ABSTRACT

Information for the wind tunnel force and moment test on a 0.01875 scale, (S-5) model of the MSC Orbiter Shuttle (August configuration) at the McDonnell-Douglas Low Speed Wind Tunnel is presented in this document. This test was conducted from January 19 through January 23, 1970. The primary objective was to obtain data describing the longitudinal and lateral stability characteristics of the MSC orbiter configuration for an angle-of-attack range from -30° to 90° and a sideslip-angle range from -10° to 10° . Data were also collected for two possible wing positions and for several horizontal stabilizers. Elevator power was determined for control during subsonic cruise. These data were collected at Mach numbers 0.16 and 0.25.

TEST CONDITIONS

The model was installed in the wind tunnel on a single support system (see Figure 10). The model was attached to a sting which was connected perpendicular to, and upstream of, a single floor-mounted strut. In this arrangement the model and sting-tunnel centerline was assumed to be coincident. Upon installation, the model was rolled +90 degrees so that the wings were in the tunnel's vertical plane. In this attitude, angle of attack was achieved by rotating the model in the tunnel horizontal plane (mechanically rotating the sting-strut assembly, which is mounted on a turntable). Angle of sideslip was achieved by off-setting the sting in the tunnel's vertical plane. This was done by manually rotating the sting about the sting-strut attach point and locked at prescribed settings via a drift pin.

For the sideslip evaluation, the model was rolled back to zero placing the model in an upright position. In this attitude, angle of sideslip is measured in the tunnel's horizontal plane by mechanically rotating the sting-strut turntable. Angle of attack was achieved by off-setting the sting in the tunnel's vertical plane and locked with a drift pin.

Prior to each test, the output signal from each of the balance strain gauges were nulled and recorded as tare measurements. Additionally, the tare measurements were also recorded after each test.

It was found that an angle of attack greater than 40° , with the dynamic pressure (q) = 91 psf, produced a load which approached the balance limitations. Consequently, two sets of data were taken:

- 1) with $q = 40$ psf, α range from -10° to 90°
- 2) with $q = 91$ psf, α range from -30° to 40°

Angle of sideslip, (β), was evaluated by two methods:

- 1) for α from 0° to 20° , β varied from -10° to 10° at $\Delta\beta = 1^\circ$
- 2) for α from -10° to 90° , β varied from 0° to 10° at $\Delta\beta = 5^\circ$

DATA REDUCTION

Force and moment data were recorded in the body axis system and reduced to coefficient form using the following reference values;

$$S_{ref} = \text{wing planform area} = 46.2 \text{ in}^2 = .3208 \text{ ft}^2$$

$$l_{ref} = \bar{c}, \text{ wing mean aerodynamic chord} = 2.773 \text{ in} = .2317 \text{ ft.}$$

$$b_{ref} = b, \text{ wing span} = 18 \text{ in.} = 1.5 \text{ ft.}$$

Moments are referenced about the wing mean aerodynamic chord quarter point ($\bar{C}/4$) with the wing in either fuselage location. This longitudinal point is at fuselage station 13.837. The vertical and lateral reference points are water line 2.4 and buttock line 0.0 respectively.

Axial force correction (for base pressure to free stream pressure), sting deflection (for angular data), and tunnel correction (flow angularity and blockage) are accounted for in the data reduction program.

Figures 2 through 9 are drawings of the configurations tested. Trip strip (0.1 inch wide and grit size 100) were placed at distances of 10% of the chord from the leading edge of the wings, horizontal, and vertical stabilizer, and one-inch aft around the nose, at the base, and on both sides of the fuselage (10% of the height). The above configurations were tested at elevator deflections, positive with trailing edge down, of -20, -10, 0, 2, 10, 20, and 30 degrees at a tail incidence angle of zero degree and at tail incidence angles of -10, -5, and 0 degrees at zero elevator deflection. Data were also taken at tail dihedral angles of 0 and 15 degrees.

* Wings $\bar{c}/4$ located at 54.71% of the body length; on all other configurations tested the wings $\bar{c}/4$ was located at 53.47% of the body length.

TEST FACILITY DESCRIPTION

The McDonnell Low Speed Wind Tunnel is a closed circuit, single return, atmospheric tunnel with a test section 8 1/2-feet high, 12-feet wide, and 18-feet long. It is capable of a maximum continuous velocity of 240 mph with a clear test section.

The tunnel circuit is 412.6-feet long and consists of two 164-foot legs and two 42.3-foot legs. The entrance cone contraction ratio is 7.35 to 1 and the total diffuser angle is 7.5°. Cooling is accomplished by a spray system passing water over the outside tunnel shell.

The main drive motor, housed in a nacelle 30 feet downstream of the third leg of the circuit, is a Westinghouse 1750 hp wound rotor motor equipped with a liquid rheostat for coarse rpm control and a dynamic brake, coupled to the motor shaft, for fine rpm control. The four-bladed fan is 20 feet in diameter.
