to obtain nodal displacements and reactions. Due to computer core limitations and the desire to minimize program running time, an iterative method of determining nodal deflections and reactions, once the stiffness matrix was established, was programmed. An iterative method eliminates the need for matrix inversion.

The requirement for plastic supports calls for multiple solutions of sets of equations very nearly the same. These sets of simultaneous equations are represented by matrix Equation (4-8), relating unknown nodal deflections to known applied forces. This type of problem is best handled by an iterative solution, since the required nodal deflections are approximately known after the initial elastic solution is determined, thus minimizing computing time. Four iterative techniques were programmed; Gauss-Siedel, Gauss-Siedel with Aitkens Delta Squared improvements, the Overrelaxation method, and the Conjugate Gradient technique. Reference (4) describes the first three methods and Reference (5) the latter. Any one of these techniques may be best suited for a specific structural problem. However, experience dictates that for highly redundant space frames, such as the legged lander, the Conjugate Gradient technique appears to be the best suited of the above solution methods.

After nodal displacements have been determined using the iteration procedure, the unknown support reactions are obtained by substitution of these nodal displacements into matrix Equation (4-9). Forces on elements in the Local Coordinate System are found by transforming the nodal displacements into the Local Coordinate System using Equation (4-2) and applying the appropriate force-displacement relationships using Equation (4-1).

The program also is capable of solving problems wherein the nodal displacements are known, as in problems where some supports settle. Combinations of known applied forces and known nodal displacements may be input, and all forces and displacements will be determined. Boundary conditions imposed on the problem must be sufficient to prevent rigid body motion. Partitioning of Equation (4-7) for this case results in Equation (4-12), relating unknown nodal displacements to known applied forces and known nodal displacements, and in Equation (4-13), which relates unknown forces and reactions to the now known (determined in Equation (4-12)) nodal displacements. Subscript n for this case implies either zero or nonzero known boundary conditions.

$$\{F_{(m-n)}\} = [A]\{\delta_{(m-n)}\} + [B]\{\delta_n\} \tag{4-12}$$

$$\{F_n\} = [B']\{\delta_{(m-n)}\} + [D]\{\delta_n\} \tag{4-13}$$

This solution is simply a more general case of the initial partitioning (Equation (4-8) and (4-9)), where the only known nodal displacements were zero and terms involving δ_n were therefore not included.

4.1.1.4 Plastic Support - When analyzing a space frame it may be desirable to idealize support members with restricted load-carrying capability. An upper (positive) and lower (negative) limit can be set on the magnitude of any force or moment component in such a support member. Initial solution of the space frame redundancy assumes elastic deformation, but the magnitude of the load components at the support are compared with input limits to ascertain if these have been exceeded. Those load components (reactions) which exceed the input limits are then assumed to be at the input cutoff values. The new set of boundary conditions (new column matrix of deflections and forces) are then employed with the stiffness matrix to obtain a new solution. The load components at the supports and the limits are again compared. If the limits are exceeded, the process is repeated until no limits are exceeded and equilibrium is achieved.

A plastic attenuator support can be modeled with this feature by setting the appropriate input limit to the force causing plastic deformation. Cables with one end attached to a support and the other to a structural joint can be idealized by making one of the limits on each reaction force component zero, allowing the cable to carry only tension and no compression. Determination of the proper limit (positive or negative) to use on a particular force component depends on whether the desired limit is in the positive or negative global coordinate direction. If a desired tension force in a cable results in a force component in the positive global direction at the support, the lower (negative) limit is set equal to zero. If the desired tension force component is in the negative global direction, the upper (positive) limit is set equal to zero.

4.1.1.5 Modal Analysis - The frequencies and mode shapes for the free-free center body structure are determined once the unrestrained stiffness matrix of the center body (Section 4.1.1.2) has been obtained. This modal analysis is performed in the optional Modal Analysis Routine in the Center Body Option of the Structural Analysis Program.

Free vibrations of the center body structure are defined by Equation (4-14)

$$[M]\{\ddot{q}(s, t)\} + [K]\{q(s, t)\} = 0 \tag{4-14}$$

where

$[M]$ = mass matrix of the center body.
$[K]$ = stiffness matrix of the center body.
$\{\ddot{q}\}, \{q\}$ = accelerations and displacements describing the motion of the control points throughout the center body.
s = space coordinates in the center body.
t = time.

The above representation of the stiffness and inertia characteristics of the center body are input data for the Modal Analysis Routine. An eigenvalue routine is used to obtain the vibratory free-free mode shapes and corresponding frequencies.

The large order center body stiffness matrix results in an eigenvalue problem which is too large to solve practically. The computer run time required to obtain the frequencies and mode shapes would be excessive. In addition, the eigenvalue problem would exceed the allotted computer core storage requirements. For these reasons, the size of the center body's structural stiffness matrix is reduced before solving the eigenvalue problem. This reduction technique is discussed in Reference (6).

In the reduction procedure, a number of degrees of freedom, corresponding to various displacements and rotations at the center body joints, are removed. To remove these, it is assumed that the inertia forces and/or moments associated with these degrees of freedom are negligible. In this procedure, all of the strain energy associated with the removed degrees of freedom is retained. This reduction procedure is outlined as follows.

$$\begin{Bmatrix} P \\ \hdashline 0 \end{Bmatrix} = \left[\begin{array}{c:c} K_{11} & K_{12} \\ \hdashline K_{21} & K_{22} \end{array}\right] \begin{Bmatrix} q_1 \\ \hdashline q_2 \end{Bmatrix} \tag{4-15}$$

where

K_{11}, K_{12}, K_{21}, K_{22} = segments of total center body stiffness matrix.

q_1 = degrees of freedom on which forces and moments (P's) exist.

q_2 = degrees of freedom on which negligible forces and moments exist.

In the above, the total stiffness matrix has been reordered such that the elements associated with the degrees of freedom to be retained appear first.

Equation (4-15) is equivalent to the two following expressions

$$\{P\} = [K_{11}]\{q_1\} + [K_{12}]\{q_2\} \tag{4-16}$$

$$\{0\} = [K_{21}]\{q_1\} + [K_{22}]\{q_2\} \tag{4-17}$$

Solving the second of these for $\{q_2\}$ gives

$$\{q_2\} = -[K_{22}]^{-1}[K_{21}]\{q_1\} \tag{4-18}$$

Substituting this into Equation (4-16) results in the reduced form

$$\{P\} = \Big[[K_{11}] - [K_{12}][K_{22}]^{-1}[K_{21}]\Big] \{q_1\} \tag{4-19}$$

from which the reduced stiffness matrix, [K*], is defined as

$$[K^*] = [K_{11}] - [K_{12}][K_{22}]^{-1}[K_{21}] \tag{4-20}$$

The eigenvalue problem associated with the reduced system is

$$[M^*]\{\ddot{q}_1\} + [K^*]\{q_1\} = 0 \tag{4-21}$$

where [M*] is a diagonal mass matrix whose elements represent the distribution of the center body mass at the degrees of freedom to be retained. Frequencies and mode shapes of the total elastic center body structure are obtained using Equations (4-18) and (4-21). Reference (7) summarizes the Householder-Ortega-Wilkinson Method used to determine mode shapes and natural frequencies. An example of the use of this routine is given in Section 4.3.1.3.

4.1.2 Landing Gear Option - The Landing Gear Option of the Structural Analysis Program can be used to investigate the energy absorption characteristics and internal loads in inverted tripod or cantilever landing gears. The finite element stiffness method employed in this option of the program is based on large displacement (nonlinear) finite element theory.

In linear finite element theory, changes in the stiffness matrix due to displacements are assumed to be negligible. Landing gear struts experience large rotational and extensional displacements during stroking of the gear. These displacements require that the finite element idealization of the struts include "rotational" and "extensional" nonlinearities. To illustrate the nonlinear nature of the problem, consider a planar gear subjected to the displacements shown in Figure 4-14. Stiffness of the gear changes appreciably during stroking from the original to the displaced position. This change is due to the following displacement nonlinearities:

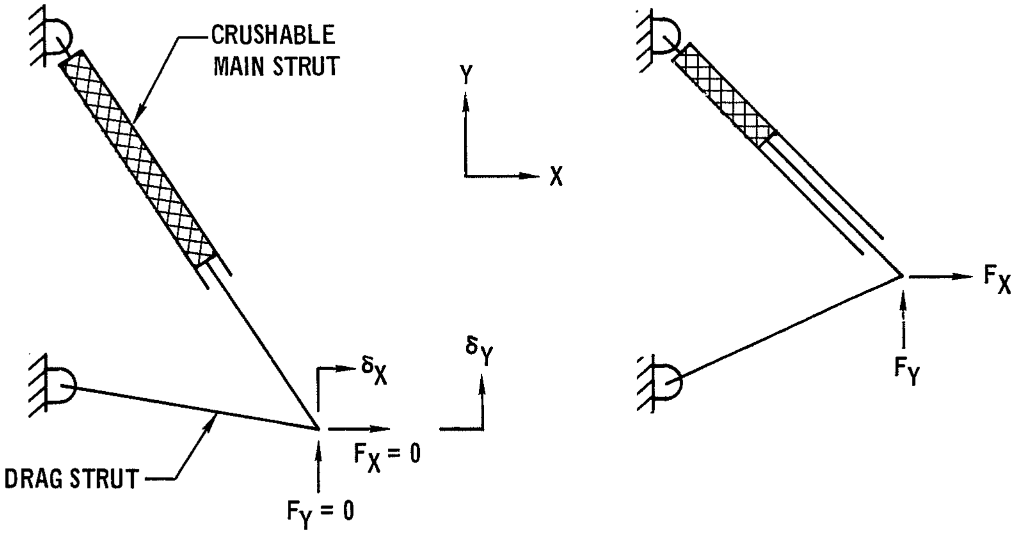
(1) rotational nonlinearities - large rotations cause significant changes in strut orientation and the resulting stiffness;

(2) extensional nonlinearities - compressive (or tensile) strut crushing changes the strut length and slope of the axial load-stroke curve (referred to as axial stiffness) both of which alter the stiffness.

For these reasons linear theory cannot be used in the analysis of landing gears since changes in the stiffness matrix due to displacements are not negligible.

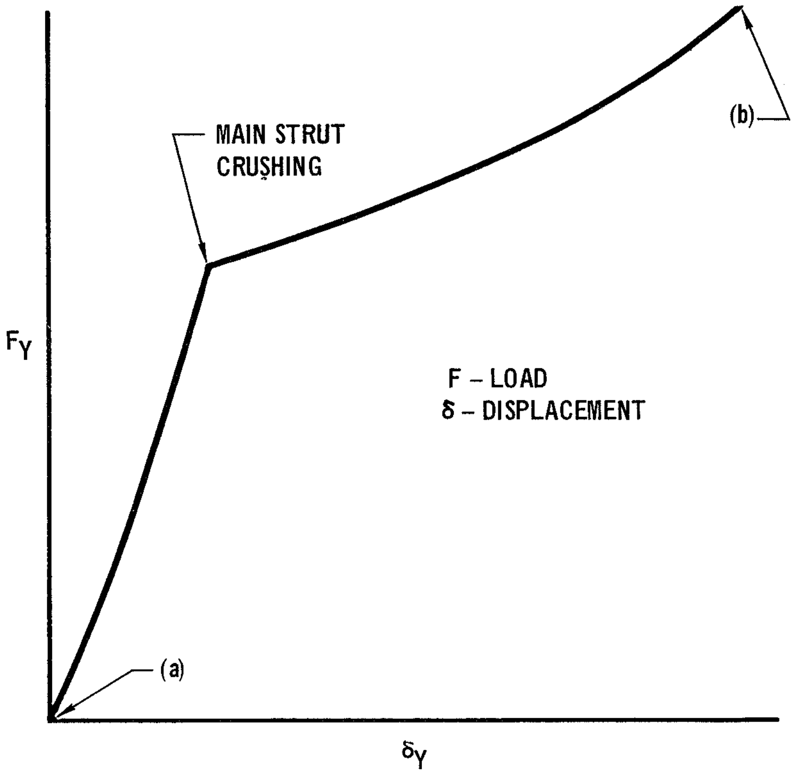
4.1.2.1 Modified Incremental Stiffness Method - To account for the nonlinearities associated with landing gear analysis, the incremental stiffness finite element method is employed. A modification of this method is made to insure that load unbalances do not result in the gear due to the linear approximations made in each step of the solution technique.

In the incremental stiffness method, nonlinear behavior is approximated through a sequence of linear solutions. The loading is divided into a number of incremental steps. For each step, an increment of the external load is applied and incremental displacements determined. These displacements, when added to the structural positions at the conclusion of the previous step, define updated geometry. The incremental stiffness matrix, used to determine these incremental displacements, is updated at the conclusion of each step to reflect changes due to displacement nonlinearities. Because small increments



(a) ORIGINAL GEAR POSITION

(b) DISPLACED GEAR POSITION



(c) TYPICAL NONLINEAR LOAD–STROKE CURVE

FIGURE 4–14 LARGE DISPLACEMENTS OF A TYPICAL TWO–DIMENSIONAL GEAR are used, a linear small displacement problem is solved at each step. The method is illustrated in Figure 4-15 for a typical nonlinear load-stroke curve. For each step n, the incremental displacement ($\delta_n - \delta_{n-1}$) corresponding to the applied incremental load ($F_n - F_{n-1}$) is determined from the equation

$$\delta_n = \delta_{n-1} + (F_n - F_{n-1})/S_n, \quad n = 1, \ldots, m \tag{4-22}$$

where m is the total number of incremental steps. In this equation, S_n is the incremental stiffness of the structure corresponding to the displaced state, δ_{n-1}. For example, at the conclusion of step 1 (point A_1 in Figure 4-15), the incremental stiffness S_2 (at point P_1) is determined for the displaced state, δ_1. This stiffness and the next incremental load ($F_2 - F_1$) are then used in Equation (4-22) to determine δ_2 (defining point A_2),

$$\delta_2 = \delta_1 + (F_2 - F_1)/S_2 \tag{4-23}$$

This process is repeated until all load increments have been applied. For the gear of Figure 4-14 the above method would be applied simultaneously to the nonlinear load-stroke curves in the X and Y directions.

Due to the linear approximation at each step of the incremental stiffness method, error in the solution accumulates as a function of step size. This can be seen in Figure 4-15 where at the conclusion of step 4 the difference between points A_4 and P_4 is significant. This error, the difference between the applied load (F_4) and the true load corresponding to the displaced state (the force at point P_4), is defined as the load unbalance. To eliminate this unbalance, the incremental stiffness method is combined with an iteration procedure to assure convergence to the correct solution. For each incremental step, iteration is employed to insure that the internal loads, corresponding to the displaced state, are in equilibrium with the applied loads.

The iteration approach as applied to the nth incremental step of Figure 4-15 is illustrated in Figure 4-16. The incremental displacement $\delta_n - \delta_{n-1}$, corresponding to the incremental applied load $F_n - F_{n-1}$, is sought. Knowing the incremental stiffness S_1 at the beginning of the nth incremental step, the first estimate of the incremental displacement, $\Delta\delta_1$, is found from

$$\Delta\delta_1 = (F_n - F_{n-1})/S_1 \tag{4-24}$$

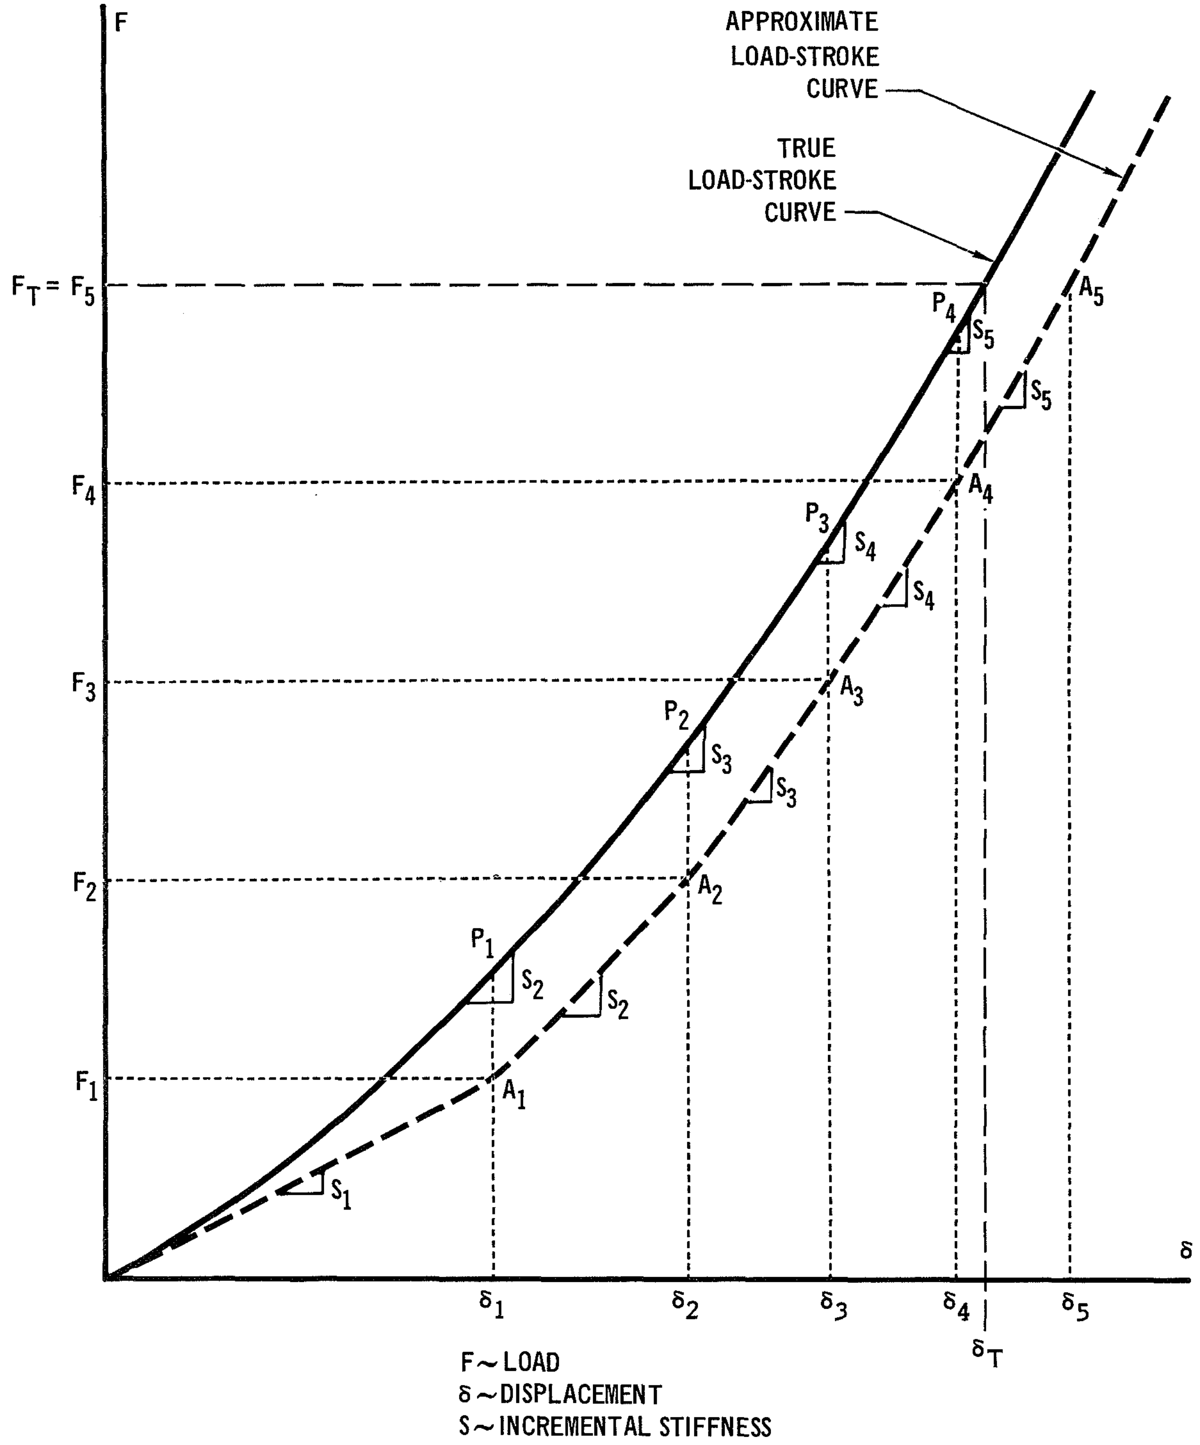


FIGURE 4–15 INCREMENTAL STIFFNESS METHOD APPLIED TO A TYPICAL NONLINEAR LOAD-STROKE CURVE

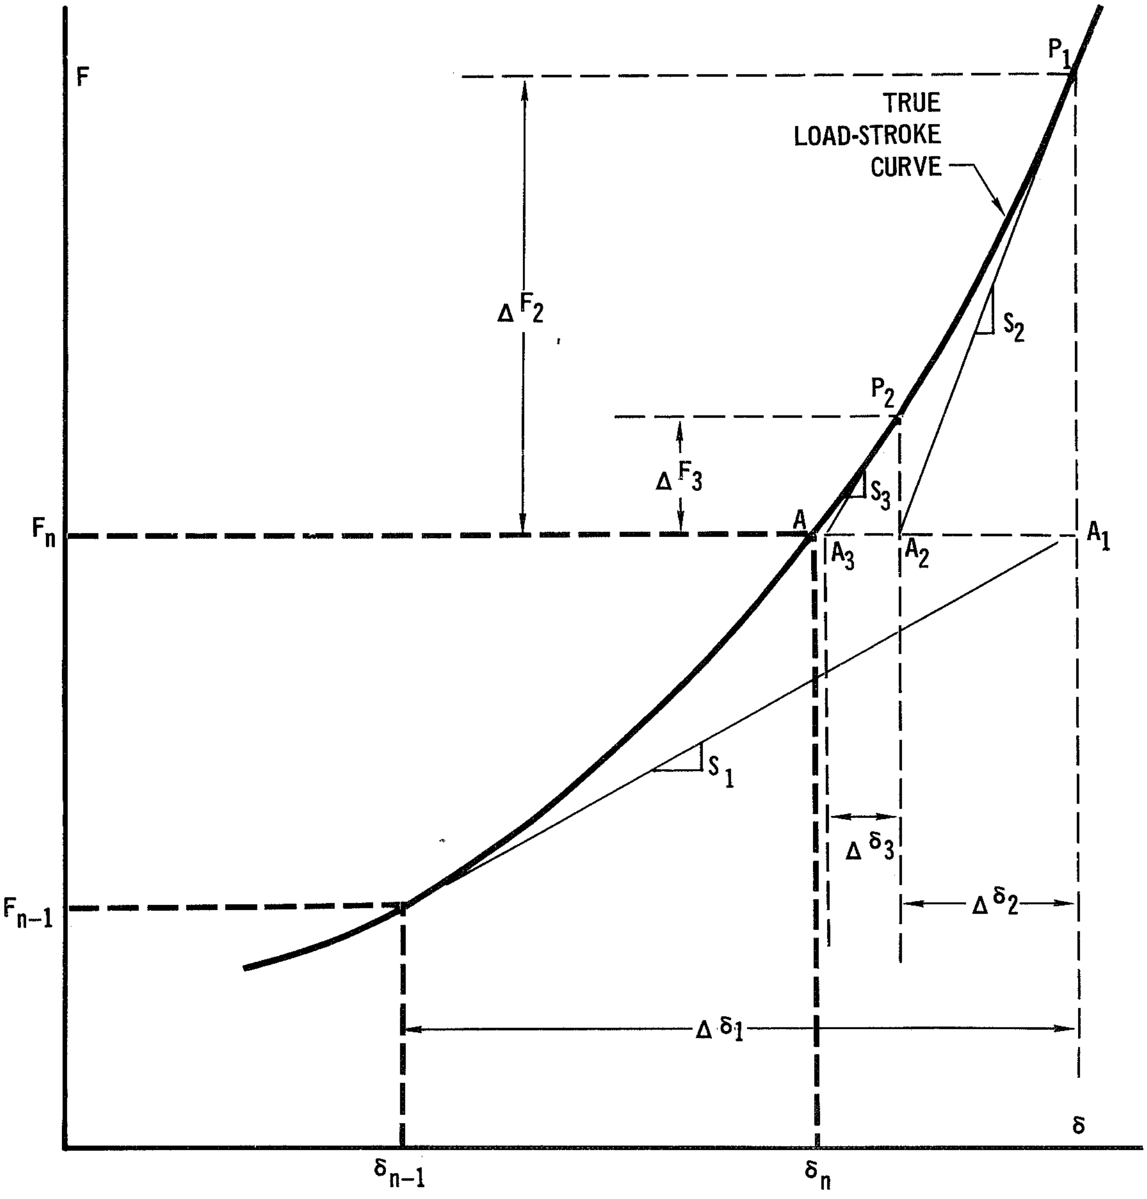


F ~ LOAD
δ ~ DISPLACEMENT
S ~ INCREMENTAL STIFFNESS

FIGURE 4–16 TYPICAL INCREMENTAL STEP OF MODIFIED INCREMENTAL STIFFNESS METHOD

This yields point A_1. The true incremental stiffness S_2 and the resultant strut reaction load $F_n + \Delta F_2$ corresponding to the displacement state $\delta_{n-1} + \Delta\delta_1$ are defined by point P_1. The force unbalance ΔF_2, the difference between the total applied load, F_n, and the reaction load $F_n + \Delta F_2$, is applied to the structure whose incremental stiffness is S_2. Thus, the new estimate of the incremental displacement, $\Delta\delta_1 + \Delta\delta_2$, is determined where $\Delta\delta_2$ is defined by

$$\Delta\delta_2 = \Delta F_2/S_2 \tag{4-25}$$

This process is repeated and a new estimate of the incremental displacement, $\sum_{i=1}^{\ell} \Delta\delta_i$, is determined using the relation

$$\Delta\delta_\ell = \Delta F_\ell/S_\ell, \quad \ell = 3, \ldots. \tag{4-26}$$

until ΔF_ℓ is arbitrarily small (convergence at point A). When this occurs, the applied load is balanced by the reaction load and equilibrium has been attained.

For the gear of Figure 4-14, the above method would be applied simultaneously to the nonlinear load-stroke curves in the X and Y directions. For each of these directions, the force unbalance would be the difference between the applied load in that direction and the sum of the internal drag strut and main strut loads in that direction.

The modified incremental stiffness method is well suited to the analysis of landing gears. When employing this method, errors will not be introduced when structural stiffness properties change abruptly as is common in landing gear members containing attenuation. The error at each step of the process is known since the system is in equilibrium within a predetermined tolerance. In addition, the method provides a displacement-load history for any desired number of increments of applied gear stroke. This is essential for determining energy absorption characteristics of landing gears.

The modified incremental stiffness method, as applied to three dimensional inverted tripod or cantilever gears, requires the solution of the matrix equation

$$\Delta\{F\} = [S]\,\Delta\{\delta\} \tag{4-27}$$

Equation (4-27) is solved several times for each step of the loading. In this equation, $\Delta\{F\}$ is a column matrix of incremental forces applied at the nodes of the gear; $\Delta\{\delta\}$ is a column matrix of incremental nodal displacements; and [S] is the instantaneous incremental stiffness of the gear. For landing gear analysis, the independent variables in Equation (4-27) for each step of the process will be the applied displacements. The method of employing Equation (4-27) for each step of the process is as follows:

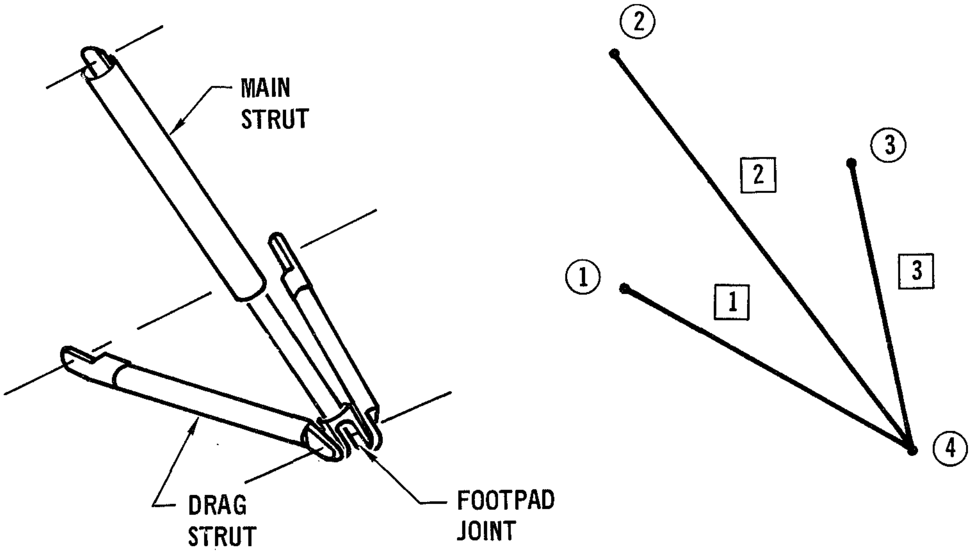
(i) Equation (4-27) is solved once for the case where $\Delta\{\delta\}$ is the total applied displacement vector divided by the number of incremental steps. The incremental stiffness matrix [S] of the gear corresponds to the displaced conditions existing at the conclusion of the previous step. This resulting equation is analogous to Equation (4-22). The nodal locations are then updated.

(ii) Equation (4-27) is then solved repeatedly (iteration is employed) until the largest load unbalance component is less than a predetermined tolerance. At the conclusion of each iteration, nodal locations are updated. For the first of these iterations, [S] corresponds to the displaced condition existing at the conclusion of (i). For all succeeding iterations, [S] corresponds to the displaced condition existing at the conclusion of the previous iteration. $\Delta\{F\}$ is a vector representing the difference between the applied load components and the components of internal load corresponding to the displaced condition existing at the conclusion of the previous iteration. Hence, $\Delta\{F\}$ represents the load unbalances. Each of the above equations is analogous to Equation (4-26).

4.1.2.2 Structural Idealization - The Landing Gear Option employs a fixed idealization for inverted tripod and cantilever landing gears. This idealization (node point and element numbering) must be adhered to when employing this option of the program.

The inverted tripod landing gear is idealized in the program with four nodes and three pin-ended elements (the main strut and two drag struts) as shown in Figure 4-17(a). These elements are capable of carrying axial loads only and may contain honeycomb attenuation for both tension and compression. Each element may be made of a different material. Each node is assumed to be

(a) INVERTED TRIPOD GEAR



NOTE:

② JOINT NUMBER

$\boxed{4}$ ELEMENT NUMBER

(b) CANTILEVER GEAR

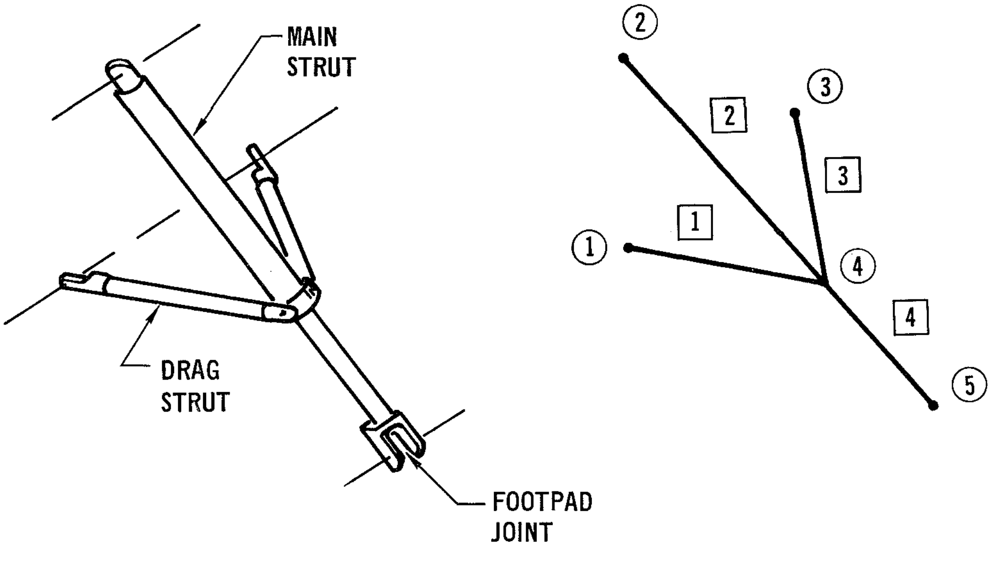


FIGURE 4–17 LANDING GEAR IDEALIZATIONS

a pin which can support three force components but no moments. Each element of a gear has associated with it a set of three nodes (p, q, and r) which defines the Local Coordinate System, as explained in Section 4.1.2.3, for that element. The fixed idealization of the inverted tripod gear employs the following nodal point numbering system for the elements:

Element No.	p	q	r
1	1	4	2
2	2	4	3
3	3	4	2

The cantilever landing gear is idealized with five nodes and four elements as shown in Figure 4-17(b). The main strut is idealized with two elements, both of which are capable of carrying bending as well as axial loads. These members (elements 2 and 4 in Figure 4-17(b)) are assumed to be rigidly connected at node 4. This provides moment continuity along the main strut. For elements 2 and 4 of the main strut, the moment of inertia about any axis normal to the element is assumed to be constant. However, the moment of inertia for element 2 may be different than that for element 4. For each of these elements, the modulus of elasticity for bending displacements may be different than the modulus for axial displacements. The junctions of the main strut with the center body (node 2) and the footpad (node 5) are assumed to be pinned. The drag struts (elements 1 and 3) are pin-ended with axial load-carrying capability only. Thus, a drag strut cannot carry bending moments at either end. Both drag struts (elements 1 and 3) and the lower element of the main strut (element 4) may contain honeycomb attenuation for both tension and compression. Each strut of the cantilever gear may be made of a different material. The fixed idealization of the cantilever gear employs the following nodal point numbering system for the elements:

Element No.	p	q	r
1	1	4	2
2	2	4	RP
3	3	4	2
4	5	4	RP

Point r (RP) for elements 2 and 4 is a floating reference point whose coordinates are continually changing. Initially, this point is selected as node 1. As the main strut bends, the floating reference point is located as described in Section 4.1.2.5.

For either of the above gears, struts which can carry axial loads only (all elements of the inverted tripod gear and elements 1 and 3 of the cantilever gear) are defined as "axial struts." Struts which are capable of carrying bending as well as axial loads (elements 2 and 4 of the cantilever gear) are defined as "bending struts."

For a strut which contains honeycomb attenuation, the material defining the strut properties is assumed to have a load-stroke curve for axial displacements similar to that shown in Figure 4-18. This curve represents the stroking characteristics of stacked honeycomb cartridges housed within a landing gear strut. Each cartridge is assumed to crush at constant load as the strut is stroked. Cartridges possessing different crushing strengths may be stacked in series to form a desired load-stroke characteristic. Up to five cartridges can be used to attenuate compression loads and up to five to attenuate tension loads.

For the typical load-stroke curve shown in Figure 4-18, determination of the axial load corresponding to stroking causing compression in the strut is explained in the following discussion. The axial load corresponding to tensile stroking of the strut would be determined in a similar manner.

As the strut initially begins to stroke, the strut load increases linearly with stroke to point 1 where the first crush load is reached. The load then remains constant with stroke until either the stroke reverses direction or a second elastic portion is reached. If the direction of stroke reverses, point 2, one of the following load-stroke sequences is possible:

(1) Elastic unloading to an intermediate point between 2 and 4, such as point 3, at which time the compressive stroke again increases. This results in the load increasing elastically to point 2 and then following the original load-stroke curve.

(2) Elastic unloading through point 3 to point 4. A continued decrease in stroke to point 5 occurs at a zero strut load. With a reversal of stroke the strut will compress with zero load until point 4 is

SCMAX – MAX STROKE (COMPRESSION)
STMAX – MAX STROKE (TENSION)

FIGURE 4–18 TYPICAL STRUT LOAD-STROKE CURVE again reached. The load will then increase linearly to point 2 and continue to follow the original load-stroke curve.

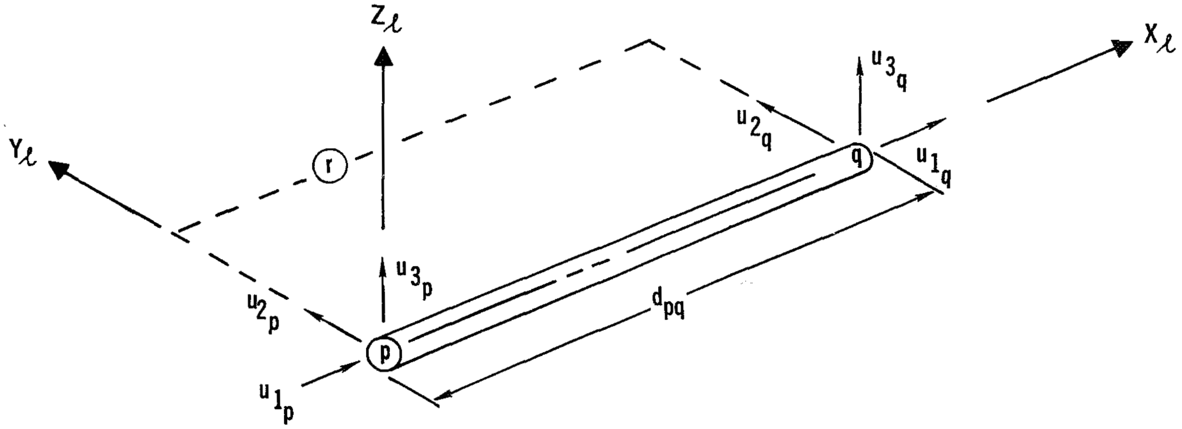
(3) Elastic unloading through points 3, 4, and 5, followed by a continued decrease in stroke until the strut goes into tension. At this point, the strut load is governed by its tension load-stroke characteristics.

If at point 2 the stroke had not reversed direction, the load would remain constant until point 6 was reached. The force would then increase linearly with stroke and continue to follow the load-stroke curve until unloading took place. When the compressive stroke exceeds the maximum allowable stroke (SCMAX) the strut is assumed to have bottomed out.

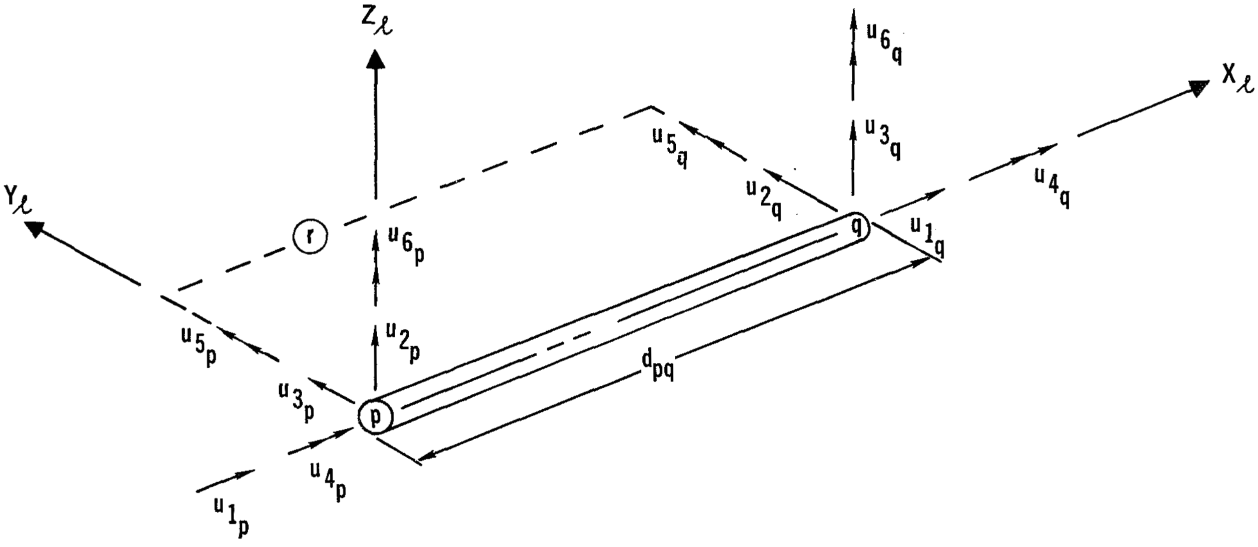
Two options are available for selecting the slope of the strut's elastic unloading characteristic. This slope may be either the slope of the next elastic portion of the load-stroke curve, or it may be some input value. The first option is governed by the assumption that at any point in the stroking of a strut, the elastic slope of the load-stroke curve is determined by the elastic properties of the uncrushed cartridges acting in series. Thus, when a cartridge crushes, its elastic characteristic is no longer reflected in the strut load-stroke curve.

For a bending strut which may or may not contain honeycomb attenuation, the bending properties (modulus of elasticity for bending displacements and the moment of inertia) are assumed to remain constant.

4.1.2.3 Coordinate Systems - Two types of right-hand orthogonal coordinate systems employed in the Landing Gear Option are the Local Coordinate System and the Global Coordinate System. Each axial strut or bending strut of either gear has its set of local coordinates as illustrated in Figure 4-19. The Local Coordinate System origin for each strut is located at node "p," with the X_ℓ axis aligned along the member axis. Positive X_ℓ is on the side of node "p" towards node "q." The Y_ℓ axis is perpendicular to X_ℓ and is located in the "pqr" plane. Positive Y_ℓ is on the side of X_ℓ towards "r." The Z_ℓ axis is then established using the right hand rule. Nodes p, q, and r, which establish each strut's local axis system, were preselected for all struts of the inverted tripod and cantilever gears.



(a) Axial Struts



(b) Bending Struts

FIGURE 4–19 STRUT DISPLACEMENTS IN LOCAL COORDINATE SYSTEM

Unless noted otherwise, in the following the terms "displacement" and "load" refer to incremental displacement or incremental load occurring during a step of the modified incremental stiffness method. The symbol "Δ" signifying an incremental quantity (see Equation (4-27)) is dropped for convenience.

Displacement notation of a typical axial strut capable of carrying axial load only is indicated in Figure 4-19(a) for the Local Coordinate System. Subscript 1 refers to displacement due to axial load while subscripts 2 and 3 are for displacements due to shear loads. Although axial struts can carry axial load only, displacements due to shear loads must be included in large displacement analysis as will be seen in the following sections. Cross-sectional area A, and modulus of elasticity E_A for axial displacements, must be specified for each axial strut relative to its Local Coordinate System. For an axial strut which contains honeycomb attenuation, this information is supplied in the form of the load-stroke curve shown in Figure 4-18.

Displacement notation of a typical bending strut capable of carrying axial load, shear in two directions, and bending in two directions is indicated in Figure 4-19(b) for the Local Coordinate System. Subscript 1 refers to a displacement due to axial load, subscripts 2 and 3 are for displacements due to shear loads, subscript 4 is for rotation due to torque, and subscripts 5 and 6 are for rotations due to moments. Although bending struts are not capable of carrying torsional loads, it is advantageous to include the torsional degrees of freedom since matrix transformation to a common coordinate system will be accomplished later and in this system all nodes will have six degrees of freedom. Cross-sectional area A, and modulus of elasticity E_A for axial displacements, must be specified for each bending strut relative to its Local Coordinate System. For a bending strut which contains honeycomb attenuation, this information is supplied in the form of the load-stroke curve shown in Figure 4-18. Moment of inertia I, and the modulus of elasticity E_B for bending displacements, are specified for each bending strut relative to its Local Coordinate System. The moment of inertia is assumed to be constant about any axis normal to X_ℓ.

Two Global Coordinate Systems employed in the Landing Gear Option are the Lander Coordinate System and the Surface Coordinate System as shown in

Figure 4-20. The origins of these coordinate systems are assumed coincident. Coordinates of all nodes of the gear are input in the Lander Coordinate System.

The Surface Coordinate System must be chosen such that the axis normal to the surface, X_S in Figure 4-20, is pointed outward. Three Euler angles defined as yaw (ψ), pitch (θ), and roll (ϕ), are used to orient the Surface Coordinate System with respect to the Lander Coordinate System. That is, the orientation of the Surface Coordinate System can be found by rotations in the order ψ, θ, and ϕ about the rotated Z_S, Y_S and X_S surface axes, respectively. The transformation matrix $[T_G]$ relating vector components in the Surface Coordinate System (VX_S, VY_S, VZ_S) to vector components in the Lander Coordinate System (VX_L. VY_L, VZ_L) is defined by Equation (4-28).

$$\begin{Bmatrix} VX_S \\ VY_S \\ VZ_S \end{Bmatrix} = [T_G] \begin{Bmatrix} VX_L \\ VY_L \\ VZ_L \end{Bmatrix} \tag{4-28}$$

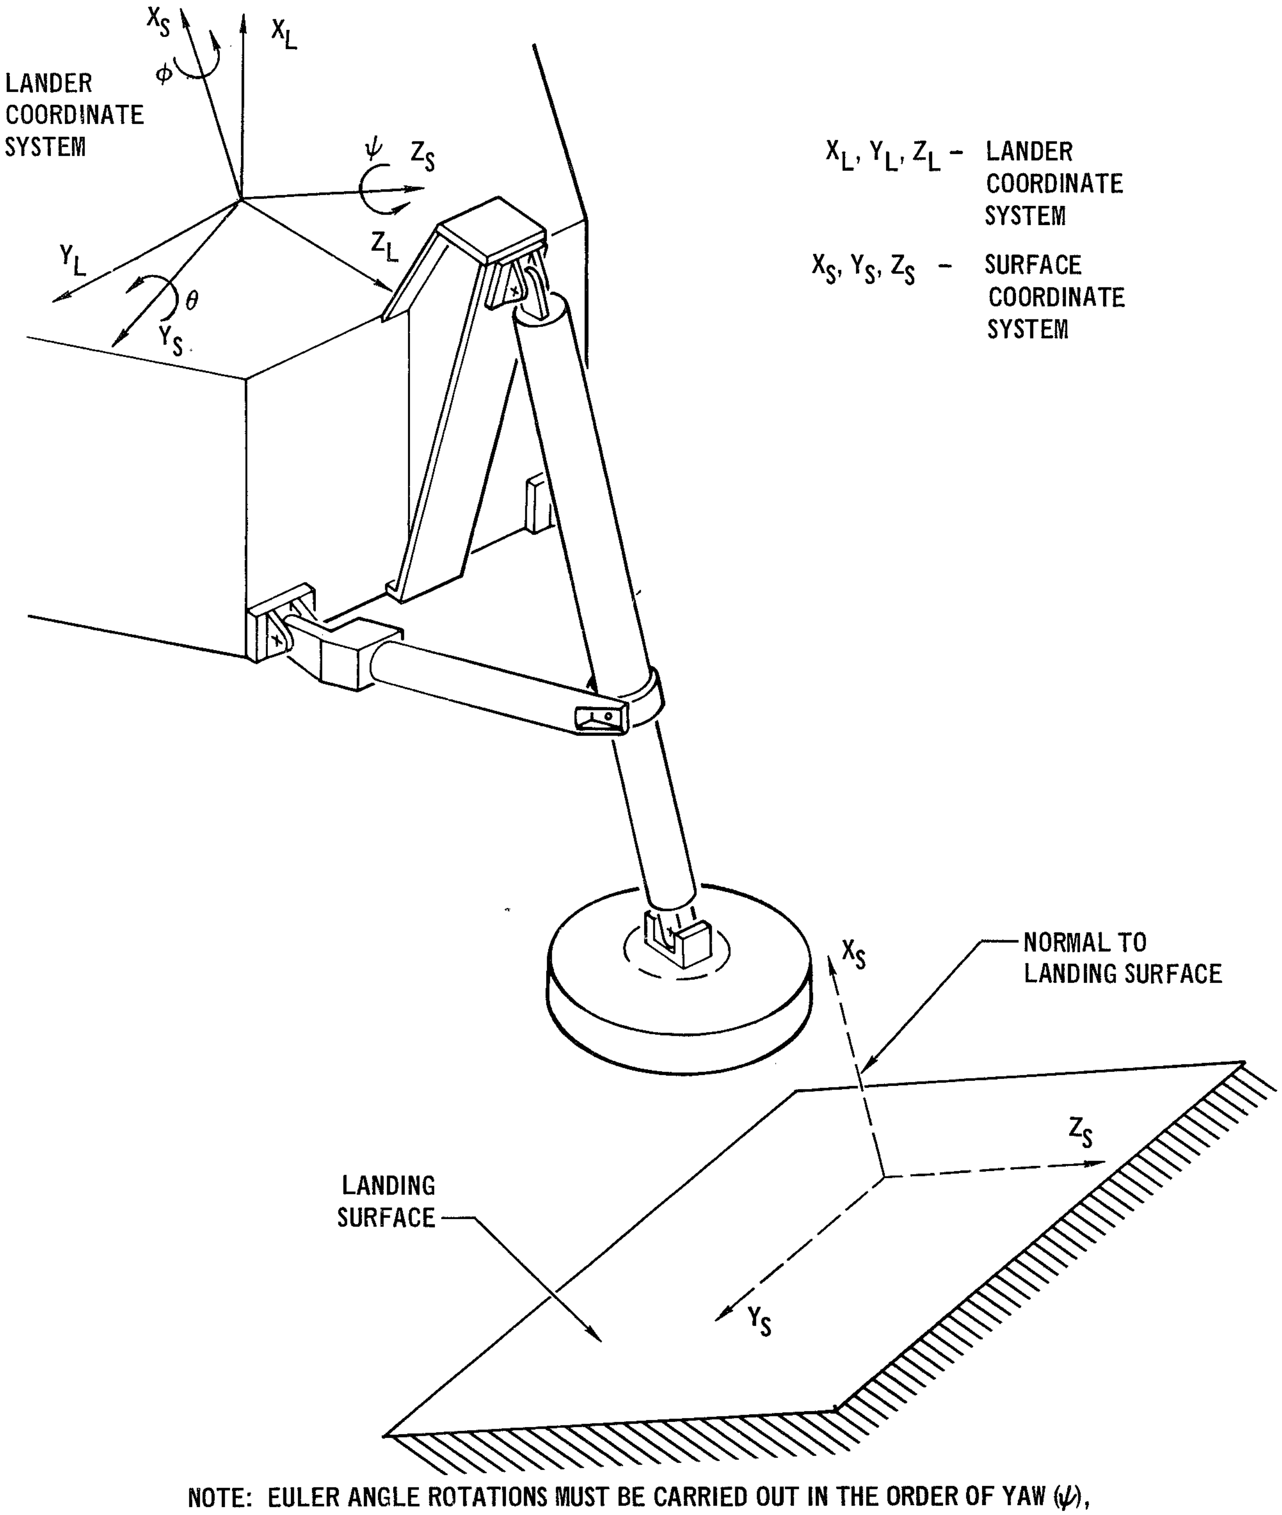
Terms in the transformation matrix $[T_G]$ are defined in Equation (4-29).

$$[T_G] = \begin{bmatrix} D_{11} & D_{12} & D_{13} \\ D_{21} & D_{22} & D_{23} \\ D_{31} & D_{32} & D_{33} \end{bmatrix} \tag{4-29}$$

$$\begin{aligned}
D_{11} &= \text{Cos } \theta \text{ Cos } \psi \\
D_{12} &= \text{Cos } \theta \text{ Sin } \psi \\
D_{13} &= -\text{Sin } \theta \\
D_{21} &= \text{Sin } \phi \text{ Sin } \theta \text{ Cos } \psi - \text{Cos } \phi \text{ Sin } \psi \\
D_{22} &= \text{Sin } \phi \text{ Sin } \theta \text{ Sin } \psi + \text{Cos } \phi \text{ Cos } \psi \\
D_{23} &= \text{Sin } \phi \text{ Cos } \theta \\
D_{31} &= \text{Cos } \phi \text{ Sin } \theta \text{ Cos } \psi + \text{Sin } \phi \text{ Sin } \psi \\
D_{32} &= \text{Cos } \phi \text{ Sin } \theta \text{ Sin } \psi - \text{Sin } \phi \text{ Cos } \psi \\
D_{33} &= \text{Cos } \phi \text{ Cos } \theta
\end{aligned}$$

Coordinates of all node points of the gear are transformed to surface coordinate orientation using Equation (4-28).

The Surface Coordinate System is established as the common system for all elements of a gear so that element total and incremental loads and displacements may be related to a common frame of reference. The term "total",when applied to loads or displacements,refers to the sum of incremental quantities which have occurred during the incremental steps which have been taken to the



NOTE: EULER ANGLE ROTATIONS MUST BE CARRIED OUT IN THE ORDER OF YAW (ψ), PITCH (θ), AND ROLL (ϕ) ABOUT SURFACE COORDINATE AXES.

FIGURE 4-20 LANDING GEAR COORDINATE SYSTEMS current point of interest. Displacement notation for the axial strut and bending strut in the Surface Coordinate System is shown in Figure 4-21. In this figure and in the following discussion, the Surface Coordinate System X_S, Y_S, Z_S will be referred to as $\overline{X}$, $\overline{Y}$, $\overline{Z}$. Footpad loading conditions (see Section 4.1.2.7) are specified in this system. Matrix assembly and solution of equations for each step of the modified incremental stiffness method (see Section 4.1.2.6) are also accomplished in the surface system. That is, external loads and displacements at all nodes of the gear, as well as the total energy absorbed by the gear, are determined in surface coordinate components.

4.1.2.4 Incremental Stiffness Matrix - The incremental stiffness matrix, employed in the modified incremental stiffness method, is generated for both an "axial" strut and "bending" strut in the Local Coordinate System. This stiffness matrix will be shown to be the sum of the standard small displacement stiffness and the large displacement geometric stiffness. The geometric stiffness matrix is derived in Reference (8) using basic nonlinear theory in conjunction with the incremental stiffness method.

For each strut of a landing gear, incremental loads and displacements in the Local Coordinate System are related in matrix form by

$$\Delta\{F_\ell\} = [S_\ell]\,\Delta\{\delta_\ell\} \tag{4-30}$$

In Equation (4-30), $[S_\ell]$ is the incremental stiffness matrix; $\Delta\{F_\ell\}$ is a column matrix of applied incremental loads at the nodes; and $\Delta\{\delta_\ell\}$ is the column matrix of incremental displacements at the nodes. In the following, for convenience, the Δ symbol will be dropped. Accordingly, unless otherwise noted, the terms displacement and load refer to incremental quantities.

A. Axial Struts - As defined in Section 4.1.2.2, all elements of the inverted tripod gear and elements 1 and 3 of the cantilever gear (Figure 4-17(b)) are "axial" struts with load-carrying capability in the axial direction only. Displacement notation in the Local Coordinate System for a typical axial strut was shown in Figure 4-19(a).

The incremental stiffness matrix $[S_\ell]$ of an axial strut (in local coordinates) is the sum of the small displacement stiffness matrix shown in Figure 4-22 and the geometric stiffness matrix shown in Figure 4-23. The small displacement stiffness matrix of an axial strut is equivalent to the stiffness

\end{array}
$$

FIGURE 4–23 GEOMETRIC STIFFNESS MATRIX OF AN AXIAL STRUT matrix of the general bar element in the Center Body Option (see Figure 4-4) with $I_N = I_T = J = 0$ and only the translational degrees of freedom included. In Figure 4-22, A is the cross-sectional area; E_A the modulus of elasticity for axial displacements; and dpq the current length of the strut. For an axial strut composed of honeycomb attenuation, the terms ($A\ E_A$/dpq) in the small displacement stiffness matrix are replaced by the slope of the load-stroke curve (see Figure 4-18) corresponding to the current axial stroke of the strut.

The geometric stiffness matrix, shown in Figure 4-23, includes the effect of "total" internal axial loads on the equilibrium equations in the presence of large rotational displacements. In the stiffness terms, P_o is the total internal axial load in the strut corresponding to the current total axial displacement (stroke) of the strut. Positive values for P_o signify that the strut is in tension.

B. Bending Struts - As defined in Section 4.1.2.2, the main strut of the cantilever gear (elements 2 and 4 in Figure 4-17(b)) is composed of "bending" struts with bending capability as well as axial capability. Displacement notation in the Local Coordinate System for a typical bending strut was shown in Figure 4-19(b).

The incremental stiffness matrix $[S_\ell]$ of a bending strut (in local coordinates) is the sum of the small displacement stiffness matrix shown in Figure 4-24 and the geometric stiffness matrix shown in Figure 4-25. The small displacement stiffness matrix is equivalent to the stiffness matrix of the general bar element in the Center Body Option (see Figure 4-4) with $J = 0$ and $I_N = I_T = I$. In Figure 4-24, A is the cross-sectional area; E_A the modulus of elasticity for axial displacements; E_B the modulus of elasticity for bending displacements; I the moment of inertia about any axis normal to the strut; and dpq the current length of the strut. For a bending strut whose axial capability is defined by honeycomb attenuation, the terms ($A\ E_A$/dpq) in the small displacement stiffness matrix are replaced by the slope of the load-stroke curve (see Figure 4-18) corresponding to the current axial stroke of the strut.

The geometric stiffness matrix, shown in Figure 4-25, includes the effect of total internal axial loads on the equilibrium equations in the presence of large rotational displacements. In Figure 4-25, P_o is the total internal axial load in the strut corresponding to the current total axial displacement (stroke). Positive values for P_o signify tension.

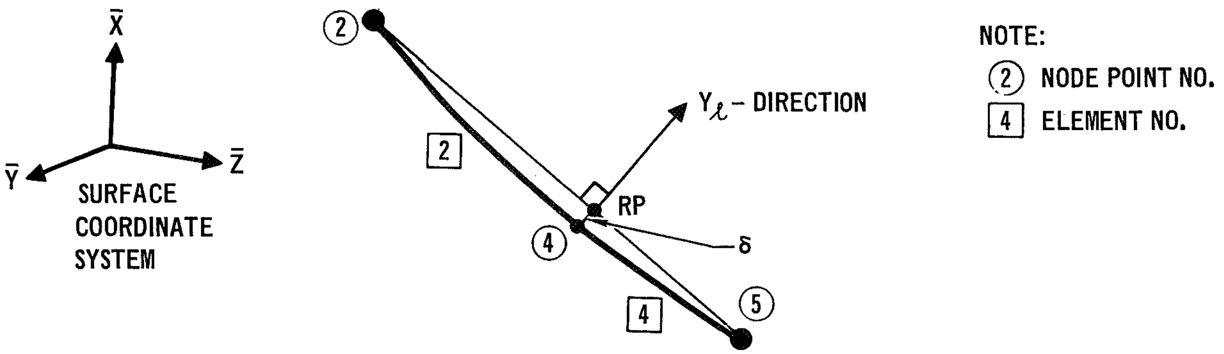
FIGURE 4–25 GEOMETRIC STIFFNESS MATRIX OF A BENDING STRUT

4.1.2.5 Internal Loads - For each iteration at each step of the modified incremental stiffness method, the total internal loads in each strut must be determined for the current displaced state of the strut. The total internal loads must be calculated so that load unbalances can be determined (see Section 4.1.2.1).

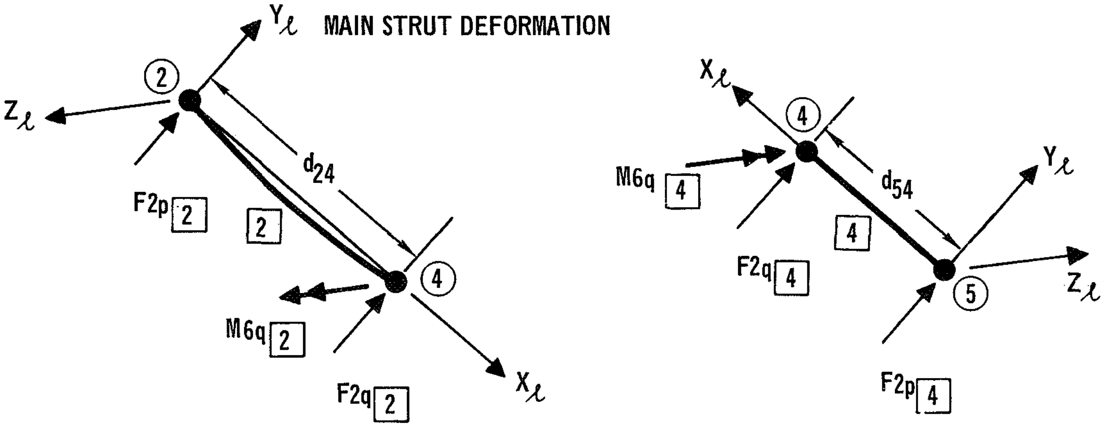
For axial struts, the total internal loads are simply the axial tension or compression forces which would have to be applied to the ends of the strut to extend or compress it to its present state. The extension or compression of a strut (the stroke) is the difference between the current length and the original length. Total axial force is the product of stroke and the small displacement stiffness term ($A\ E_A/dpq$) defined in Section 4.1.2.4. A positive stroke corresponds to extension of the strut and yields a positive (tensile) total axial force. For an axial strut composed of honeycomb attenuation, the total axial force is determined by the load-stroke curve (see Figure 4-18).

The total internal loads for bending struts consist of axial forces, shear forces, and bending moments. The axial forces are calculated in the same way as for axial struts. Calculation of bending loads (shear forces and bending moments) in the deflected main strut of the cantilever gear (elements 2 and 4 in Figure 4-17) is shown in Figure 4-26. Because the main strut is pinned at both ends, loads causing bending are shear loads ($F2p_{\boxed{2}}$ and $F2p_{\boxed{4}}$) applied at the ends in the plane of the deformed strut and directed along the Y_ℓ axis. The Y_ℓ direction is defined by a line passing through node 4 perpendicular to the line connecting nodes 2 and 5 and intersecting it at reference point RP. Since there is bending continuity at node 4, internal loads in elements 2 and 4 are shears ($F2q_{\boxed{2}}$ and $F2q_{\boxed{4}}$) and equal bending moments ($M6q_{\boxed{2}}$ and $M6q_{\boxed{4}}$). Coordinates of the floating reference point (RP) for elements 2 and 4 are also calculated in Figure 4-26.

4.1.2.6 Matrix Assembly and Solution of Equations - As explained in Section 4.1.2.3, the Surface Coordinate System is used for all elements of a gear to relate total and incremental loads and displacements to a common frame of reference. For each element of the gear, the incremental stiffness matrix is transformed from Local to Surface Coordinate System as described in Section 4.1.1.2.



MAIN STRUT DEFORMATION



INTERNAL LOADS IN ELEMENTS 2 AND 4

DEFINITIONS:

$a = \bar{X}_5 - \bar{X}_2$

$b = \bar{Y}_5 - \bar{Y}_2$

$c = \bar{Z}_5 - \bar{Z}_2$

$e = \bar{X}_5 - \bar{X}_4$

$f = \bar{Y}_5 - \bar{Y}_4$

$g = \bar{Z}_5 - \bar{Z}_4$

$d_{25} = d_{24} + d_{54}$

E_{B2} = BENDING MODULUS OF ELASTICITY (ELEMENT 2)

E_{B4} = BENDING MODULUS OF ELASTICITY (ELEMENT 4)

I_2 = MOMENT OF INERTIA (ELEMENT 2)

I_4 = MOMENT OF INERTIA (ELEMENT 4)

$$\delta = \frac{1}{d_{25}} \sqrt{(bg - cf)^2 + (ce - ag)^2 + (af - be)^2}$$

$$T = \frac{\delta}{\left[\dfrac{(d_{24})^3 d_{54}}{3} - \dfrac{(d_{24})^4 d_{54}}{3\,d_{25}}\right] / E_{B_2} I_2 + \left[\dfrac{(d_{24})^2 (d_{25})^2}{3} - (d_{24})^3 d_{25} + (d_{24})^4 - \dfrac{(d_{24})^5}{3\,d_{25}}\right] / E_{B_4} I_4}$$

REFERENCE POINT COORDINATES:

$\bar{X}_{RP} = \bar{X}_4 + (c^2e - acg - abf + b^2e)/(d_{25})^2$

$\bar{Y}_{RP} = \bar{Y}_4 + (a^2f - abe - bcg + c^2f)/(d_{25})^2$

$\bar{Z}_{RP} = \bar{Z}_4 + (b^2g - bcf - ace + a^2g)/(d_{25})^2$

TOTAL INTERNAL LOADS:

$F2p_{\boxed{2}} = d_{54}\,T = -F2q_{\boxed{2}}$

$F2p_{\boxed{4}} = d_{24}\,T = -F2q_{\boxed{4}}$

$M6q_{\boxed{2}} = M6q_{\boxed{4}} = d_{24}\,d_{54}\,T$

FIGURE 4-26 INTERNAL BENDING LOADS IN MAIN STRUT OF CANTILEVER GEAR

Before matrix assembly can be accomplished, the incremental stiffness matrix in the Surface Coordinate System for all elements of the gear must be of the same order. All elements of the inverted tripod gear are axial struts and hence have incremental stiffness matrices of the same order. For the cantilever gear, the incremental stiffness matrices of the axial struts (elements 1 and 3 in Figure 4-17) must be expanded to the row and column format of the bending strut stiffness matrices of elements 2 and 4. This is accomplished by adding rows and columns of zeros corresponding to the six rotational degrees of freedom.

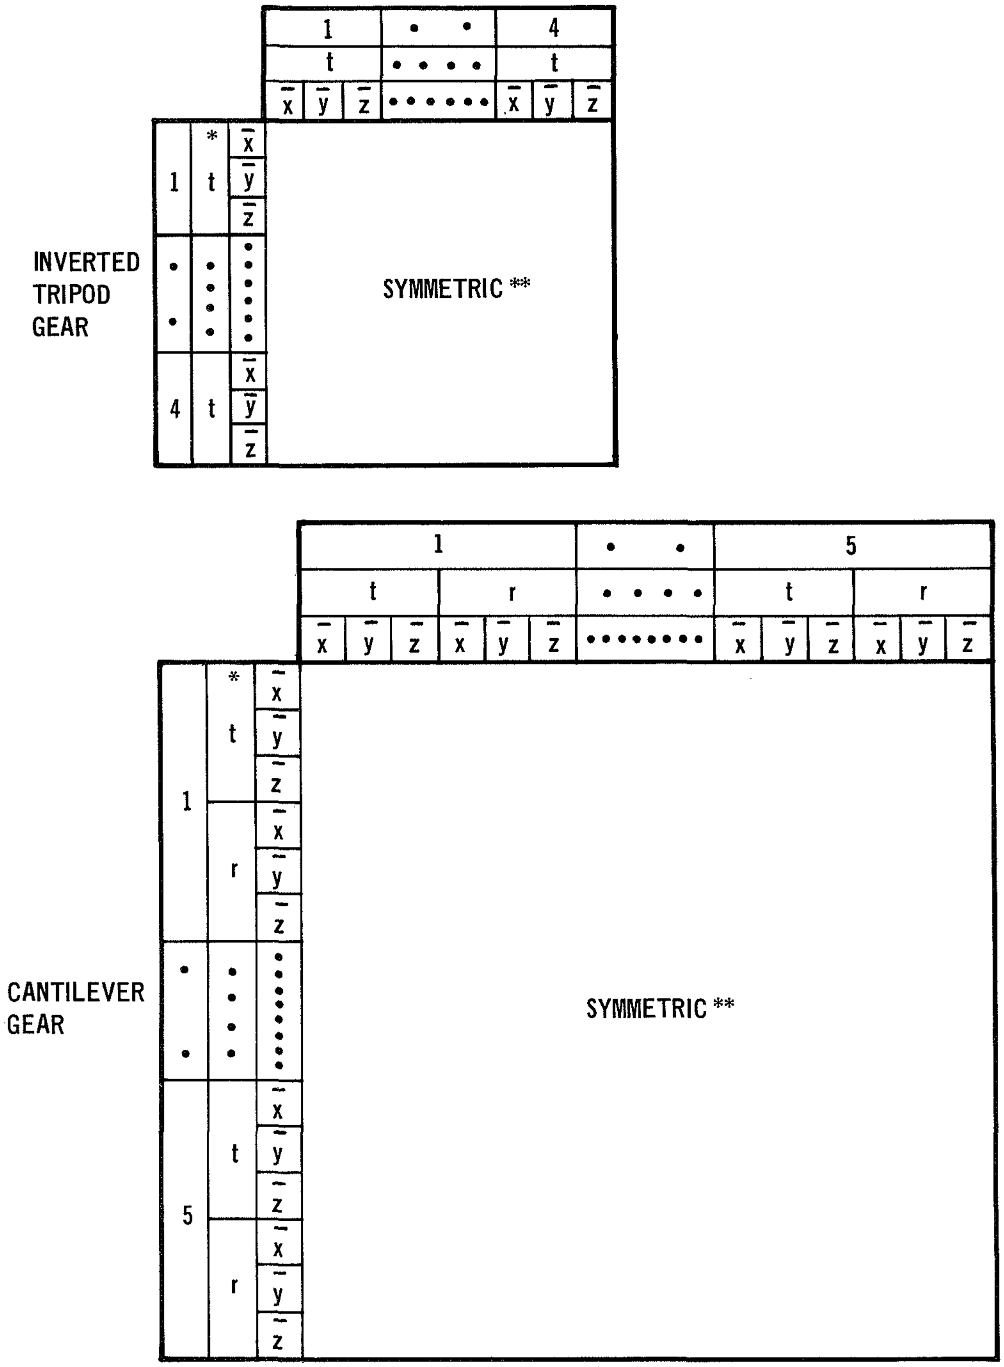
The total incremental stiffness matrix $[\overline{S}]$ (in the Surface Coordinate System) for the assembled gear is generated by systematically adding the transformed element stiffness matrices (according to the p and q nodes of the element) as shown in Figure 4-27. Node points on the inverted tripod gear are numbered consecutively from 1 to 4 (see Figure 4-17). The incremental stiffness matrix $[\overline{S}]$ of this gear is assembled with a row and column format corresponding to the three translational degrees of freedom in the Surface Coordinate System at each node in sequence. In this case, the size of the stiffness matrix is 12 by 12. For the cantilever gear, node points are numbered consecutively from 1 to 5. The incremental stiffness matrix $[\overline{S}]$ of this gear is assembled with a row and column format corresponding to the three translational followed by the three rotational degrees of freedom in the Surface Coordinate System at each node in sequence. In this case,the size of the stiffness matrix is 30 by 30.

The assembled incremental stiffness matrix $[\overline{S}]$ is related to the column matrices of incremental surface coordinate loads and displacements at each node by Equation (4-31).

$$\Delta\{\overline{F}\} = [\overline{S}]\ \Delta\{\overline{\delta}\} \tag{4-31}$$

For the fixed idealization of the inverted tripod gear (see Figure 4-17), nodes 1, 2, and 3 are pinned and thus have zero translational displacements. Since only translational displacements are included in the stiffness formulation for this gear, the degrees of freedom of interest are the translations of node 4. Therefore, for the inverted tripod, Equation (4-31) reduces to

$$\Delta\{\overline{F}'\} = [\overline{S}']\ \Delta\{\overline{\delta}'\} \tag{4-32}$$



* SYMBOLS t AND r INDICATE TRANSLATIONAL AND ROTATIONAL INCREMENTAL DISPLACEMENTS, RESPECTIVELY.

** TERMS IN THE MATRICES OF INDIVIDUAL ELEMENT INCREMENTAL STIFFNESSES IN THE SURFACE COORDINATE SYSTEM ARE SUCCESSIVELY ADDED INTO THE APPROPRIATE LOCATIONS IN THE FRAMEWORK OF THIS MATRIX.

FIGURE 4–27 ASSEMBLED INCREMENTAL STIFFNESS MATRIX FORMAT

In this equation, $\Delta\{\overline{F}'\}$ is a column matrix of three incremental force components at node 4; $\Delta\{\overline{\delta}'\}$ a column matrix of three incremental translations at node 4; and $[\overline{S}']$ a 3 by 3 matrix of stiffness terms, extracted from $[\overline{S}]$, corresponding to the degrees of freedom retained at node 4.

For the fixed idealization of the cantilever gear (see Figure 4-17), nodes 1, 2, and 3 are pinned and hence have zero translational displacements. Accordingly, equations associated with the 3 translational degrees of freedom at each of these nodes are not of interest. Elements 1 and 3 have zero bending capability. Therefore, the six equations associated with the rotational degrees of freedom at nodes 1 and 3 are not of interest. The remaining degrees of freedom for a cantilever gear are three rotations at node 2, three translations and three rotations at node 4, and three translations and three rotations at node 5. Thus, for the cantilever gear Equation (4-31) reduces to

$$\Delta\{\overline{F}''\} = [\overline{S}''] \, \Delta\{\overline{\delta}''\} \qquad (4\text{-}33)$$

In Equation (4-33), $\Delta\{\overline{F}''\}$ is a column matrix containing three incremental moment components at node 2, three incremental force components and three incremental moment components at node 4, and three incremental force components and three incremental moment components at node 5; $\Delta\{\overline{\delta}''\}$ a column matrix of the fifteen incremental displacements described above; and $[\overline{S}'']$ a 15 by 15 matrix of stiffness terms, extracted from $[\overline{S}]$, corresponding to the 15 degrees of freedom retained.

Equation (4-32) or (4-33) is solved repeatedly at each step of the modified incremental stiffness method (see Section 4.1.2.1). A least squares solution technique is programmed for solution of these equations. The independent variables for each of these solutions are discussed in Section 4.1.2.7. After the incremental nodal displacements have been determined, the updated nodal locations can be found as the sum of the previous nodal coordinates and the incremental nodal displacements. For the updated nodal locations, the total internal loads can then be determined as described in Section 4.1.2.5.

4.1.2.7 Applied Displacement Options - For each step of the modified incremental stiffness method, the governing matrix equation, Equation (4-32) for an inverted tripod gear or Equation (4-33) for a cantilever gear, is solved as outlined below. Both of these equations are analogous to Equation

(4-27) and the solution technique is the same as discussed in Section 4.1.2.1.

(i) Equation (4-32) (or Equation (4-33)) is solved once for the case where $\Delta\{\bar{\delta}'\}$ (or $\Delta\{\bar{\delta}''\}$), the total applied displacement vector divided by the number of incremental steps, is the (known) independent variable.

(ii) Equation (4-32) (or Equation (4-33)) is solved repeatedly for the case where $\Delta\{\bar{F}'\}$ (or $\Delta\{\bar{F}''\}$), the load unbalance vector, is the (known) independent variable. The load unbalance vector is calculated as the difference between applied external nodal loads and total internal nodal loads. Calculation of internal loads is described in Section 4.1.2.5.

Two options are available for specifying the total applied displacement vector discussed in (i) above. In the first option, total displacement of the footpad joint (node 4 for the inverted tripod gear and node 5 for cantilever gear) normal to a landing surface, and the coefficient of friction of the surface are specified. For example, suppose it is desired to investigate the displaced state of the gear at each of N steps for an applied normal displacement value of D units. For this case, the program determines N equilibrium configurations for the gear. For each of these configurations, the footpad joint is located in one of N different planes spaced D/N units apart. Whether the footpad slides on the landing surface as the footpad joint is displaced from the (n-1)st plane to the nth plane (n = 1, ..., N) depends on the friction coefficient. As explained in Section 4.1.2.3, the landing surface can be arbitrarily oriented with respect to the Lander Coordinate System.

In the second option available for specifying the applied displacement vector, three components of footpad joint displacement are specified in the Surface Coordinate System ($\bar{X}$, $\bar{Y}$, $\bar{Z}$). For example, if it is desired to investigate the displaced state of the gear at each of N steps when the applied footpad joint displacement components are $\bar{X}_f$, $\bar{Y}_f$, and $\bar{Z}_f$, the program determines N equilibrium configurations for the gear. In each of these configurations, the footpad joint is located at one of the positions $(\bar{X}_o + n\,\bar{X}_f/N,\ \bar{Y}_o + n\,\bar{Y}_f/N,\ \bar{Z}_o + n\,\bar{Z}_f/N)$ where n = 1, ..., N. The original position of the footpad joint (see Figure 4-17) is assumed to be ($\bar{X}_o$, $\bar{Y}_o$, $\bar{Z}_o$).

4.1.2.8 Energy Absorption - For each step of the landing gear displacement history, energy absorbed by the gear during the step is calculated in both Surface and Lander Coordinate System components.

Although an element representing the footpad is not included in the landing gear idealization, energy associated with crushing of footpad honeycomb can be included in the analysis. Footpad honeycomb attenuation is idealized with up to three levels of crushing in compression as shown in Figure 4-28.

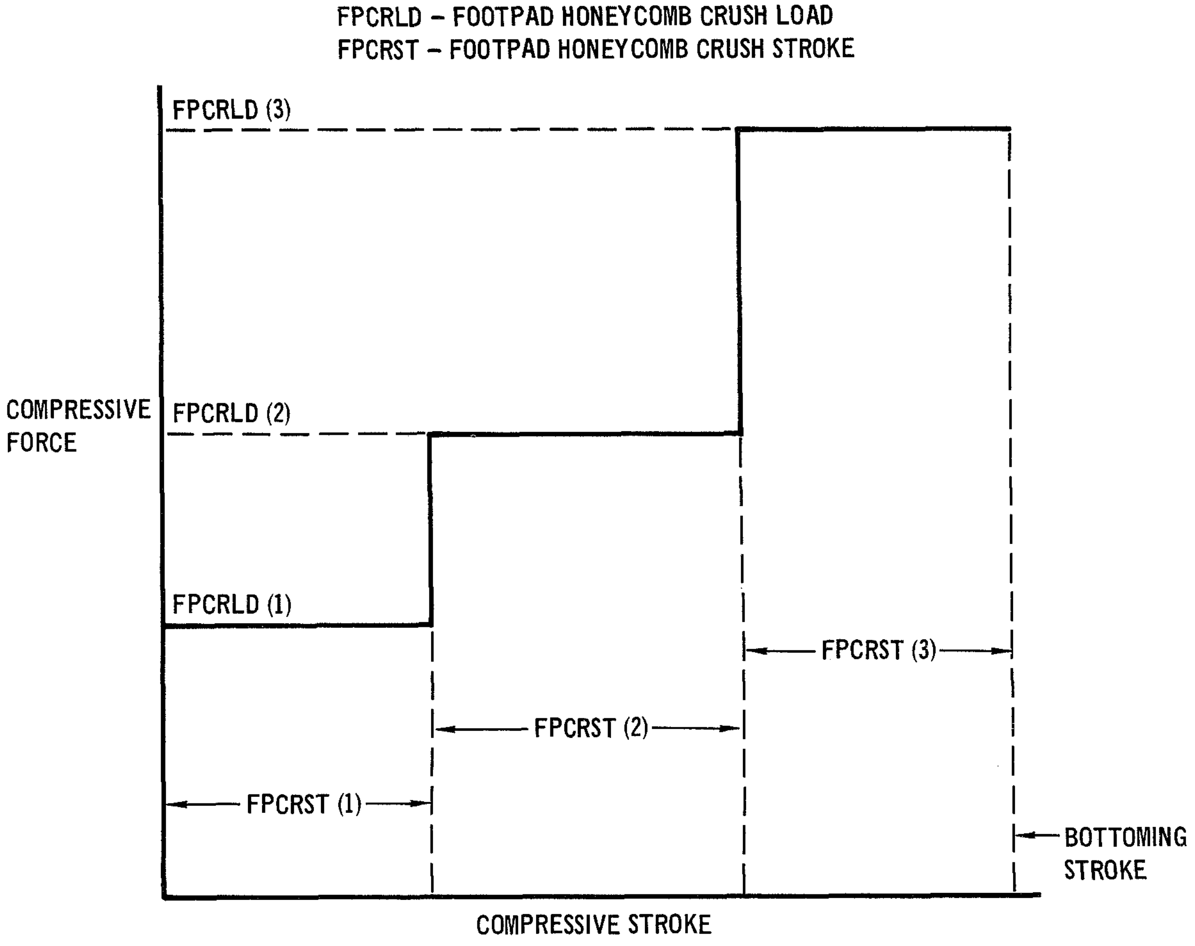


FIGURE 4-28 ASSUMED LOAD-STROKE CURVE FOR FOOTPAD HONEYCOMB

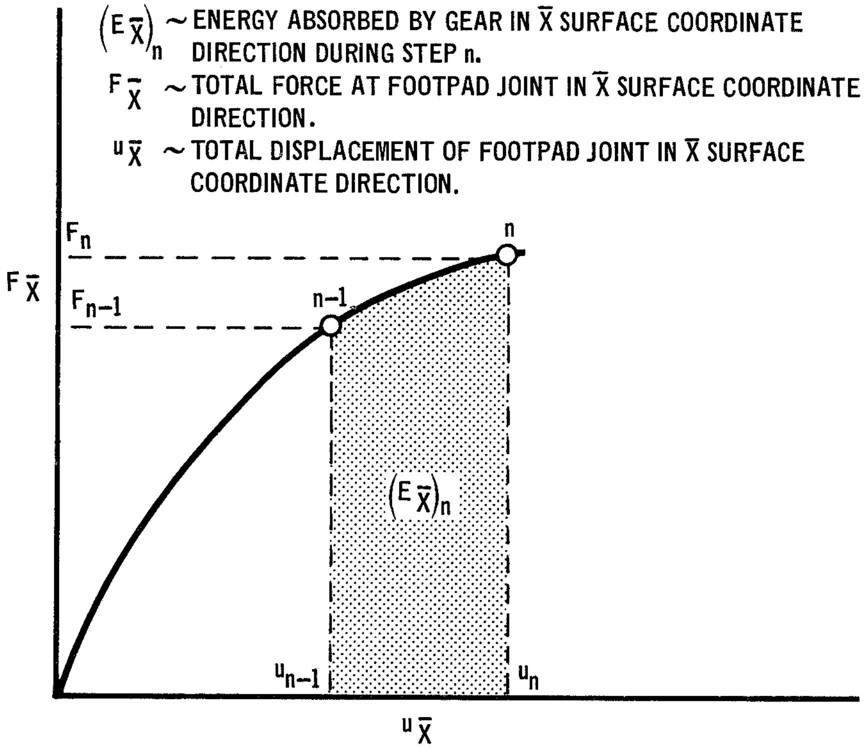
Each surface coordinate energy component absorbed at the footpad joint during a step is the sum of strut crush energy and footpad crush energy. Strut crush energy in a given surface coordinate direction is calculated as the product of the average force component (in that direction) over the step and the incremental displacement component (in the same direction) which occurred during the step. Figure 4-29 presents an example calculation of strut crush energy component absorbed in the $\overline{X}$ surface coordinate direction during the n^{th} incremental step. For a gear which has footpad attenuation with up to three levels of crush force, footpad crush energy may be added into the surface coordinate energy component in the direction normal to the landing surface. For a given incremental step, footpad crush energy is added into this energy component if the force component in the normal direction (see Figure 4-20) at the footpad joint exceeds one of the footpad honeycomb crush forces (Figure 4-28) for the first time. When this occurs, the associated level of honeycomb crush is assumed to have bottomed out during the step. Footpad crush energy component associated with this crushing is the product of crush load (FPCRLD) and the crush stroke (FPCRST). For example, the surface coordinate direction normal to the landing surface is $\overline{X}$ (Figure 4-20). If during incremental step n, the force in the $\overline{X}$ direction at the footpad joint exceeds the first crush force FPCRLD(1) in Figure 4-28, and this has not occurred for any previous step, the energy term FPCRLD(1) times FPCRST(1) will be added to the $\overline{X}$ strut crush energy component for this step.

Components of energy absorption during a given incremental step are obtained similarly in Lander Coordinate System components. In both coordinate systems, total energy absorption components are determined after n incremental steps as the sum of the energy components obtained in each of the n steps taken.

4.2 Program Description - Organization of the Structural Analysis Program is described in this section. Included are flow diagrams and discussions of subroutine functions for both the Center Body Option and Landing Gear Option.

4.2.1 Subroutines - The Structural Analysis Program is divided into nine Fortran OVERLAY segments. OVERLAY organization and description of the function of each subroutine are shown in Figure 4-30. This organization is required to stay within the allotted core storage requirements. The main OVERLAY (0, 0) acts as the principal executive routine and determines the order in which primary OVERLAYs (1, 0) through (5, 0) are called. OVERLAY (1, 0) processes the data set header cards and handles the data sets and initialization relating to the Center Body Option. OVERLAY (2, 0) generates the total stiffness matrix for the Center Body Option. OVERLAY (3, 0) determines the displacements and rotations for the Center Body Option and prints the results. The modal analysis portion of the Center Body Option is handled in OVERLAY (4, 0). OVERLAY (5, 0) contains the routines for the Landing Gear Option and has three supporting secondary overlays; OVERLAY (5, 1) which reads the landing gear data cases, OVERLAY (5, 2) which contains the executive routine for the inverted tripod gear, and OVERLAY (5, 3) which contains the executive routine for the cantilever gear.



FOR STEP n:

$(E_{\bar{X}})_n$ = AREA UNDER CURVE BETWEEN POINTS n-1 AND n

$$= \frac{(F_n + F_{n-1})}{2} (u_n - u_{n-1})$$

FIGURE 4-29 EXAMPLE CALCULATION OF STRUT CRUSH ENERGY

OVERLAY	SUBROUTINE	FUNCTION
(0, 0)	MAIN	PROGRAM EXECUTIVE ROUTINE
	ERPNT1	ERROR PROCESSING ROUTINE FOR ALL OVERLAYS
	ERPNT2	SECOND ENTRY POINT TO ERPNT1
	WRSTRK	SPARSE MATRIX PRINT ROUTINE
(1, 0)	INITAL	EXECUTIVE ROUTINE
	DATSET	HEADER CARD PROCESSOR AND CENTER BODY OPTION DATA CASE READER
	RDDATA	CENTER BODY OPTION DATA CASE PROCESSOR
	SHRPAN	CONVERT SHEAR PANELS TO EQUIVALENT DIAGONAL BAR ELEMENTS
	CROSSX	CALCULATE THE CROSS PRODUCT OR DOT PRODUCT OF TWO VECTORS
(2, 0)	STIFF	EXECUTIVE ROUTINE
	SETSTF	INITIALIZE STRUCTURAL STIFFNESS MATRIX STORAGE ARRAY IN A SPARSE BLOCKED FORMAT
	STFTRN	CALCULATE ELEMENT STIFFNESS AND TRANSFORMATION MATRICES
	STORSM	CONSTRUCT ASSEMBLED STIFFNESS MATRIX
	TRASMK	TRANSFORM ELEMENT STIFFNESS MATRICES FROM LOCAL TO GLOBAL COORDINATE SYSTEM
	WRBDAT	PRINT ELEMENT STIFFNESS AND TRANSFORMATION MATRICES
	BRSTRA	SECOND ENTRY POINT TO WRBDAT, PRINTS TRANSFORMED ELEMENT STIFFNESS MATRICES
	WRSTDK	WRITE ELEMENT STIFFNESS AND TRANSFORMATION MATRICES ON FILE 2
(3, 0)	FINIAL	EXECUTIVE ROUTINE
	PANDTK	PRINT AND STORE ON FILE 9 THE ASSEMBLED STIFFNESS MATRIX SET-UP FOR SOLUTION
	SOLVE	DISPLACEMENTS AND ROTATIONS DETERMINED USING ITERATIVE METHOD. GLOBAL FORCES AND MOMENTS ON JOINTS CALCULATED
	PNTFMV	PRINT DISPLACEMENTS, ROTATIONS, AND GLOBAL FORCES AND MOMENTS
	FMBARS	ELEMENT BAR FORCES AND MOMENTS CALCULATED USING RESULTS OF SOLVE
(4, 0)	NLMDAL	EXECUTIVE ROUTINE
	PUNPACK	DATA HANDLING ROUTINE FOR SUBROUTINE REDUCE
	REDUCE	PRINT ASSEMBLED STIFFNESS MATRIX AND REDUCE TO DESIRED SIZE (REDUCED MATRIX 102 x 102 OR LESS)
	STFMAS	CREATES MATRIX SYSTEM, USING INPUT DIAGONAL MASS MATRIX AND REDUCED STIFFNESS MATRIX, FOR WHICH EIGENVALUES CAN BE FOUND
	FNALEV	EIGENVECTORS OF REDUCED SYSTEM TRANSFORMED INTO EIGENVECTORS OF FULL SYSTEM
	EEPNT	WRITE EIGENVALUES AND EIGENVECTORS
	TRIDIA	MATRIX SYSTEM IS TRI-DIAGONALIZED USING HOUSEHOLDER'S METHOD
	EIGVAL	SPECIFIED NUMBER OF SMALLEST EIGENVALUES OF MATRIX SYSTEM ARE CALCULATED USING ORTEGA'S METHOD (PLUS SIX RIGID BODY NATURAL FREQUENCIES OF ZERO)

	PRNT1	MODAL DATA OUTPUT ROUTINE FOR REDUCED SYSTEM
	PRNT2	SECOND ENTRY POINT OF PRNT1 TO OUTPUT MODAL DATA OF FULL SYSTEM
	P1A721	PRINT SUPPORT ROUTINE FOR PRNT1 AND PRNT2
(5, 0)	GEAREX	EXECUTIVE ROUTINE
	OUTPUT	LANDING GEAR OPTION OUTPUT
	ENERGY	COMPUTE AND SUM ENERGY QUANTITIES
	TRNFSM	TRANSFORM ELEMENT STIFFNESS MATRIX
	TRALMG	TRANSFORM FORCE-MOMENTS FROM LOCAL TO GLOBAL COORDINATES
	STFMIT	COMPUTE NON-BENDING ELEMENT STIFFNESS MATRIX
	TRANSM	COMPUTE ELEMENT LENGTH AND TRANSFORMATION MATRIX
	DMFSS	DETERMINE THE RANK OF A SYMMETRIC POSITIVE SEMI-DEFINITE MATRIX
	DMLSS	CALCULATE THE LEAST SQUARES SOLUTION OF A SYSTEM OF SIMULTANEOUS EQUATIONS WITH SYMMETRIC POSITIVE SEMI-DEFINITE COEFFICIENT MATRIX WHOSE RANK IS KNOWN
	STRUT	COMPUTE ELEMENT AXIAL LOAD AND STIFFNESS
(5, 1)	INPUT	READ LANDING GEAR OPTION DATA CASES
	GEOM	COMPUTE LANDER COORDINATE TO SURFACE COORDINATE TRANSFORMATION MATRIX FROM EULER ANGLES
(5, 2)	INVTRP	EXECUTE INVERTED TRIPOD DATA COMMANDS
(5, 3)	CANTIL	EXECUTE CANTILEVER DATA COMMANDS
	BNDLDS	COMPUTE BENDING LOADS FOR CANTILEVER GEAR
	STFMCF	COMPUTE BENDING ELEMENT STIFFNESS MATRIX

FIGURE 4–30 STRUCTURAL ANALYSIS PROGRAM SUBROUTINES

4.2.2 Flow Diagram - The Structural Analysis Program is shown schematically in Figure 4-31. While detailed steps, such as those required in the iteration loop of the Center Body Option, are not presented, the basic sequence of events is shown for both options of the program. A listing of the program is given in Appendix H.

4.3 Program Operation - Information necessary to operate both options of the Structural Analysis Program is contained in this section.

4.3.1 Center Body Option - This section includes definition of input requirements and format, and output interpretation for the Center Body Option of the program. Examples of input and output data for a typical problem are contained in Appendices A and B.

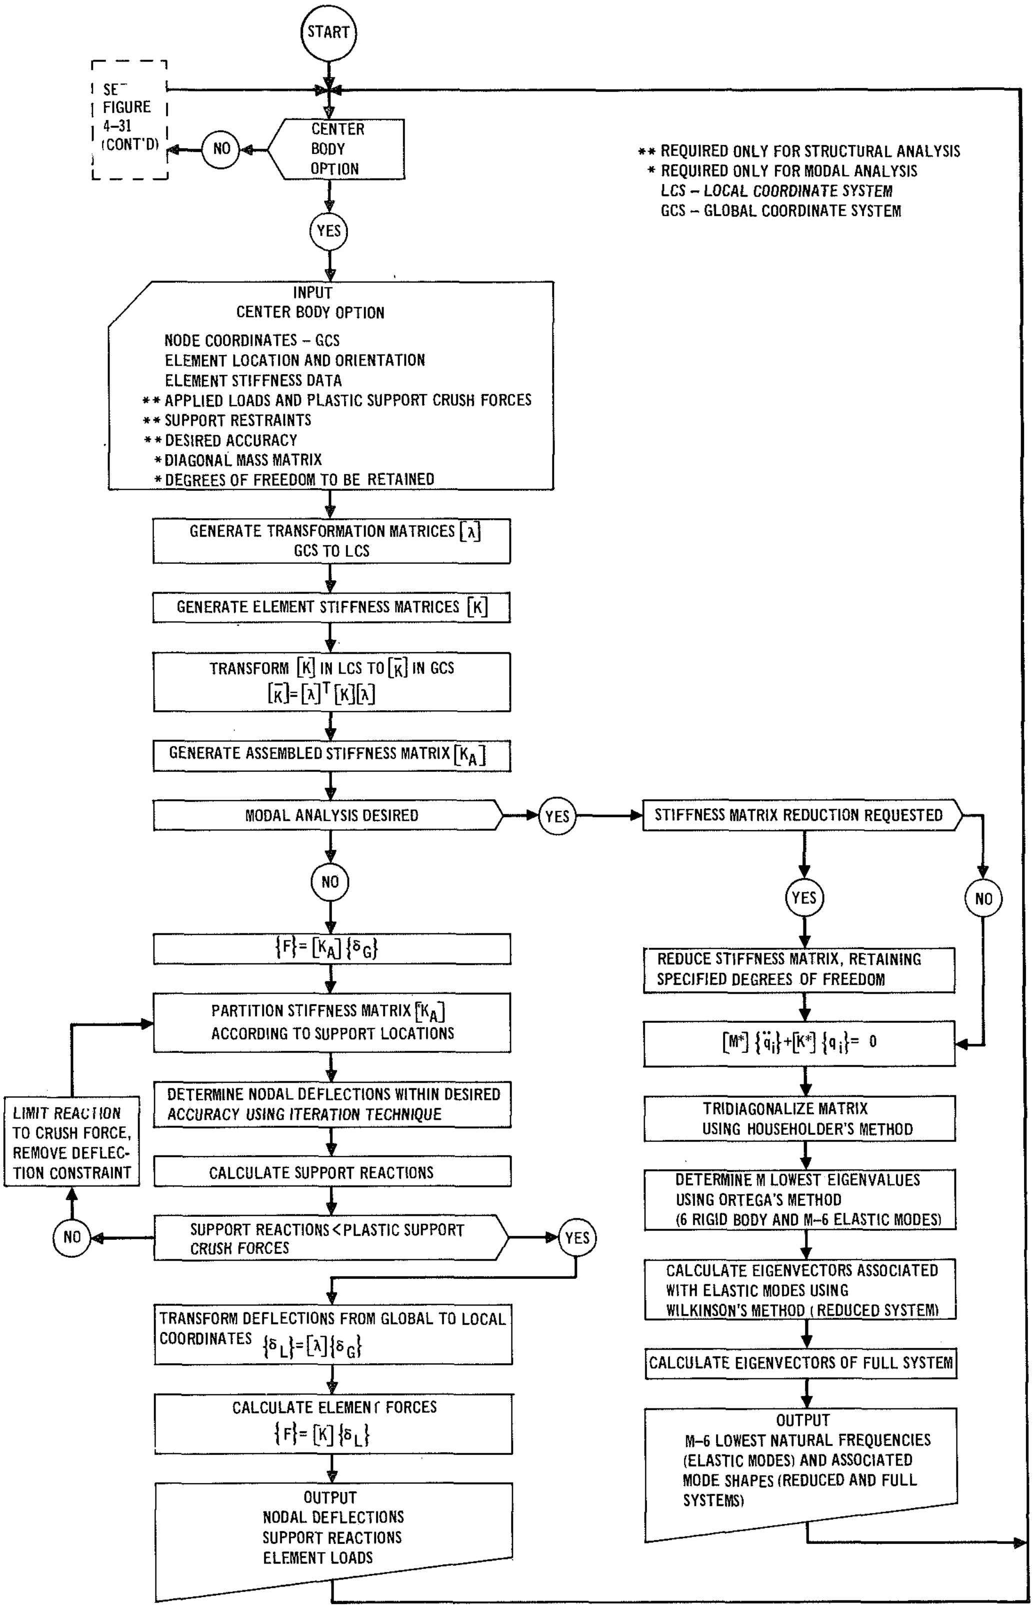
4.3.1.1 Input Data - For each Center Body Option data set, a data case header card and information describing geometry, supports, applied loads and displacements, member properties, and indicators needed to control program operation are required as input data. Multiple data cases may be run by stacking data sets. Each data set must consist of the following:

Header Card
Data Cards
Data Option Indicator (NAMELIST) Card(s)

A. Header Card - The first card of a data set must be a header card. This card indicates that the Center Body Option will be employed and must contain the characters STRUCTURE in columns 1 through 9 as indicated in Figure 4-32.

B. Data Cards - The input format for data cards employs a system of code numbers, located in column 1, to identify the type of data being read. The nine code numbers and corresponding type of information being input are as follows:

(0) Comment cards
(1) Joint information cards
(2) Reference point information cards
(3) Force and moment limits or specified displacement and rotation cards
(4) Specified force vector cards
(5) Specified moment vector cards
(6) Bar information cards
(7) Rectangular shear web information cards
(8) Data terminator card



** REQUIRED ONLY FOR STRUCTURAL ANALYSIS
* REQUIRED ONLY FOR MODAL ANALYSIS
LCS – LOCAL COORDINATE SYSTEM
GCS – GLOBAL COORDINATE SYSTEM

FIGURE 4–31 FLOW DIAGRAM STRUCTURAL ANALYSIS PROGRAM

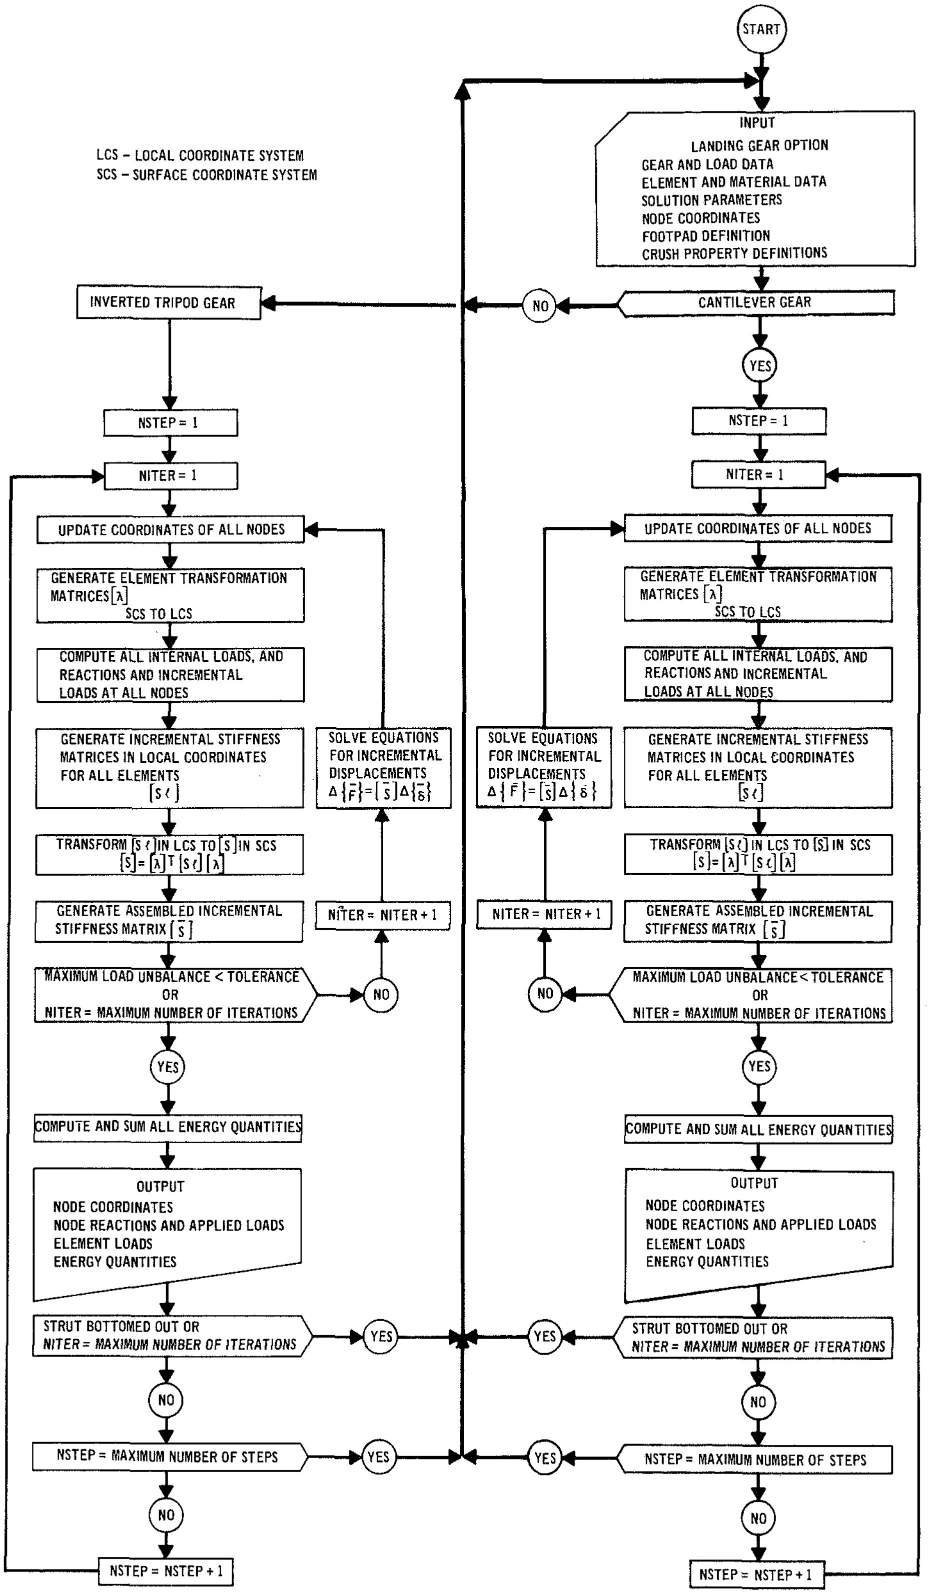


FIGURE 4–31 FLOW DIAGRAM STRUCTURAL ANALYSIS PROGRAM (Continued)

B.0 Comment Cards - As many comment cards as desired may be input by leaving columns 1 through 6 blank and entering the comments in columns 7 through 80. These comment cards may be located anywhere within the data cards as long as they precede the data terminator.

B.1 Joint Information Cards - Joint information is input on data cards in which a 1 is placed in column 1. Location of joint data in the fields of the card is indicated in Figure 4-32. Joints must be numbered sequentially (right-justified in columns 2 through 5) from 1 through the total number of joints (maximum of 74). The global coordinates, $\overline{X}$, $\overline{Y}$, and $\overline{Z}$, may be any right hand orthogonal coordinate system (see Figure 4-2). If the structure is planar, it will be simpler to choose a Global Coordinate System such that two of the axes lie in the plane of the structure. Advantage should be taken of any structural symmetry which may exist in selecting global axes.

Six data fields located between columns 36 and 53 are used to indicate various constraints at a particular joint. These constraints may be combinations of specified displacements (global deflections and/or rotations) and limits on reaction loads (global forces and/or moments) at a joint. Leaving these columns blank causes the program to assume that there are no displacement constraints at a joint; however, there are applied loads at the joint. These applied loads are discussed in the next paragraph. Constraints are defined by inserting nonzero integer identifying indicators (right-justified) in the fields of this region. The absolute value of these identifying indicators corresponds to the limit number on the code 3 data card defining the magnitudes of the particular constraint. When positive identifying indicators are used, the program assumes that upper and lower plastic limits are placed on the appropriate loads at a support and that the corresponding displacement or rotation is zero as defined on the related code 3 data card. For negative identifying indicators, the program assumes that no restraints are placed on the loads, but the displacements are specified on the related code 3 data card. The same code 3 data card may be used to define identical constraints at a number of joints. The maximum number of plastic loads and specified displacements is 88.

Applied forces are indicated by placing a separate set of integer identifying indicators in columns 54 through 57 (right-justified). The program looks for the three global components of force on cards with code number 4 in

(Header Card and Card Codes 0, 1, and 2)

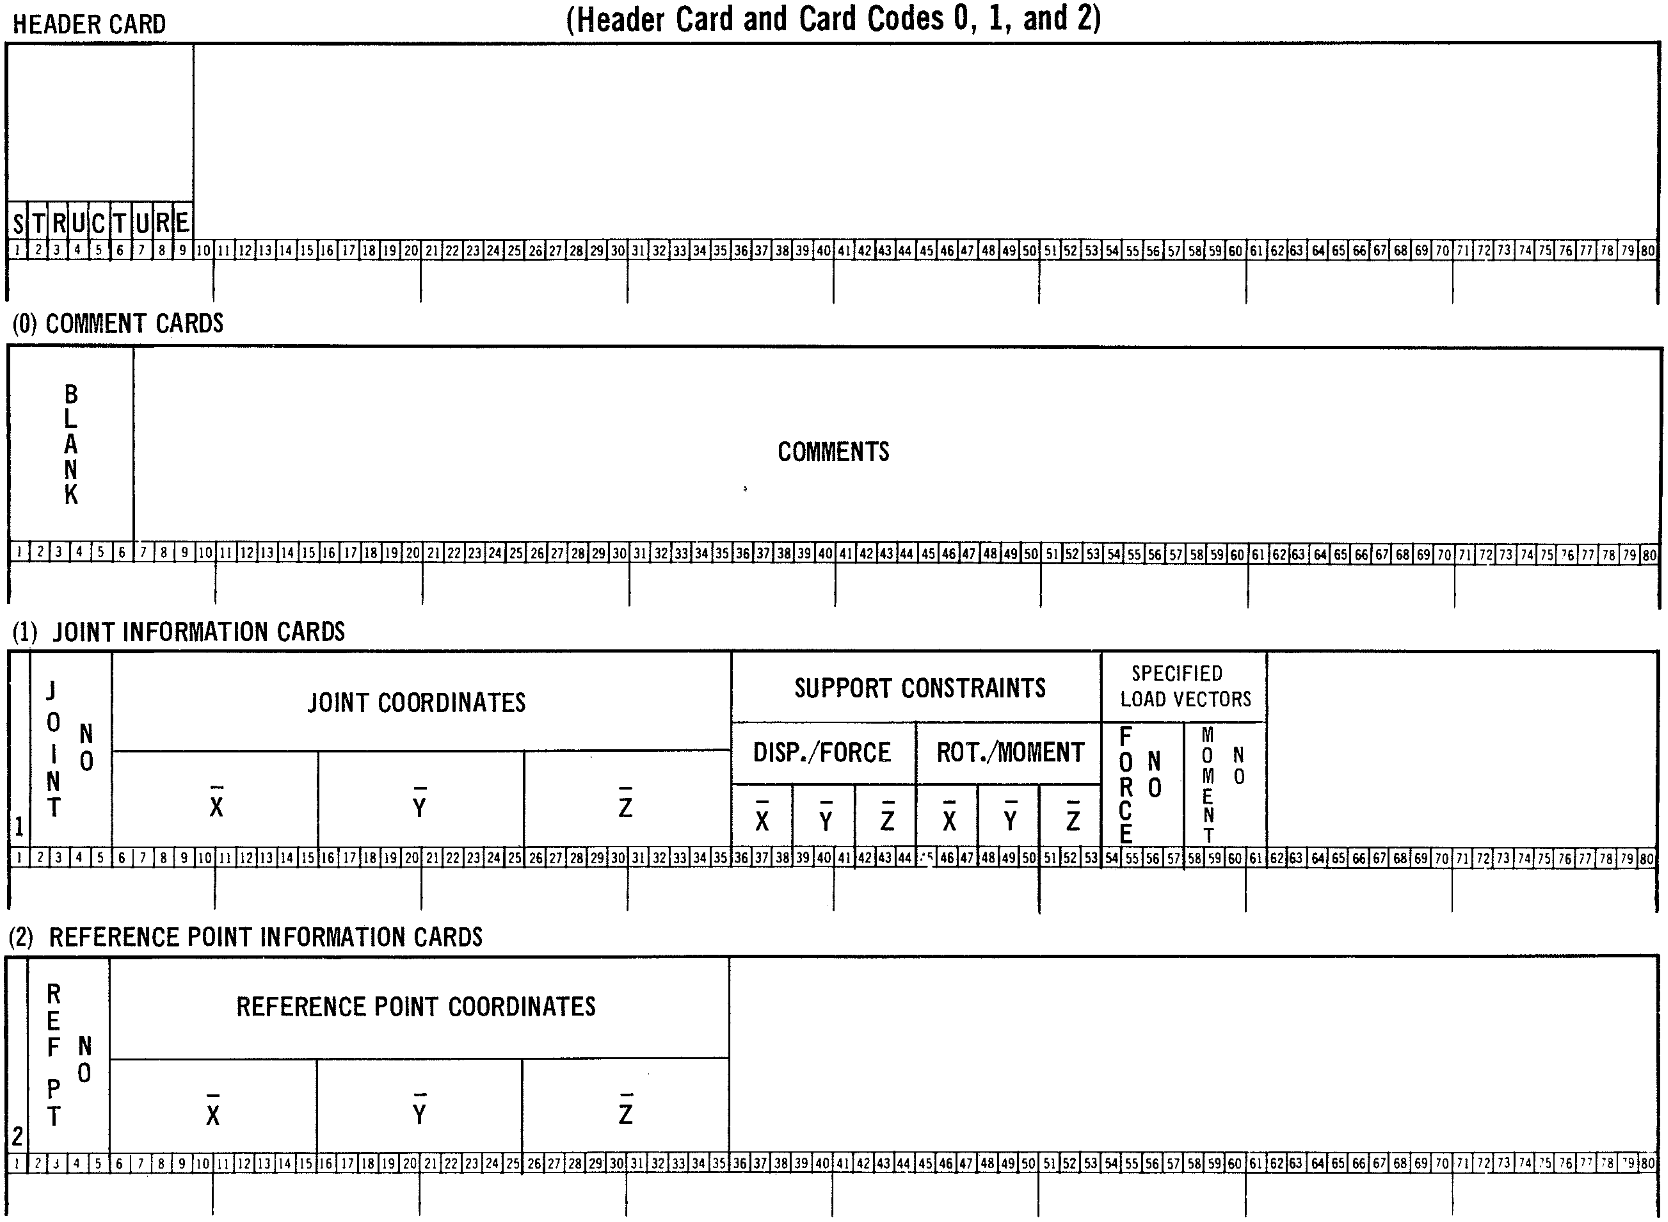

FIGURE 4-32 INPUT DATA FORMAT – CENTER BODY OPTION

column 1, and the corresponding identifying indicator in columns 2 through 5. Identifying force indicators must be sequential with a maximum of 74. Applied moments are numbered separately, with this set of identifying indicators being placed in columns 58 through 61, and the three corresponding global moment components being located on cards with a 5 in column 1. A total of 74 identifying moment indicators may be used. If either of these identifying indicators is zero (or blank), the appropriate applied load is zero and no corresponding code 4 or 5 data card is required. If displacements and/or rotations have already been restrained in specific directions, forces and/or moments may not be applied in these same directions.

Since free-free modes are obtained with the modal analysis routine, no constraints or applied loads should be specified when employing this program option. Thus, for modal analysis data cases, columns 36 through 61 should be left blank on all code 1 data cards.

B.2 Reference Point Information Cards - A code number 2 in column 1 indicates the data represents global coordinates and identifying joint number of a reference point. Reference points are provided to permit orientation of bar local coordinate (bending) axes, where structural joints will not suffice. Numbering of these reference points begins with one greater than the number of joints and is sequential through the total number of reference points. For example if there are 36 structural joints, the first reference point must be 37.

B.3 Force and Moment Limit Cards - A 3 in column 1 indicates data on the card is either a known displacement or rotation (columns 26 through 35), or upper and lower plastic force or moment constraints (columns 6 through 15 for an upper bound and 16 through 25 for a lower bound). The integer identifying number (limit number) in columns 2 through 5 corresponds to an identifying indicator or indicators on code 1 data cards, previously discussed. These limit numbers must be sequential in order. The sign of the identifying indicator on the code 1 data card determines what data are being read: A plastic force constraint and zero displacement (positive sign) or known displacement (negative sign). The known displacement may be nonzero or zero, simulating a conventional support. If the force is to be limited in the positive global direction, use the upper limit. A lower limit indicates a constraint on the

FIGURE 4–33 INPUT DATA FORMAT – CENTER BODY OPTION

force in the negative global direction.

For modal analysis data cases, code 3 data cards should not be input.

B.4 Specified Force Vector Cards - Applied forces at a joint are input as three or less global force components on cards with a 4 in column 1. The identifying number (force number), right-justified in columns 2 through 5, corresponds to an identifying indicator on code 1 data cards thereby defining the joint or joints where forces will be applied.

For modal analysis data cases, code 4 data cards should not be input.

B.5 Specified Moment Vector Cards - Applied moments at a joint are input as three or less global moment components on cards with a 5 in column 1. The identifying number (moment number), right-justified in columns 2 through 5, corresponds to an identifying indicator on code 1 data cards to define the joint or joints where the moments will be applied.

Code 5 data cards should not be input for modal analysis data cases.

B.6 Bar Information Cards - A card with a 6 in column 1 indicates bar data are being input. Bar number is entered in columns 2 through 5, right-justified, with numbering being sequential from one through the total number of bars (130 maximum). Bar origin (point "p"), end (point "q"), and direction of the Y_ℓ bending axis (point "r"), locating the bar Local Coordinate System (Figure 4-1), are determined by specifying joint numbers in the appropriate locations in columns 6 through 14 (all right-justified). A reference point may be used for point "r," but points "p" and "q" must be nodes (joints) on the structure. Point "r" must not be on the line "pq" or its extension.

Bar cross-sectional area perpendicular to the "pq" (X_ℓ) axis, A; moment of inertia about the Z_ℓ axis, I_N; moment of inertia about the Y_ℓ axis, I_T; and torsional constant, J, are entered in the appropriate columns as indicated in Figure 4-33. Members pinned at both ends for bending about the Z_ℓ axis can be simulated by making the moment of inertia I_N equal to zero. Similarly making I_T equal to zero simulates a member pinned at both ends for bending about the Y_ℓ axis. If A is set equal to zero, no axial load will be carried by the member, and setting J equal to zero prevents the member from carrying torsion. Any combination of these may be utilized. Modulus of elasticity, E, and shear modulus, G, for the bar material are entered in columns 53 through 61 and 62 through 70, respectively. If E-format is used it must be right-justified.

Caution must be exercised when using pinned members or members with A, I_T, I_N, or J equal to zero, because a joint may be left with no load carrying capability in one of the three global directions or with no rotational restraint about one of the three global axes. An example of this would be two bars in the same plane pinned together. An artificial restraint (support) must be placed on the joint in the global direction in which there is no load carrying capability, even though there will be no force induced in this support direction. This instruction is input on code 1 data cards. The program will automatically reject any problem in which load carrying capability (translational or rotational) does not exist at any joint.

The program has the ability to account for the effect of bar shear strain on bending deflections. If a zero (blank) is placed in column 15, shear strain is not accounted for. A 1 in column 15 causes the program to read the values of shear form factors, K_N and K_T, and account for the effect of shear strain. The factor K_N is the total cross-sectional area divided by the area effective in carrying shear in the Y_ℓ direction, while K_T is the total area divided by the area effective in carrying shear in the Z_ℓ direction (see Figure 4-6).

The program can also idealize a bar pinned at one end and rigidly attached at the other. To exercise this option a zero must be placed in column 15. If the rotational release is to be for bending about the Y_ℓ axis (I_T), a 1 or 2 is placed in column 16. A 1 indicates the "p" end is pinned while a 2 indicates the "q" end is pinned. The same number code (1 - "p" end pinned, 2 - "q" end pinned) is used in column 17 if the rotational release is for bending about the Z_ℓ axis (I_N). Values inserted for K_N and K_T for these cases will be automatically utilized.

B.7 <u>Rectangular Shear Web Information Cards</u> - Shear web information is input on data cards in which a 7 is placed in column 1. Location of shear web data in the fields of the card is illustrated in Figure 4-34. Shear webs must be numbered sequentially from 1 through the total number of shear webs (maximum of 30). The integer representing the shear web number is right-justified in columns 2 through 5.

FIGURE 4–34 INPUT DATA FORMAT – CENTER BODY OPTION

Four data fields located between columns 6 and 17 are used to specify the joints A, B, C, and D, numbered counterclockwise (see Figure 4-7), which represent the corners of the rectangular web. These integers must be right-justified in their respective fields. Care must be taken to insure that the joints A, B, C, and D define a plane and form a rectangle. The program will reject any problem in which this is not true.

Three data fields located between columns 18 and 47 are used to specify the material properties and thickness of the web. The Poisson's ratio, ν, modulus of elasticity, E, and thickness, t, of the web are input in these fields as indicated in Figure 4-34. These values must be right-justified in their fields if E-Format is used.

B.8 Data Terminator Card - After all data needed on code 1 through 7 data cards and the desired comment cards are input, a data terminator card is required to signify the end of the data. This card must contain an 8 in column 1 and may contain any desired comments in columns 7 through 80.

C. Data Option Indicator (NAMELIST) Card(s) - Following the previously described input data, a NAMELIST system of input indicated by $INDATA is used to define option indicator cards for selection of output options, iteration method, modal analysis routine, program termination, and tape options. Figure 4-34 presents the card format to be used. $INDATA is entered in columns 2 through 8 of the first data option card. Columns 10 through 68 on the first and any succeeding cards are used to specify optional data indicator values. $END must be entered in columns 69 through 72 of the last data option card.

Data option indicators and their nominal and optional values are defined in Figure 4-35. If nominal values are acceptable for all NAMELIST items, $INDATA is entered in columns 2 through 8, $END is entered in columns 69 through 72, and the rest of the card left blank. By listing any of the option data indicators, such as INDNMA = 1, the nominal control is overridden, as in this case where normal mode analysis would be utilized. A data option indicator need be listed only if a value other than the nominal value is desired.

INDICATOR	NOMINAL VALUE	OPTIONAL VALUE	CONTROL FUNCTION
INDSFL	1		DO NOT } WRITE BAR LOCAL STIFFNESS AND TRANSFORMATION MATRICES.
		0	DO
INDSFG	1		DO NOT } WRITE BAR TRANSFORMED STIFFNESS MATRICES
		0	DO
IND1SL	0		WILL NOT } INPUT AN INITIAL SOLUTION OF DISPLACEMENTS AND ROTATIONS IN "SOLVEC",
		1	WILL
INDITR	3X(NO. OF ROWS IN STRUCTURAL STIFFNESS MATRIX)	K (ANY INTEGER)	THE ITERATIVE SOLUTION OF THE SIMULTANEOUS EQUATIONS WILL BE STOPPED AFTER ("INDITR" + 1) ITERATIONS
ERRTOL	.0001	A (ANY REAL NUMBER)	THE ABSOLUTE VALUE OF "ERRTOL" IS USED AS THE ERROR TOLERANCE TO TERMINATE THE ITERATIVE SOLUTION FOR DISPLACEMENTS AND ROTATIONS.
SOLVEC	$0._{(i)}$		THE INITIAL SOLUTION OF DISPLACEMENTS AND ROTATIONS IS ZERO.
		$A_{(i)}$	THE A i's (i = 1, 6X(NO. JOINTS)) ARE INPUT VALUES (SEPARATED BY COMMAS) DEFINING AN INITIAL SOLUTION OF DISPLACEMENTS AND ROTATIONS. (SOLVEC IS DIMENSIONED 444) ie. $A_{(1)} = \bar{X}$ DISPLACEMENT OF JOINT 1 . . $A_{(4)} = \bar{X}$ ROTATION OF JOINT 1 . . $A((j-1)X6+1) = \bar{X}$ DISPLACEMENT OF JOINT j . . $A((j-1)X6+4) = \bar{X}$ ROTATION OF JOINT j.

FIGURE 4–35 NAMELIST ($INDATA) DATA OPTION INDICATORS

INDICATOR	NOMINAL VALUE	OPTIONAL VALUE	CONTROL FUNCTION
RELAXF	1.		EMPLOY GAUSS-SIEDEL SOLUTION METHOD
		A (1.0 $\leq$ A $\leq$ 2.0)	THE RELAXATION FACTOR EMPLOYED IF THE OVERRELAXATION METHOD OF SOLUTION IS USED. RECOMMENDED OPTIONAL VALUE = 1.2
INDRLX	2		EMPLOY CONJUGATE GRADIENT SOLUTION TECHNIQUE.
		1	EMPLOY GAUSS-SIEDEL METHOD OF SOLUTION WITH NOMINAL RELAXATION FACTOR OF 1., OR USE OVERRELAXATION SOLUTION METHOD WITH OPTIONAL RELAXATION FACTOR DEFINED IN "RELAXF."
		0	EMPLOY GAUSS-SIEDEL SOLUTION METHOD WITH AITKEN'S Δ^2 IMPROVEMENTS.
INDRKT	0		DO NOT — READ STRUCTURAL STIFFNESS MATRIX, AND BAR LOCAL STIFFNESS AND TRANSFORMATION MATRICES FROM PHYSICAL TAPE 9.
		1	DO
INDWKT	0		DO NOT — WRITE STRUCTURAL STIFFNESS MATRIX AND BAR LOCAL STIFFNESS AND TRANSFORMATION MATRICES ON PHYSICAL TAPE 9.
		1	DO
INDPLS	0		DO NOT — CONSIDER PLASTICITY THROUGH USE OF LIMITS ON FORCES/MOMENTS.
		1	DO
MINRST	6	K (ANY INTEGER)	LESS THAN "MINRST" RESTRAINTS WILL CAUSE PROGRAM TERMINATION DURING SOLUTION OF SIMULTANEOUS EQUATIONS.
INDNMA	0		DO NOT — RUN NORMAL MODE ANALYSIS.
		1	DO

FIGURE 4–35 NAMELIST ($INDATA) DATA OPTION INDICATORS (Continued)

INDICATOR	NOMINAL VALUE	OPTIONAL VALUE	CONTROL FUNCTION
IRWKP	$0_{(i)}$	K(i) (INTEGERS)	ROW NUMBERS IN ASCENDING ORDER (SEPARATED BY COMMA'S) TO BE KEPT IN REDUCED STIFFNESS MATRIX WHEN RUNNING NORMAL MODE ANALYSIS ($i = 1, 2 \ldots , n$ WHERE $n \leq 102$; "IRWKP" IS DIMENSIONED 103).
AMASS	$0._{(i)}$	A_i	DIAGONAL MASS MATRIX ELEMENTS (SEPARATED BY COMMAS) IN ASCENDING ORDER, INPUT WHEN RUNNING NORMAL MODE ANALYSIS ($i = 1, 2, \ldots , n$ WHERE $n \leq 102$; "AMASS" IS DIMENSIONED 102).
IREDTO	ORDER OF STIFFNESS MATRIX	K ($K \leq 102$)	THE REQUIRED ORDER OF REDUCED STIFFNESS MATRIX WHEN RUNNING NORMAL MODE ANALYSIS.
INDWNM	0	1	DO NOT DO WRITE NORMAL MODE DATA ON TAPE FOR USE IN TASK ORDER TWO LANDING LOADS AND MOTIONS PROGRAM OR THE CENTER BODY LOADS PROGRAM.
TMAX	9999.	A (ANY REAL NUMBER)	NUMBER OF SECONDS AFTER WHICH MACHINE WILL PRINT PRESENT SOLUTION AND STOP, IF CONVERGENCE TO PRESCRIBED TOLERANCE HAS NOT BEEN REACHED (RECOMMENDED OPTIONAL VALUE = .9X (CP TIME)).
ISFDIM	12,904	K (INTEGER)	THE NUMBER OF WORDS OF STORAGE RESERVED TO STORE THE TOTAL STIFFNESS MATRIX. THE LENGTH OF LABELED COMMON, "CMAIN", MUST BE RE-DEFINED TO ALLOW STORAGE OF A STIFFNESS MATRIX WHICH REQUIRES "K" WORDS OF STORAGE SPACE, WHERE $K > 12904$.
INDWTS	0	1	DO NOT DO PRINT THE NONZERO ELEMENTS OF THE TOTAL STIFFNESS MATRIX.
NEIGVL	5	M ($5 \leq M \leq$ IREDTO-6)	NUMBER OF NON-RIGID BODY MODES TO BE CALCULATED IF MODAL ANALYSIS IS EMPLOYED, "NEIGVL" MUST BE A MULTIPLE OF 5.

FIGURE 4–35 NAMELIST ($INDATA) DATA OPTION INDICATORS (Continued)

The ERRTOL control is important, since it affects computer time. The value specified, multiplied by 100, is the maximum acceptable percent error in the solution. The error for the Gauss-Siedel method, the Gauss-Siedel method with Aitken's Delta Squared improvements, and the overrelaxation method is defined as the largest relative difference between consecutive displacement and rotation solutions. This relative difference is calculated by taking the difference between given solution values for two successive iterations and dividing by the last value of the solution.

The error for the Conjugate Gradient Method is defined as the largest term found when the residual vector (see Reference (5)) is divided by the largest element in the force/moment vector. The program will run until it achieves the accuracy prescribed by ERRTOL or exceeds the maximum number of iterations (INDITR).

An initial set of nodal deflections may be input using the indicator SOLVEC. This option allows the program to start with these values for deflections and achieve convergence more rapidly. This option is also useful if minor changes are made in a structure after an initial solution has been obtained.

The maximum number of iterations allowed (INDITR), nominally three times the number of rows in the stiffness matrix, should be selected based on the size and sparsity of the stiffness matrix and desired length of computer run time. The nominal iteration method used is the Conjugate Gradient Method. If INDRLX is set equal to 0 the Gauss-Siedel method with Aitken's Delta Squared Improvements is employed. If INDRLX is set equal to 1, the Overrelaxation Method is employed and a value of RELAXF (the relaxation factor) between 1.0 and 2.0 should then be input. A nominal relaxation factor of 1.0 is set in the program, which is equivalent to a standard Gauss-Siedel solution (without Aitken's Delta Squared Improvements). For employing the Overrelaxation Method, a RELAXF equal to 1.2 has been found to result in minimum machine time and rapid convergence for a number of typical problems. Experience dictates that for highly redundant space frames, such as the legged lander, the nominal solution technique (the Conjugate Gradient Method) is the best suited of the above methods and is recommended.

The MINRST option is selected based on the minimum number of restraints (supports) which must exist for stability (nominally six). If, at any time, less than this number of supports exist, the program will automatically terminate with an error message.

If it is desired to perform a normal mode analysis, INDNMA is set equal to 1. If reduction is to be employed, the required order of the reduced stiffness matrix is input in IREDTO. The row numbers to be retained in the reduced stiffness matrix must be listed in ascending order in IRWKP if reduction is employed. Values for the diagonal mass matrix terms associated with the degrees of freedom retained in the reduced stiffness matrix, are input in AMASS. If all six degrees of freedom at a particular joint are retained, the first three numbers in AMASS would represent the mass associated with this joint. The next three numbers would represent the mass moment of inertia associated with this joint relative to the directions of the global $\bar{X}$, $\bar{Y}$ and $\bar{Z}$ axes. If degrees of freedom at a joint are removed in the reduced stiffness matrix, the corresponding mass or inertia items should not be input in AMASS. If reduction is not required, no data is required for IRWKP and IREDTO and the number of terms in AMASS must equal the order of the system stiffness matrix.

The number of nonrigid body modes to be calculated is input in NEIGVL. NEIGVL,which has a nominal value of 5, can optionally be any multiple of five, and must be less than or equal to IREDTO less six.

Care must be exercised in the use of the reduction routine. It is possible to eliminate so many rows from the stiffness matrix that a number of the remaining degrees of freedom are no longer independent. This has the effect of eliminating one or more of the system's six rigid body modes. To insure that this does not occur for a general space frame, at least two translational degrees of freedom in each of three global coordinate directions should remain following reduction. For the special case of a straight beam, two torsional rotations should remain in addition to these translations.

Error messages are printed if the user accidentally specifies a reduction which leads to the elimination of too many rows from the stiffness matrix.

Should more than 12904 words be required to store the stiffness matrix in a given problem, ISFDIM must be set equal to the required number of words and labeled COMMON must be redimensioned accordingly.

4.3.1.2 Output Data - Center Body Option output includes all input data, NAMELIST indicator values used, nodal displacements and rotations, number of iterations required for convergence, maximum error, nodal forces and moments, bar forces and moments, shear flows in shear webs, and a CPU time summary. Modal analysis output includes all input data, NAMELIST indicator values used, natural frequencies, mode shapes, generalized inertia properties, and a CPU time summary. All input data is printed out in a block format. Classification of input data is by code number in column 1, as described in Section 4.3.1.1.

For problems not requiring modal analysis, nodal displacements and rotations are printed out. The number of iterations required for the solution as well as the maximum error in the solution are then printed. Global forces and moments acting on the joints are also output. Forces and moments acting on both ends of all bars are printed. The p, q, and r joint numbers used for each bar are also listed to aid in interpretation of the direction of these forces and moments (positive local sign convention is indicated in Figure 4-1). Shear flows and identifying joints are printed for all shear webs. Positive local sign convention for establishing directions of shear flows is given in Figure 4-7.

When plastic force constraints are violated, the program prints out the elastic solution, which constraints were violated, and the plastic solution (nodal deflections and rotations, and nodal forces and moments). Forces and moments acting on both ends of all bars as well as shear flows in all shear webs are printed out for the final solution. The last output item is a CPU time summary showing a breakdown of CPU time usage.

When employing the modal analysis routine, output data include: input data, the specified number of lowest natural frequencies (excluding rigid body modes), corresponding mode shapes (normalized) for both the reduced and complete systems, generalized inertia properties, and a CPU time summary.

On an optional basis, this modal analysis output may be placed on magnetic tape. This information is required by the Center Body Landing Loads Program, as discussed in Appendix E. In addition, the data on this tape is compatible with the Task Order Two Landing Loads and Motion Program, Reference (2). In this case, the Task Order Five modal analysis could be employed for a footpad structure of a platform lander. Thus the improved matrix reduction routine could be taken advantage of.

4.3.1.3 Example of Program Operation - Examples of typical structural and modal analysis problems are included to illustrate interpreting input instructions and output data.

An example of obtaining deflections and internal loads for a center body structure subject to external loads is presented in Section 6.2.4 for the Task Order Three lander center body subject to typical landing loads. Input data and output listing for this problem are presented in Appendix A.

Input data and resulting output data when employing the modal analysis routine of the Center Body Option is given in Appendix B. This analysis was conducted on the center body structure of the Task Order Three lander. The idealization of the center body structure and plots of a number of the mode shapes are presented in Section 6.2.1. This modal data was input to the Landing Loads and Motions Program when studying the effects of center body flexibility on correlation with drop test data for this lander. This landing analysis is discussed in Section 6.2.2.

The data set shown in Appendix B is for a structural idealization with 33 joints and 53 bar members. This results in a stiffness matrix of order 198. The matrix reduction routine was employed to reduce this to order 99. This was accomplished by removing the rotations at all of the joints. Thus, the input mass matrix contained terms associated with each of the three translations at each joint. Twenty modes were requested from the modal analysis routine. Only the mode shapes for the complete system are shown in Appendix B.

4.3.2 Landing Gear Option - This section includes definition of input requirements and format, and output interpretation for the Landing Gear Option of the Structural Analysis Program. Examples of input and output data for a typical problem are contained in Appendix C.

4.3.2.1 Input Data - For each Landing Gear Option data set a data case header card and information describing landing gear type, loading information, strut properties, gear geometry, footpad information, energy absorption requirements, and indicators needed to control program operation are required as input data. Multiple data cases may be run by stacking data sets. Each data set must consist of a header card followed by the appropriate data cards.

A. Header Card - A header card is required as the first card of a data set to indicate that the Landing Gear Option will be employed. This card must contain the characters GEAR in columns 1 through 4 as indicated in Figure 4-36.

B. Data Cards - The input format for data cards employs a system of code numbers, right-justified in columns 1 and 2, to identify the type of data being read. The seventeen code numbers and corresponding type of input information are as follows:

(0) Comment cards
(1) Gear and load card
(2) Friction card
(3) Applied displacement card
(4) Strut material cards
(5) Solution parameter card
(6) Nodal point cards
(7) Footpad card
(8) Material parameter cards
(9) Material crush cards
(10) Compression crush distance cards
(11) Tension crush distance cards
(12) Compression spring rate cards
(13) Tension spring rate cards
(14) Compression plastic force cards
(15) Tension plastic force cards
(16) Data terminator card

B.0 Comment Cards - As many comment cards as desired may be input by leaving columns 1 through 6 blank and entering comments in columns 7 through 80 as shown in Figure 4-36. These comment cards may be located anywhere within the data cards and must precede the data terminator card.

(Header Card and Card Codes 0, 1, and 2)

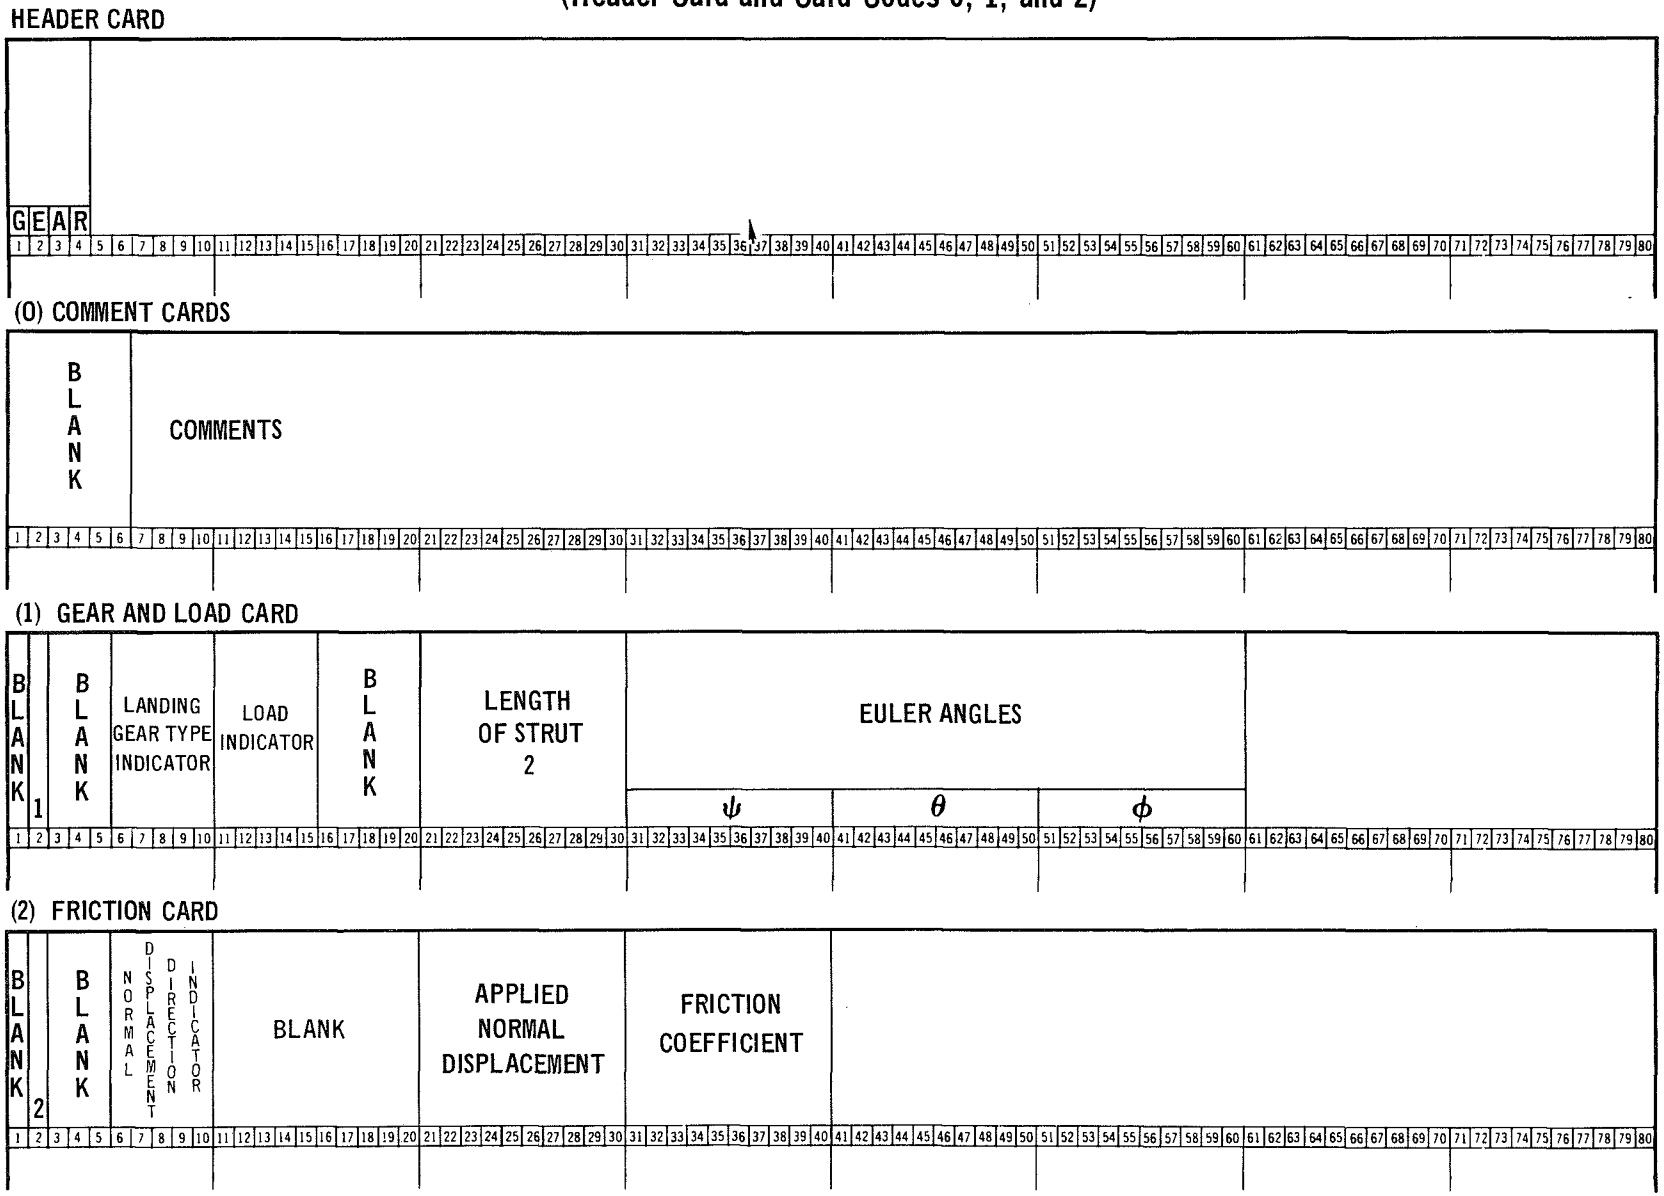

FIGURE 4–36 INPUT DATA FORMAT – LANDING GEAR OPTION

B.1 <u>Gear and Load Card</u> - Information describing landing gear type, type of applied loading, strut parameter for the cantilever gear, and the orientation of the landing surface is input on a data card in which a 1 is placed in column 2. Location of data fields on this card is illustrated in Figure 4-36. A 1 right-justified in columns 6 through 10 signifies that the gear being analyzed is an inverted tripod. Similarly, a 2 in this field indicates a cantilever gear.

A 1 right-justified in columns 11 through 15 indicates that the applied loading is of the frictional type in which the displacement normal to a landing surface is specified. For this type of loading, a code 2 data card is required as input data to specify the applied normal displacement and the friction coefficient. A 2 right-justified in columns 11 through 15 indicates that three applied displacement components are specified. For this case an associated code 3 data card must be input. As explained in Section B.2, a code 2 data card must also be input to specify the direction normal to the landing surface if the footpad has attenuation.

For the cantilever gear only, the length of strut 2 (see Figure 4-17) must be input in columns 21 through 30. This information is required to locate node 4 on the cantilever gear. For the inverted tripod gear this data field is left blank.

Three data fields located between columns 31 and 60 are used to specify the Euler angles ψ, θ, and ϕ which orient the Surface Coordinate System relative to the Lander Coordinate System. These Euler angles must be input in degrees. A definition of these angles and the associated sign convention is given in Figure 4-20.

B.2 <u>Friction Card</u> - Information describing the direction and magnitude of applied displacement (normal to the landing surface) at the footpad joint and the coefficient of friction of the surface is input on a data card in which a 2 is placed in column 2. Location of data fields on this card is illustrated in Figure 4-36. A 1, 2, or 3 right-justified in columns 6 through 10 of this card signifies that the positive direction normal to the landing surface is the X, Y, or Z surface coordinate direction, respectively. This information as well as the information supplied in the remaining data fields of this card must be specified if loading of the friction type is selected on the code 1 data card. Should the three applied displacement components case be specified on the code 1 data card and the footpad have at least 1 level of attenuation, the normal displacement direction indicator must be supplied on the code 2 data card to indicate the surface coordinate direction to check for footpad crushing. For this case, the remaining information on the data card is not used. Care must be exercised when selecting the coordinate system to insure that the normal surface coordinate direction is out of the surface.

The magnitude of the applied normal displacement in the surface coordinate direction indicated in columns 6 through 10 is supplied in columns 21 through 30. The coefficient of friction of the landing surface is entered in columns 31 through 40.

B.3 Applied Displacement Card - For the case in which three displacement components at the footpad joint are specified, the three surface coordinate components of applied displacement are entered on a data card with a 3 in column 2. Location of data fields on this card is illustrated in Figure 4-37. Three data fields located between columns 21 and 50 are used to enter the three components of applied displacement at the footpad joint. These displacement components must be given in the Surface Coordinate System.

B.4 Strut Material Cards - Each strut of a gear must be assigned a material identification number to indicate which material, input on code 8 through 15 data cards, makes up the strut. The material identification number of each element (strut) is input on data cards with a 4 in column 2. Location of data fields on this card is illustrated in Figure 4-37. One card must be input for each element of the gear, i.e., three for the inverted tripod and four for the cantilever.

The element number must be right-justified in columns 6 through 10. The number identifying the material of which this element is made is right-justified in columns 11 through 15. More than one element may have the same material identification number. This is convenient in the case of a gear which has identical drag struts since then only one set of material properties has to be defined for these struts.

FIGURE 4–37 INPUT DATA FORMAT – LANDING GEAR OPTION

B.5 Solution Parameter Card - The number of steps for investigating the applied loading, the number of iterations to be allowed, the number of different materials used in the gear idealization, an indicator to specify in which direction to check the energy absorbed, the energy absorption cutoff, and the solution tolerance are input on a data card with a 5 in column 2. Location of data fields on this card is illustrated in Figure 4-37.

Four data fields located between columns 6 and 25 are used to specify the number of steps to divide the applied loading, the number of iterations allowed before the solution is assumed to be nonconvergent, the number of different materials employed in idealizing the struts of the gear, and an indicator to specify in which surface coordinate direction to check the energy absorption associated with the loads acting on the footpad. These integers must be right-justified in their respective fields. The energy check indicator is set to 1, 2, or 3 if the energy absorption is to be checked in the X, Y, or Z surface coordinate direction, respectively.

The energy cutoff used to make the energy absorption check is input in columns 31 through 40. In assigning a sign to this cutoff it must be remembered that a plus sign signifies that the force and corresponding displacement components of interest are in the same direction while a minus sign signifies that they are opposite in direction. The tolerance used to check for solution convergence is input in columns 41 through 50. For input data employing units of centimeters and dynes, the solution would be assumed converged to a tolerance specified as 4.0×10^4 when the magnitude of the largest unbalance, between any internal and external load component at any joint of the gear, was less than 4.0×10^4 dynes or 4.0×10^4 dyne-cm as the case may be. For each loading step,the program will run until the solution converges to the tolerance of the maximum number of iterations is exceeded.

B.6 Nodal Point Cards - For each node point (joint) of the gear, except for node 4 of the cantilever gear, the initial node coordinates in the Lander Coordinate System are input on cards with a 6 in column 2. The location of data fields on these cards is illustrated in Figure 4-37. Four of these cards must be input for both the inverted tripod and cantilever gears. On each card, the node point number must be right-justified in columns 6 through 10. Three data fields located between columns 21 and 50 are used to input the X, Y, and Z coordinates of the node in the Lander Coordinate System.

B.7 Footpad Card - Information regarding attenuation on the bottom of the footpad is input on a card with a 7 in column 2. Location of data fields on this card is illustrated in Figure 4-38. An attenuation indicator to signify whether or not the footpad has attenuation is right-justified in columns 6 through 10. A 1 signifies that the footpad has attenuation while a 2 indicates that there is none. The number of attenuation crush levels is entered, right-justified, in columns 11 through 15.

Three data fields located between columns 21 and 50 are used to input the magnitudes of up to three attenuation crush forces (see Figure 4-28). These crush forces must be entered in the order of increasing magnitude. The crush stroke magnitudes, associated with up to three crush levels, are entered in three data fields located between columns 51 and 80. Each stroke entry represents the stroke of the footpad honeycomb during crushing of the level of interest and does not include the stroking that may have occurred due to crushing of lower levels. For a footpad without attenuation the information in columns 21 through 80 will be ignored.

B.8 Material Parameter Cards - For each different material, the material identification number, plasticity indicator for axial displacements, moduli of elasticity, and cross-sectional properties are input on a card with an 8 in column 2. Location of data fields on this card is illustrated in Figure 4-38. Material identification number is entered, right-justified, in columns 6 through 10. A plasticity indicator for this material is entered, right-justified, in columns 11 through 15. A plasticity indicator of 1 signifies that for axial displacements the material behaves elastically. A plasticity indicator of 2 indicates that for axial displacements the material behaves plastically. That is, the axial characteristics of this material are those of honeycomb attenuation.

Two data fields located between columns 21 and 40 are used to input the moduli of elasticity for bending and axial displacements of the strut composed of the material identified in columns 6 through 10. Two data fields located between columns 41 and 60 are used to input the moment of inertia for bending displacements and the cross-sectional area of the strut composed of the material identified in columns 6 through 10.

For a material with plastic axial capability (a plasticity indicator of 2), the modulus of elasticity for bending displacements and the moment of

FIGURE 4-38 INPUT DATA FORMAT – LANDING GEAR OPTION

inertia must be entered if the strut composed of this material can carry bending loads. These parameters should not be entered if the strut cannot carry bending loads. For either of the above materials, the modulus of elasticity for axial displacements and the cross-sectional area will be ignored since this information regarding axial capability is input in the crush property cards (card codes 9 through 15) for a material with plastic axial capability. The material for the lower member of the main strut (element 4 in Figure 4-17(b)) of the cantilever gear is an example of a material with plastic axial capability for which the bending properties must be input. The material for the main strut (element 2 in Figure 4-17(a)) of the inverted tripod gear is an example of a material with plastic axial capability for which bending properties would not be input.

For a material with elastic axial capability (a plasticity indicator of 1), the modulus of elasticity for axial displacements and the cross-sectional area must be entered. The modulus of elasticity for bending displacements and the moment of inertia are input only if the associated strut has bending capability. The material for the upper member of the main strut (element 2 in Figure 4-17(b)) of the cantilever gear is an example of a material with elastic axial capability for which bending properties must be input. For an inverted tripod gear with rigid drag struts, the material for the drag struts (elements 1 and 3 in Figure 4-17(a) is an example of a material with elastic axial capability for which bending properties would not be input.

B.9 Material Crush Cards - For each material with plastic axial capability (a material which has a plasticity indicator of 2 on the code 8 data card), the material identification number, crush indicators, allowable strokes, and unloading spring rates must be input on a data card with a 9 in column 2. The location of data fields on this card is illustrated in Figure 4-38. The material identification number is right-justified in columns 6 through 10. An unloading indicator is right-justified in columns 11 through 15. A value of 0 for this indicator signifies that unloading of this material will be along a slope specified by the spring rates input in columns 41 through 60 of this card. An unloading indicator of 1 signifies that the material will unload along a slope specified by the next spring rate associated with the load-stroke curve. An initial stroke indicator is input, right-justified, in columns 16 through 20.

A value of 1 for this indicator signifies that the strut which is composed of this material will initially stroke in tension. A value of -1 indicates that this strut will initially stroke in compression. This information is needed for a crushable material to indicate whether the stiffness of the strut at the start of the loading should reflect the first spring rate in tension or that in compression.

Two data fields located between columns 21 and 40 are used to input the magnitudes of allowable (bottoming) strokes in compression and tension. For the material of a strut which can stroke in one direction only, the appropriate bottoming stroke should be input as 1.E-20. Two data fields located between columns 41 and 60 are used to input the unloading spring rate magnitudes in compression and tension. These values should be input only if the unloading indicator is input as 0 in columns 11 through 15.

B.10 <u>Compression Crush Distance Cards</u> - For each material with plastic axial capability, the crush distances in compression (see Figure 4-18) must be input on a data card with a 10 in columns 1 and 2. Data fields on this card are defined in Figure 4-38. The material identification number is right-justified in columns 6 through 10.

Five data fields, located between columns 21 and 70, are used to define the magnitudes of up to five crush distances in compression. Any number of crush distances between one and five may be input. The last crush distance input must be greater than the allowable compression stroke input on a code 9 data card for this material. This crush distance should have a fictitious value of 1.E+20 to insure that it will not be exceeded during program iteration prior to final convergence. For the material of a strut which can stroke only in tension, one compressive crush distance should be input at a value of 1.E+20.

B.11 <u>Tension Crush Distance Cards</u> - For each material with plastic axial capability, the crush distances in tension (see Figure 4-18) must be input on a data card with an 11 in columns 1 and 2. Data fields on this card are defined in Figure 4-39. The material identification number is right-justified in columns 6 through 10.

Five data fields, located between columns 21 and 70, are used to define the magnitudes of up to five crush distances in tension. Any number of crush distances between one and five may be input. The last crush distance input

must be greater than the allowable tension stroke input on a code 9 data card for this material. This crush distance should have a fictitious value of 1.E20 to insure that it will not be exceeded during program iteration prior to final convergence. For the material of a strut which can stroke only in compression, one tension crush distance should be input at a value of 1.E+20.

B.12 Compression Spring Rate Cards - For each material with plastic axial capability, the spring rates in compression (see Figure 4-18) must be input on a card with a 12 in columns 1 and 2. Data fields on this card are defined in Figure 4-39. The material identification number is right-justified in columns 6 through 10.

Five data fields located between columns 21 and 70 are used to define the magnitudes of up to five spring rates in compression. Any number of spring rates between 1 and 5 may be input. For the material of a strut which can only stroke in tension, one spring rate in compression should be input at a value equal to the bottoming spring rate.

B.13 Tension Spring Rate Cards - For each material with plastic axial capability, the spring rates in tension (see Figure 4-18) must be input on a data card with a 13 in columns 1 and 2. Data fields on this card are defined in Figure 4-39. The material identification number is right-justified in columns 6 through 10.

Five data fields located between columns 21 and 70 are used to define the magnitude of up to five spring rates in tension. Any number of spring rates between 1 and 5 may be input. For the material of a strut which can only stroke in compression, one spring rate in tension should be input at a value equal to the bottoming spring rate.

B.14 Compression Plastic Force Cards - For each material with plastic axial capability, the plastic forces in compression (see Figure 4-18) must be input on a data card with a 14 in columns 1 and 2. Data fields on this card are defined in Figure 4-39. Material identification number is entered, right-justified, in columns 6 through 10.

Five data fields located between columns 21 and 70 are used to define the magnitudes of up to five plastic forces in compression. Any number of plastic forces between 1 and 5 may be input. For the material of a strut which can only stroke in tension, one plastic force in compression should be input at a value slightly less than the product of SRC(1) and CDC(1).

B.15 Tension Plastic Force Cards - For each material with plastic axial capability, the plastic forces in tension (see Figure 4-18) must be input on a data card with a 15 in columns 1 and 2. Data fields on this card are defined in Figure 4-40. Material identification number is right-justified in columns 6 through 10.

Five data fields located between columns 21 and 70 are used to define the magnitudes of up to five plastic forces in tension. Any number of plastic forces between 1 and 5 may be input. For the material of a strut which can only stroke in compression, one plastic force in tension should be input at a value slightly less than the product of SRT(1) and CDT(1).

B.16 Data Terminator Card - After all data needed on code 1 through 15 data cards and the desired comment cards are input, a data terminator card is required to signify the end of the data set. This card must contain a 16 in columns 1 and 2.

4.3.2.2 Output Data - Output data from the Landing Gear Option includes all input data, initial conditions, displaced conditions for the gear at each step of the specified loading, and a CPU time summary.

The initial conditions printed for the gear include the X, Y, and Z coordinates of all nodes in the Surface Coordinate System.

The displaced conditions, printed for the gear at each step of loading, include the following: step of loading; number of iterations required to reach convergence; coordinates of all nodes in the Surface Coordinate System; external forces and moments at the nodes in the Surface Coordinate System; the internal axial force, stroke, and axial stiffness of each element; the internal shear force and moment at each end of all elements; the total energy absorbed at the footpad in both surface and lander coordinate components; the number of remaining (noncrushed) footpad attenuation levels; and surface and lander coordinate components of the energy absorbed by footpad attenuation during the loading step concerned.

Should a particular loading step fail to converge, the solution existing in the program, after the maximum number of iterations had been employed, would be printed out and program termination would occur. Should the allowable stroke in any of the members be exceeded or the load normal to the footpad be

(Card Codes 15 and 16)

FIGURE 4-40 INPUT DATA FORMAT – LANDING GEAR OPTION

tensile for any loading step, the current solution and an appropriate error message would be printed, and program termination would occur. The program will continue through all loading steps unless one of the above errors occurs causing termination. If at any loading step the energy cutoff in the appropriate surface coordinate direction is exceeded, a message will be printed to indicate this fact and the program will continue.

4.3.2.3 Example of Program Operation - To illustrate interpretation of input instructions and output data, a typical example of the Landing Gear Option is included. An example problem where the inverted tripod gear of the Task Order Three lander was analyzed is discussed in Section 6.1.1. Input data and output listing for this example are presented in Appendix C.

5. LANDING LOADS AND MOTIONS PROGRAM

The Landing Loads and Motions Program provides the capability of predicting the landing dynamics of a legged lander. Program output presents the time histories of the landing gear loads and the spatial positions, velocities, and accelerations of the lander. Options are available for determining the distribution of landing loads throughout the lander structure and lander stability information.

The lander is comprised of up to five landing gears connecting the center body to the footpads which make contact with the landing surface. The center body may be treated as either a rigid structure with up to six rigid body degrees of freedom, or the effects of a flexible structure may be superimposed on these rigid body motions. Inverted tripod or cantilever landing gears having elastic-plastic load-stroke characteristics, velocity dependent energy absorption characteristics, or a combination of the two may be considered. Two soil mechanics routines are available and, on an optional basis, footpad attenuation material may be located on the bottom of each footpad.

Analytical methods developed for this program are presented in Section 5.1. Organization of the computer program is presented in Section 5.2 and operating instructions are discussed in Section 5.3. A program listing is given in Appendix I.

5.1 Analytical Methods - Analytical methods associated with the Landing Loads and Motions Program are presented below. Included are discussions of coordinate systems, equations of motion, structural idealization, soil mechanics routines, and footpad attenuation system.

5.1.1 Coordinate Systems - Four types of coordinate systems, as shown in Figure 5-1, are used to locate the lander as a function of time. These consist of two axis systems fixed relative to the planet, and two systems moving with the lander. These coordinate systems are all right-handed, and each has three orthogonal axes.

The coordinate systems are defined as follows:

Surface Coordinate System (X_s, Y_s, Z_s) - A coordinate system fixed in the planet and oriented with respect to the slope of the local

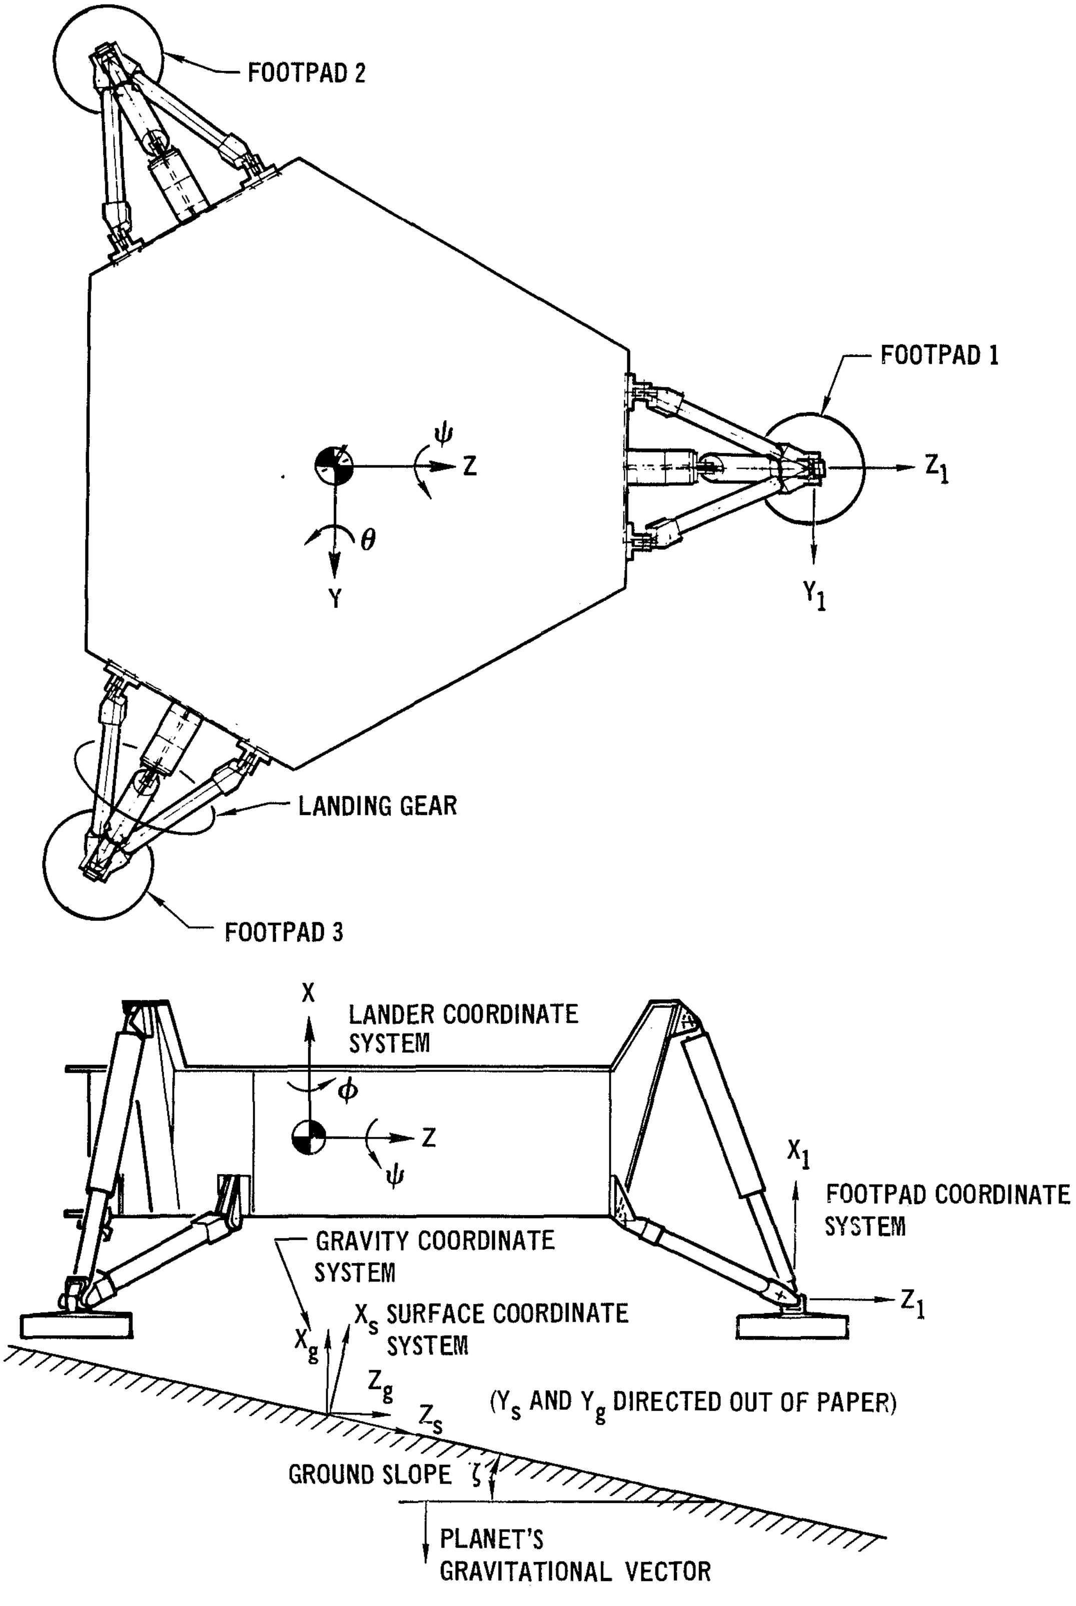

FIGURE 5-1 COORDINATE SYSTEMS

surface. The X axis of this system is perpendicular to the ground surface. The Z axis corresponds to the principle direction along the ground slope and the Y axis is 90 degrees across the slope.

Gravity Coordinate System (X_g, Y_g, Z_g) - A coordinate system fixed relative to the planet's local acceleration of gravity vector. The X_g axis is directed opposite to the local gravitational vector and the Y_g axis is parallel to the Surface Coordinate System Y_s axis. The Z_g axis is perpendicular to the gravitational vector and in the same general direction as the Surface Coordinate System Z_s axis.

Lander Coordinate System (X, Y, Z) - A coordinate system moving with the lander and fixed at the center of gravity of the center body. The lander's angular positions are defined in terms of the three Euler angles ψ, θ, and ϕ. Definition of the lander's angular position relative to the landing surface is based on a specific order for these Euler angle rotations. The order required for these rotations consists of an initial rotation, ψ, about the Z_s axis, followed by a rotation, θ, about the displaced Y axis and finally by a rotation, ϕ, about the direction of the displaced X axis resulting from the previous two rotations. Note, that when all three of these Euler angles are zero, the Lander Coordinate System is aligned with the Surface Coordinate System.

Footpad Coordinate System (X_i, Y_i, Z_i) - A coordinate system moving with the ith footpad and fixed at the footpad-main strut pivot point. The Y_i -Z_i plane remains parallel to the bottom of the footpad as the footpad impacts the landing surface. Footpad 1 may be located anywhere relative to the Lander Coordinate System. The remaining footpads are numbered consecutively in a positive angular direction about the X axis.

The Lander Coordinate System is related to the Surface Coordinate System by the following expression:

$$\begin{Bmatrix} X_s \\ Y_s \\ Z_s \end{Bmatrix} = \begin{bmatrix} DC11 & DC12 & DC13 \\ DC21 & DC22 & DC23 \\ DC31 & DC32 & DC33 \end{bmatrix} \begin{Bmatrix} X \\ Y \\ Z \end{Bmatrix} \qquad (5\text{-}1)$$

The elements in the lander's direction cosine matrix, [DC] are given as follows:

$$
\begin{aligned}
DC11 &= \text{Cos } \theta \text{ Cos } \psi \\
DC12 &= \text{Sin } \phi \text{ Sin } \theta \text{ Cos } \psi - \text{Cos } \phi \text{ Sin } \psi \\
DC13 &= \text{Cos } \phi \text{ Sin } \theta \text{ Cos } \psi + \text{Sin } \phi \text{ Sin } \psi \\
DC21 &= \text{Cos } \theta \text{ Sin } \psi \\
DC22 &= \text{Sin } \phi \text{ Sin } \theta \text{ Sin } \psi + \text{Cos } \phi \text{ Cos } \psi \\
DC23 &= \text{Cos } \phi \text{ Sin } \theta \text{ Sin } \psi - \text{Sin } \phi \text{ Cos } \psi \\
DC31 &= -\text{Sin } \theta \\
DC32 &= \text{Sin } \phi \text{ Cos } \theta \\
DC33 &= \text{Cos } \phi \text{ Cos } \theta
\end{aligned}
\tag{5-2}
$$

In addition to the above transformations, relationships between the time derivatives of the Euler angles and the angular velocity components about the lander coordinate axes are required. Integration of these define the lander's angular position as a function of time. The required relationships are expressed as

$$
\begin{aligned}
\dot{\phi} &= \dot{\Omega}_x + \text{Tan } \theta(\dot{\Omega}_y \text{Sin } \phi + \dot{\Omega}_z \text{Cos } \phi) \\
\dot{\theta} &= \dot{\Omega}_y \text{Cos } \phi - \dot{\Omega}_z \text{Sin } \phi \\
\dot{\psi} &= (\dot{\Omega}_z \text{Cos } \phi + \dot{\Omega}_y \text{Sin } \phi)/\text{Cos } \theta
\end{aligned}
\tag{5-3}
$$

where $\dot{\Omega}_x$, $\dot{\Omega}_y$, and $\dot{\Omega}_z$ are the components of the lander's angular velocity in the Lander Coordinate System.

5.1.2 <u>Equations of Motion</u> - The lander's equations of motion are discussed in two parts. The first presents the rigid body equations for the footpads considered to be in contact with the landing surface. The second part presents the development of the center body equations of motion, including the effects of a flexible center body structure.

5.1.2.1 <u>Contacting Footpads</u> - A footpad is termed "contacting" for two conditions. In the first, a footpad is considered to be contacting only after the footpad actually makes contact with the landing surface. Footpads not considered in contact with the landing surface are included in the center body equations as discussed in Section 5.1.2.2.

Secondly, on an optional basis, all of the lander's footpads may be treated as contacting footpads even if some of the footpads have not yet impacted the landing surface. In this case, inertia loading of the landing gear struts, due to the footpad mass, is simulated.

Each footpad considered to be in contact with the landing surface has three rigid body translation degrees of freedom. Two of these are in the plane of the landing surface and the third is normal to the landing surface. Equations of motion for each contacting footpad are written in the form

$$\begin{bmatrix} m_i & 0 & 0 \\ 0 & m_i & 0 \\ 0 & 0 & m_i \end{bmatrix} \begin{Bmatrix} \ddot{X}_i \\ \ddot{Y}_i \\ \ddot{Z}_i \end{Bmatrix} = \begin{Bmatrix} F_{x_i} \\ F_{y_i} \\ F_{z_i} \end{Bmatrix} + \begin{Bmatrix} -m_i \; g \; \text{Cos} \; \zeta \\ 0 \\ m_i \; g \; \text{Sin} \; \zeta \end{Bmatrix} \tag{5-4}$$

Terms in Equation (5-4) are defined as follows:

m_i = mass of ith footpad.

$\ddot{X}_i$, $\ddot{Y}_i$, $\ddot{Z}_i$ = translational accelerations of ith footpad in Surface Coordinate System.

F_{x_i}, F_{y_i}, F_{z_i} = sum of forces acting on ith footpad in Surface Coordinate System.

g = local acceleration of gravity.

ζ = local surface slope.

Two sets of forces are acting on each contacting footpad. These are the loads due to the stroking of the landing gear struts and the loads resulting from the interaction between the soil and the footpad attenuation system. These soil loads are zero when the footpad is clear of the landing surface.

5.1.2.2 Center Body - The effects of a flexible center body structure on the center body's motion have been included in the analysis. This is an optional feature of the Landing Loads and Motions Program and may be suppressed through input data. If suppressed, the center body is treated as a rigid body with up to six degrees of freedom.

To completely describe the dynamic motion of the elastic center body, a continuous elastic body must be considered. However, for the analysis of complex structures, the structure is often idealized as a network of finite elements. Motions of the idealized structure are determined at a finite number of arbitrarily selected control points distributed throughout the body. The motion of each control point on this body is expressed in terms of three translational and three rotational displacements. This idealization results in a total number of equations of motion equal to six times the number of control points selected.

In order to reduce the number of equations to be solved in the Landing Loads and Motions Program, the normal mode method, References (9) and (10), was employed. In this method the motion of the center body is approximated by the combination of a limited number of vibratory modes plus the six rigid body modes. By selecting the vibratory modes which will be excited for a given landing condition, the behavior of the flexible center body structure is obtained.

For the analysis of the legged lander, the center body's free-free (unrestrained) modes were chosen as the vibratory modes. The rigid body modes were assumed to be the three translational displacements defining the position of the center body center of gravity in the Surface Coordinate System and three angular displacements defined in the Lander Coordinate System.

In developing the center body equations of motion, expressions defining the motion of a point on the center body were obtained. These were used to evaluate the kinetic and potential energy of the center body. The final form of the center body's equations of motion were obtained by applying the Lagrangian equations to these energy expressions.

The total displacement of a point on the center body, point j in Figure 5-2, is defined as

$$\bar{r}_j = \bar{R} + \bar{\rho}_j \qquad (5\text{-}5)$$

$\bar{r}_j$ = position vector of point j relative to the Surface Coordinate System.

$\bar{R}$ = position vector of center body center of gravity relative to Surface Coordinate System.

$\bar{\rho}_j$ = position vector of point j relative to the Lander Coordinate System.

Because the center body is experiencing angular velocities and accelerations, the velocity and acceleration of point j are expressed as

$$\dot{\bar{r}}_j = \dot{\bar{R}} + \dot{\bar{\rho}}_j + (\dot{\bar{\Omega}} \times \bar{\rho}_j)$$

$$\ddot{\bar{r}}_j = \ddot{\bar{R}} + \ddot{\bar{\rho}}_j + (\ddot{\bar{\Omega}} \times \bar{\rho}_j) + \dot{\bar{\Omega}} \times (\dot{\bar{\Omega}} \times \bar{\rho}_j) + 2(\dot{\bar{\Omega}} \times \dot{\bar{\rho}}_j) \qquad (5\text{-}6)$$

In the above, the following definitions apply

$\dot{\bar{\Omega}}$ = angular velocity of center body in the Lander Coordinate System.
$\ddot{\bar{\Omega}}$ = angular acceleration of center body in the Lander Coordinate System.
$\dot{\bar{r}}_j$ = velocity vector of point j relative to the Surface Coordinate System.
$\ddot{\bar{r}}_j$ = acceleration vector of point j relative to the Surface Coordinate System.
$\dot{\bar{R}}$ = velocity vector of center body center of gravity relative to the Surface Coordinate System.
$\ddot{\bar{R}}$ = acceleration vector of center body center of gravity relative to the Surface Coordinate System.
$\dot{\bar{\rho}}_j$ = velocity vector of point j relative to the Lander Coordinate System.
$\ddot{\bar{\rho}}_j$ = acceleration vector of point j relative to the Lander Coordinate System.

It is assumed that the position vector locating the point on the center body can be separated into a term which varies with time and a term which remains constant with time. Thus, the location of point j relative to the Lander Coordinate System is

$$\bar{\rho}_j(s_j, t) = \bar{\rho}_{oj}(s_j) + \bar{\rho}_{ej}(s_j, t) \qquad (5\text{-}7)$$

where

s_j = coordinates of point j in Lander Coordinate System ($s_j = X_j$, Y_j, and Z_j).
$\bar{\rho}_{oj}$ = undeformed position of point j in Lander Coordinate System.
$\bar{\rho}_{ej}$ = deformed position of point j in Lander Coordinate System measured from the undeformed position of that point.

These position vectors are shown in Figure 5-3.

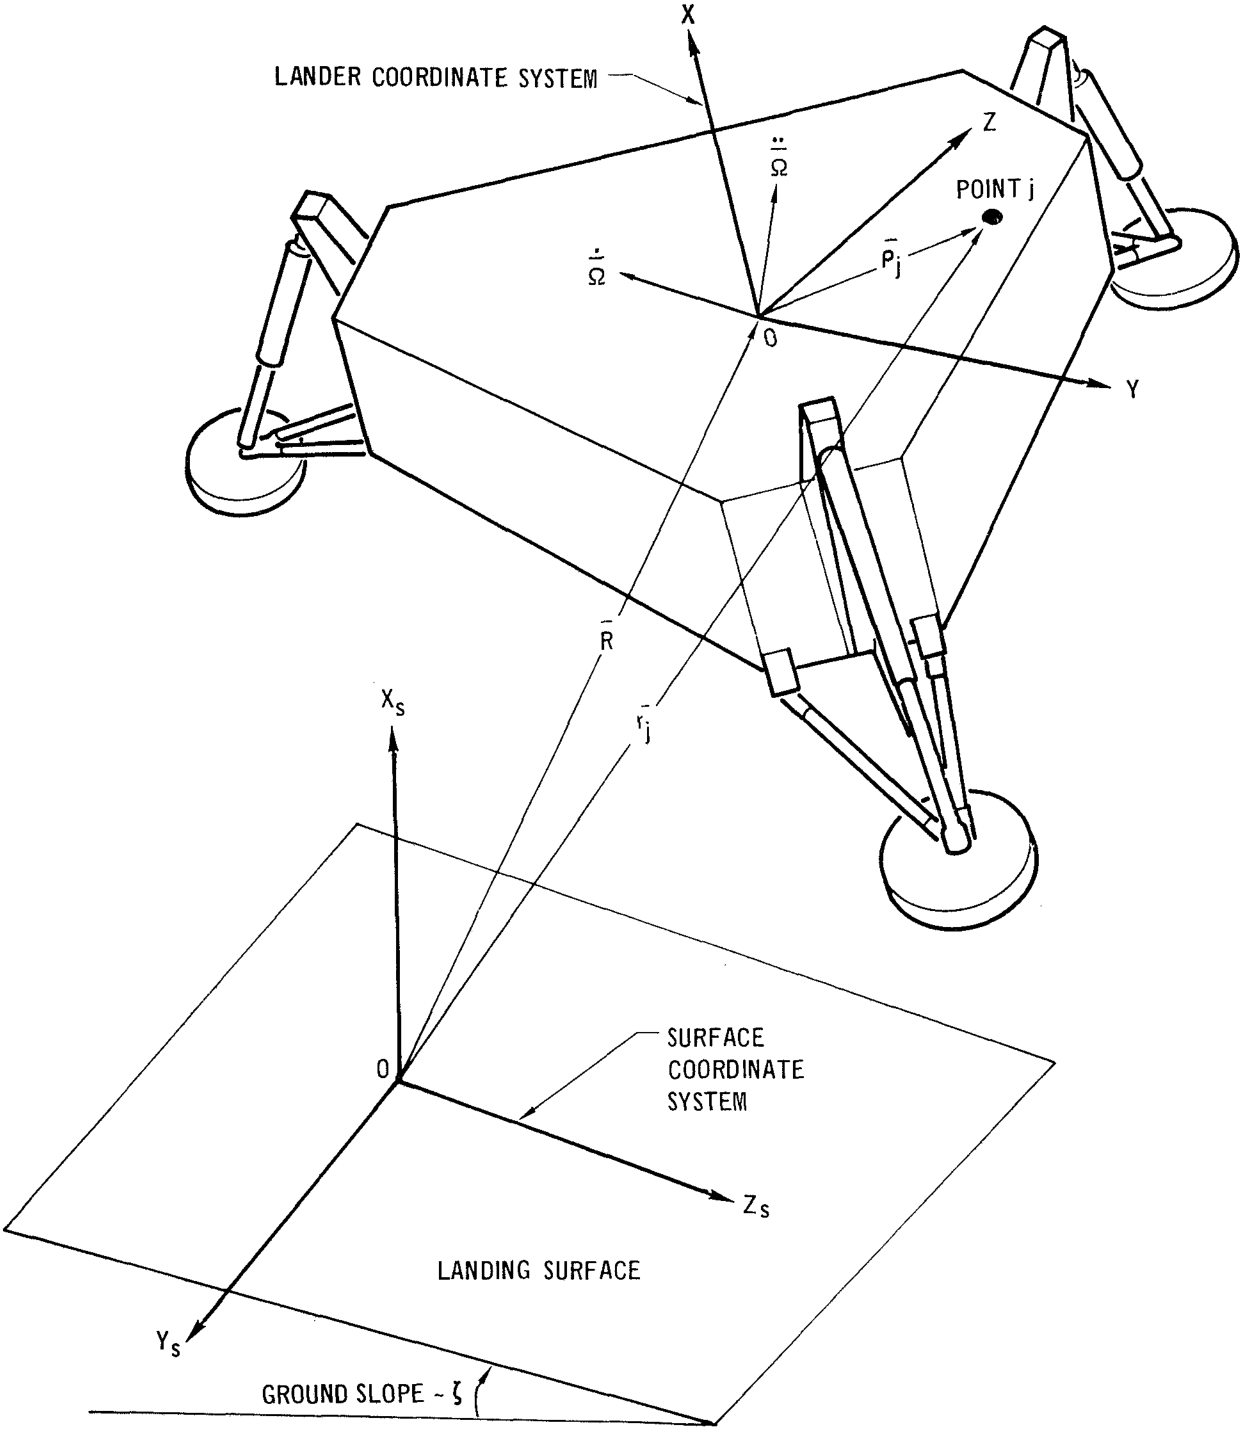

FIGURE 5–2 POSITION OF POINT ON CENTER BODY IN SURFACE COORDINATE SYSTEM

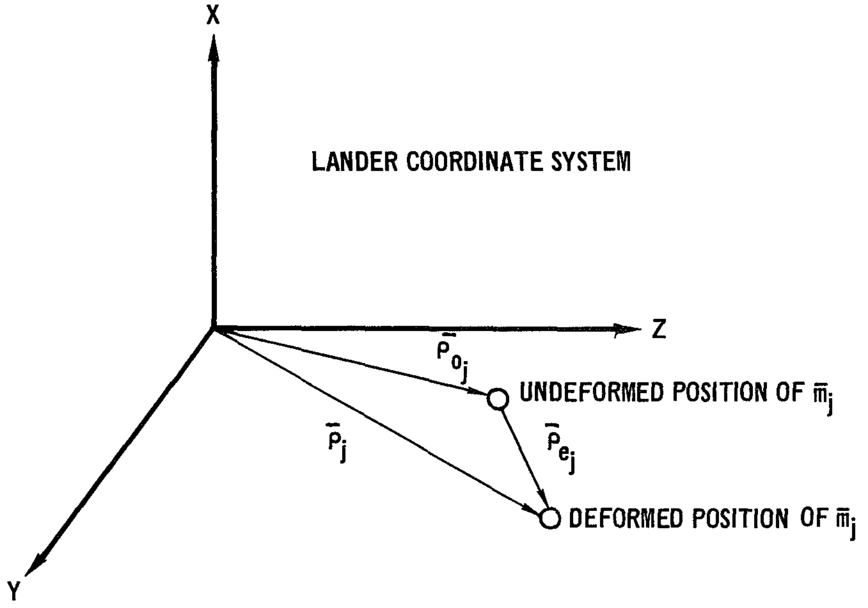

FIGURE 5-3 POSITION OF POINT ON CENTER BODY IN LANDER COORDINATE SYSTEM

Employing the assumption that the elastic deformation is represented by the superposition of a limited number of vibratory modes, the deformed position of point j is

$$\bar{\rho}_{ej} = \sum_{n}^{N} \bar{\phi}_{nj} q_n(t) \tag{5-8}$$

where

N = number of modes included.

$\bar{\phi}_{nj}$ = magnitude of nth elastic mode shape at point j. These are a function of the coordinates s_j.

q_n = generalized coordinate associated with nth mode. These are a function of time.

Expressing the deformed position of point j as components in the three axes of the Lander Coordinate System results in the following

$$\bar{\rho}_{ej} = \rho^j_{ex}\bar{i} + \rho^j_{ey}\bar{j} + \rho^j_{ez}\bar{k} \tag{5-9}$$

In the above, $\bar{i}$, $\bar{j}$, and $\bar{k}$ are the unit normal vectors in the Lander Coordinate

System. Combining Equations (5-8) and (5-9) results in the following expression for the deformed position of point j.

$$\bar{\rho}_{ej} = \sum_{n}^{N} (\phi^{j}_{xn}\bar{i} + \phi^{j}_{yn}\bar{j} + \phi^{j}_{zn}\bar{k})q_{n} \tag{5-10}$$

The terms, ϕ^{j}_{xn}, ϕ^{j}_{yn}, and ϕ^{j}_{zn} are the components of the nth mode shape at point j in the three lander axes directions.

The total velocity of point j is obtained by combining Equations (5-6) and (5-7).

$$\dot{\bar{r}}_{j} = \dot{\bar{R}} + \dot{\bar{\rho}}_{ej} + \dot{\bar{\Omega}} \times (\bar{\rho}_{oj} + \bar{\rho}_{ej}) \tag{5-11}$$

The total kinetic energy of the center body, T, is obtained by summing the kinetic energy of all control points on the center body each having a mass $\bar{m}_{j}$

$$T = \frac{1}{2} \sum_{j}^{J} \bar{m}_{j}\dot{\bar{r}}_{j} \cdot \dot{\bar{r}}_{j} \tag{5-12}$$

where J equals the total number of mass points on the center body. Combining Equation (5-12) with the definitions given in Equations (5-10)and (5-11), results in the following kinetic energy expression

$$\begin{aligned} T = {} & \frac{1}{2} M(\dot{q}_{x}^{2} + \dot{q}_{y}^{2} + \dot{q}_{z}^{2}) + \frac{1}{2} (I_{xx}\dot{q}_{rx}^{2} + I_{yy}\dot{q}_{ry}^{2} + I_{zz}\dot{q}_{rz}^{2}) \\ & - (I_{xy}\dot{q}_{rx}\dot{q}_{ry} + I_{xz}\dot{q}_{rx}\dot{q}_{rz} + I_{yz}\dot{q}_{ry}\dot{q}_{rz}) \\ & + \frac{1}{2} \dot{q}_{rx}^{2} \sum_{n}^{N} [(P_{yn} + P_{zn})q_{n} + \frac{1}{2} N_{xn}q_{n}^{2}] \\ & + \frac{1}{2} \dot{q}_{ry}^{2} \sum_{n}^{N} [(P_{xn} + P_{zn})q_{n} + \frac{1}{2} N_{yn}q_{n}^{2}] \\ & + \frac{1}{2} \dot{q}_{rz}^{2} \sum_{n}^{N} [(P_{xn} + P_{yn})q_{n} + \frac{1}{2} N_{zn}q_{n}^{2}] \\ & + \frac{1}{2} \sum_{n}^{N} m_{n}q_{n}^{2} \end{aligned} \tag{5-13}$$

Terms in Equation (5-13) are defined as follows, where the q_k's and q_{rk}'s are the generalized coordinates of the center body's rigid body modes.

M = center body mass.

I_{xx}, I_{yy}, I_{zz} = center body moments of inertia

I_{xy}, I_{xz}, I_{yz} = center body products of inertia.

$q_k, \dot{q}_k, \ddot{q}_k$ = rigid body translational displacement, velocity, and acceleration of center body center of gravity in the Surface Coordinate System (for $k = X_s, Y_s$, or Z_s axes).

$q_{rk}, \dot{q}_{rk}, \ddot{q}_{rk}$ = rigid body angular displacement, velocity, and acceleration relative to Lander Coordinate System (for $k = X, Y$, or Z).

m_n = generalized mass of nth elastic mode,

$$= \sum_j^J \bar{m}_j \bar{\phi}_{nj} \cdot \bar{\phi}_{nj} .$$

In addition, the following center body generalized inertia properties are expressed as

$$P_{xn} = \sum_j^J X_j \bar{m}_j \phi^j_{xn}$$

$$P_{yn} = \sum_j^J Y_j \bar{m}_j \phi^j_{yn}$$

$$P_{zn} = \sum_j^J Z_j \bar{m}_j \phi^j_{zn}$$

$$N_{xn} = \sum_j^J \bar{m}_j ({\phi^j_{yn}}^2 + {\phi^j_{zn}}^2)$$

$$N_{yn} = \sum_j^J \bar{m}_j ({\phi^j_{xn}}^2 + {\phi^j_{zn}}^2)$$

$$N_{zn} = \sum_j^J \bar{m}_j ({\phi^j_{xn}}^2 + {\phi^j_{yn}}^2)$$

The potential energy of the center body consists of the potential due to the planet's gravity field and the strain energy due to the center body's elastic deformation.

The potential due to the gravity field is

$$U_g = gM(\text{Cos}\ \zeta\ q_x - \text{Sin}\ \zeta\ q_z) \tag{5-14}$$

and the center body's strain energy is

$$U_s = \frac{1}{2}\sum_n^N m_n\omega_n^2 q_n^2 \tag{5-15}$$

where ω_n is the natural frequency at the nth free-free mode. Combining these expressions, the total potential energy of the center body is

$$U = gM(\text{Cos}\ \zeta\ q_x - \text{Sin}\ \zeta\ q_z) + \frac{1}{2}\sum_n^N m_n\omega_n^2 q_n^2 \tag{5-16}$$

The final form of the center body's equations of motion were obtained by applying the Lagrangian equations to the energy terms of Equations (5-13) and (5-16). The Lagrangian equations are expressed as

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}_c}\right) - \frac{\partial T}{\partial q_c} + \frac{\partial U}{\partial q_c} = Q_c. \tag{5-17}$$

where

q_c, $\dot{q}_c$ = cth generalized coordinate and generalized velocity (either rigid body or elastic modes).

T = center body's kinetic energy.

U = center body's potential energy.

Q_c = generalized force or moment in cth mode.

The generalized forces of the rigid body translational modes are the combination of the inertia effects of noncontacting footpads and the sum of the landing gear strut forces in the respective axis directions. The generalized moments of the rigid body rotational modes are the sum of the moments at the center body center of gravity, about the center body's axes. These consist of the inertia effects of the noncontacting footpads and moments due to the landing gear strut loads. For the elastic modes, the generalized force in the nth mode is

$$Q_n = \sum_{p}^{P} (F_x^p \phi_{nx}^{\ p} + F_y^p \phi_{ny}^{\ p} + F_z^p \phi_{nz}^{\ p}) \tag{5-18}$$

In the above, p refers to the pth point on the center body where a force is applied. There are a total of P forces, each of which has been resolved into components in the Lander Coordinate System axes.

To evaluate the inertia effects of a noncontacting footpad, consider the position vectors shown in Figure 5-4. The position of a footpad in question is given as

$$\bar{r}_{f_i} = \bar{R} + \bar{f}_i \tag{5-19}$$

where

$\bar{r}_{f_i}$ = position vector of ith noncontacting footpad relative to Surface Coordinate System.

$\bar{R}$ = position vector of center body center of gravity relative to Surface Coordinate System.

$\bar{f}_i$ = position vector of ith noncontacting footpad relative to Lander Coordinate System.

With the assumption that the noncontacting footpad is on an extension of the center body structure, its acceleration, $\ddot{r}_{f_i}$, is expressed as

$$\ddot{\bar{r}}_{f_i} = \ddot{\bar{R}} + (\ddot{\bar{\Omega}} \times \bar{f}) + \dot{\bar{\Omega}} \times (\dot{\bar{\Omega}} \times \bar{f}) \tag{5-20}$$

In the above, the terms $\ddot{\bar{R}}$, $\ddot{\bar{\Omega}}$, and $\dot{\bar{\Omega}}$ are defined in Figure 5-2 and Equation (5-6). Thus, the total inertia loads of all the noncontacting footpads at the center body center of gravity are

$$\bar{F}_f = - \sum_{i}^{I} m_i \ddot{\bar{r}}_{f_i}$$

and (5-21)

$$\bar{T}_f = - \sum_{i}^{I} m_i (\bar{f}_i \times \ddot{\bar{r}}_{f_i})$$

where I is the total number of noncontacting footpads, each with a mass m_i.

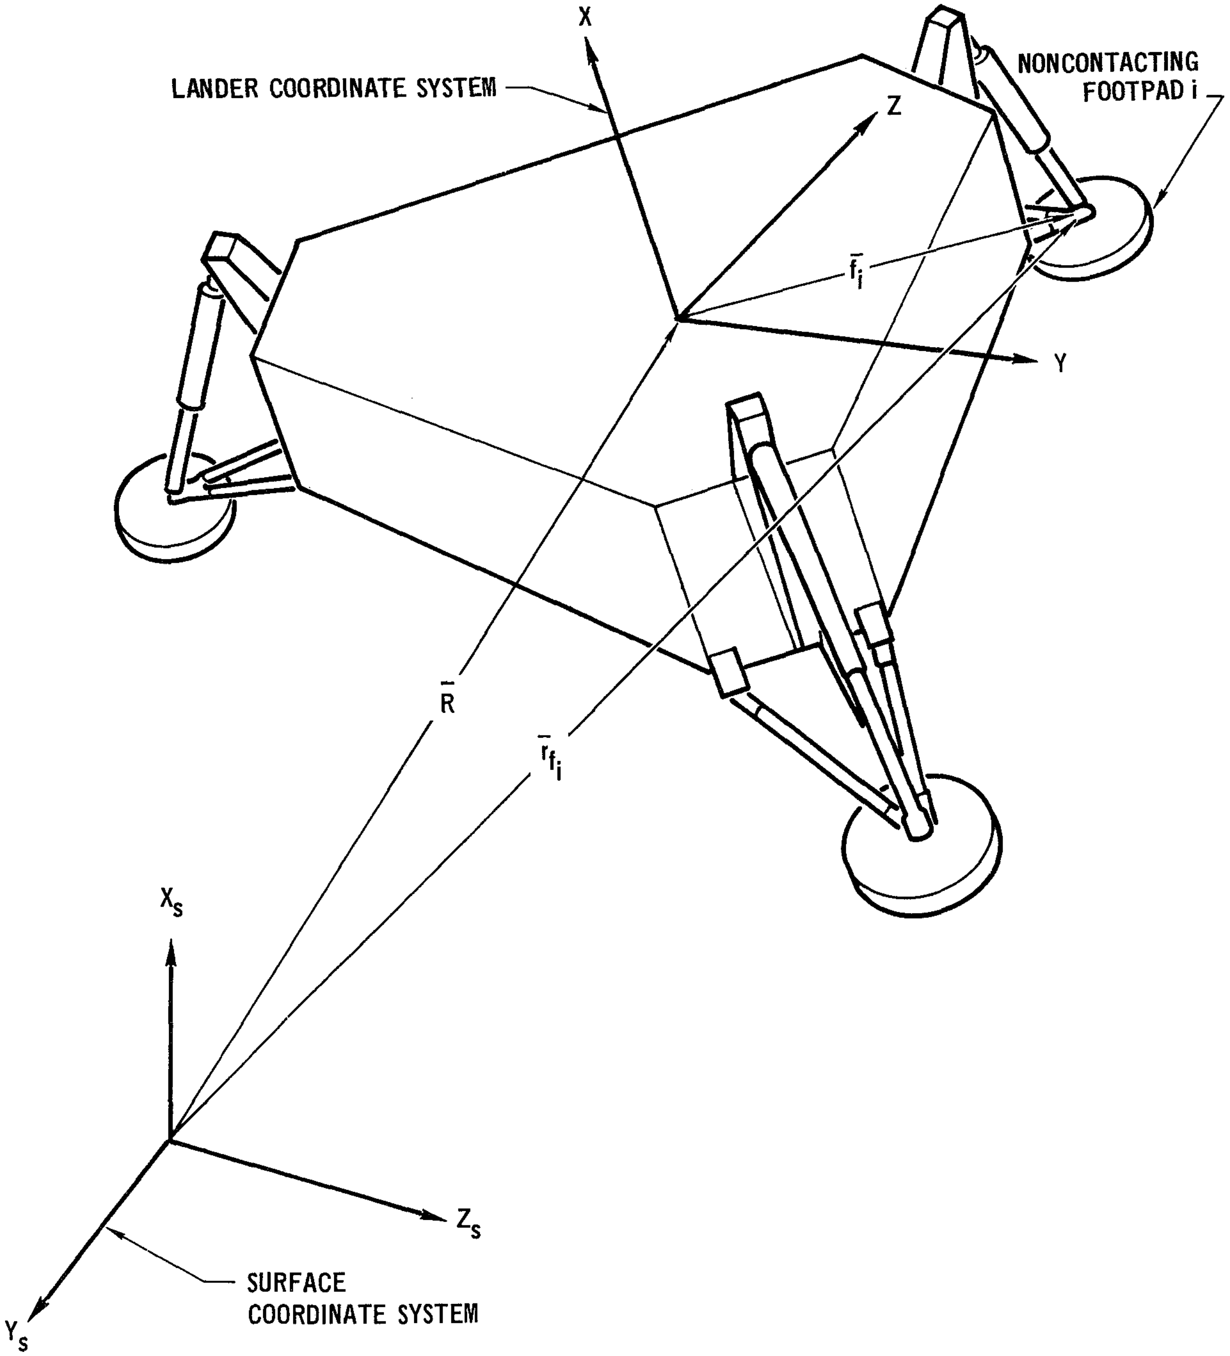

FIGURE 5–4 POSITION OF NONCONTACTING FOOTPAD IN SURFACE COORDINATE SYSTEM

Equations (5-21) may be written as

$$\begin{Bmatrix} F_{xf} \\ F_{yf} \\ F_{zf} \end{Bmatrix} = -\sum_{i}^{I} m_i \begin{Bmatrix} \ddot{q}_x \\ \ddot{q}_y \\ \ddot{q}_z \end{Bmatrix} - \sum_{i}^{I} m_i \, [DC] \begin{bmatrix} 0 & -f_{z_i} & f_{y_i} \\ f_{z_i} & 0 & -f_{x_i} \\ -f_{y_i} & f_{x_i} & 0 \end{bmatrix} \begin{Bmatrix} \ddot{q}_{rx} \\ \ddot{q}_{ry} \\ \ddot{q}_{rz} \end{Bmatrix}$$

(5-22)

$$-\sum_{i}^{I} m_i \, [DC] \begin{Bmatrix} \dot{q}_{ry} (\dot{q}_{rx} f_{y_i} - \dot{q}_{ry} f_{x_i}) - \dot{q}_{rz} (\dot{q}_{rz} f_{x_i} - \dot{q}_{rx} f_{z_i}) \\ \dot{q}_{rz} (\dot{q}_{ry} f_{z_i} - \dot{q}_{rz} f_{y_i}) - \dot{q}_{rx} (\dot{q}_{rx} f_{y_i} - \dot{q}_{ry} f_{x_i}) \\ \dot{q}_{rx} (\dot{q}_{rz} f_{x_i} - \dot{q}_{rx} f_{z_i}) - \dot{q}_{ry} (\dot{q}_{ry} f_{z_i} - \dot{q}_{rz} f_{y_i}) \end{Bmatrix}$$

and

$$\begin{Bmatrix} T_{xf} \\ T_{yf} \\ T_{zf} \end{Bmatrix} = -\sum_{i}^{I} m_i \begin{bmatrix} (f_{y_i}{}^2 + f_{z_i}{}^2) & -f_{x_i} f_{y_i} & -f_{x_i} f_{z_i} \\ -f_{x_i} f_{y_i} & (f_{x_i}{}^2 + f_{z_i}{}^2) & -f_{y_i} f_{z_i} \\ -f_{x_i} f_{z_i} & -f_{y_i} f_{z_i} & (f_{x_i}{}^2 + f_{y_i}{}^2) \end{bmatrix} \begin{Bmatrix} \ddot{q}_{rx} \\ \ddot{q}_{ry} \\ \ddot{q}_{rz} \end{Bmatrix}$$

$$-\sum_{i}^{I} m_i \begin{bmatrix} 0 & -\tilde{f}_{z_i} & \tilde{f}_{y_i} \\ \tilde{f}_{z_i} & 0 & -\tilde{f}_{x_i} \\ -\tilde{f}_{y_i} & \tilde{f}_{x_i} & 0 \end{bmatrix} \begin{Bmatrix} \ddot{q}_x \\ \ddot{q}_y \\ \ddot{q}_z \end{Bmatrix}$$

(5-22) (Continued)

$$-\sum_{i}^{I} m_i \begin{Bmatrix} f_{x_i} \dot{q}_{rx} (f_{y_i} \dot{q}_{rz} - f_{z_i} \dot{q}_{ry}) + (f_{y_i}{}^2 - f_{z_i}{}^2) \dot{q}_{ry} \dot{q}_{rz} + f_{y_i} f_{z_i} (\dot{q}_{rz}{}^2 - \dot{q}_{ry}{}^2) \\ f_{y_i} \dot{q}_{ry} (f_{z_i} \dot{q}_{rx} - f_{x_i} \dot{q}_{rz}) + (f_{z_i}{}^2 - f_{x_i}{}^2) \dot{q}_{rx} \dot{q}_{rz} + f_{x_i} f_{z_i} (\dot{q}_{rx}{}^2 - \dot{q}_{rz}{}^2) \\ f_{z_i} \dot{q}_{rz} (f_{x_i} \dot{q}_{ry} - f_{y_i} \dot{q}_{rx}) + (f_{x_i}{}^2 - f_{y_i}{}^2) \dot{q}_{rx} \dot{q}_{ry} + f_{x_i} f_{y_i} (\dot{q}_{ry}{}^2 - \dot{q}_{rx}{}^2) \end{Bmatrix}$$

where

$$\begin{Bmatrix} \tilde{f}_{x_i} \\ \tilde{f}_{y_i} \\ \tilde{f}_{z_i} \end{Bmatrix} = [DC] \begin{Bmatrix} f_{x_i} \\ f_{y_i} \\ f_{z_i} \end{Bmatrix}$$

are the components of the ith footpad location, from the center body center of gravity, in the Surface Coordinate System and

f_{x_i}, f_{y_i}, f_{z_i} = components of position vector locating ith noncontacting footpad in the Lander Coordinate System

[DC] = direction cosine matrix, Equation (5-1), relating Lander Coordinate System to Surface Coordinate System.

F_{xf}, F_{yf}, F_{zf} = inertia forces due to noncontacting footpads, relative to Surface Coordinate System.

T_{xf}, T_{yf}, T_{zf} = inertia moments due to noncontacting footpad, relative to Lander Coordinate System.

Using the center body energy expressions, Equations (5-13) and (5-16), and the noncontacting footpad inertia loads, Equation (5-22), in conjunction with the Lagrangian equation leads to the center body equations of motion given in Equation (5-23).

5.1.3 Landing Gear Strut Idealization - The two landing gear configuration options available in the Landing Loads and Motions Program are applicable to the inverted tripod gear and the cantilever gear. Each landing gear consists of a main strut and two drag struts. It is assumed that these are pinned struts and thus moments or torsion are not introduced at their ends. Both the main strut and the drag struts are capable of carrying tension and compression loads and may possess either velocity dependent energy absorption characteristics, stroke dependent characteristics, or a combination of the two. The energy absorption characteristics of all main struts in a given lander are the same. Similarly, characteristics of all the drag struts are the same, however they may be different than those of the main struts. For a cantilever gear, the effect of bending in the main strut is included by altering the energy absorption properties of the drag struts.

Relative motion between each footpad and the center body is used to determine the stroke and velocity of stroke in each strut. This information is used to determine the load in a landing gear strut employing the subroutine STRUT.

5.1.3.1 Stroke Dependent Attenuation - The primary type of energy absorption mechanism for the landing gear system consists of crushable

cartridges housed inside the landing gear struts. Each cartridge crushes at a constant load when the landing gear strut is stroked. Several cartridges, possessing different crushing strengths, may be stacked in series to form a desired load-stroke characteristic. In the present study, all struts may contain a maximum of five cartridges to attenuate compression loads and five to attenuate tension loads.

The idealization of the crushable landing gear struts in the Landing Loads and Motions Program is the same as is employed in the Landing Gear Option of the Structural Analysis Program. A discussion explaining the procedure for determining strut loads during strut stroking is presented in Section 4.1.2.2. In addition, a typical load-stroke relationship for a strut is shown in Figure 4-18.

5.1.3.2 Main Strut Bending - For a cantilever gear, the drag strut loads acting normal to the main strut in combination with the lateral loads on the footpad cause lateral deflections of the main strut. The assumption is made that the effect of this main strut deflection can be approximated through a modification of the drag strut load-stroke relationship.

The main strut is idealized as a simply supported beam whose elastic axis is defined by simple beam theory. Neglecting the effect of axial loads on the lateral deflection of the main strut, the deflected main strut is shown in Figure 5-5. The force F_n is the component of the drag strut force normal to the main strut axis. This force is defined as

$$F_n \bar{n} = F(\bar{s} \cdot \bar{n}) \bar{n} \qquad (5\text{-}24)$$

where F is the force in the drag strut, $\bar{n}$ is a unit vector normal to the main strut, and $\bar{s}$ is a unit vector in the direction of the drag strut. The flexural stiffness of the main strut on either side of the drag strut attach point is defined as EI_1 and EI_2.

The lateral deflection of the main strut due to the load F_n is expressed as

$$\Delta \bar{n} = F_n \left[\frac{1}{EI_1} \left(\frac{a^3 b}{3\ell} - \frac{a^4 b}{3\ell^2} \right) + \frac{1}{EI_2} \left(\frac{a^4}{\ell} - \frac{a^5}{3\ell^2} + \frac{a^2 \ell}{3} - a^3 \right) \right] \bar{n} \qquad (5\text{-}25)$$

The magnitude of this deflection, λ , in the direction of the drag strut axis is

$$\lambda\bar{s} = \Delta(\bar{s}\cdot\bar{n})\bar{s} \tag{5-26}$$

A spring constant reflecting the bending deflection of the main strut is defined as

$$K_B = \frac{F}{\lambda} \tag{5-27}$$

This expression is evaluated with the aid of Equations (5-24), (5-25) and (5-26) and results in

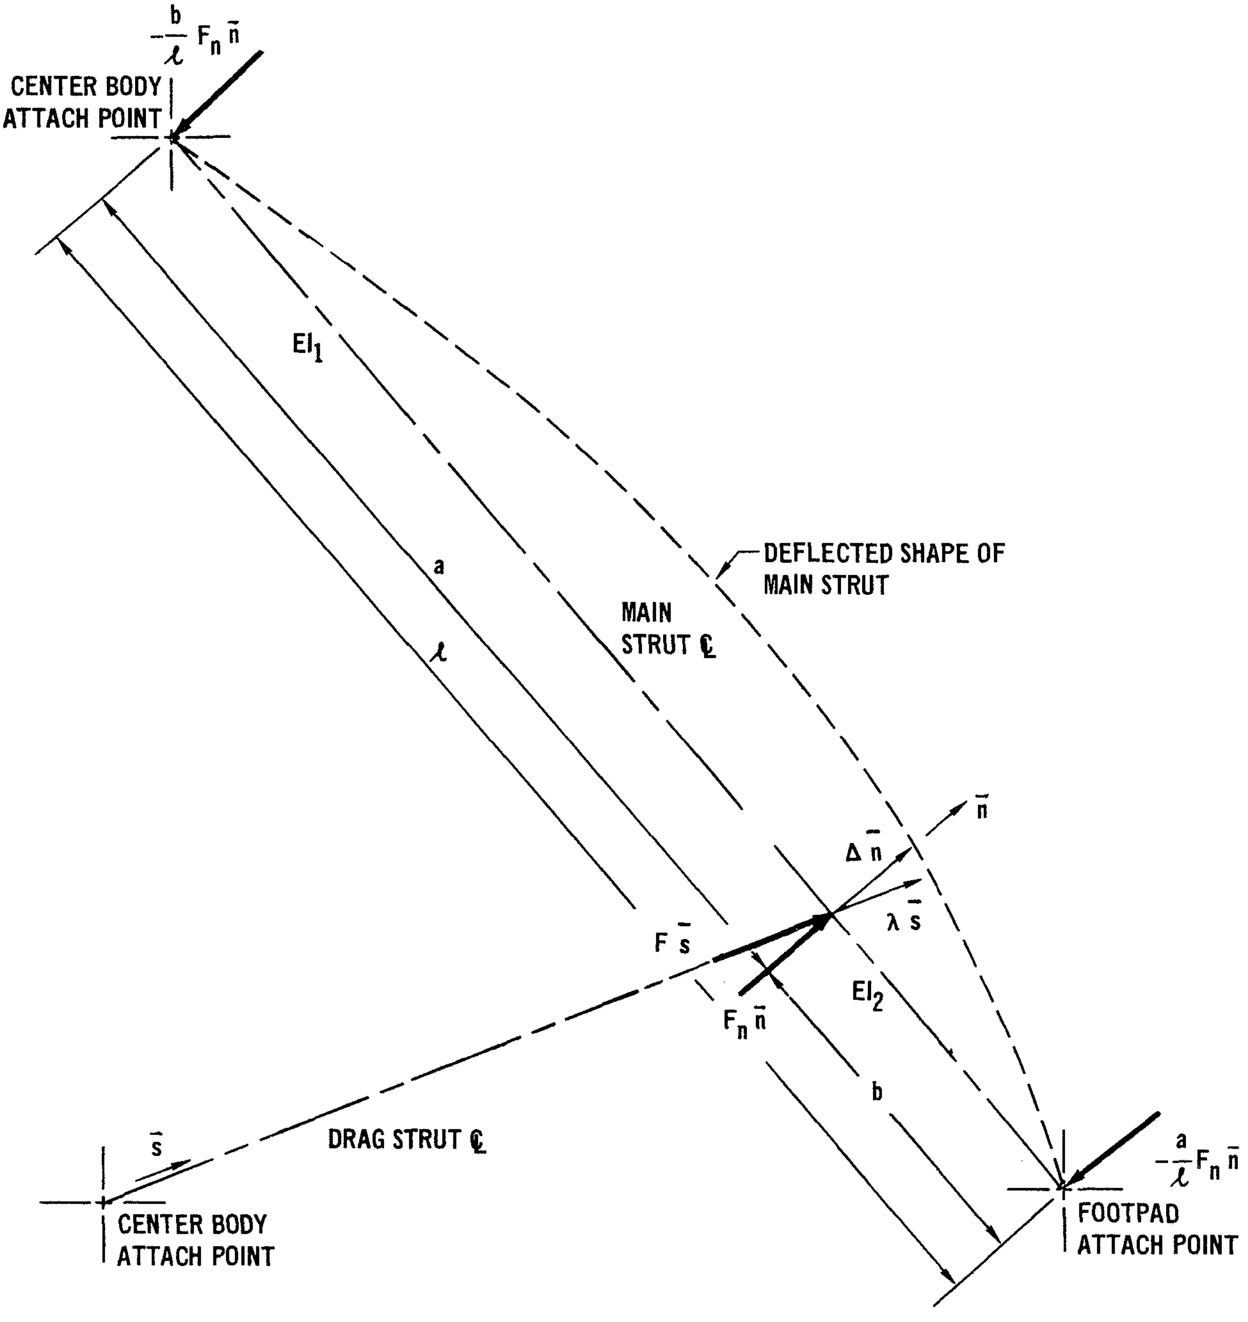
$$K_B = \frac{1}{(\bar{s}\cdot\bar{n})^2\left[\frac{1}{EI_1}\left(\frac{a^3b}{3\ell} - \frac{a^4b}{3\ell^2}\right) + \frac{1}{EI_2}\left(\frac{a^4}{\ell} - \frac{a^5}{3\ell^2} + \frac{a^2\ell}{3} - a^3\right)\right]} \tag{5-28}$$

This linear spring is assumed to be in series with the spring defining each elastic portion of the load-stroke diagram of the drag strut. A modified spring constant for these elastic portions of the load-stroke curve is calculated to reflect the main strut bending. This modified spring constant is used to define a modified load-stroke relationship for the drag strut. A typical drag strut modified load-stroke curve is shown in Figure 5-6. This modified curve is then employed to define the loads in the drag strut.

During stroking of the main strut, its bending characteristics change due to the change in strut length. These changes in bending characteristics are incorporated by continually modifying the spring constant of the drag strut load-stroke curve. As a result the drag strut load-stroke relationship is continually updated to reflect these changes in main strut bending characteristics.

5.1.3.3 Velocity Dependent Attenuation - Provisions are available for the inclusion of a constant friction force and a velocity dependent damping force in each strut. Both of these are applied in a direction opposite to the velocity of the stroking motion in the strut. The combination of these force terms is expressed as

$$F_v = -\frac{\dot{S}}{|\dot{S}|}\left[F_r + C\gamma\,|\dot{S}|^{\gamma}\right] \tag{5-29}$$



FOLLOWING RELATIONSHIPS HOLD:

$F_n \bar{n} = F(\bar{s} \cdot \bar{n}) \bar{n}$

$\lambda \bar{s} = \Delta (\bar{n} \cdot \bar{s}) \bar{s}$

FIGURE 5–5 DEFLECTION OF CANTILEVER GEAR MAIN STRUT

F_v = total velocity dependent force along axis of strut.

$\dot{S}$ = stroking velocity of strut.

F_r = magnitude of constant friction force (input quantity).

$C\gamma$ = coefficient of velocity proportional force (input quantity).

γ = power of velocity in velocity proportional force (input quantity).

This force is superimposed on the crushing force or may be included by itself.

5.1.4 Soil Mechanics - Two methods of representing the footpad-soil interaction are incorporated in the Landing Loads and Motions Program. The first of these, referred to as the Primary Soil Mechanics Method, is a modification of the soil mechanics analyses developed during the Lunar Module (LM) soil mechanics studies. This modification is similar to that employed during the Surveyor analysis. An alternate soil mechanics method, referred to as the Secondary Soil Mechanics Method, determines the soil force through a simple elastic-plastic relationship between soil pressure and depth of soil penetration. On an optional basis, a crushable footpad attenuation system located on the bottom of the footpads may be included with either of these soil mechanics routines. The footpad attenuation system is discussed in Section 5.1.5. Symbols employed in the soil mechanics routines are defined in Figure 5-7. The soil forces are determined in the subroutine SOIL.

The surface of each footpad is represented by a number of concentric conical and/or cylindrical segments as shown in Figure 5-8. It is assumed that the footpad is always aligned with the plane of the landing surface. Upon entering the soil mechanics routine, the footpad velocities and soil penetration indicated in Figure 5-8 are available. The three components of the soil force in the Footpad Coordinate System are returned from the soil mechanics routine.

5.1.4.1 Primary Soil Mechanics - The footpad-soil interaction method developed in Reference (11) for the LM shaped footpad utilized principles which are fundamental to the interaction phenomenon occurring during soil penetration. Applicability of this basic method to a different footpad shape was demonstrated by the good agreement obtained between telemetered Surveyor lunar impact data and predicted landing dynamics as reported in Reference (12).

FIGURE 5–8 FOOTPAD REPRESENTATION

In Reference (11) a theory of soil elasto-plastic deformation is used to define the force between the footpad and the deformed soil surface. The soil mass, displaced by the moving footpad, is considered as a degree of freedom independent of the lander system. A spring, representing the soil elasticity, is placed between the footpad and the soil mass. Additional external forces applied to the soil mass represent a momentum transfer force and a force due to the soil strength.

It was shown in the Surveyor simulation that sufficient accuracy can be obtained by neglecting soil elasticity and assuming that the moving soil mass is attached rigidly to the footpad. This simplification results in the removal of the soil mass differential equation from the analysis. Therefore, the soil force acting on the footpad is considered to be the sum of a soil strength term, a soil drag term, and a term approximating the effect of the changing soil mass.

The Primary Soil Mechanics Method employs the empirical relationships discussed in Reference (12). Forces acting on each footpad consist of an axial force, F_{ap}, parallel to the velocity vector of the footpad and a force, F_{np}, normal to the velocity vector.

The axial force is the sum of the forces due to the soil strength, soil drag, and effect of the changing soil mass and is expressed as

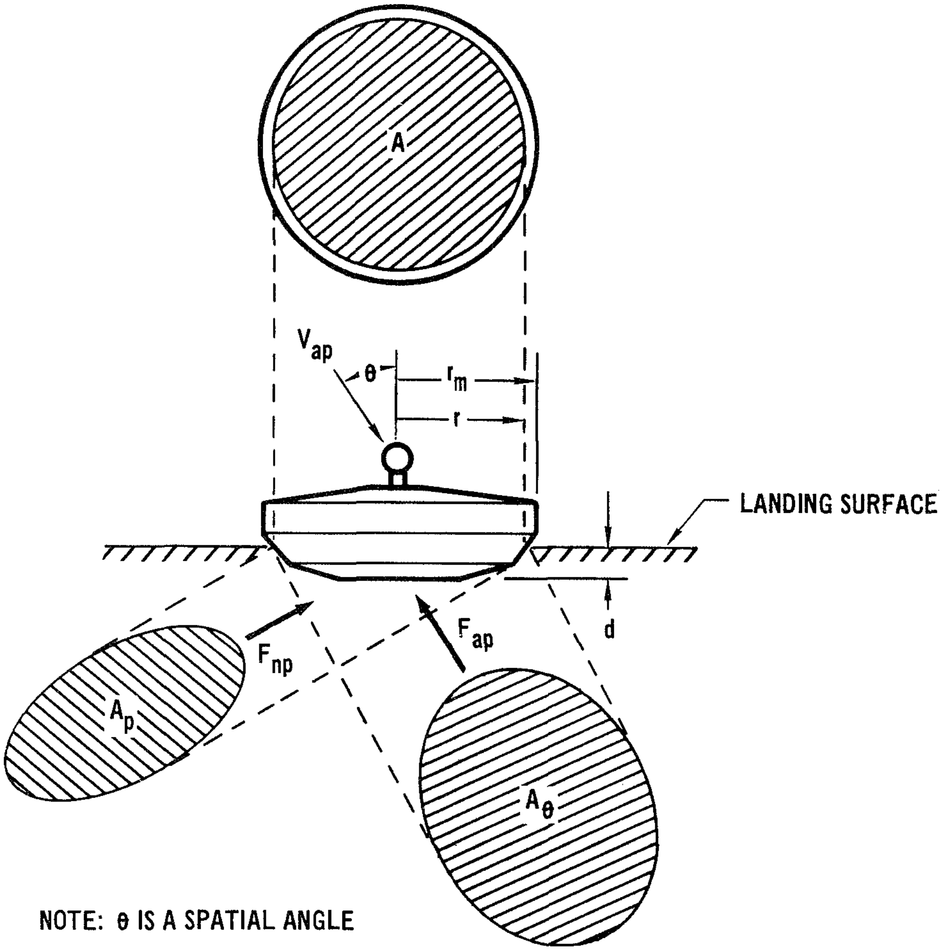
$$F_{ap} = C_{ms}\rho g d A_\theta + C_d \rho A_\theta V_{ap}^2 + 3\eta\rho r^2 \frac{dr}{dd}\left(\frac{A_\theta}{A}\right)^{3/2} V_{ap}^2 \operatorname{Cos}\theta \qquad (5\text{-}30)$$

Coefficients C_{ms} and C_d, representing the soil dynamic mechanical strength and drag coefficients respectively, are empirical factors determined from test and discussed further in later paragraphs. The wedge shape factor for moving soil mass, η, is a function of angle of internal friction of the soil, and is also discussed further in the section on empirical relationships. The term $(A_\theta/A)^{3/2}$ accounts for the effect of the angle θ. Change in footpad radius with respect to depth of the footpad, dr/dd, is defined by footpad geometry at the current depth of soil penetration.

The force acting on a footpad normal to the velocity vector is

$$F_{np} = \lambda F_{ap} \qquad (5\text{-}31)$$

This force is always directed out of the soil and is in the plane defined by the surface normal and the velocity vector. The quantity λ is discussed in the paragraphs defining the empirical relationships. Figure 5-9 presents a diagramatic representation of these two soil forces.



NOTE: θ IS A SPATIAL ANGLE

FIGURE 5-9 SOIL FORCES PRIMARY SOIL MECHANICS METHOD

Empirical relationships are determined in terms of the soil properties from impact and drag tests conducted during the LM study. Properties of twelve soils are described in Figure 5-10. The most significant of these properties are: unit weight, γ (bulk mass density, ρ, times g_e); relative density, D_r; the angle of internal friction, ϕ; and, to a lesser degree, the elastic modulus of the soil, E. Based on results reported in Reference (12), the properties γ, D_r and ϕ are adequate to describe the soil for landing dynamics and are used in the present study. In the soil mechanics subroutine, the empirical relationships for C_{ms}, C_d, λ, and η used for the Surveyor footpad, are employed during the determination of the soil forces acting on each footpad. These relationships are presented in Figure 5-11.

FIGURE 5–10 PROPERTIES OF SOILS

WEDGE SHAPE FACTOR FOR MOVING SOIL MASS:

$$\eta = \frac{\pi}{3} \; \frac{1 + \mathrm{TAN}\,\phi/2}{1 - \mathrm{TAN}\,\phi/2}$$

SOIL DYNAMIC MECHANICAL STRENGTH COEFFICIENT:

$$C_{ms} = 29\,e^{1.4\,D_r}\,\mathrm{TAN}\,\phi$$

SOIL DRAG COEFFICIENT:

$$C_d = 0.8 + \left(\frac{g}{g_e}\right)(4 + 80\,D_r)\left(\frac{r}{r_m}\right)^2 f(\theta)\,\mathrm{TAN}\,\phi \quad \mathrm{FOR}\ D_r < 0.5$$

$$C_d = 0.8 + 4\left(\frac{g}{g_e}\right) e^{4.83\,D_r}\left(\frac{r}{r_m}\right)^2 f(\theta)\,\mathrm{TAN}\,\phi \quad \mathrm{FOR}\ D_r \geq 0.5$$

WHERE:

$$f(\theta) = 1 - \frac{2\theta}{\pi} \quad \mathrm{FOR}\ 0 \leq \theta < 45^0$$

$$f(\theta) = 0 \quad \mathrm{FOR}\ \theta \geq 45^0$$

RATIO OF AXIAL TO NORMAL SOIL FORCE:

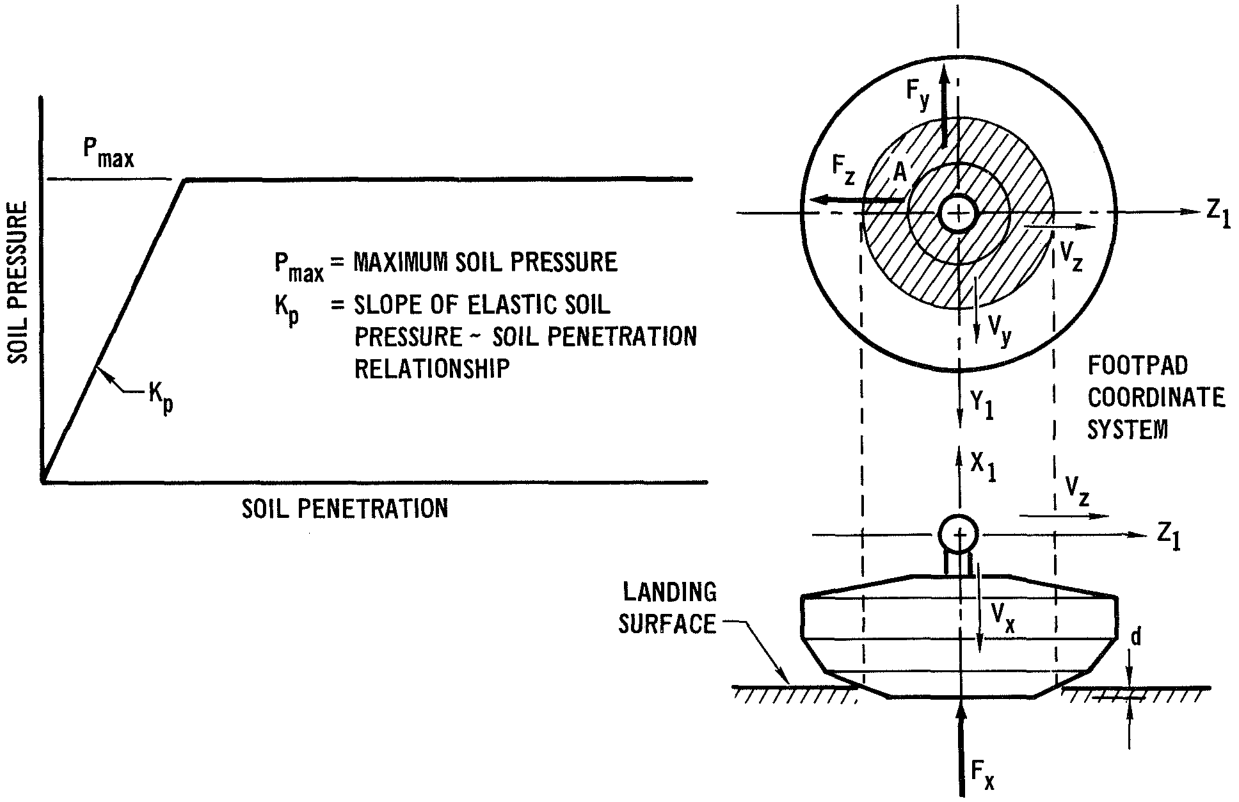
$$\lambda = 0.25\left(\frac{A_p}{A_\theta}\right)(1 - e^{-50\theta})(1 + \mathrm{SIN}\,\theta) \quad \mathrm{FOR}\ 0 \leq \theta < 90^0$$

$$\lambda = 0.5\left(\frac{A_p}{A_\theta}\right) \quad \mathrm{FOR}\ 90^0 \leq \theta < 135^0$$

$$\lambda = 0 \quad \mathrm{FOR}\ \theta \geq 135^0$$

FIGURE 5-11 EMPIRICAL SOIL RELATIONSHIPS

5.1.4.2 Secondary Soil Mechanics - An alternate soil mechanics routine is available in the Landing Loads and Motions Program. This method determines the pressure acting on a footpad in terms of depth of penetration of the footpad. The pressure-penetration relationship is defined as shown in Figure 5-12. Initially the soil pressure increases linearly from zero at zero penetration to a selected pressure at a specified cutoff depth. Beyond this depth, the pressure remains constant. The normal soil force is the product of the pressure determined from the relationship shown in Figure 5-12 and the area of the footpad projected on the landing surface.



THE SOIL FORCE NORMAL TO THE LANDING SURFACE OBTAINED BY THE SECONDARY SOIL MECHANICS METHOD IS GIVEN AS

$F_x = A\,d\,K_p$ OR $F_x = A\,P_{max}$

WHICHEVER IS LESS.

FIGURE 5-12 NORMAL SOIL FORCE SECONDARY SOIL MECHANICS METHOD

During the integration of the footpad's equations of motion, the normal soil force is compared to the force required to bring the footpad to rest during the next integration time step. This critical soil force is determined by

$$F_{cr} = m_i\left(g \ \text{Cos}\,\zeta - \frac{V_x}{\Delta t}\right) - S_x \tag{5-32}$$

where

F_{cr} = critical soil force.
m_i = mass of footpad.
g = local acceleration of gravity.
ζ = ground slope.
V_x = velocity of footpad into landing surface.
Δt = integration step size.
S_x = component of landing gear strut loads normal to landing surface.

The normal soil force applied to the footpad is never allowed to be greater than the magnitude of the force determine by Equation (5-32).

A force, acting in the plane of the landing surface, is obtained by multiplying the **normal** force by the selected value for the coefficient of friction. This force is applied in a direction opposite to the footpad's velocity in the plane of the landing surface. The components of this inplane soil force are expressed as

$$\begin{aligned} F_y &= - \frac{V_y}{\sqrt{V_y^{\,2} + V_z^{\,2}}}\ \mu F_x \\ F_z &= - \frac{V_z}{\sqrt{V_y^{\,2} + V_z^{\,2}}}\ \mu F_x \end{aligned} \tag{5-33}$$

where

V_y and V_z = inplane footpad velocities as shown in Figure 5-12.
F_y and F_z = components of inplane soil force.
μ = coefficient of friction.
F_x = normal soil force.

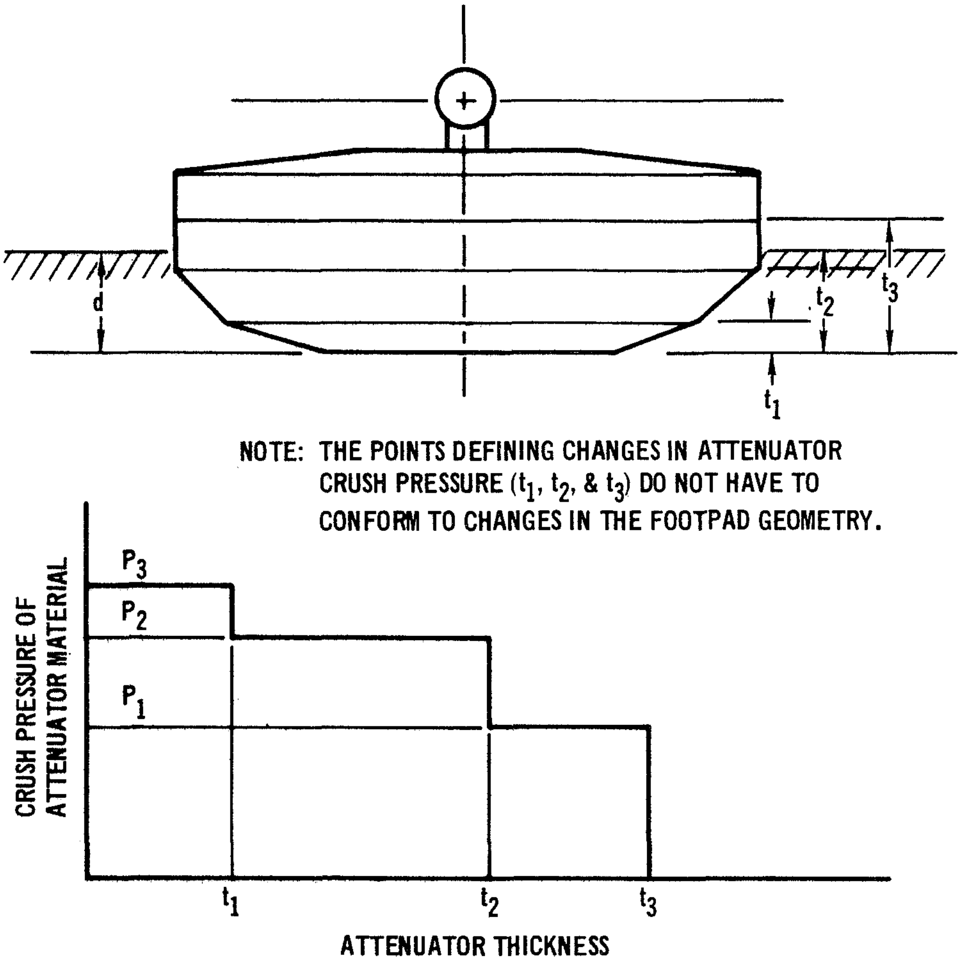
It should be noted that the force, F_x, employed in Equation (5-33), is the magnitude of the normal soil force obtained after the force resulting from the relationships of Figure 5-12 is compared with the critical soil force given by Equation (5-32).

5.1.5 Footpad Attenuation System - An additional attenuation system may be located on the bottom of the footpads to limit the landing loads of the footpads. Provisions have been made for including a crushable material on any or all of the conical segments used to represent the footpad shape. The amount of attenuation material crushing for each footpad is determined by a balance between the attenuator force and the soil force. The footpad attenuation system may be included with either the Primary or Secondary Soil Mechanics Methods. Forces associated with the footpad attenuation system are determined in the soil mechanics subroutine.

The footpad attenuation system may have three crush levels and the pressure-stroke relationship for the attenuator material is shown in Figure 5-13. It is assumed that the attenuator is crushed in a direction normal to the plane of the landing surface. The depth of soil penetration and amount of attenuator crushing, are determined by comparing the crush pressure with the soil pressure. With a soft soil and a stiff footpad attenuation material, most of the deformation will take place in the soil. For a very hard soil, a majority of the deformation will occur in the attenuator material. Intermediate values result in deformation of both the soil and attenuator materials.

At the end of a time interval, the attenuator thickness of each footpad which experiences crushing is adjusted to reflect this deformation. This is done by subtracting the crush distance from the coordinate locating the bottom of the footpad. Thus, if the lander rebounds, the crushed shape of the footpad attenuator is retained for the next impact. When the attenuator on a footpad is completely crushed the footpad attenuation portion of the analysis is bypassed, and the soil forces are applied directly to the footpad.

5.1.6 Footpad Sliding Motion - The two forces determined by the soil mechanics in the plane of the landing surface (F_y and F_z) are components of the inplane soil force F_f which is in a direction opposite to the sliding velocity of the footpad. This force tends to retard the sliding motion of the footpad along the landing surface.



NOTE: THE POINTS DEFINING CHANGES IN ATTENUATOR CRUSH PRESSURE (t_1, t_2, & t_3) DO NOT HAVE TO CONFORM TO CHANGES IN THE FOOTPAD GEOMETRY.

FIGURE 5-13 FOOTPAD ATTENUATION SYSTEM

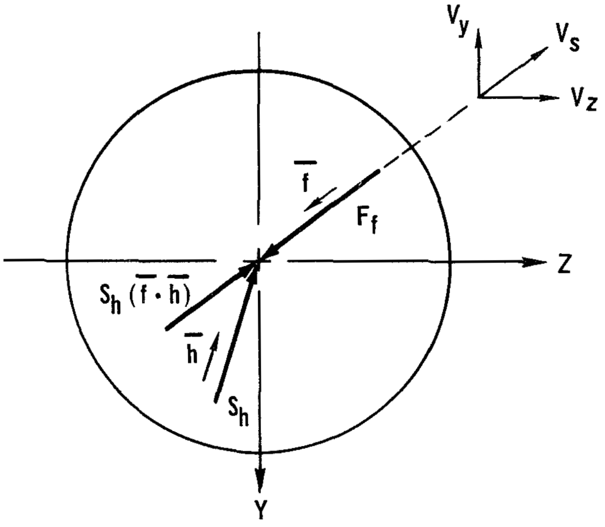
Referring to Figure 5-14, the equation of motion for the footpad in the plane of the landing surface and in the direction of the sliding motion is

$$m_i \frac{dV_s}{dt} = - F_f - S_h \, (\bar{f}\cdot\bar{h}) \qquad (5\text{-}34)$$

Therefore, the velocity of the footpad at the end of an integration step is

$$V_s \Big|_{t_n+\Delta t} = - \frac{F_f + S_h(\bar{f}\cdot\bar{h})}{m_i} \Delta t + V_s \Big|_{t_n} \qquad (5\text{-}35)$$

The critical value of F_f, which will just bring the footpad to rest is obtained from Equation (5-35) by setting the velocity at the end of the integration step ($V_s \big|_{t_n+\Delta t}$) equal to zero. Thus,



V_S = SLIDING VELOCITY OF FOOTPAD
S_h = COMPONENT OF LANDING GEAR STRUT LOAD PARALLEL TO LANDING SURFACE
$\bar{h}$ = UNIT VECTOR IN DIRECTION OF S_h
F_f = COMPONENT OF SOIL FORCE IN PLANE OF LANDING SURFACE
$\bar{f}$ = UNIT VECTOR IN DIRECTION OF F_f
m_i = MASS OF FOOTPAD
Δt = INTEGRATION STEP SIZE

WHEN THE FORCES F_f AND S_h OPPOSE EACH OTHER, THE FOLLOWING HOLDS

$$(\bar{f}\cdot\bar{h}) < 0$$

WHILE

$$(\bar{f}\cdot\bar{h}) > 0$$

WHEN THESE FORCES ACT IN THE SAME DIRECTION.

FIGURE 5–14 EVALUATION OF IN-PLANE SOIL FORCE MAGNITUDE

$$F_{fc} = \left.\frac{m_i V_s}{\Delta t}\right|_{t_n} - S_h\,(\bar{f}\cdot\bar{h}) \qquad (5\text{-}36)$$

Equation (5-36), in conjunction with Equation (5-37), is employed to maintain the magnitude of F_f at a value equal to or less than that which is required to bring the footpad to rest during the next integration step. When the relationship of Equation (5-37) holds, the magnitude of F_f determined by the soil mechanics routine is not changed.

$$F_f \leq F_{fc} \tag{5-37}$$

If the condition of Equation (5-37) is not met, the magnitude of F_f is recalculated by Equation (5-38) when F_f and $S_h(\bar{f}\cdot\bar{h})$ are in opposite directions and

$$F_f = \left.\frac{m_i V_s}{\Delta t}\right|_{t_n} - S_h\,(\bar{f}\cdot\bar{h}) \tag{5-38}$$

Equation (5-39) governs the magnitude of F_f when $S_h(\bar{f}\cdot\bar{h})$ and F_f are in the same direction.

$$F_f = \left.\frac{m_i V_s}{\Delta t}\right|_{t_n} \tag{5-39}$$

5.1.7 Lander Stability - To determine the stability of a legged lander configuration, the "plane of lander motion," as shown in Figure 5-15, is defined. This plane is defined by the gravity vector $\bar{g}$, and the translational velocity $\dot{\bar{R}}$, of the lander's center of gravity. The lander is considered unstable when the gravity vector passes outside of the area bounded by the lander footpads. If all the lander footpads are on the same side of the plane of lander motion, the lander is said to be experiencing yaw instability.

The more common case is when two footpads are astride the plane of lander motion, as shown in Figure 5-15. In this case, the vector $\bar{L}$, extending from the lander center of gravity to the intersection point of a line between these two footpads and the plane of lander motion, is obtained. The stability angle is then defined as

$$S = \text{Cos}^{-1}\left\{\frac{(\bar{L}\cdot\bar{g})}{|\bar{L}|\;|\bar{g}|}\right\} \tag{5-40}$$

As long as S is positive, the lander is considered to be stable, When S passes through zero the lander is said to be experiencing pitch instability.

To aid in the evaluation of the lander stability, the pitching velocity is also determined. This quantity is the component of the lander's total angular velocity in the plane of lander motion.

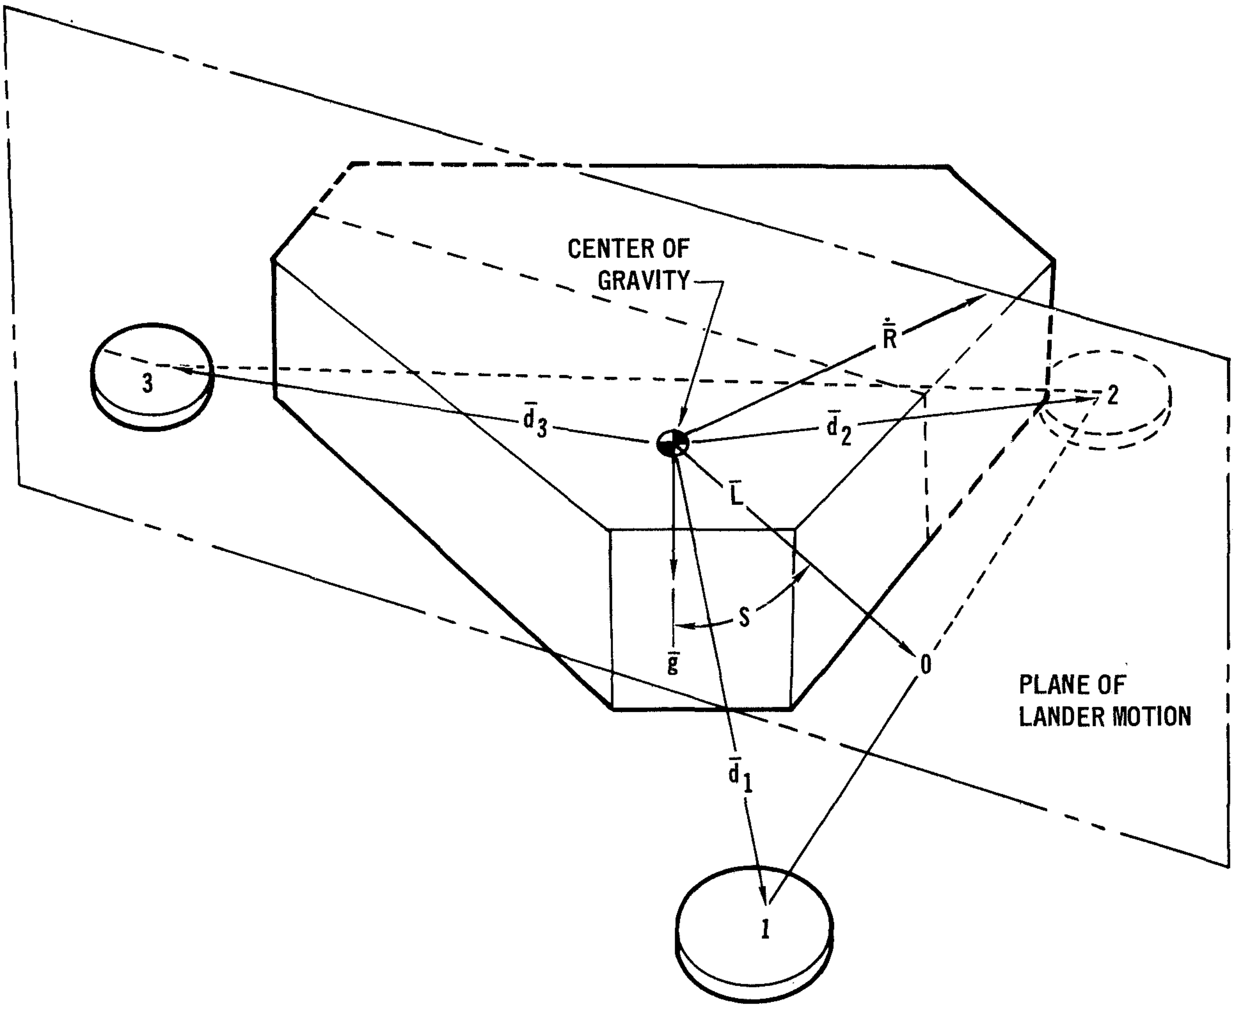


FIGURE 5-15 LANDER STABILITY ANGLE

This stability determination is made in the subroutine STABLE. It is an optional routine of the Landing Loads and Motions Program and is performed if the input indicator JCKSAB is set equal to 1. If the lander becomes unstable, the run is terminated with a printed message stating which type of instability was experienced.

5.2 Program Description - The Landing Loads and Motions Program is best described by defining functions of the program subroutines and examining program organization, as presented in a flow diagram. A listing of the program is given in Appendix I. All programming is in FORTRAN 2.0 for machine computation on CDC 6600 computers.

5.2.1 Subroutines - The Landing Loads and Motions Program is divided into three OVERLAY segments. Each segment consists of an executive subprogram and a number of subroutines as shown in Figure 5-16. This organization has been used to minimize the core storage requirements of the program. Several subroutines have multiple entry points, as indicated in Figure 5-16. The function of each subroutine, depending on the point of entry, is defined in Figure 5-16.

OVERLAY(LLMPT5,0,0) consists of the executive subprogram LLMP. LLMP calls the other two overlays in the proper order and contains all of the COMMON blocks.

READIT is the executive subprogram in OVERLAY(LLMPT5,1,0). This segment of the program reads and prints the input data and initializes all the routines before integration of the equations of motion.

LLMPEX is the executive subprogram in OVERLAY(LLMPT5,2,0). It controls the solution of the equations of motion. Subroutines in this portion of the program obtain the forces in the landing gear struts and determine the soil forces. These forces are summed on the center body and contacting footpads, resulting accelerations determined, equations of motion integrated, and time history quantities printed. At the completion of a time history, program control is returned to OVERLAY(LLMPT5,0,0) for the possible consideration of an additional data set.

Two numerical integration methods are incorporated in the subroutine RKCUT. These consist of a constant step Runge-Kutta method and a variable step Runge-Kutta method. A description of these integration techniques is presented in Appendix F.

SUBPROGRAM NAME	SUBROUTINE NAME	ENTRY POINT	OVERLAY LOCATION	SUBPROGRAM OR SUBROUTINE OPERATIONS
LLMP		LLMP	OVERLAY (LLMPT5,0,0)	MAIN EXECUTIVE SUBPROGRAM. CONTROLS THE EXECUTION OF THE TOTAL PROGRAM.
READIT		READIT	OVERLAY (LLMPT5,1,0)	EXECUTIVE SUBPROGRAM IN OVERLAY (LLMPT5,1,0). ALSO READS THE INPUT DATA AND DETERMINES IF THE AMOUNT OF DATA IS CONSISTENT WITH THE INPUT CONTROL INDICATORS. IF NOT, THE PROGRAM IS TERMINATED. INITIALIZES THE PROGRAM.
	DATAOT	DATAOT		PRINTS INPUT DATA.
LLMPEX		LLMPEX	OVERLAY (LLMPT5,2,0)	EXECUTIVE SUBPROGRAM IN OVERLAY (LLMPT5,2,0). CONTROLS INTEGRATION OF EQUATIONS OF MOTION.
	FTPAD	FTPAD		CONTROLS DETERMINATION OF LOADS IN LANDING GEAR STRUTS AND SOIL FORCES.
	GEOM	GEOM		DETERMINES DIRECTION COSINE MATRIX AND TIME DERIVATIVES OF EULER ANGLES.
	STRUT	STRUT		DETERMINES LOAD IN LANDING GEAR STRUTS.
	SOIL	SOIL		DETERMINES SOIL FORCES.
	INITUP			NUMERICAL INTEGRATION INITIALIZATION SUBROUTINE.
		LOC		DEFINES AND STORES CUTOFF VARIABLES.
		INUPD		SETS UP STORAGE FOR INTEGRATED VARIABLES.
	RKCUT			RUNGE-KUTTA NUMERICAL INTEGRATION SUBROUTINE.
		SETUP		INITIALIZATION OF RKCUT ROUTINE.
		INTEG		INTEGRATION OF EQUATIONS OF MOTION.
		UPDATE		UPDATES INTEGRATION VARIABLES AND MODIFIES INTEGRATION INTERVAL.
		CUT		CHECKS CUTOFF LIMITS.
	OUTPUT	OUTPUT		PRINTS TIME HISTORY INFORMATION.
		SUMMRY		PRINTS SUMMARY INFORMATION AT THE END OF A DATA CASE.
	STABLE	STABLE		CHECKS STABILITY OF LANDER.
	MATINV	MATINV		MATRIX INVERSION SUBROUTINE.
	GMPRD	GMPRD		MATRIX MULTIPLICATION SUBROUTINE.

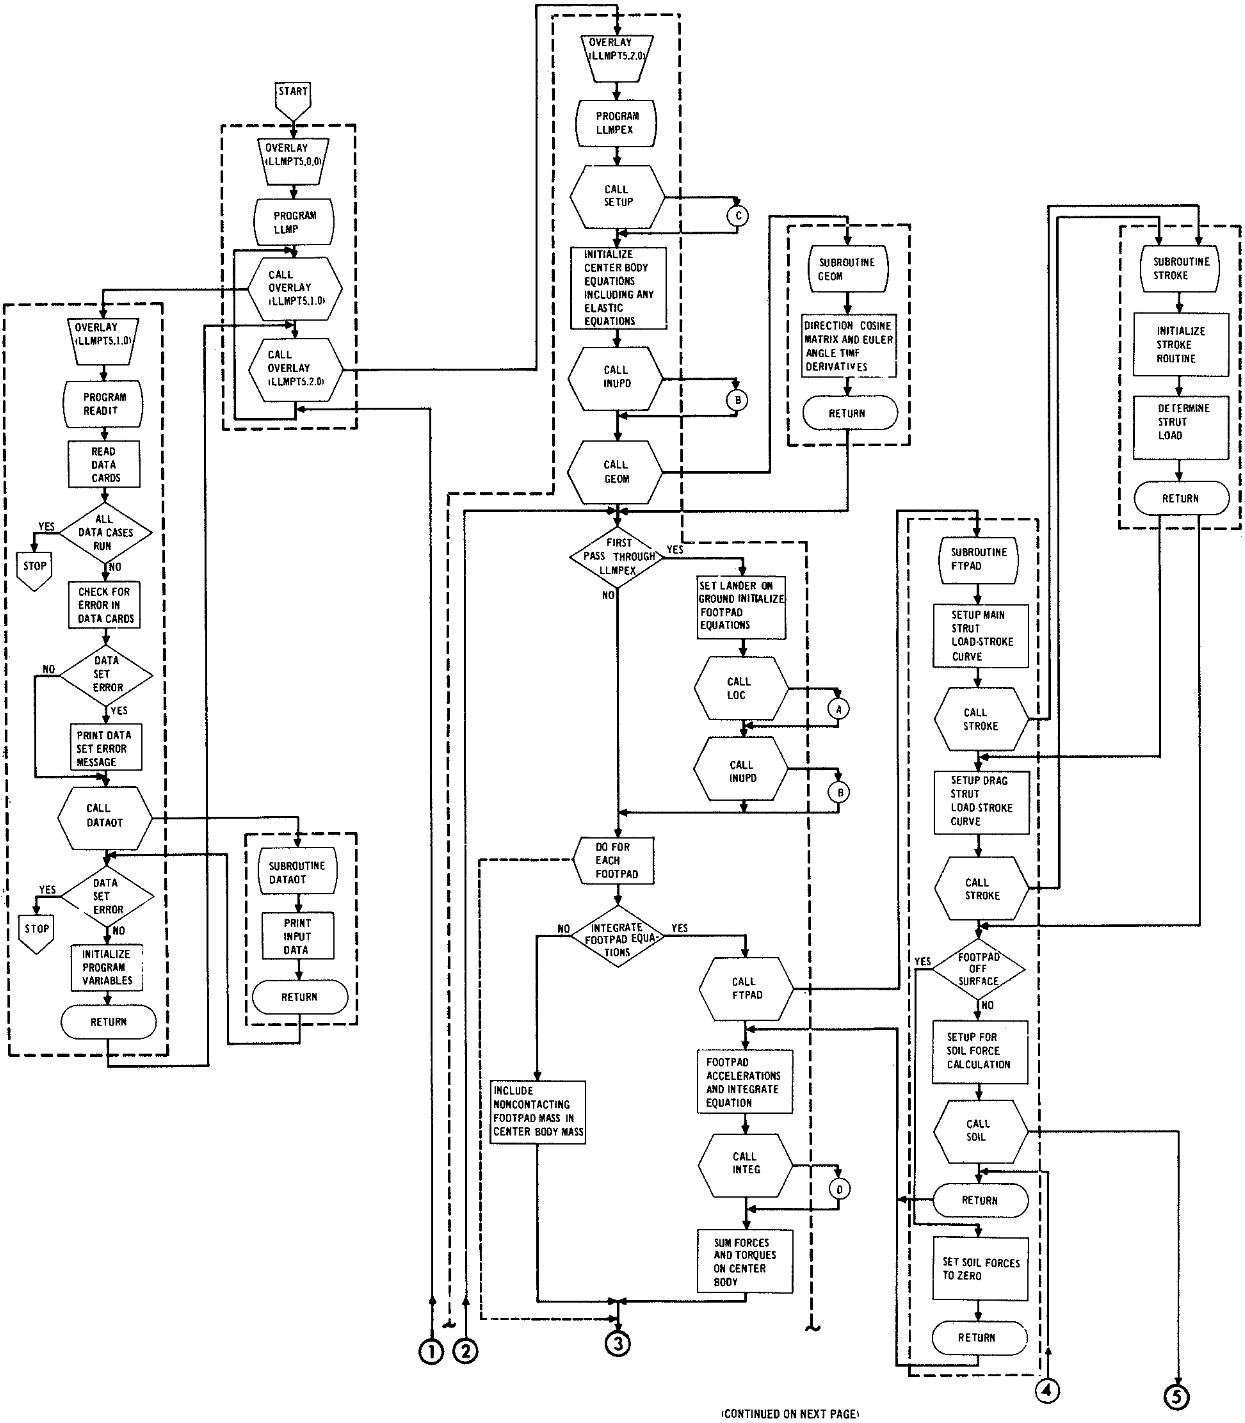
FIGURE 5-16 LANDING LOADS AND MOTIONS PROGRAM SUBROUTINES AND SUBPROGRAMS

5.2.2 Flow Diagram - A flow diagram showing the general operation of the Landing Loads and Motions Program is presented in Figure 5-17. The three OVERLAY segments are shown in addition to the various subprograms and subroutines which are located in each OVERLAY. This diagram is not intended to be a comprehensive programming chart, but shows the general flow of the program logic and indicates the order of operations within each subroutine. A complete listing of the Landing Loads and Motions Program is given in Appendix I.

5.3 Program Operation - Successful operation of the Landing Loads and Motions Program depends on proper input of data and correct interpretation of output data. These considerations are discussed in the following paragraphs. Examples of required input data and resulting output data for a typical landing condition are given in Appendix D.

5.3.1 Input Data - Required as input data is information describing the geometric and inertia properties of the specific lander to be studied; initial lander attitudes; linear and rotational velocities; surface conditions such as ground slope and soil properties; and the indicators needed to control the program's operation. This section defines the format of the input data cards and contains instructions for properly supplying input data to the program.

Figure 5-18 shows the required format for the input data cards. Columns 6 through 9 contain a card number, which must be right justified. Input data is placed in floating point form in columns 11-20, 21-30, 31-40, 41-50, and 51-60. Data input in a F format need not be right justified, but data in an E format must be right justified. In either case, the data must be contained entirely within the field of 10 columns provided. Columns 61 and on may be used for sequence numbers, identification statements, or comments. Following the last card of a data set, a card with NEXT in columns 1 through 4, must appear. Multiple cases may be run by stacking the data sets. Note that the input indicator IDSETN(Card 8) must be equal to 1 if another data set follows the current data set. The data cards for any additional data sets follow the first data set, and each of these are terminated with a NEXT in columns 1 through 4. A card with STOP in columns 1 through 4 signals the end of all the data sets.



(CONTINUED ON NEXT PAGE)

FIGURE 5-17 FLOW DIAGRAM LANDING LOADS AND MOTIONS PROGRAM

(CONTINUED FROM PREVIOUS PAGE)

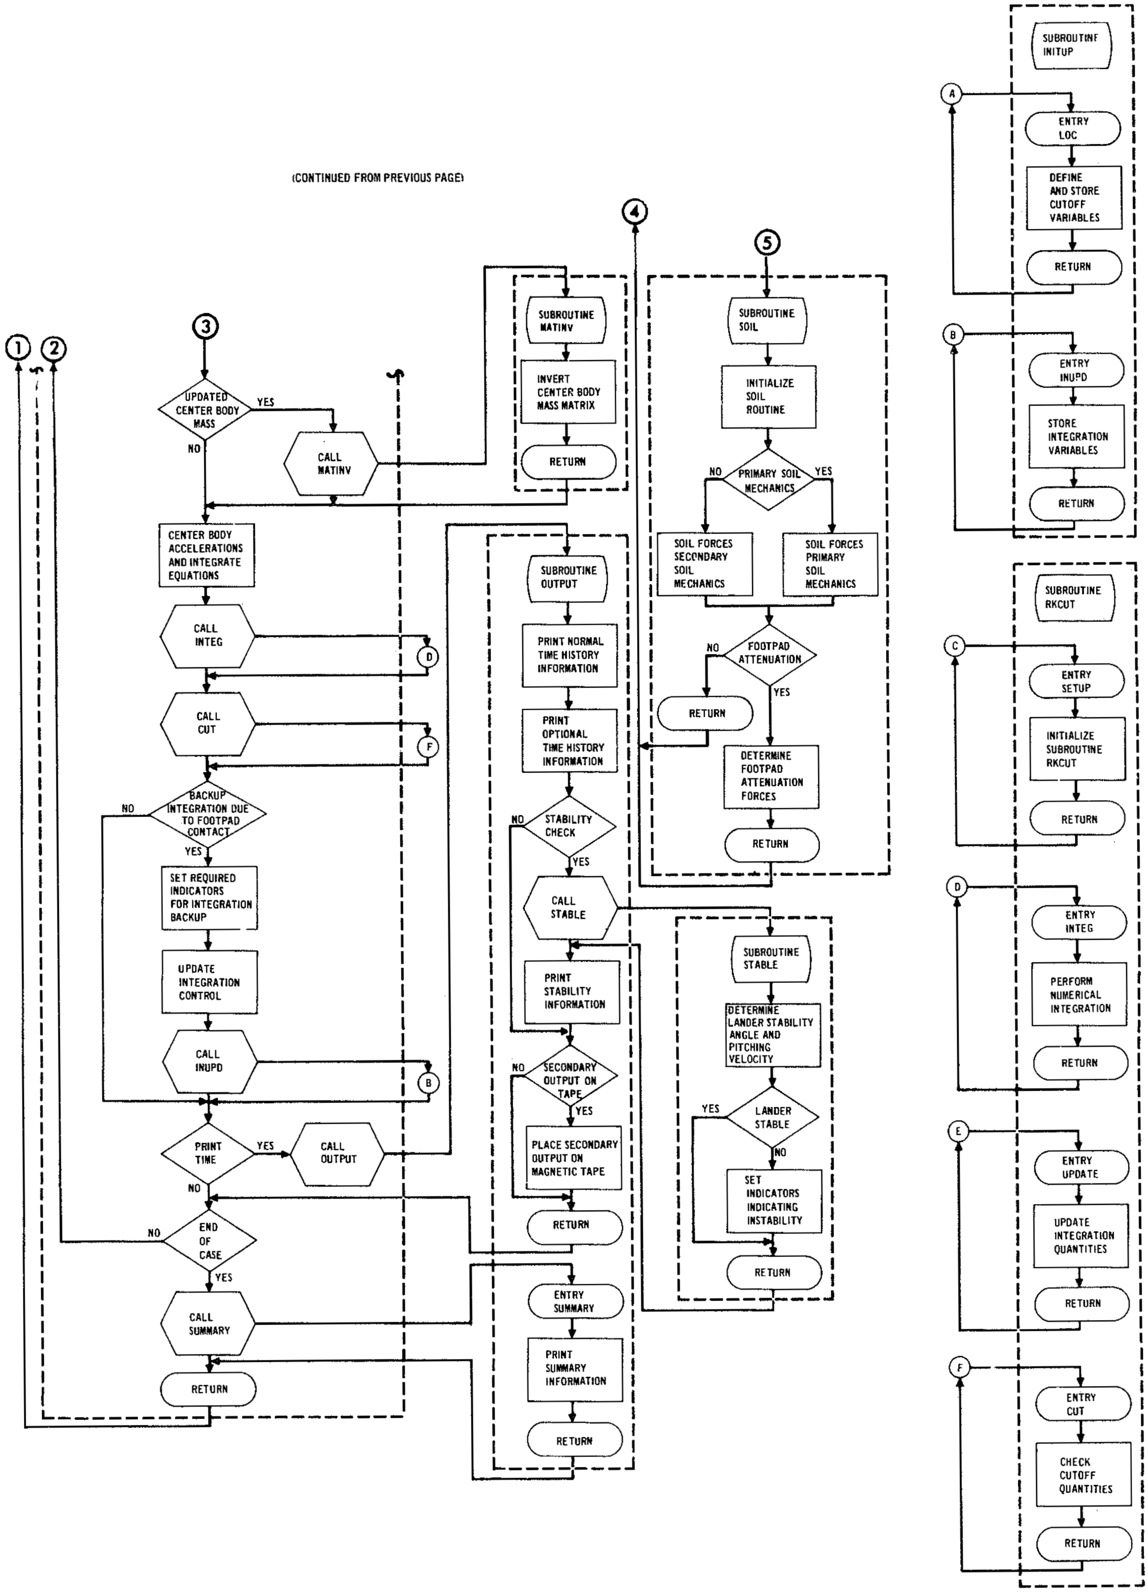


FIGURE 5-17 FLOW DIAGRAM LANDING LOADS AND MOTIONS PROGRAM (Continued)

There are a number of indicators and counters which check the input data as it is read to ensure that the correct amount of information has been input. If the number of data cards is incorrect, the run will be terminated, and error messages printed to indicate where the data error occurred. All of the indicators governing these input options are discussed in Figure 5-19.

Data cards for the first data set must contain all of the information required to completely initialize the first case. Only optional data, consistent with the input control indicators, may be left out of the first data set. For following data sets, only the information which is to be different (or in addition to that of the preceding case) needs to be changed on the appropriate cards.

There is no specific order in which the low number data cards, Cards 1 through 42, must appear in a data set. However, the order of the higher numbered cards (Cards 100 through 1700) is of importance. All of these cards with higher numbers define variables which are subscripted in the Landing Loads and Motions Program. Therefore, all the cards with the same card number must be input in the order in which the user requires this information stored in the program.

All input parameters and their associated data card numbers are defined in Figure 5-20. Most of these parameters are adequately explained in this figure, and Figure 5-19, but a number require additional comments.

There is no specific system of units associated with the input information, except for the angular quantities which must be expressed in degrees. All other parameters may be expressed in any consistent set of units, either English or Metric (inches or centimeters, pounds or dynes).

Care must be exercised to ensure that lander velocity, position, and attitude are correctly initialized. All lander initial conditions are referenced to the Gravity Coordinate System, Figure 5-1. The three components of velocity VELX, VELY, and VELZ are parallel to the axes of the Gravity Coordinate System. Note that a negative VELX is directed into the landing surface.

The desired ground slope, relating the Surface Coordinate System to the Gravity Coordinate System, must be established. This is accomplished by rotating the Surface Coordinate System about the Gravity Coordinate System Y_g axis an amount ζ equal to the ground slope. A positive slope corresponds to a rotation in the positive sense about Y_g.

The lander's initial angular orientation is obtained by three successive rotations about the three lander axes. The first is a rotation, ANGX, of the Lander Coordinate System about the Gravity Coordinate System X_g axis. This is followed by a rotation, ANGY, about the displaced position of the Lander Coordinate System Y axis. Final angular orientation is obtained by the rotation, ANGZ, about the direction of the Z axis resulting from the first two rotations. When these three rotations are zero, the initial attitude of the Lander Coordinate System is aligned with the Gravity Coordinate System.

The input quantity CUTERR (Card 7) defines a tolerance band, above the landing surface, which governs the placement of a footpad's equations of motion into the integration routine. When a footpad enters this band, the inertia effects of the footpad are removed from the center body equations of motion, initial conditions for the footpad are determined by center body motions, and integration of footpad equations of motion begun. This tolerance parameter has meaning only when INLEG (Card 2) is 0.

When including the effects of an elastic center body structure, the indicator MODEIN (Card 42) governs the number of center body modes which are input. NMODES (Card 3) governs the number of modes actually included in the analysis, and may be less than or equal to MODEIN.

A discussion of the input data required for a typical landing condition is presented in Sections 5.3.3 and 6.2.2 and the computer output for this case is given in Appendix D.

5.3.2 Output Data - At specified times during the integration of the equations of motion, various time varying quantities defining the position, velocities, and accelerations of the lander center body and footpads are printed. At the completion of a run, a summary page listing the maximum strokes in the landing gear struts, the reason for termination of the run, and

FIGURE 5–20 INPUT DATA LANDING LOADS AND MOTIONS PROGRAM (Continued) case run time are presented. In addition, optional output data, as requested through input indicators, may be obtained. These consist of lander stability angle and pitching velocity, all of the individual integrated quantities when considering a flexible center body, and accelerations at points other than the center body center of gravity. In this latter case, the coordinates of the points at which the accelerations are desired are included as input data. The individual integrated quantities are of interest when considering a flexible structure because the normal output presents the combination of the rigid body and elastic motions. Examples of the output data obtained from the Landing Loads and Motions Program are presented in Appendix D.

The units of the output data are consistent with the system of units used in the input data. Only the angular quantities are output in the specific units of degrees.

An additional output option is available in the Landing Loads and Motions Program. This option allows the output of the landing gear strut forces and all of the time history variables required to determine the inertia loading throughout the center body structure. With this information, the internal loads of the center body structural members may be determined with the Center Body Option of the Structural Analysis Program. This data is output at points in time corresponding to the times when printed output is generated by the program. This option results when the input indicator NFORC (Card 8) is equal to 1 and the data is placed on magnetic tape for future use. The Center Body Landing Loads Program, which is used to retrieve this data from the tape and generate input information for the Structural Analysis Program, is discussed in Appendix E.

5.3.3 Example of Program Operation - A listing of the input data, and the resulting printed output obtained from the Landing Loads and Motions Program is presented in Appendix D. The output pages in this appendix present the input data, the beginning of the time history, and the last pages of the time history including the summary information. This data set corresponds to a computer run demonstrating correlation with the third drop test conducted at NASA Langley Research Center on the Task Order Three lander.

For this example case, the fixed step, Runge-Kutta integration routine was used with output printed every 10 integration steps. An integration time step of 0.0001 sec with a total real time of 0.1 sec was requested. In addition to the normal printed output, the center body time histories and landing gear loads were output on magnetic tape for later use with the Structural Analysis Program. The retrieval of this information from the tape is discussed in Appendix E. Flexible center body input data was determined with the Structural Analysis Program, as discussed in Sections 4.3.1.3 and 6.2.1.

The lander had three inverted tripod gears with crushable main struts and elastic drag struts. The Secondary Soil Mechanics routine was used in conjunction with a footpad attenuation system. Since the landing case considered was planar in nature, the unnecessary rigid body degrees of freedom were suppressed to conserve computer run time. The equations of motion for all the footpads were integrated during the complete run.

This run, including a flexible center body structure represented with three free-free modes, and the real time of 0.1 sec required 53 sec of CDC 6600 CP time. Computer runs for this length of real time required approximately 34 CP sec to run a case with a rigid center body.

Plots showing various time histories obtained from this run are given in Section 6.2.2. Also shown is a comparison of the results of this run with those obtained with a rigid center body.

6. DEMONSTRATION OF PROGRAM CAPABILITIES

Examples of the capabilities of the various developed computer programs are presented in the following sections. The Task Order Three lander configuration, shown in Figure 1-1, was chosen for many of these analyses since experimental data was available with which to compare the computer results. In general, the correlation between experimental data and the analytical studies was quite good. In addition to the planar landings of the Task Order Three Lander, results for spatial landings on different types of soil are discussed.

6.1 Large Displacement Analysis of Landing Gears - The Landing Gear Option of the Structural Analysis Program was employed to analyze typical inverted tripod and cantilever landing gear configurations. An analysis of the Task Order Three inverted tripod gear to determine drag strut loads versus stroke normal to a landing surface is presented. Predicted drag strut loads are correlated with loads obtained in the sixth drop test on the Task Order Three landing gear performed at NASA Langley Research Center. In addition, drag strut loads as a function of stroke are predicted for an arbitrarily oriented friction plane to indicate the influence on these loads of a non-symmetrically loaded gear.

Analysis of the one-sixth scale LM cantilever gear to determine maximum energy absorption capability for various orientations of the landing surface is discussed in Section 6.1.2. Friction coefficient of the surface was varied to show the way in which friction affects energy absorption.

The fixed finite element idealization of inverted tripod and cantilever landing gears, employed in the Structural Analysis Program Landing Gear Option, was shown in Figure 4-17.

6.1.1 Inverted Tripod Gear - The inverted tripod gear of the Task Order Three Lander was analyzed to determine drag strut loads as a function of gear stroke. A listing of input information and output data for this problem is presented in Appendix C. Only selected pages of computer output are included due to the volume of output. Header card (see Figure 4-36) for this data case does not appear in the output listing although it was the first card of the data set.

Main strut honeycomb properties used for the gear are given in Figure 6-1. The Surface Coordinate System and Lander Coordinate System were assumed to be coincident, with the X_L and X_S axes normal to (and pointing out of) the landing surface (see Figure 4-20). Hence, the Euler angles ψ, θ, and ϕ are equal to 0. This condition corresponds to a "straight-in" drop of a lander such that the drag struts of a gear are loaded symmetrically. Behavior of the gear was investigated in 60 steps for an applied displacement of 15.24 cm normal to the landing surface. Friction coefficient of the surface was assumed to be .8. Footpad honeycomb crush forces of 1.102×10^9 dynes and 4.18×10^9 dynes and corresponding crush strokes of 1.27 cm and 4.45 cm were assumed.

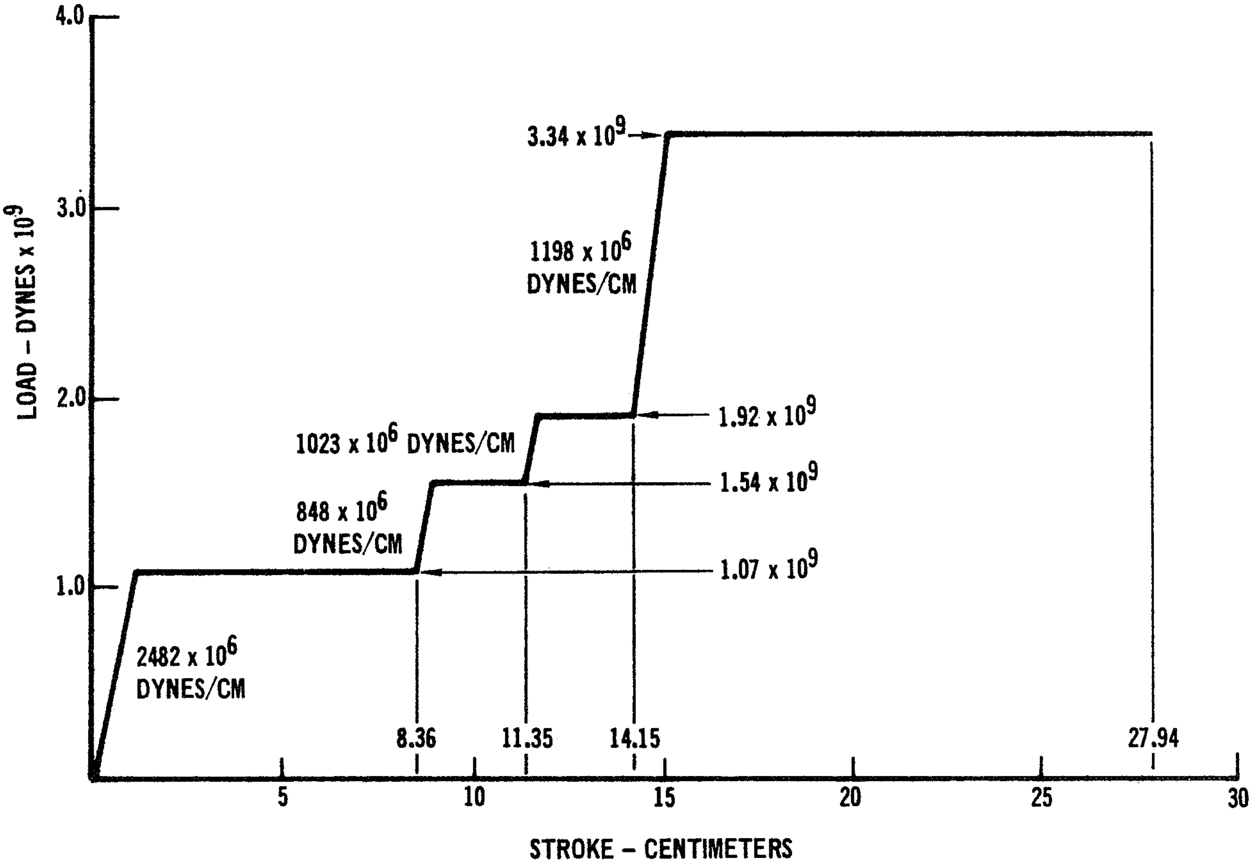

FIGURE 6-1 LOAD - STROKE CURVE FOR MAIN STRUT OF INVERTED TRIPOD GEAR - TASK ORDER THREE LANDER

A correlation between drag strut loads obtained in the computer run (steps 1, 2, 9, 10, 59 and 60 shown in Appendix C) and loads obtained for this gear during the sixth leg drop test performed at NASA Langley Research Center is depicted in Figure 6-2. As illustrated, at the onset of stroking the experimental drag strut loads appear to build up instantaneously. This is due to large footpad inertia forces acting during initial footpad impact; thus, correlation of drag strut loads at the onset of stroking is poor since the program assumes that the struts are initially unloaded. Footpad inertia forces are negligible after a normal (X_S) stroke of about 1 cm and from this point on correlation is reasonably good. In the figure, only one curve is shown for predicted drag strut loads since the drag struts were loaded equally because of symmetry. This example indicates that the static analysis employed in the Landing Gear Option can be used to obtain an estimate of dynamic drag strut loads.

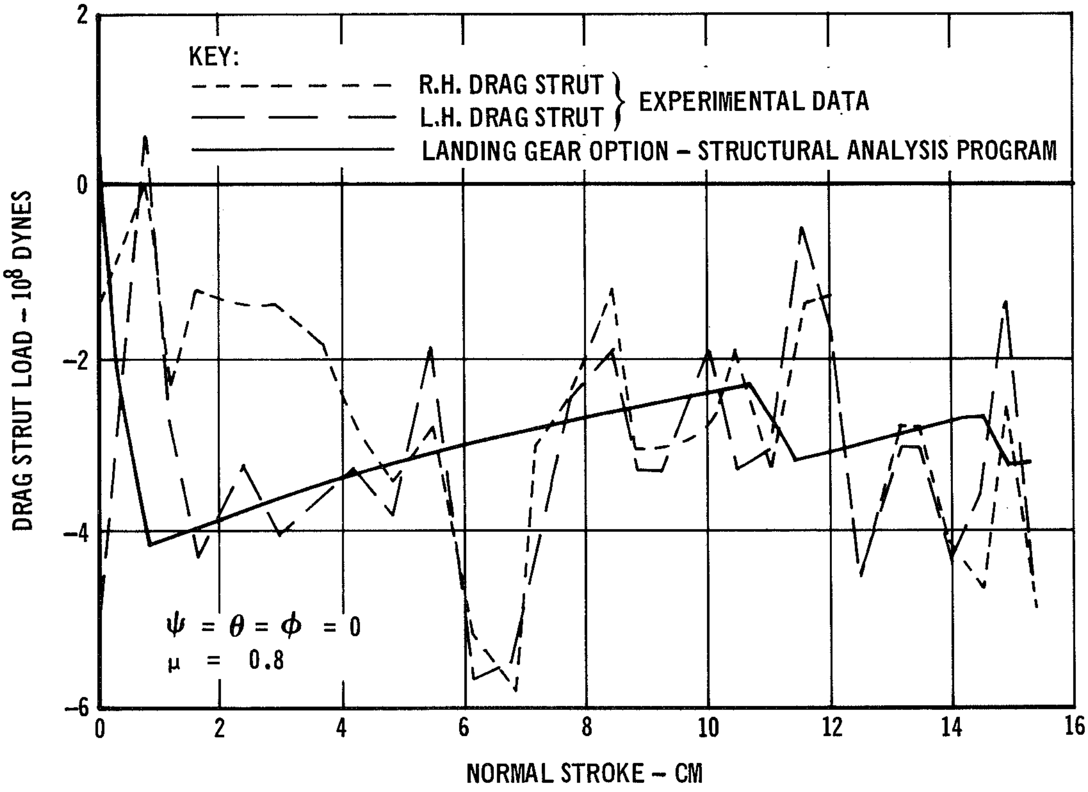

FIGURE 6-2 DRAG STRUT LOAD CORRELATION – INVERTED TRIPOD GEAR

For a nonsymmetrically loaded gear, the drag strut loads may be considerably higher than for the symmetrically loaded case. To emphasize this fact, the inverted tripod gear described above was analyzed with the program using the same input data with the exception that the landing surface was oriented such that $\psi = 25°$ and $\theta = \phi = 0$. This condition can be visualized by referring to Figure 4-20 and imagining that the landing surface is rotated 25° about the Z_S direction. For this run, drag strut loads as a function of stroke normal to the rotated landing surface are shown in Figure 6-3. As shown, one drag strut is in tension while the other is in compression. The maximum drag strut load of 4.52×10^9 dynes is considerably higher than the drag strut loads shown in Figure 6-2 for the symmetrically loaded gear.

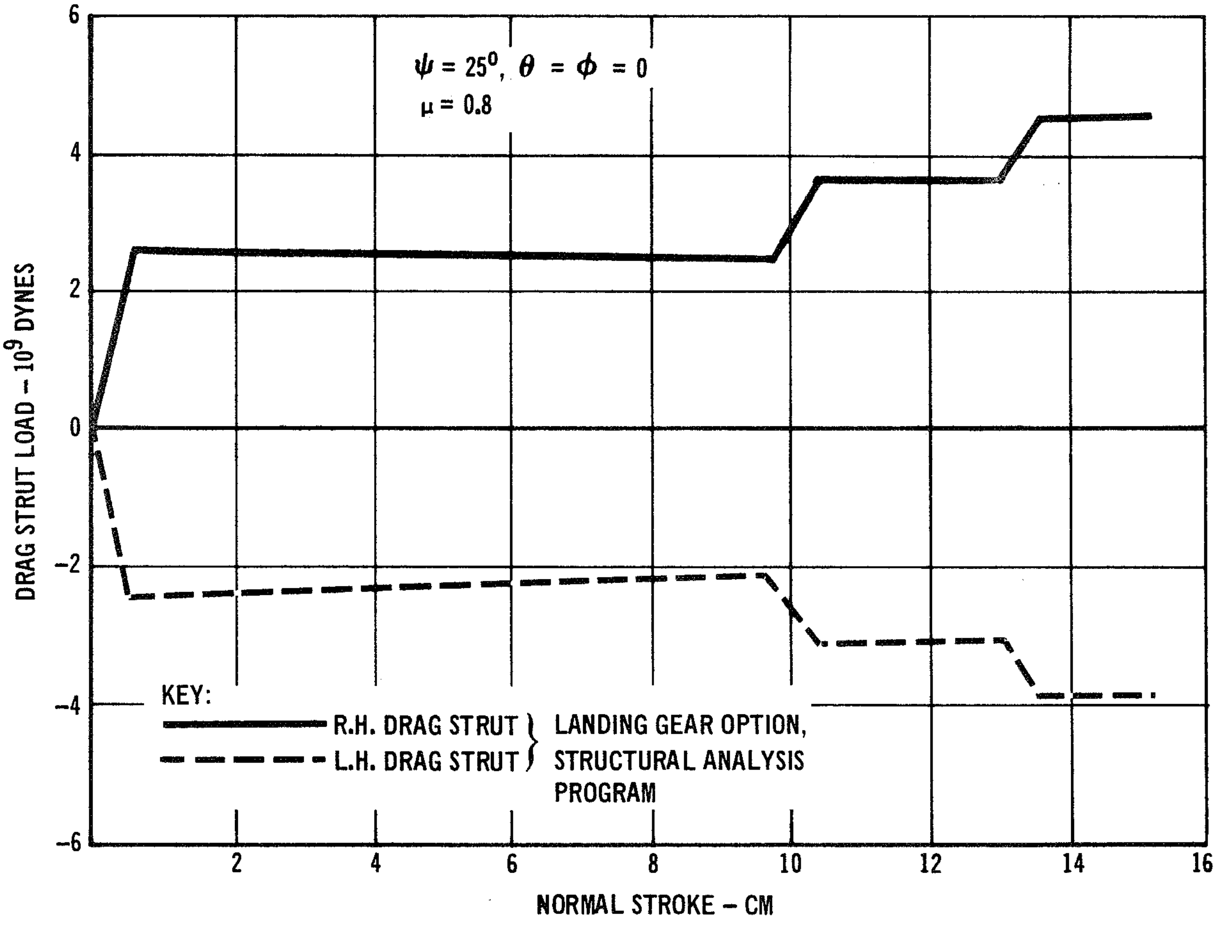

FIGURE 6-3 ANTICIPATED DRAG STRUT LOADS FOR INVERTED TRIPOD GEAR

6.1.2 Cantilever Gear - The one-sixth scale LM cantilever gear was analyzed to determine maximum energy absorption capability as a function of landing surface orientation and friction coefficient.

Honeycomb crush properties assumed for the main strut and drag struts of the gear are shown in Figures 6-4 and 6-5. Various orientations of the landing surface (see Figure 4-20) were considered, each of which provided symmetrical loading of the drag struts. These orientations are described by the Euler angle combinations $\psi = 0°$, $\phi = 0°$, and θ varied from 0° to 40°. The maximum value of 40° is the sum of the maximum ground slope relative to the local horizontal (30°) and the maximum pitch-up of the lander (10°) specified in typical design constraints, Section 3.1. Behavior of the gear was investigated by applying a displacement of 30.48 cm, normal to the landing surface, in 100 steps. This large value of normal displacement was selected to insure that the gear bottomed out before all steps were taken. For each coefficient of friction considered, a series of computer runs, were made in which θ was varied from 0° to 40°. Friction coefficients of 0.2, 0.8, and 1.0 were considered.

Maximum energy absorbed by the gear in a direction normal to the landing surface (X_S direction) is presented in Figure 6-6. Each point in the figure represents the total energy absorbed by the gear before the main strut bottomed out. Curves for friction coefficients of 0.8 and 1.0 are the same because in each case the friction was sufficient to prevent the footpad from sliding. For the friction coefficient of 0.2, the curve includes the effect of footpad sliding on the landing surface. As evidenced in this figure, energy absorption capability of the gear is minimum for values of θ between 20° and 30°.

6.2 Analysis of Task Order Three Lander - A complete analysis of a typical legged lander configuration is discussed in the following sections. This study consisted of performing a modal analysis on the center body structure employing the Center Body Option of the Structural Analysis Program. This modal data was then incorporated in the Landing Loads and Motions Program to account for the effects of a flexible center body on the landing response of the vehicle. Output from the landing program was used, in conjunction with the Center Body Landing Loads Program, to determine the distribution of inertia, gravity, and landing gear strut loads throughout the center body. These loads were then input to the Center Body Option of the Structural Analysis Program to determine internal member load distributions.

The legged lander considered was the 3/8 mass version of the Task Order Three lander. Figure 6-7 shows the structural configuration of this vehicle. Included in following analysis of this lander are examples of correlation between predicted results obtained with the Landing Loads and Motions Program and the results of the third drop test conducted at NASA Langley Research Center.

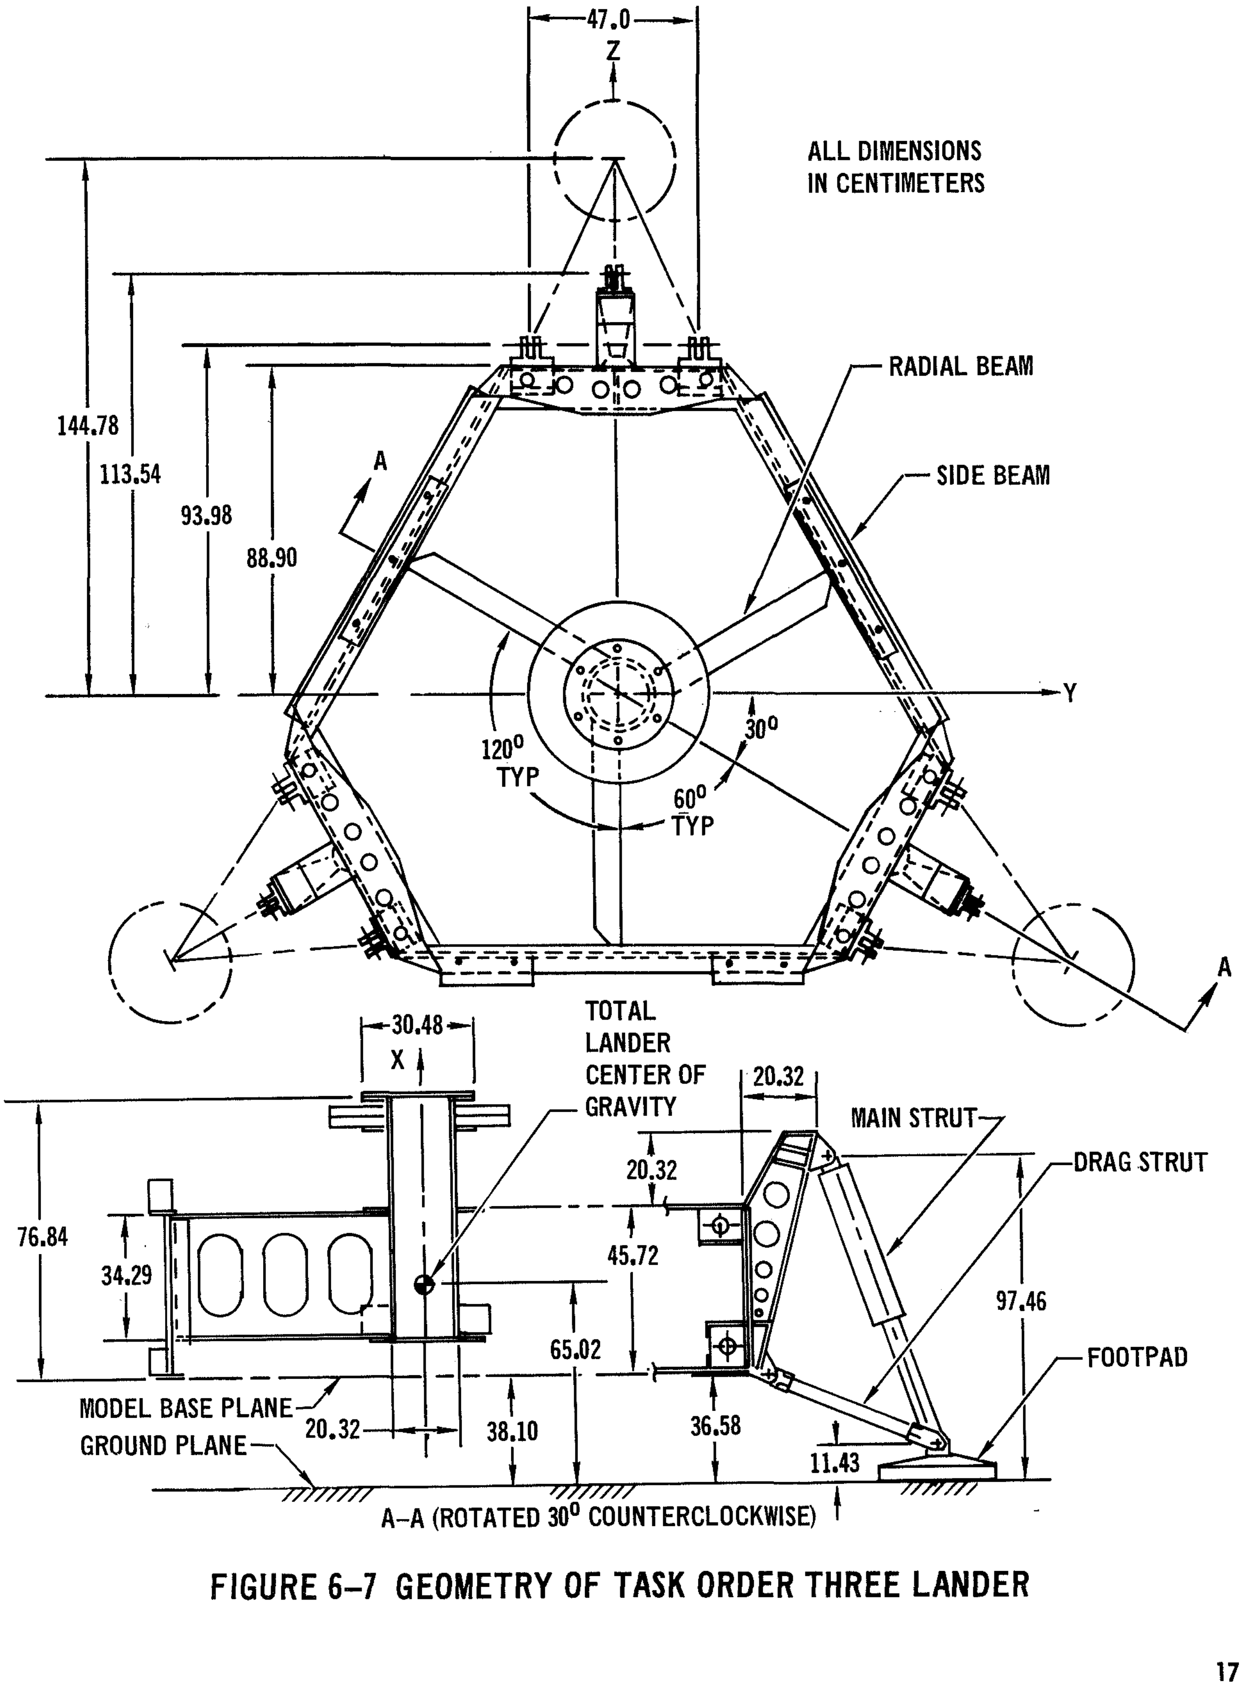

FIGURE 6–7 GEOMETRY OF TASK ORDER THREE LANDER

6.2.1 Modal Analysis of Center Body Structure - The finite element idealization of the center body structure is shown in Figure 6-8. The member stiffness properties for each pair of bars representing a side beam (for example, members 10 and 11) and a radial beam (members 48 and 49) are such that the total stiffness of these deep beams is maintained. The moment carrying capabilities of members 46, 47, 48, 49, 50, and 51 about the lander X axis, where these members attach to the side beams, were removed. This was done to simulate the high flexibility associated with these attach points.

This idealization resulted in a stiffness matrix containing 33 joints with 198 degrees of freedom. Before obtaining the structure's frequencies and mode shapes, the stiffness matrix was reduced to 99 degrees of freedom by removing the three rotational degrees of freedom at each joint. Thus, the input mass matrix contained translational masses associated with all of the joints shown in Figure 6-8.

Twenty elastic modes were requested and the program output for this modal analysis is shown in Appendix B. Three modes, with frequencies of 34.6 Hz, 48.2 Hz, and 101 Hz were obtained whose modal deformation patterns were predominately in the lander Y-Z plane and are the type of modes that would be excited by a landing such as the third drop test of the Task Order Three lander. These are the modes which were included in the data for the Landing Loads and Motions Program, Section 6.2.2, when considering the effects of a flexible center body structure. Figures 6-9 through 6-11 show the mode shapes associated with these three frequencies.

6.2.2 Correlation with Third Drop Test - The predicted landing response for the initial conditions corresponding to NASA Langley's third drop test were obtained considering both a rigid and flexible center body structure. The initial conditions for this drop test condition are shown in Figure 6-12. A portion of the output from the Landing Loads and Motions Program for the flexible body is presented in Appendix D.

The main strut load-stroke relationship shown in Figure 6-1 was used for these correlation runs. A sketch of the actual footpad geometry, including footpad attenuation, and the footpad idealization employed in the landing analyses are shown in Figure 6-13. The Secondary Soil Mechanics routine was employed with the following soil parameters:

Soil elasticity constant = 1.4 x 10^7 dynes/cm^3
Coefficient of friction = 0.9

The distribution of center body mass and inertia and footpad masses used for the 3/8 mass Task Order Three lander in these runs is summarized in Figure 6-14. This breakdown was obtained by requiring that the combination of the center body mass moments of inertia and the footpad masses, multiplied by the square of their respective moment arms, approximated the moments of inertia of the total 3/8 mass Task Order Three lander. In addition, the center of gravity location for the total lander was maintained with this mass distribution.

Predicted center of gravity acceleration time histories and loads in the outside drag strut of leg 2 for a rigid center body are compared with the experimental data in Figures 6-15 and 6-16. The high frequency oscillations present in both the predicted load and acceleration results are the spring-mass effect of the footpad mass in conjunction with the landing gear struts. In addition, oscillation in the drag strut load near the end of the time history (when the footpad is off the ground) is the gear-mass system experiencing free vibration.

Comparison between measured and predicted center of gravity accelerations, main strut loads, main strut strokes, and drag strut loads when center body flexibility was included, is shown in Figures 6-17 through 6-22. Correlation between analytical and experimental results is good in this case. The inclusion of center body flexibility results in a less rapid buildup of center of gravity accelerations upon initial impact, especially in the Z direction. In addition, the inclusion of structural flexibility can readily be seen by the low frequency oscillation present in the center of gravity Z acceleration.

An interesting point is indicated in Figure 6-22. It can be seen that there is an initial oscillatory load in this drag strut before the footpad impacts the landing surface. This is the result of the inertia loading of the footpad mass on the end of the elastic landing gear struts. This inertia loading effect of the noncontacting footpad is also indicated in Figure 6-18 by the buildup of main strut load in leg 1 before footpad impact.

6.2.3 Center Body Landing Loads - Observing the center of gravity acceleration time histories shown in Figure 6-17, it is seen that there are several points of apparent high acceleration of the center body structure. The time history data stored on magnetic tape during this run was retrieved with the Center Body Landing Loads Program and total load distributions on the center body were determined at several of these points during the landing. The load distribution at the landing time of 0.011 seconds was selected as critical because it yielded the largest loads in the -Z direction at the center body center of gravity. Appendix E presents the load distribution obtained with the Center Body Landing Loads Program for this time.

6.2.4 Center Body Internal Load Distribution - The Center Body Option of the Structural Analysis Program was employed to determine joint displacements and internal load distributions in the center body structure for landing loads defined in Section 6.2.3 at a time of 0.011 seconds. The center body idealization shown in Figure 6-8 was employed. A listing of input information and output data for this problem is presented in Appendix A. Header card (see Figure 4-32) for this data case does not appear in the output listing although it was the first card of the data set.

In the center body finite element idealization, attach points for legs 2 and 3 were assumed to be joints 12, 15, 17, 22, 25, and 27. This is an approximation since the physical attach points for the drag struts are located at the ends of clevis fittings which are adjacent to the above joints. The center body was supported at joints 12, 15, 17, 22, 25 and 27 which were assumed to be pinned with zero translational displacements and zero applied moments. The center body landing loads distribution at 0.011 seconds is given in Appendix E. Due to the assumed drag strut locations in the center body idealization, unbalances in these loads are indicated, especially moment about the lander Y axis. To insure a static balance, the negative of these unbalance loads were applied at the center of gravity (joint 33) in addition to the three force components at this joint. For computer input, nominal values were selected by default for all data option indicators except INDITR and TMAX. INDITR (maximum number of iterations allowed) was set at 2000. TMAX (maximum CP seconds allowed for solution) was specified as 100.

Included in computer output are displacements and external loads for all joints and internal loads in all bar elements. The displacements at the center of gravity and the internal bending moments about the local Z axis for the radial beam (elements 46 through 51) are of particular significance. Results of this analysis are compared with the results for a redesigned center body structure in Figure 6-28, Section 6.3.

In order to emphasize the importance of proper idealization of the structure when determining displacements and internal loads, the loading condition defined above was applied to a refined idealization of the Task Order Three Lander Center Body as discussed in Appendix G. Displacements and internal loads obtained when employing the refined idealization are different than those obtained when employing the idealization in Figure 6-8 and probably are more accurate. For the purpose of demonstrating program capabilities, the idealization shown in Figure 6-8 is entirely adequate and will be employed in the following sections.

It must be kept in mind that a more refined idealization requires more computer run time. For example, run time for the idealization in Figure 6-8 was 46 CP seconds while that for the refined idealization in Appendix G was 106 CP seconds. A compromise between idealization refinement and computer run time must be made.

6.3 <u>Analysis of Modified Task Order Three Lander</u> - The analysis of the Task Order Three lander, Section 6.2, indicated considerable flexibility of the center body structure in the lander Y-Z plane. This inplane flexibility is indicated in the measured Z center of gravity acceleration, Figure 6-15, obtained during the NASA drop test program.

A modification of the Task Order Three lander center body structure to increase the stiffness and improve the load carrying capability in the Y-Z plane was studied. Three configurations, incorporating the addition of a number of tension straps, were considered in arriving at the Modified Task Order Three lander. These consisted of 9-strap, 12-strap, and 18-strap configurations. The 12-strap configuration is shown in Figure 6-23. The 9-strap configuration was the same as the 12-strap configuration with the upper straps 63, 64, and 65 removed. The 18-strap configuration was like the 12-strap with six additional straps added to the upper portion of the center body. These upper straps were located in a manner similar to the lower straps 57 through 62.

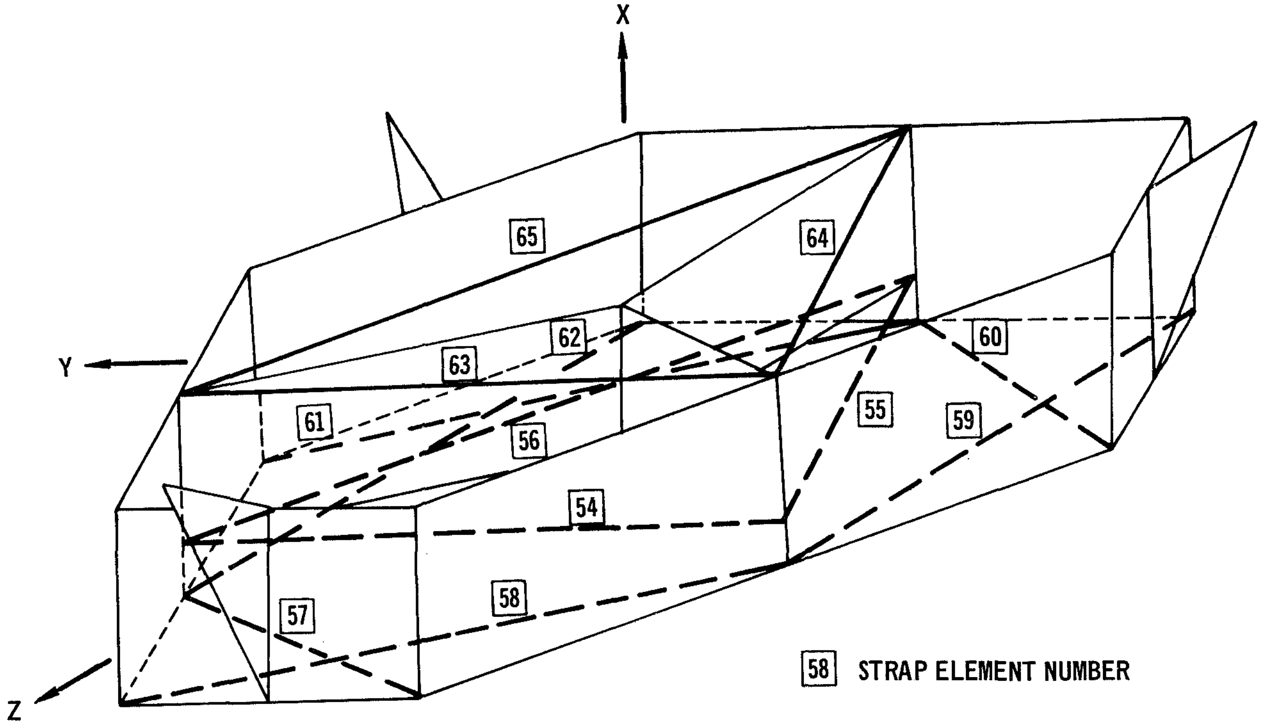

FIGURE 6-23 CENTER BODY IDEALIZATION INCLUDING TENSION STRAPS

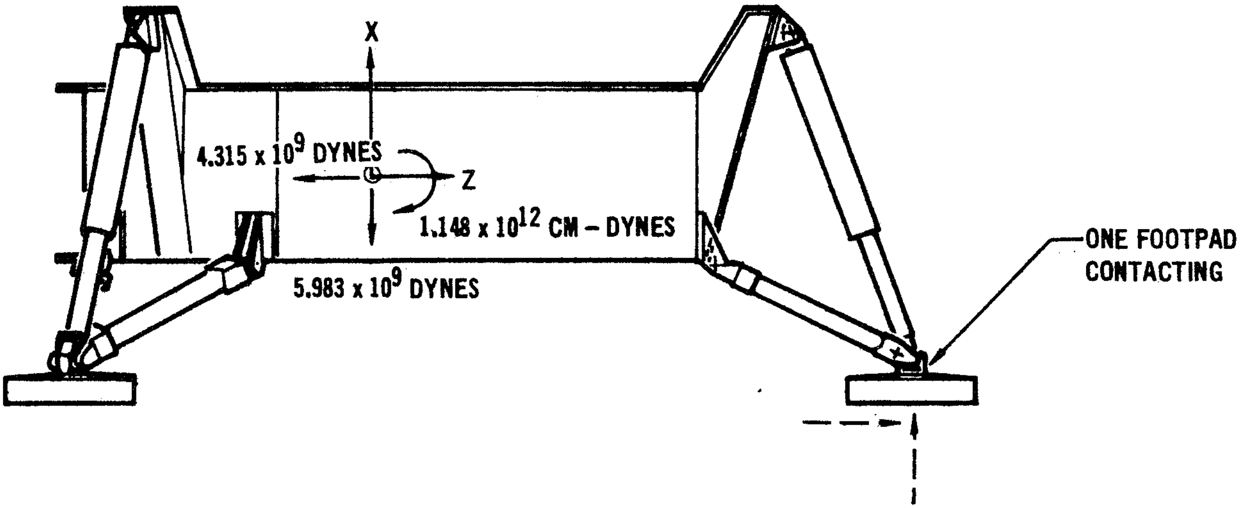
A representative loading condition was applied to a finite element idealization of these three strap configurations employing the Center Body Option of the Structural Analysis Program. For this study, the basic center body structure was idealized as shown in Figure 6-8. Each set of tension straps was then added to this idealization, as indicated in Figure 6-23 for the 12-strap configuration. In each case, all straps were assumed to have a cross-sectional area of 1.29 square centimeters and a modulus of elasticity of 2.068×10^{12} dynes/cm^2.

Figure 6-24 shows the loading condition which was employed to evaluate each of the tension strap configurations. This condition was found to be the critical one when the most severe center of gravity accelerations noted during the analysis of the Task Order Three lander in Section 6.2 were combined for one and two leg landings. Employing the criterion of reducing both the radial beam bending moments about the local Z axes and inplane displacements, the comparison shown in Figure 6-25 was made for the three tension strap configurations. Based on the results shown in this figure, the 12-strap configuration was chosen as the Modified Task Order Three lander. This configuration resulted in a 3.1 reduction factor for radial beam bending moment and a 5.45 multiplication factor for center body inplane stiffness when compared to the Task Order Three lander structure. The 18-strap configuration was not selected because the slight improvement in the parameters of interest was not sufficient to justify six additional straps. The weight of the twelve tension straps was removed from the ballast weights in the idealization of the modified Task Order Three configuration to maintain the same total lander weight.



LOADS APPLIED AT CENTER OF GRAVITY WERE DETERMINED BY ASSUMING:

+ X ACCELERATION OF 50 g's
+ Z ACCELERATION OF 36 g's

WEIGHT OF HUB AND RADIAL BEAMS = 1.196×10^8 DYNES, CONCENTRATED AT CENTER OF GRAVITY

THEREFORE, LOADS SHOWN ARE:

$F_X = -m\ddot{X} = -5.983 \times 10^9$ DYNES

$F_Z = -m\ddot{Z} = -4.315 \times 10^9$ DYNES

M_Y = MOMENTS SUMMED ABOUT CONTACTING FOOTPAD = -1.148×10^{12} CM–DYNES

FIGURE 6-24 LOADING CONDITION FOR EVALUATION OF MODIFIED TASK ORDER THREE LANDER CENTER BODY STRUCTURE

STRAP CONFIGURATION	MAXIMUM RADIAL BEAM TRANSVERSE BENDING MOMENT* (CM–DYNES ULT.)	CENTER BODY INPLANE STIFFNESS** (DYNES/CM)

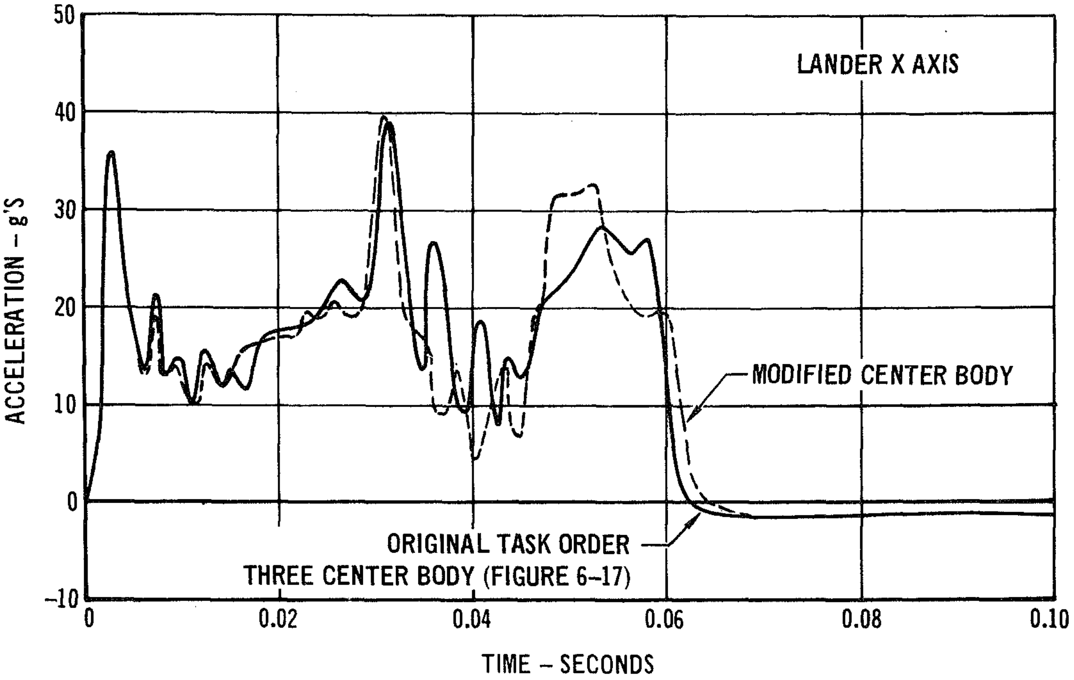
* BENDING MOMENTS ARE ABOUT LOCAL Z AXIS OF ELEMENT AT "Q" END

** CENTER BODY INPLANE STIFFNESS WAS OBTAINED BY APPLYING A UNIT LOAD AT THE CENTER OF GRAVITY IN THE –Z GLOBAL DIRECTION. THE STIFFNESS FACTOR IS THIS LOAD DIVIDED BY THE RESULTING CENTER OF GRAVITY GLOBAL Z DISPLACEMENT

FIGURE 6–25 COMPARISON OF VARIOUS TENSION STRAP CONFIGURATIONS

Employing the finite element idealization shown in Figures 6-8 and 6-23, a modal analysis was performed on the Modified Task Order Three lander center body. Three modes, with frequencies of 75.2 Hz, 149 Hz, and 163 Hz, were obtained whose modal deformations were predominantly in the lander Y-Z plane. These modal frequencies are much higher than the comparable frequencies obtained for the Task Order Three Lander, Section 6.2.1, thus illustrating the stiffening effect of the straps.

The drop test three landing conditions were used to evaluate the Modified Task Order Three lander center body structure. Using the above three modes to represent the center body flexibility effects, the accelerations and drag strut load shown in Figures 6-26 and 6-27 were predicted with the Landing Loads and Motions Program. These quantities are superimposed on the predicted results obtained for the original Task Order Three lander center body. The oscillatory nature of the Z acceleration is due to the large excitation of the 75.2 Hz mode for the initial conditions considered.



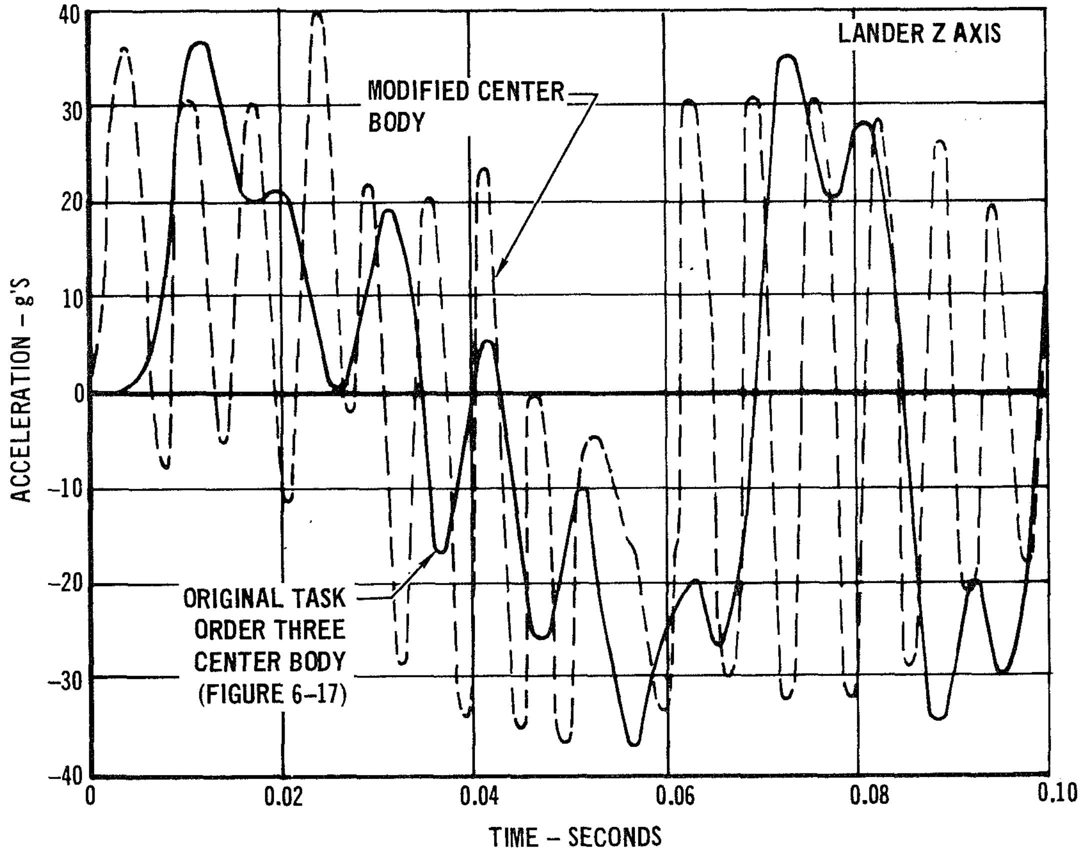


FIGURE 6-26 CENTER OF GRAVITY ACCELERATIONS WITH MODIFIED CENTER BODY STRUCTURE

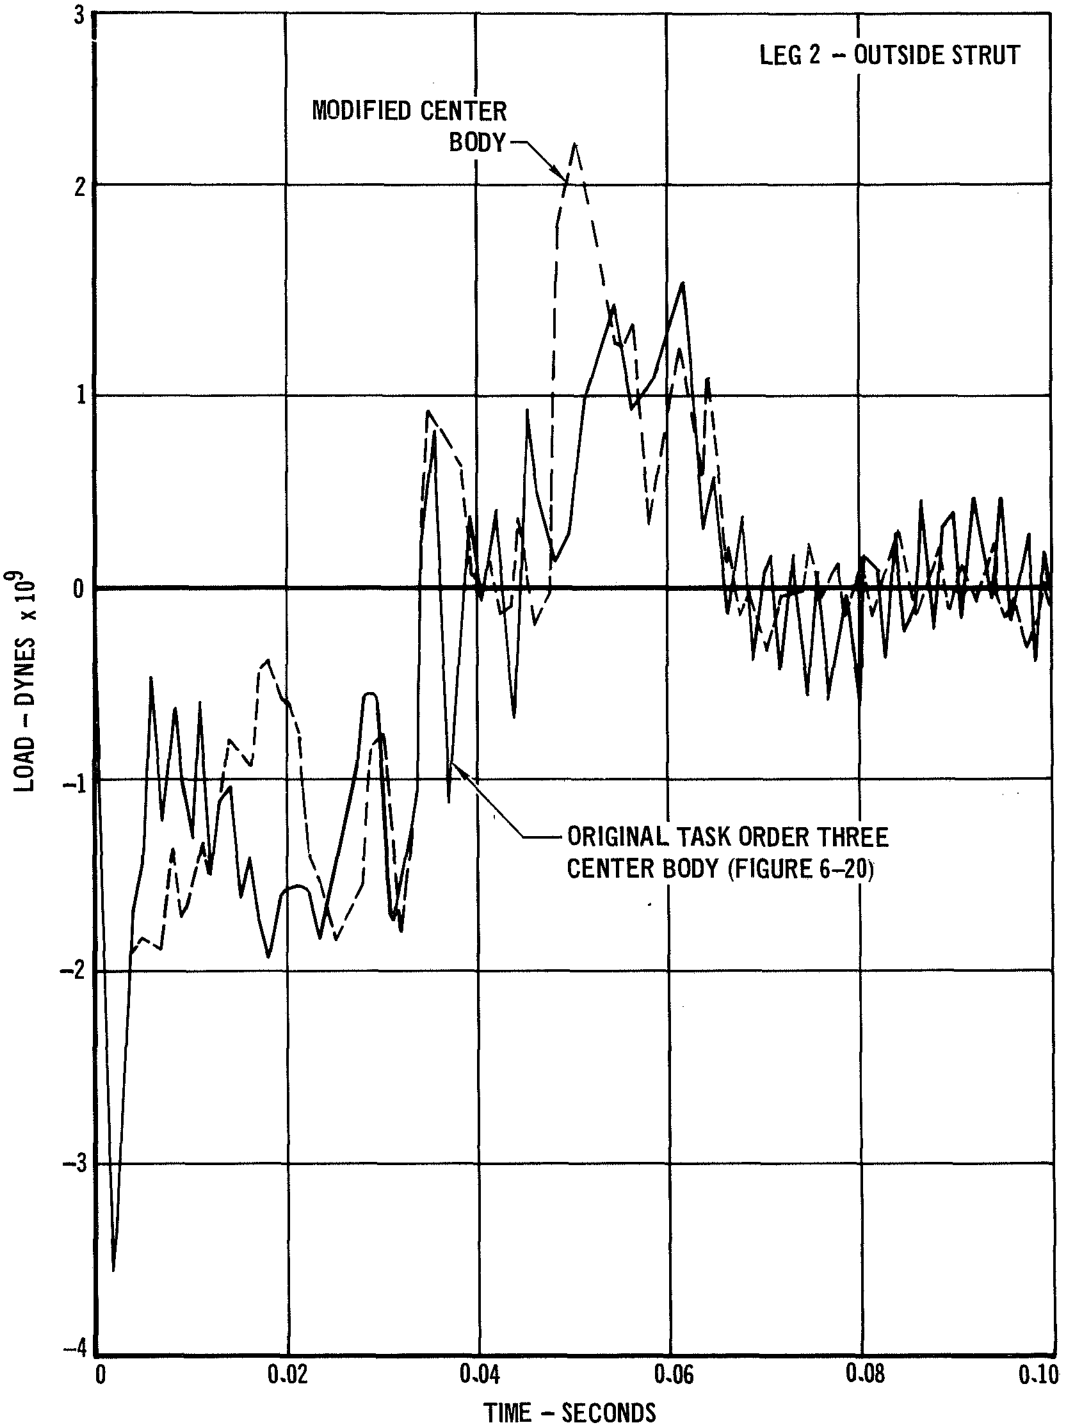

FIGURE 6–27 OUTSIDE DRAG STRUT LOAD WITH MODIFIED CENTER BODY STRUCTURE

The distribution of landing loads throughout the center body structure was obtained for a number of points during the landing time history. At a real time of 0.011 seconds, the center body experienced high loads and this point was chosen for analysis with the Center Body Option of the Structural Analysis Program. Employing the center body finite element idealization shown in Figures 6-8 and 6-23, internal member loads and joint displacements at this time were determined. A comparison of these loads and displacements with the loads and displacements obtained for the Task Order Three lander, Section 6.2.4, are presented in Figure 6-28. As can be seen, the radial beam bending moments in the Modified Task Order Three center body are lower than those obtained for the Task Order Three Center body. In addition, the global Z displacement of the center body center of gravity is less for the Modified Task Order Three center body. This trend of lower member loads and reduced displacements is a result of the additional center body load paths and increased stiffness provided by the tension straps.

6.4 Landing Analysis of Full-Mass Task Order Three Lander - Several additional studies for the Task Order Three lander were performed. For all of the following discussions, the structural configuration, landing gear properties, and footpad idealization were the same as discussed in Section 6.2. The mass properties were that of a full mass Task Order Three lander and a local acceleration of gravity of 375 cm/sec^2 was employed.

A lander, horizontal with respect to the local acceleration of gravity, with a vertical velocity of -610 cm/sec along the gravity vector, and landing on a 10° slope, was considered. The initial orientation of the lander was such that a single footpad impacted the landing surface. For comparison, three short runs were made with these initial conditions and the following soil properties.

SS Dense Soil (Figure 5-10):

Primary soil mechanics routine

Relative soil density = .69

Soil unit weight = 1681 dynes/cm^3

Soil internal friction angle = 39°

SS Loose Soil (Figure 5-10):

Primary soil mechanics routine

Relative soil density = 0

Soil unit weight = 1488 dynes/cm^3

Soil internal friction angle = 29°

Secondary Soil:

Secondary soil mechanics routine

Soil elasticity constant = 144 x 10^7 dynes/cm^3

Coefficient of friction = 0.9

The Secondary Soil is the same soil idealization as that employed during the correlation studies conducted for the third drop of the Task Order Three lander discussed in Section 6.2.2.

	JOINT 33 DISPLACEMENT (CM)		
	X	Y	Z
TASK ORDER THREE LANDER (SECTION 6.2.4)	-9.577×10^{-2}	-1.322×10^{-4}	-4.289×10^{-1}
MODIFIED TASK ORDER THREE LANDER	-4.794×10^{-2}	-1.555×10^{-4}	-7.834×10^{-2}

	RADIAL BEAM BENDING MOMENT ABOUT LOCAL Z AXIS AT "Q" END (CM – DYNE)

MODIFIED TASK ORDER THREE LANDER	1.863×10^{9}	1.573×10^{9}	-1.869×10^{9}	-1.611×10^{9}	1.818×10^{7}	3.716×10^{6}

FIGURE 6–28 COMPARISON OF COMPUTER RESULTS FOR ORIGINAL AND MODIFIED TASK ORDER THREE LANDER

Figure 6-29 presents a comparison between the resulting main strut time histories for the three soils considered. As can be seen, the largest main strut load and stroking motion resulted when the Secondary Soil was used. This is reasonable since these soil properties were used to idealize the very rigid landing surface of the Task Order Three lander drop test program. The main strut stroke was much less for the SS Loose Soil than for the other soils.

A second set of initial conditions for the full mass lander were as follows:

Ground slope = 10°

Initial rotation about X_g axis = 20°

Vertical velocity = -610 cm/sec

For this run, the SS Dense Soil employed in the previous case was used.

Figures 6-30 and 6-31 present the accelerations and main strut loads resulting from this spatial landing. The spatial nature of this landing is obvious from these time histories. The main struts in each leg load up sequentially as their respective footpads impact the landing surface. These loads then drop off as the lander's initial kinetic energy is absorbed by the crushable struts.

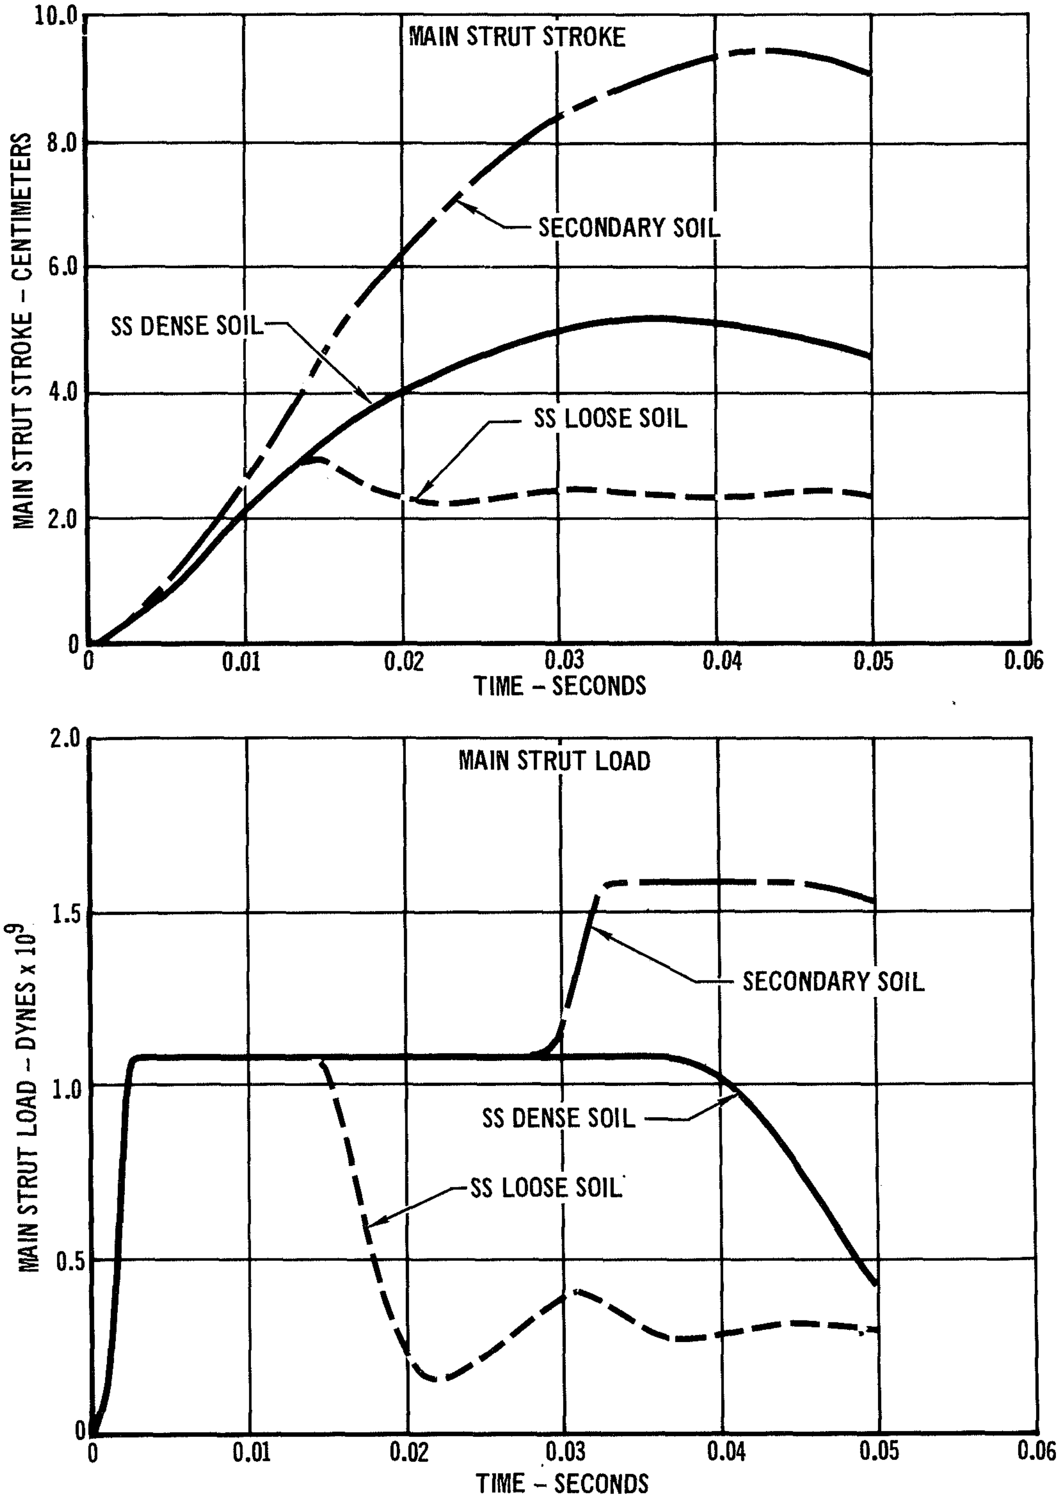

FIGURE 6-29 MAIN STRUT TIME HISTORIES FOR VARIOUS LANDING SURFACE SOIL IDEALIZATIONS

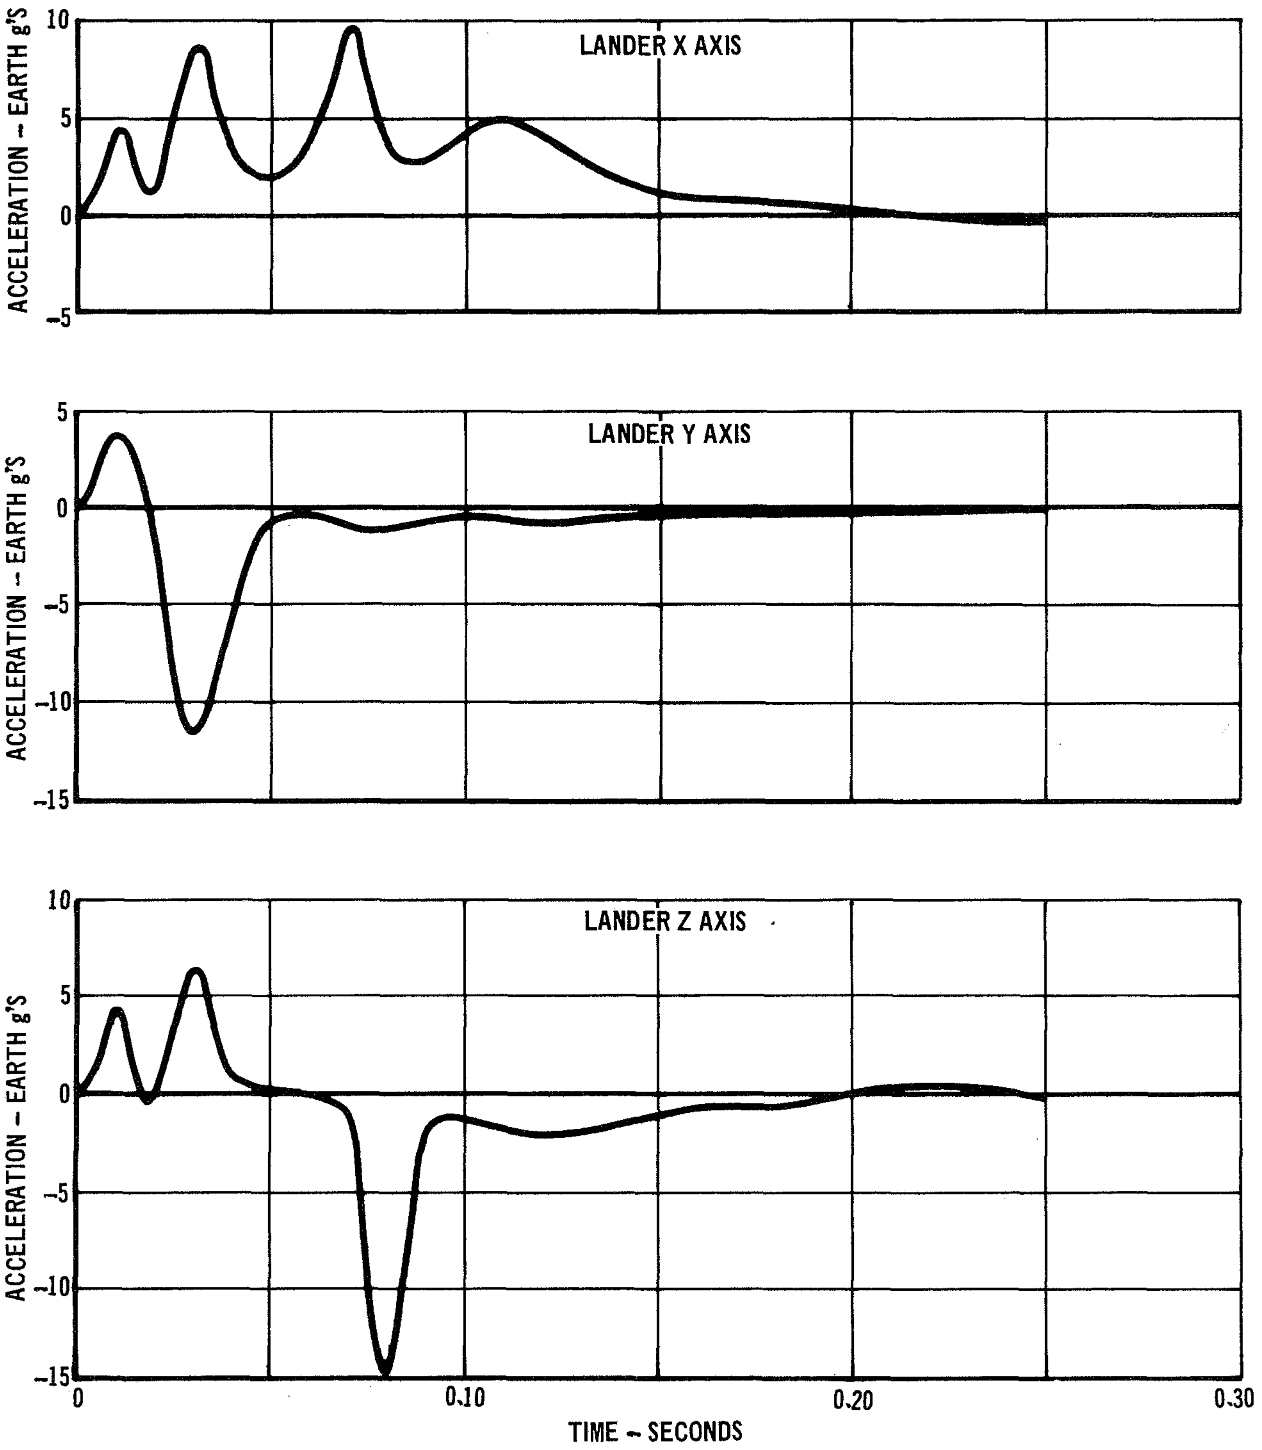

FIGURE 6–30 FULL-MASS TASK ORDER THREE LANDER CENTER OF GRAVITY ACCELERATION TIME HISTORIES

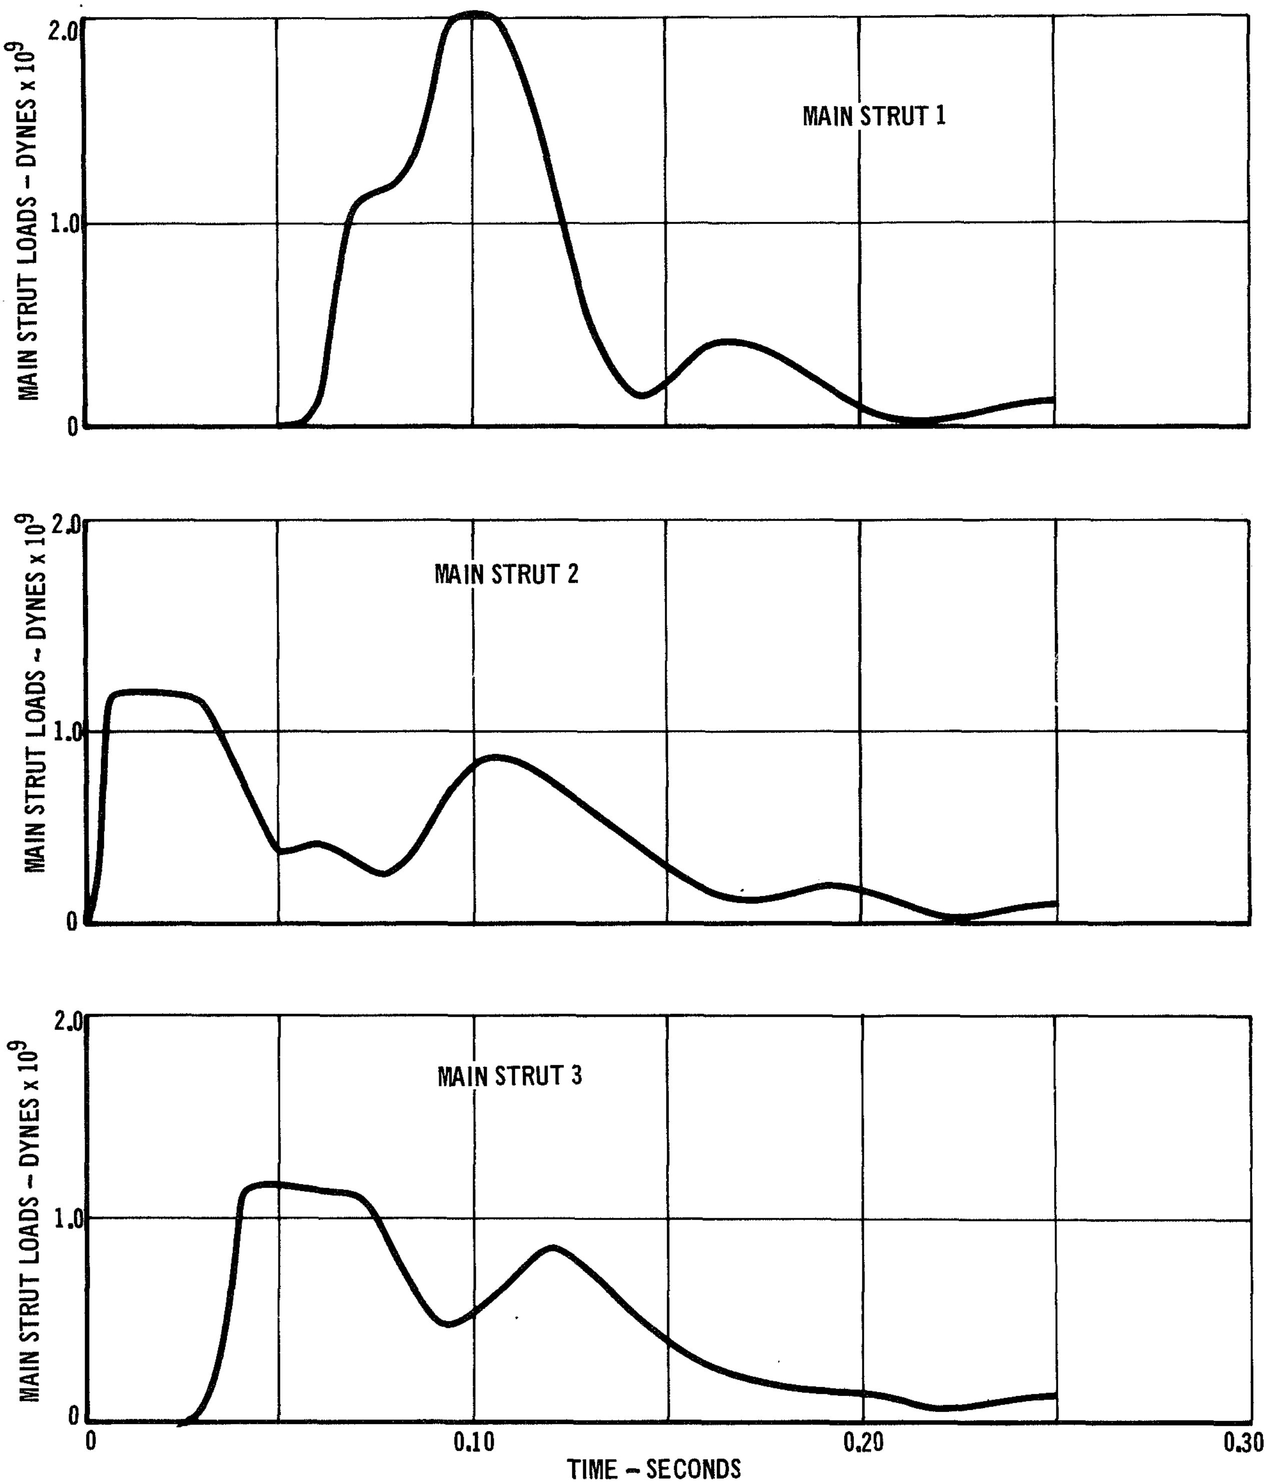

FIGURE 6–31 FULL-MASS TASK ORDER THREE LANDER MAIN STRUT LOAD TIME HISTORIES

7. CONCLUSIONS

Two methods of analysis and associated computer programs were developed for the investigation of legged landers. One program, the Landing Loads and Motions Program, is used to predict landing loads and spatial motions of a lander. The second, the Structural Analysis Program, determines the internal load distributions in the lander center body structure or frequencies and mode shapes for a free-free center body structure. Energy absorption characteristics of an individual landing gear are also determined with this program. Each program contains options and capabilities which were shown to be important in the analysis of legged lander configurations. For example, in the Landing Loads and Motions Program, options to include the effect of center body flexibility and a comprehensive soil mechanics routine were included. An option to investigate large displacement stroking behavior of a landing gear was incorporated in the Structural Analysis Program.

In addition to the limited analyses made within the constraints of Task Order Five, comparisons of experimental and analytical results for ten additional unpublished tests conducted at the NASA Langley Research Center show that the programs are working satisfactorily. However, the effects of friction between the footpads and the landing surface are very difficult to simulate analytically because of the uncertainties involved in defining these effects during dynamic model testing. The limited analyses presented in this report do serve to demonstrate primary program capabilities. As a result of these analyses, the following conclusions are possible:

(1) Center body flexibility significantly affects landing loads and motions. This was illustrated during the landing studies conducted on the Task Order Three lander, Section 6.2.2. For a rigid center body, the drag strut loads (Figure 6-16) were higher than with a flexible center body (Figure 6-20). In addition, the center of gravity accelerations in the rigid center body (Figure 6-15) built up more rapidly than was indicated in either the test data or in the analysis with flexibility included (Figure 6-17). Very good correlation with test data resulted when center body flexibility was included.

(2) Soil properties significantly affect landing gear strut behavior. In Figure 6-29, it was shown that much higher landing gear strut strokes and loads result when landing on hard soil. When landing in loose sand, strut stroke increased gradually with time with resulting lower strut loads. Overall lander motions are highly dependent upon soil properties. Therefore, it is important that programs for studying landing motions, include the capability for properly representing soil characteristics.

(3) Care must be exercised in the finite element idealization of the center body structure. As discussed in Section 6.2, the predicted internal load distributions were different for two different idealizations of the same structure. However, it was also shown that the first idealization presented in Section 6.2 resulted in very good center body flexibility data for use with the Landing Loads and Motions Program. In general, a more sophisticated idealization is required for determination of internal loads than for generation of center body flexibility information for the landing program.

(4) Landing gear orientation and landing surface friction greatly influence the large displacement stroking behavior of a landing gear configuration. Comparison between Figures 6-2 and 6-3 indicate that the drag strut loads in an inverted tripod gear are much different for two different gear orientations. As shown in Figure 6-6, the energy absorption capabilities of a landing gear are dependent on the coefficient of friction employed and the orientation of the gear with respect to the landing surface.

(5) Increasing center body stiffness does not necessarily reduce peak center of gravity accelerations. As indicated in Figure 6-26, the peak predicted accelerations for the original Task Order Three center body and the Modified Task Order Three center body were of the same magnitude. The increased stiffness of the modified structure resulted in a higher frequency oscillation of the Z acceleration. However, in this case, the individual member loads were reduced due to the additional load paths available in the structure.

STRUCTURAL ANALYSIS CONTROL DATA

GENERAL DATA

INDRKT =     0       , 1 IMPLIES READ ALL MATRICES FROM TAPE
INDSFG =     1       , 0 IMPLIES WRITE GLOBAL BAR MATRICES
INDSFL =     1       , 0 IMPLIES WRITE LOCAL BAR MATRICES
INDWKT =     0       , 1 IMPLIES SAVE ALL MATRICES ON TAPE
INDWTS =     0       , 1 IMPLIES PRINT TOTAL STIFFNESS MATRIX
ISFDIM =  12904      , MAX. STORAGE FOR STIFFNESS MATRIX

DISPLACEMENT/ROTATION SOLUTION DATA

ERRTOL = 1.000E-04   , ITERATION SOLUTION TOLERANCE
IND1SL =     0       , 1 IMPLIES AN INITIAL SOLUTION IN SOLVEC
INDITR =   2000      , MAX. SOLUTION ITERATION CYCLES
INDPLS =     0       , 1 IMPLIES CONSIDER PLASTICITY
INDRLX =     2       , ITERATIVE SOLUTION METHOD

STRUCTURAL ANALYSIS CONTROL DATA

GENERAL DATA

INDPKT =     0      , 1 IMPLIES READ ALL MATRICES FROM TAPE
INDSFG =     1      , 0 IMPLIES WRITE GLOBAL BAR MATRICES
INDSFL =     1      , 0 IMPLIES WRITE LOCAL BAR MATRICES
INDWKT =     0      , 1 IMPLIES SAVE ALL MATRICES ON TAPE
INDWTS =     0      , 1 IMPLIES PRINT TOTAL STIFFNESS MATRIX
ISFDIM =12904       , MAX. STORAGE FOR STIFFNESS MATRIX

MODAL ANALYSIS DATA

INDNMA =     1      , RUN NORMAL MODE ANALYSIS
INDWNM =     1      , 1 IMPLIES WRITE MODE DATA ON TAPE
IPEDTO =    99      , ORDER OF REDUCE SYSTEM
NEIGVL =    20      , REQUIRED NON-RIGID BODY MODES

AMASS IS THE DIAGONAL MASS VECTOR OF THE REDUCE SYSTEM

APPENDIX E

OPERATING INSTRUCTIONS

CENTER BODY LANDING LOADS PROGRAM

E.1 Introduction - The Center Body Landing Loads Program retrieves and lists, for specific points in time, the information placed on magnetic tape by the Landing Loads and Motions Program. Information continuously stored on tape consists of landing gear strut forces acting on the center body; angular positions, velocities, and accelerations and the translational accelerations of the center body center of gravity; and the displacements, velocities, and accelerations of the normal modes employed in representing the flexible center body structure. The Center Body Landing Loads Program uses the information on this tape, in addition to other required input data, to obtain the distribution of landing gear strut loads and inertia loads throughout the center body structure for the selected points in time. This load information may then be used in conjunction with the Center Body Option of the Structural Analysis Program to determine the internal member load distribution for the time point of interest.

E.2 Input Data - A number of input data cards are required by the Center Body Landing Loads Program. These properly initialize the program, define the mass properties of the center body, and define the points in time during the landing time history at which the loads are to be determined. The required format for these cards is shown in Figure E-1 while the input variables are defined in Figure E-2. Also indicated in Figure E-2 is whether the various input quantities must be input as integer or floating point numbers. All integer numbers and floating point numbers input with an E format must be right justified. Floating point numbers input with an F format may appear anywhere inside their allotted field on the data card.

In addition to the required card input, two magnetic tapes are required. The mode shape data and joint coordinate information is required on TAPE4. This tape is generated when performing the modal analysis on the center body structure with the Structural Analysis Program. Secondly, the time history data obtained from the Landing Loads and Motions Program must be available on TAPE3. Since the time history data on this tape corresponds to points in time when normal printed output was obtained from the Landing Loads and Motions Program, only center body loads at these points in time may be obtained with the Center Body Landing Loads Program.

*I – INTEGER NUMBER; F – FLOATING POINT NUMBER

FIGURE E–2 INPUT DATA – CENTER BODY LANDING LOADS PROGRAM

The use of the input indicators NOSETS and MODE(I) require some additional comments. The modal analysis output obtained from the Structural Analysis Program is placed on magnetic tape in data sets each containing information for five modes. The first set contains the lowest five elastic modes, the second set contains the next five modes, etc. The input indicator NOSETS defines the number of these modal data sets that appear on TAPE4. The modes in the first data set are numbered 1 through 5, those in the second data set 6 through 10, etc. MODE(I) defines the mode number of the Ith mode which is required by the Center Body Landing Loads Program.

E.3 Output Data - For a selected point in time the landing loads at each of the joints used in the center body structural idealization are printed. These loads are the combination of the inertia loads, gravity loads, and landing gear strut loads. The components of the landing loads are given in the Lander Coordinate System and thus may be directly input to the Center Body Option of the Structural Analysis Program. In addition, the sum of forces and moments about the center of gravity are given for information purposes.

E.4 Program Operation - An example of the output from the Center Body Landing Loads Program is given on the following pages. This information was required during the analysis of the Task Order Three lander, Section 6.2.3, at a time of 0.011 seconds. This time was selected for determining internal loads distribution in the lander center body using the Center Body Option of the Structural Analysis Program as discussed in Section 6.2.4.

A listing of the Center Body Landing Loads Program follows the example output.

NUMERICAL INTEGRATION ROUTINE
LANDING LOADS AND MOTIONS PROGRAM

F.1 Introduction - The methods and procedures employed during the numerical integration of the equations of motion in the Landing Loads and Motions Program are described in the following paragraphs. These operations are performed in the subroutines RKCUT and INITUP. The sequence of program calls for these subroutines are shown in Figure 5-17 and subroutine listings are given in Appendix I.

F.2 Method - The second-order equations of motion in the Landing Loads and Motions Program are reduced to an equivalent set of simultaneous first-order equations. Each of these first order equations takes the general form of

$$\dot{y} = f(y,t) \text{ where } y(t_o) = y_o \tag{F-1}$$

At any step n in the integration of these equations with respect to time t, the quantities t_n, y_n, and $\dot{y}_n = f(y_n, t_n)$ are available. To compute y_{n+1} and thus $\dot{y}_{n+1} = f(y_{n+1}, t_{n+1})$, where $t_{n+1} = t_n + \Delta t$, and Δt (program variable HZ) is the integration interval, the following Runge-Kutta formulas are used:

$$\begin{array}{lll} y_A = y_n + \frac{\Delta t}{2}\,\dot{y}_n, & \dot{q}_n = \dot{y}_n, & \dot{y}_A = f(y_A,\ t_n + \frac{\Delta t}{2}) \\ y_B = y_n + \frac{\Delta t}{2}\,\dot{y}_A, & \dot{q}_A = \dot{q}_n + 2\dot{y}_A, & \dot{y}_B = f(y_B,\ t_n + \frac{\Delta t}{2}) \\ y_C = y_n + \Delta t\,\dot{y}_B, & \dot{q}_B = \dot{q}_A + 2\dot{y}_B, & \dot{y}_C = f(y_C,\ t_n + \Delta t) \\ y_{n+1} = y_n + \Delta t\,(\dot{q}_B + \dot{y}_C), & \dot{q}_C = \dot{y}_C, & \dot{y}_{n+1} = f(y_{n+1},\ t_n + \Delta t) \end{array} \tag{F-2}$$

References (F-1) and (F-2) present an explanation of these formulas and a discussion of the Runge-Kutta method.

These formulas are applied to the system of equations using either a fixed or variable integration interval, Δt. When a variable Δt is used, the routine computes a truncation error indicator at each step of the integration, based on the quantity

$$E_{n+1} = \text{Max}\ \{\text{Min}\ [|\Delta t(\dot{y}^i_{n+1} - \dot{y}^i_C)\ |,\ |\ \frac{\Delta t(\dot{y}^i_{n+1} - \dot{y}^i_C)}{y^i_{n+1}}\ |]\} \tag{F-3}$$

where i = 1, 2, ..., N and N is the total number of integrated variables, and the superscript i denotes the ith integrated variable. The notation of Equation (F-3), indicates that for each ith integrated variable, the minimum of the two quantities

$$|\ \Delta t\ (\dot{y}^i_{n+1} - \dot{y}^i_C)\ |\ \text{and}\ |\ \frac{\Delta t\ (\dot{y}^i_{n+1} - \dot{y}^i_C)}{y^i_{n+1}}\ |$$

is saved. The truncation error indicator, E_{n+1}, is then set equal to the maximum of these minimums. The value of E_{n+1} is compared with the two constants E_{max} (EMAX) and E_{min} (EMIN) which are the input values for the maximum and minimum allowable truncation errors, respectively. This comparison results in a modification of Δt as follows:

1. If $E_{n+1} < E_{min}$ for two consecutive integration steps, Δt is doubled and the integration continues with the new Δt. However, if Δt equals Δt_{max} (HMAX), Δt is not doubled.
2. If $E_{min} \leq E_{n+1} \leq E_{max}$, Δt is left unchanged.
3. If $E_{n+1} \geq E_{max}$, Δt is halved and the values at step n, which are saved in COMMON, are used to continue the integration. However, if Δt equals Δt_{min} (HMIN), Δt is not halved.

This procedure is continuously applied to the center body equations of motion, Equation (5-23). The equations of motion for the footpads, Equation (5-4), are continuously integrated by the above procedure when the "contacting footpad" option of the program is employed. If the "noncontacting footpad" option is specified, a footpad's equations of motion are integrated only when the footpad is determined to be in contact with the landing surface. For a footpad approaching the landing surface, contact is defined as the condition when the bottom of the footpad is found to be within a tolerance band above and below the landing surface, as shown in Figure F-1(a). If this footpad is found to have penetrated below this tolerance band as shown in Figure F-1(b), a linear interpolation procedure is employed to estimate at what time the footpad would have entered the tolerance band. The integration is backed up and then continued from this point in time with the footpad considered contacting.

F.3 Subroutine Calls - There are six calls to the integration routine. A brief description of each of the entries into the subroutines is given below.

Subroutine	Entry Point	Operation
INITUP	LOC	Sets up a list of cutoff variables and their cutoff values.
INITUP	INUPD	Sets up a list of all integrated variables.
RKCUT	SETUP	Initializes numerical integration procedure for type of integration requested.
RKCUT	INTEG	Performs all integration and computes truncation error indicator.
RKCUT	UPDATE	Updates integration variables and modifies integration interval when required.
RKCUT	CUT	Checks cutoff limits for introduction of footpad equations into integration routine.

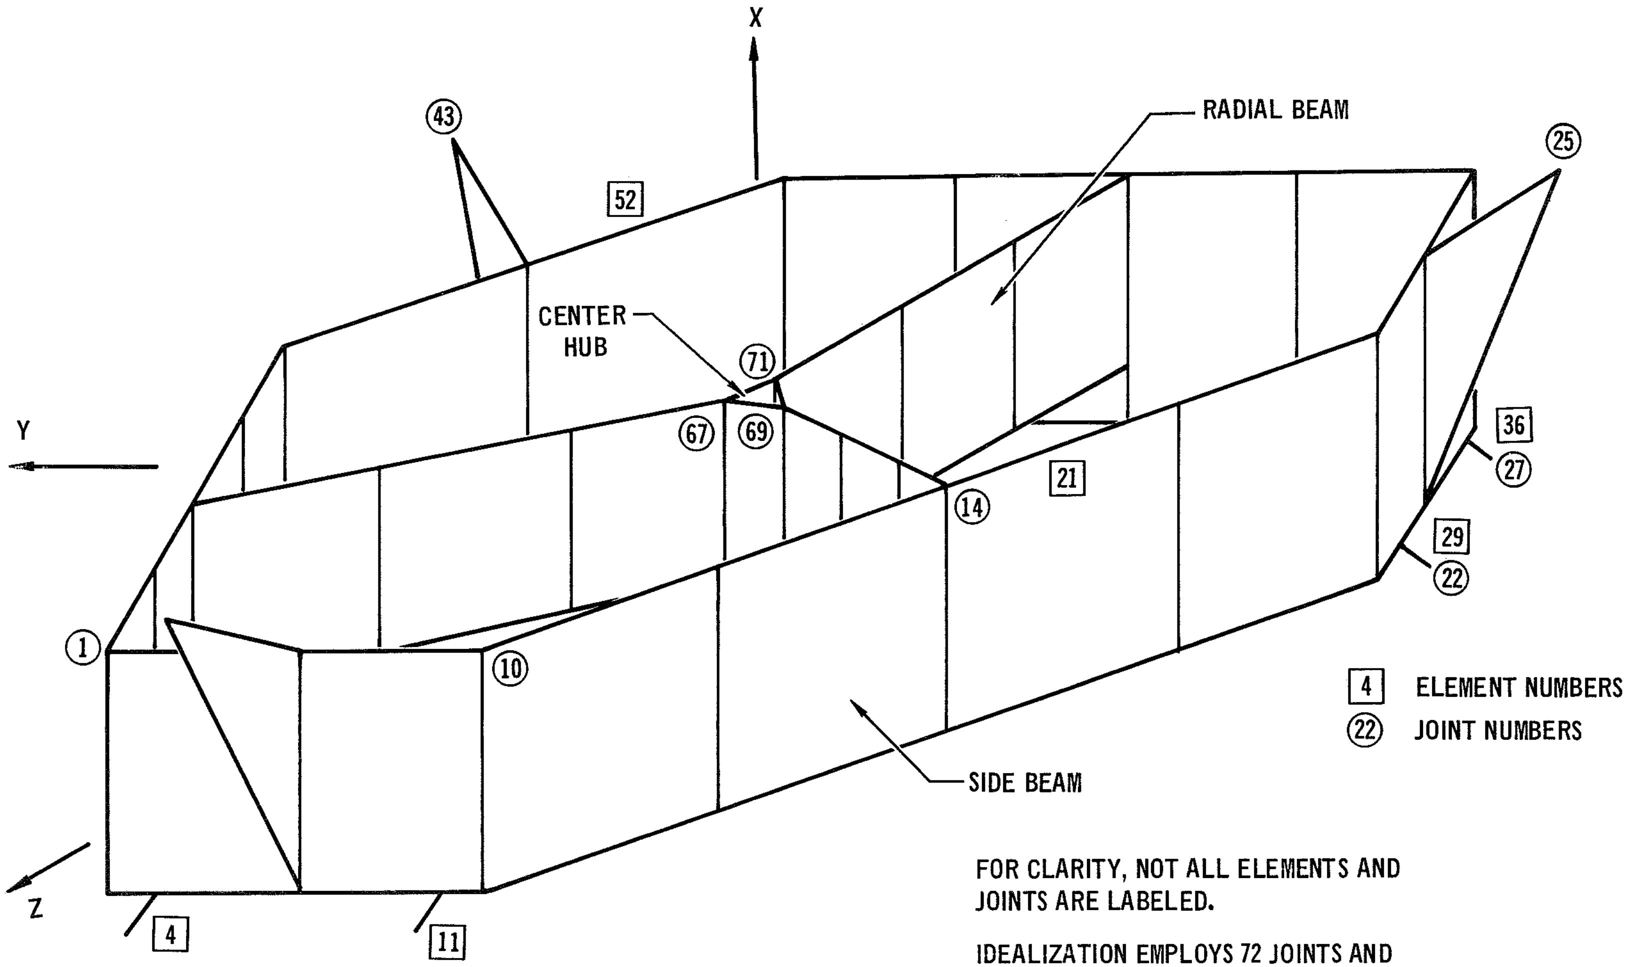
APPENDIX G

CENTER BODY INTERNAL LOAD DISTRIBUTION FOR TASK ORDER THREE LANDER USING REFINED IDEALIZATION

A refined idealization of the Task Order Three lander center body, shown in Figure G-1, was employed to determine displacements and internal loads for the loading condition defined in Section 6.2.4. This idealization, which employs 72 joints and 108 bar elements, includes a more refined model of the side beams and radial beams. The center hub was modeled with nine elements to more nearly represent a cylinder. In addition, clevis fittings, which connect the drag struts of a gear to the center body, were idealized with elements such as 4, 11, 29, and 36. Accordingly, joints 22 and 27 (and 40 and 45 which are hidden) are the actual center body attach points for gears 2 and 3 and were assumed to be pinned supports. Main strut attach points (joints 25 and 43) for gears 2 and 3 were also assumed to be pinned supports.

Loads that were applied to the joints in the idealization of Figure 6-8 were applied to coincident joints in Figure G-1. For example, loads that were applied to joint 6 in Figure 6-8 were applied to joint 10 in the refined idealization. Loads that were applied to joints 31, 32 and 33 (on the center hub) in Figure 6-8 were distributed to joints 67 through 72, some of which are hidden in Figure G-1. These loads were distributed to the refined idealization joint locations in a statically equivalent manner.

A comparison of selected displacements and internal loads obtained with the 33 joint idealization and the refined idealization is given in Figure G-2.



FOR CLARITY, NOT ALL ELEMENTS AND JOINTS ARE LABELED.

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Scientific and technical information generated under a NASA contract or grant and considered an important contribution to existing knowledge.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

TECHNOLOGY UTILIZATION PUBLICATIONS: Information on technology used by NASA that may be of particular interest in commercial and other non-aerospace applications. Publications include Tech Briefs, Technology Utilization Reports and Technology Surveys.

Details on the availability of these publications may be obtained from:
