REP. NO.

PREFACE

This document is submitted in compliance with Line Item No. 2 of the Data Requirements List as Type I Data, Contract NAS9-12836. The document is divided into four volumes for ease of handling. The contents of each volume is defined as:

- Volume I: Includes sections entitled Introduction, Mission Envelope and Flight Dynamics which correspond to Sections 1.0, 2.0 and 3.0 of the Table of Contents.
- Volume II: Includes sections entitled Introduction and Shuttle Vehicle Systems which correspond to sections 1.0 and 4.0 to 4.18 of the Table of Contents.
- Volume III: Includes sections entitled Introduction and Shuttle Vehicle Systems which correspond to sections 1.0 and 4.19 to 4.22 of the Table of Contents.
- Volume IV: Includes sections entitled External Interfaces, Crew Procedures, Crew Station, Visual Cues and Aural Cues which correspond to sections 5.0, 6.0, 7.0, 8.0 and 9.0 of the Table of Contents.

TABLE OF CONTENTS

- 1.0 Introduction
- 2.0 Mission Envelope
 - 2.1 Space Missions
 - 2.1.1 Launch Phase
 - 2.1.2 Orbit and Deorbit Phases
 - 2.1.3 Entry and Landing Phases
 - 2.1.4 Payloads, Deploy and Retrieval
 - 2.1.5 Reference Missions
 - 2.1.5.1 Vertical Tests
 - 2.1.5.2 Easterly Launch
 - 2.1.5.3 Resupply
 - 2.1.5.4 South Polar
 - 2.1.6 Timelines
 - 2.1.7 Aborts
 - 2.1.7.1 Pad and Low Altitude
 - 2.1.7.2 Return to Site (unpowered)
 - 2.1.7.3 Return to Site (powered)
 - 2.1.7.4 Once-Around Orbit
 - 2.1.7.5 To Orbit Degraded Mission
 - 2.1.7.6 Booster Powered Glide Return
 - 2.1.8 Mission Operations
 - 2.1.8.1 Staging
 - 2.1.8.2 Drop Tank Maneuver
 - 2.1.8.3 IMU Alignment

REP. NO.

- 2.1.8.4 Rendezvous
- 2.1.8.5 Docking
- 2.1.8.6 Payload Deployment
- 2.1.8.7 Payload Retrieval
- 2.1.8.8 Deorbit
- 2.1.8.9 Entry
- 2.1.8.10 Hypersonic-Supersonic Transition
- 2.1.8.11 Energy Management
- 2.1.8.12 Cruise
- 2.1.8.13 Landing and Rollout
- 2.2 Atmospheric Flights
 - 2.2.1 Horizontal Flight Test
 - 2.2.2 Ferry Flights
- 3.0 Flight Dynamics
 - 3.1 Vehicle Configurations
 - 3.1.1 Operational Space Mission Configuration
 - 3.1.1.1 Orbiter Vehicle
 - 3.1.1.2 Payload
 - 3.1.1.3 Solid Rocket Motors
 - 3.1.1.3.1 156" Booster SRM
 - 3.1.1.3.2 156" Rocket Separation SRM's
 - 3.1.1.3.3 Abort SRM's
 - 3.1.1.3.4 External Tank Deorbit SRM
 - 3.1.1.4 External Tank

1.0 Introduction

The objective of the Shuttle Vehicle and Mission Simulation Requirements report is to provide to NASA/MSD documentation of the requirements for faithful simulation of the Shuttle Vehicle, its systems, mission, operations and interfaces. To accomplish this objective the report was divided into eight topics which comprehensively cover the simulation requirements of the Shuttle mission and vehicle. The topics and their main objectives are summarized below.

Mission Envelope - This topic covers the space and atmospheric missions that are envisioned for the Shuttle program. The characteristics of each mission are described by an analysis of the mission phases, trajectory information, timelines and operations for nominal and abort conditions to the extent data was available.

Orbiter Flight Dynamics - This topic covers the flight regimes which the Shuttle vehicle will encounter in the accomplishment of its missions. The requirements were established in the following manner.

The vehicle configurations that must be simulated for horizontal and vertical test flights, operational space missions, atmospheric missions and abort modes were defined.

REP. NO.

The dynamics requirements were established by defining the forces and moments that will act on the vehicle during the entire mission envelope which include, propulsion, gravity, aerodynamic effects, payload effects, docking effects, staging effects, ground reactions and the dumping of material overboard. The translational equations of motion requirements were established by defining the vehicles, satellites and payloads whose state vectors must be calculated and by defining the coordinate systems, relative equations of motion and accuracy of the calculations. A similar analysis was performed for the rotational equations of motion. Mass property and ephemeris requirements were also identified.

Shuttle Vehicle Systems - The Shuttle vehicle systems required for simulation were identified and described.

The descriptive data generated in this effort was primarily based on the North American Shuttle proposal. The Shuttle vehicle and its system configuration is currently in a state of flux and therefore the descriptive data

contained in this report undoubtedly will become out of date as the Shuttle program progresses. However, for the purposes of this study, the data is more than adequate to define simulator requirements and a baseline design when it is tempered with the past experience of Apollo and Gemini programs. A cross correlation between the NR definition of systems and LRU's and this report is shown in Table 1-1 for reference purposes.

External Interfaces - The external interfaces of the Shuttle vehicle were identified and a preliminary type interface description established. Due to the fact that for every external interface there also exists an equivalent on-board system, the descriptive data on the workings of the interfaces is contained in the Shuttle Vehicle Systems section of the report and cross references are provided in this section.

Crew Procedures - The actual crew procedures for the Shuttle system will not be available for many years. As a result the study concentrated on identifying tasks by mission phase and crew member and identifying the probable interfaces between work stations. The data used for the

REP. NO.

Crew Station -

analysis was a RTOP study by MacDonald-Douglas, conversations with George Franklin of NASA/MSC, past experience, and the requirements of the Shuttle vehicle & mission. The latest available data at the time of the writing of this report was used to identify the configuration of the Crew Station. The shape of the interior cabin, the location of the work stations and the allocation of the C&D panels by work station were established. Detailed data on the interior composition of the cabin is not currently available.

Visual Cues -

However, simulation requirements were identified based on past experience and accepted levels of fidelity for mission simulators. The visual scene content was established for each of the mission phases. Attributes of the scene elements, to the extent feasible, were established and will be further defined in the SMSR report. The vehicle window configuration is not defined at this time but the best data available was utilized. The accelerations, velocities and displacements were established to the extent possible. Some

dynamics data was not available such as in the Abort phases of the mission. The missing information will be incorporated if it becomes available when the time frame and ground rules of the study or assumptions will be made.

Aural Cues -

The aural cues requirements associated with the mission and vehicle systems were identified and described. Detailed data on the characteristics of each sound was not available and probably will not be until the vehicle test program is in progress. This factor can be circumvented by specifying flexibility into the simulator aural cue equipment.

This report will be updated at the end of the study based on data received as of January 1, 1972.

Reference to study data sources are included in the margins and the text in order to facilitate update of this report. The numerical references are correlated with the data listing defined by Table 1-2.

REF.
KEY4.0 SHUTTLE VEHICLE SYSTEMS

166

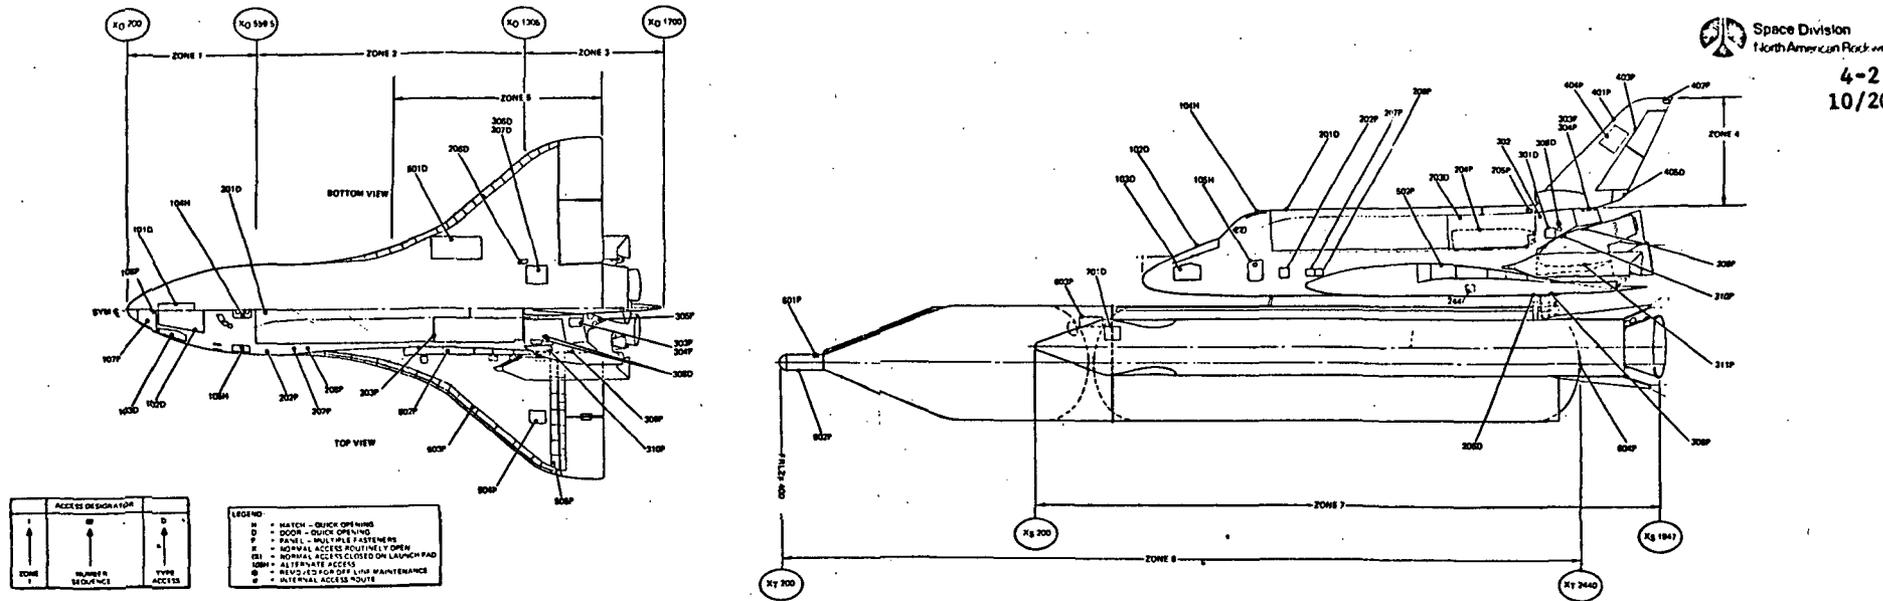

The shuttle vehicle is composed of three major units: the orbiter vehicle, the external fuel tank, and the two 156" external solid rocket motors. Figure 4.0-1 gives the relative location of the total vehicle major components. Note in this figure the Abort SRM's are shown attached to the shuttle vehicle body. In Figure 4.0-2 the shuttle vehicle does not have the ABORT SRM's in place and is in an orbital configuration. Inserts and cutaways provide general location of additional components of the shuttle vehicle. The payload shown is representative of one of the many possible configurations that may be accommodated in the shuttle payload bay.

4.0.1 Rationale for Assumptions

Not Required

4.0.2 References

REP. NO.

4.1 ELECTRICAL POWER

166

The electrical power system for the shuttle vehicle is composed of fuel cells, batteries, auxiliary power generators (AC power), and air breathing engine generators (AC power). These power sources are distributed throughout the vehicle as both AC and DC supply to operate electrical pumps, motors, valves, and avionic subsystems throughout the mission. The restartable hydrogen-oxygen fuel cell powerplants were selected as the primary source for DC power. Projected life expectancy of these cells is approximately 5000 hours. Three of these fuel cells are provided, each having an output capability of 10KW at 29 volts $\pm 5\%$. Heat and water generated by the fuel cell reaction process are input to the ECLS subsystem.

166

For the launch, landing, and during some mission operations the three 400 Hertz; 20/30 KVA; 120/208 VAC APU driven generators will provide additional power for peak loads. During ferry flights the electrical power requirements will be supplied by four ABPS driven AC generators.

166

Nickel-cadmium batteries provide the pyrotechnic and emergency power supply. The nickel-cadmium batteries use hermetically sealed cells to minimize maintenance requirements. A high-pressure safety relief vent on each cell provides the necessary safety for manned vehicles; however, the vents do not cycle under normal operating modes.

166

As a pyrotechnic and emergency power supply, two nickel-cadmium secondary batteries are employed. Each battery has nominal power of 10 amp-hours at 29 volts and 27.55 volts (nominal TBD% SOC at TBD° F. at 20 amps discharge.

166

A separate battery subsystem is provided for contingency power to meet

special requirements for the Development Flight Instrumentation (DFI).

A load analysis has indicated a requirement to supply 962 watts for a total duration of 2.5 hours, which assumes a 100-percent duty during high activity periods and a 10 percent duty cycle during low activity periods. Three Apollo CSM silver-zinc entry batteries (40 amp-hr each) provide this power requirement.

166 Battery recharging will be accomplished by DC-DC convertors. Static inverters are provided for minor AC loads when startup of the APU is not warranted. Conversion of AC to DC will be accomplished when the fuel cells are inoperative.

166 Power distribution and control is accomplished by bus networks with switching and control logic for protection of buses and circuits from power source, bus load faults, and failures.

166 The orbiter electrical system provides an electrical power umbilical compatible with the space station docking port power umbilical and is capable of receiving space station power for orbiter emergency orbital docked-phase power requirements. In addition the orbiter provides a power umbilical and is capable of transferring power to the payload module. No electrical power transfer is provided between the orbiter and booster.

4.1.1. ELECTRICAL POWER DISTRIBUTION AND CONTROL (EPDC)

166 The orbiter EPDC is shown schematically in Figure 4.1-1 Primary 28 vdc power is distributed from the three 10 kw fuel cells through three central DC distribution center near the fuel cells, to seven local distribution boxes located near the load centers. There are two 3-phase, 400 cycle AC bus systems incorporated into the vehicle. The APU generators in the aft portion of the vehicle provide three independent AC power sources. The three

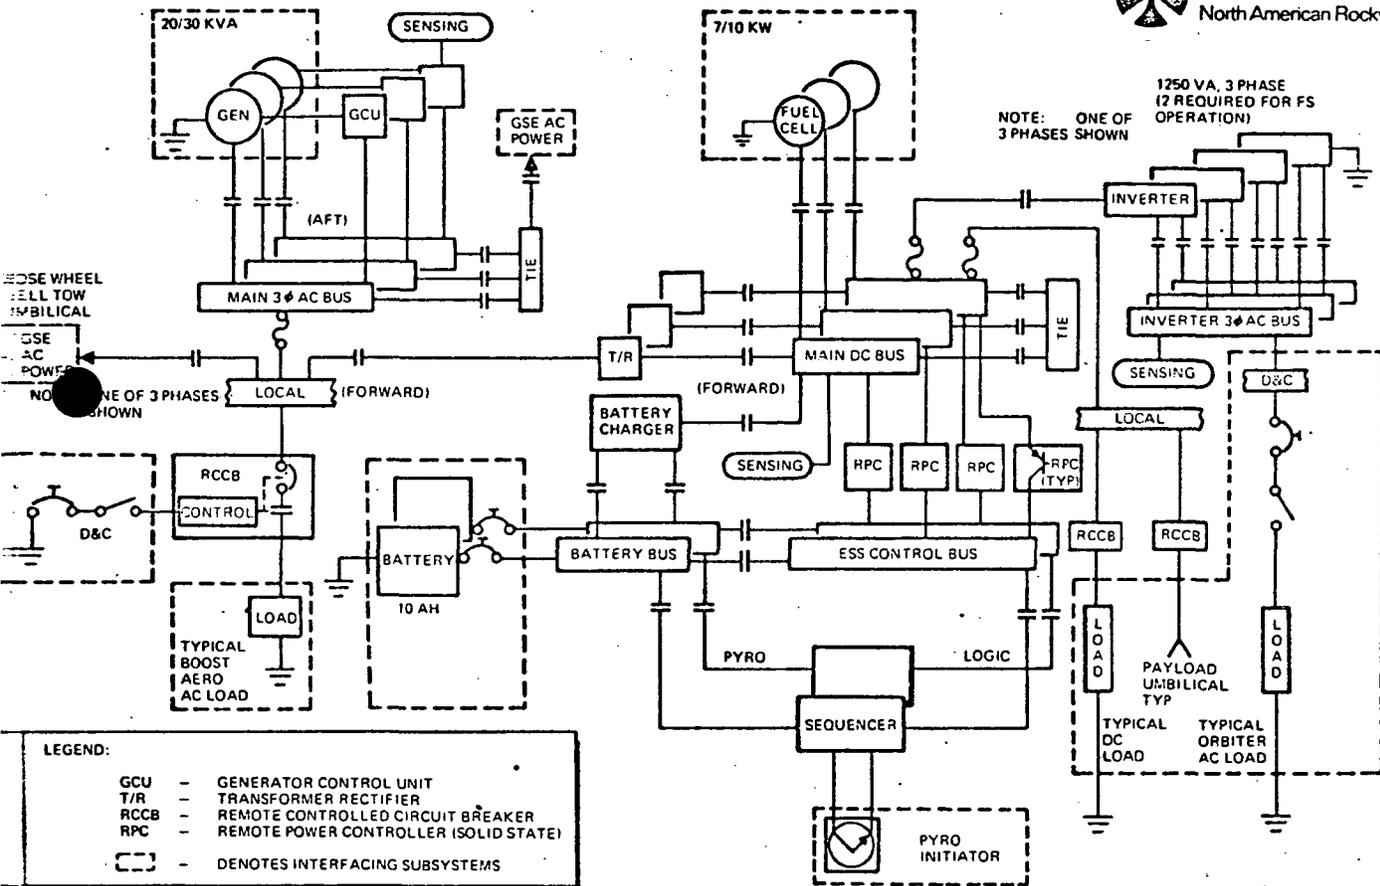

TABLE 4.1.1 System Electrical Power Distribution and Control Schematic

TABLE 4.1.1 *Equipment for EPDC*

Feature	Selected Approach	Equipment/Components
Power types DC	24-30 v at load	Fuel cells, 150-amp transformer-rectifier, 10 amp-hr batteries, battery charger
Aero, boost and entry ac	115/200-v, 400-Hz generator (MIL-STD-704A)	Generators, generator control unit
Orbit ac	115/200-v, 400 Hz central inverter system (CSM limits)	CSM 1250-v-a 3-phase inverters (refurbish-reuse)
GSE	115/200-v, 400-Hz (MIL-STD-704A)	Ac power umbilicals
Bus redundancy	Three redundant	Magnetic latch, hermetic sealed power contactors
Redundancy management	Isolated (ac nonsynchron- ized—isolation maintained from source through load) Bus transfer after source failure Redundant loads powered from redundant buses	Magnetic latch, hermetic sealed power contactors
Load control	Hardwired electromechanical	Magnetic latch, hermetically sealed RCCB's RPC's, high-reliability relays
Power current return	Structure, multipoint ground (single-point ground for signal circuits)

SIMULATION PRODUCTS DIVISION

PAGE NO. 4-8

REV.

BINGHAMTON, NEW YORK

REP. NO.

buses are non-synchronous and should not be tied to a common bus except when GSE is providing power. The APU generator has controls for governing voltage and frequency; however, there is no provision for synchronization of the generators. The solid state 1250 VA-3-phase invertors driven from the main DC buses do have synchronization between phases. Note that in case of failure of any one unit, that the other invertors can be switched to provide redundant power. Inverter power is distributed from there to the local distribution boxes.

166

From the local distribution boxes, power is distributed to loads and controlled by remote power controllers. The interface for power control and data with the Displays and Control (D&C) system is by Data Control Management Acquisition Control and Test (DCM ACT) units and data bus. As shown, certain basic power control and data functions are hardwired directly to dedicated D&C equipment. Transformer-rectifier units near the main DC distribution center supply DC power from generator sources during ferry missions, GSE AC sources for ground checkout, and space station AC sources for emergencies during docked periods. Two batteries supply emergency power control and pyrotechnic DC loads. The batteries can be recharged from fuel cell energy by a regulated charger.

166

Redundant sequencers provide positive arming and safing of pyrotechnic devices and any other unilateral safety-of-flight electrical operations required of orbiter electrical subsystems.

166

Interior lighting is provided in the flight deck, Avionics Equipment Bay, IVA tunnel, cabin, and airlock compartments. Both floodlights and spotlights are provided. Exterior lights are provided for rendezvous, docking,

and payload maneuvering during orbital flight, as well as atmospheric flight, landing and taxi. General operating characteristics of the EPDC is shown in Table 4.1-1.

4.1.2 POWER DISTRIBUTION EQUIPMENT DESCRIPTION

4.1.2.1 GENERATOR CONTROL UNITS (GCU)

166 Generator Control Units (GCU) provide voltage regulation for the AC generators, and control the Generator Load Contactor (GLC) to close (upon command from the D&C) when generator voltage and frequency are normal and open when voltage or frequency exceed limits (or a feeder fault or generator overload is sensed by the generator current transformers). The GCU will also provide failure indications to the DCM system for failure isolation to generator, GCU feeder, or GLC.

66 The three 20/30 kva, 400-Hz generators used for orbital missions are sized to power the main propulsion engine accessories, the ABPS fuel boost pumps, the ECLSS vapor cycle machines, and other similar loads applied during ascent, entry, and landing. Frequency control is in accordance with MIL-STD-704A. Synchronization of APU generator frequencies is not controlled. The generator design is a smaller model of existing spray-oil cooled units, and was designed for integration with APU gearbox zero-g lube system.

4.1.2.2 POWER CONTACTORS

166 Main AC and DC power source and bus tie contactors are the electro-mechanical type, and will have auxiliary contacts for interlock and position indication. DC types will include overcurrent sensing and trip in some applications.

4.1.2.3 INVERTERS

166 There are four inverters; single-phase units with 1250-va, 115-v 400-Hz output rating. They are completely static, solid/state, and have

provisions for sensing and limiting overload current in either of two output terminals. Synchronization and phase relationship between units is provided by an internal clock oscillator in the master inverter unit for phase A, and 120-degree lock signals between inverters connected to succeeding phases. Bus 1 and Bus 2 inverter sets will also be synchronized.

4.1.2.4 TRANSFORMER-RECTIFIERS (TR)

166 The three transformer-rectifiers (T-R) are each rated at 28-v, 150-amp output and can deliver 225-amp for five minutes and 300-amp for five seconds. The T-R's contain no active regulator to control output voltage. The regulation of the transformer and rectifier over the normal load range provides output voltage within subsystem limits.

4.1.2.5 BATTERY/CHARGER

166 A solid-state battery charger uses fuel cell energy to recharge the 10-amp-hour nickel cadmium batteries after partial discharge for pyrotechnic loads and/or emergency power control. The charger is a constant current type with maximum voltage cutoff control, and will sense battery temperature to adjust cutoff voltage.

4.1.2.6 REMOTE POWER CONTROLLERS (RPC)

166 Two types of remote power controllers are used in the local power distribution boxes: solid-state and hybrid. Solid-state power controllers protect and control DC loads rated from 1 to 10 amp. They limit overload current to 150-percent RPC rating and control turn-on and turn-off time for transient current and voltage control. They also provide trip indication to D&C through the DCM system.

166 Hybrid power controllers control and protect DC loads rated above 10 amp and AC loads. This RPC type uses solid-state sensing and control and electromechanical contacts for power switching. The hybrid RPC's have

inverse current-time overload trip characteristics, and for AC are in both single and three-pole types.

166

Both solid-state and hybrid Remote Power Controller (RPC) are trip-free, and are controlled by a 5-v, 10-ma signal for on and 0-v open circuit for off. Reset after trip is accomplished in both types by removing the control signal. All RPC's have fuseable links as back up to the solid-state overload sensing and trip circuits, and the hybrid DC RPC's also have a current trip coil.

4.1.2.7 SEQUENCERS

166

Sequencer units contain a sequencer bus which is armed only during sequence events. Dual-redundant firing relays short protective devices during all periods except firing. Connection is made to sequencer buses on logic command from the DCM.

4.1.2.8 INTERIOR LIGHTING

166

Floodlighting is provided by fluorescent lamps and spotlighting by incandescent lamps. Integral D&C panel lighting is a part of D&C and is provided by that subsystem.

4.1.2.9 EXTERIOR LIGHTING

166

For exterior lighting during orbit, flashing rendezvous lights are provided for the space station rendezvous phase. Running lights and a docking light are provided for stationkeeping and docking. A spotlight on each payload manipulator arm provides payload illumination. For atmospheric flight phases, the rendezvous light is used as an anticollision light. Other FAA lighting requirements are met by position lights and fuselage lights. Night landing requirements are met with three landing lights mounted on the landing gear. The nose-gear landing light is also used as a taxi light.

4.1.2.10 FUEL CELL SYSTEM

66 The shuttle orbiter vehicle carries three 10 KW peak power fuel cells for a prime source of power during orbital missions. During ferry missions the fuel cells remain inactive. Figure 4.1-2 gives the expected fuel cell load.

66 Redundant cryogenic tanks provide the gaseous O_2 and H_2 at nominal pressures of 900 psia and 250 psia respectively.

66 *NOTE: To date manufacturer/type of fuel cell has not been selected, however, the two types under consideration have similar characteristics.

66 The hydrogen-oxygen fuel cells are the low-temperature restartable type and are either the contained electrolyte Pratt and Whitney or the ion-exchange membrane type power units. The reaction conditions are 60 psia pressure and 200 F using a catalyst for the reaction. Refer to Figure 4.1-3.

66 Voltage control will be achieved either by inherent characteristics or by voltage regulators.

66 Controlled gas regulators will provide near equal pressures to the fuel cell chambers to prevent flooding and contamination. Preheaters will be used to precondition incoming gas flows. Purging will be accomplished on a fixed watt-hour usage by integration devices and controls. Separate purge systems are provided for both reactants. Water vapor and gaseous reactant will be separated either by a static separator (droplet collector) operating at a differential pressure caused by circulation or by wicking. Product water is routed to the EC/LSS storage tanks or overboard disposal. Check valves and pressure relief regulators are provided on fuel lines and product lines to prevent directional flow problems. Heaters are provided

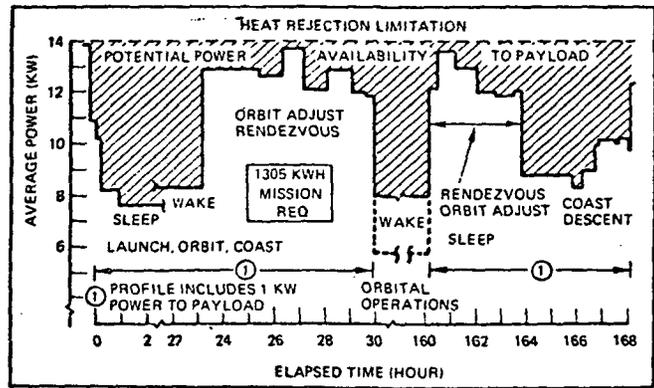

Figure 4.1.2 Fuel Cell Powerplant Subsystem Power Profile (Phase Average)

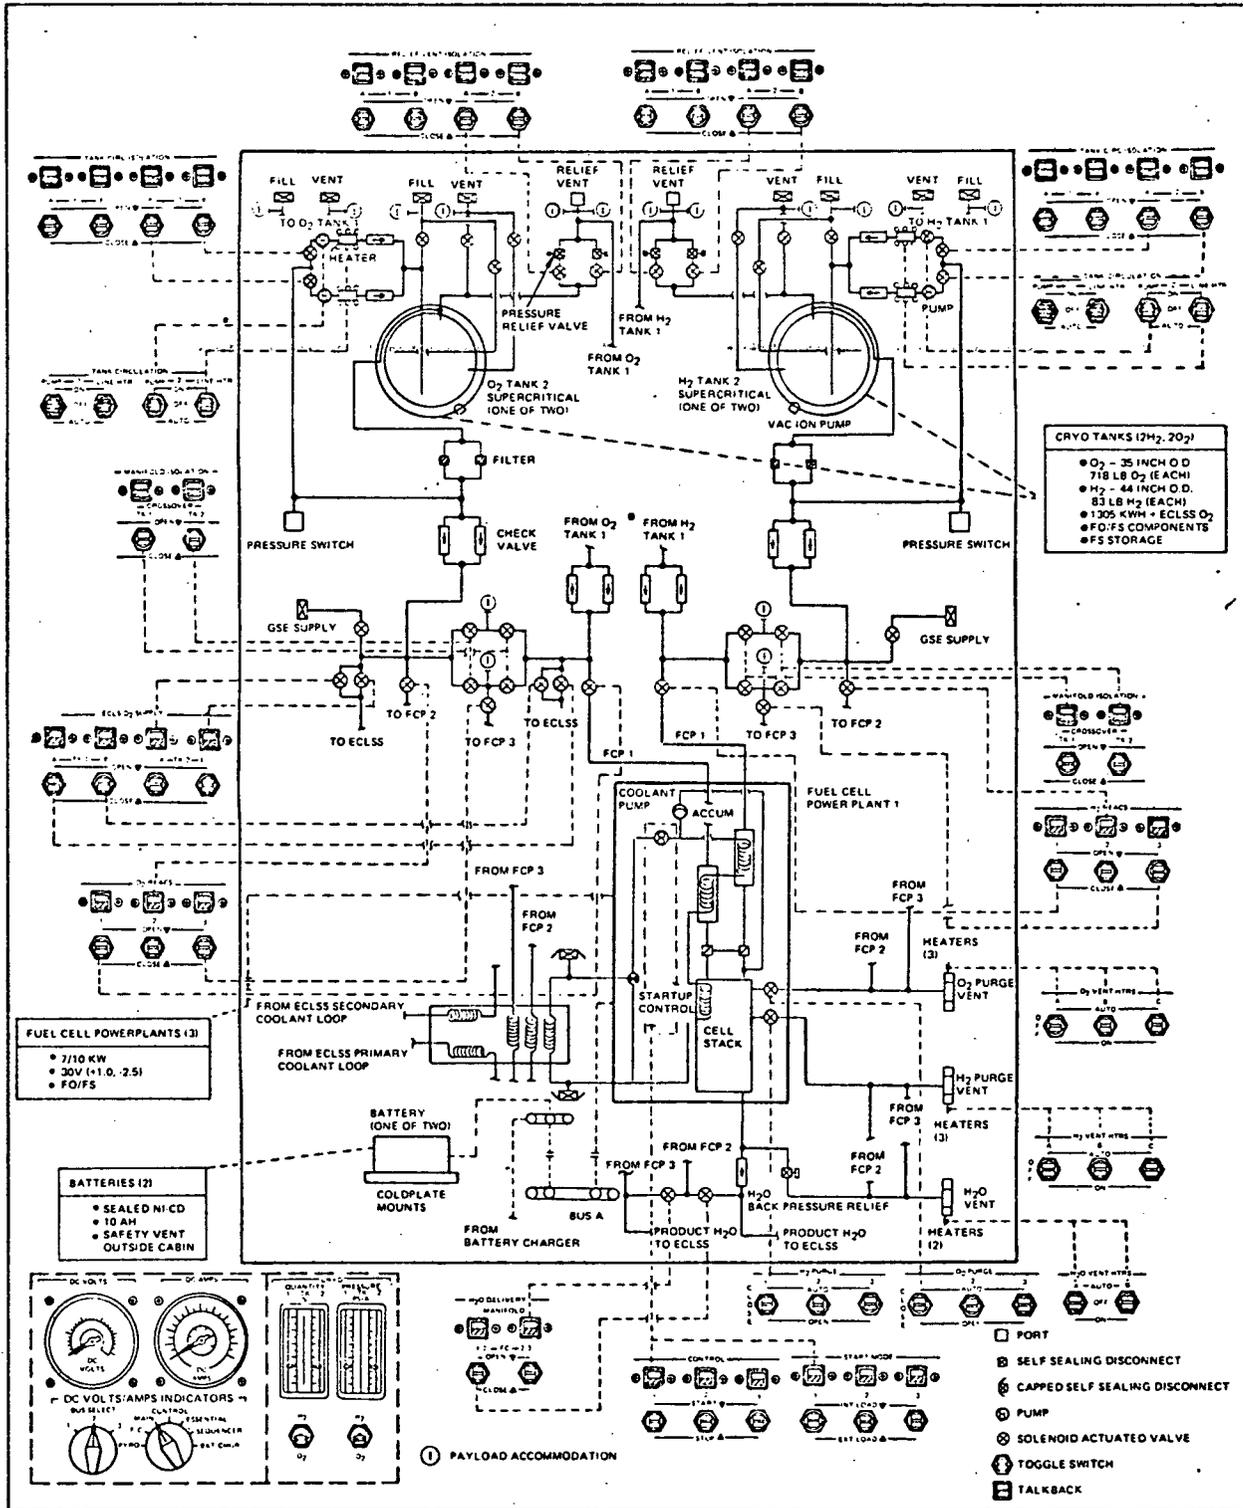

Figure 4.1.3 Fuel Cell Powerplant Subsystem Schematic

SD 72-64-50-3

on all lines and ports where water products accumulate or discharge. Waste heat from the reactor unit is removed by circulating coolant through heat exchangers, or through the electrodes. Pumps, accumulators, pressure and temperature controls circulate the reactant and coolant and provide proper fluid volumes and thermal control within the power plant unit. The waste heat from the coolant loop is transferred to the ECLSS coolant loop or to freon heat exchangers during certain vehicle operating modes.

4.1.3 ELECTRICAL POWER OPERATIONAL CHARACTERISTICS

166 The interface to the electrical-power system for most power control and data transmission is by DCM Acquisition, Control, and Test (ACT) units. Central automatic power management functions are performed by the DCM central computer complex. Certain basic power control and data functions are hardwired directly to dedicated D&C equipment.

166 The AC generators are driven by APU's during boost, entry, cruise, and landing flight phases of the orbiter mission. The generators are connected to isolated AC buses normally and controlled by Generator Control Units (GCU).

166 The orbiter Transformer Rectifier units provide DC power from ground and space station AC sources and from the onboard generators during ferry missions. Batteries supply emergency power control and pyrotechnic DC loads. Orbiter batteries can be recharged from fuel cell energy. An orbiter central inverter system supplies AC loads which require 3 phase power during orbit flight phases from two redundant 3-phase AC buses, each supplied from a set of four single-phase inverters.

166 Power feeders, protected by current limiters, feed power distribution boxes from the central buses. Locally, solid-state and hybrid power controllers control and protect load circuits, interfacing with adjacent DCM-ACT units. Redundant loads are connected to redundant buses.

166 For failure isolation, failed power sources will be isolated from the bus, and the bus will be connected to another power source through bus tie contactors.

166 Table 4.1.2 lists the orbiter electrical power characteristics which are common to those in the booster. Figures 4.1-4 and 4.1-5 depict common orbiter-booster electrical voltage transient envelopes.

Table 4.1.2 Electrical Power Characteristics at Load Interface

Item	Main Bus	Sequencer Bus

REF.
KEY4.1.4 Functional Interfaces and Support Requirements4.1.4.1 Data Control and Management (DCM)

166

The EPDC interface for power control; EPDC data; automatic, normal and emergency power management functions; and data recording will be through the DCM ACT units. The ACT unit control interface with the RPC's will be a continuous 5-v, 10-ma signal for on, 0-v open circuit for off. The ACT data interface with RPC trip signals, power contactor position, and EPDC analog data signals will be a 5-v 1-megohm input.

4.1.4.2 Displays and Controls (D&C)

166

The EPDC interface with D&C for normal crew display and control functions will be through the DCM. However, functions required for initial power-up (or power restoration) of DCM and integrated D&C will be hardwired between EPDC and D&C. Such functions include the application of GSE power, AC and DC bus switching, inverter system controls, fuel cell systems controls, and ECLSS electronics cooling controls. Where controls are required to be both manual hardwired through D&C and automatic through DCM, the circuit will be designed to permit D&C manual control to override the DCM signal. The D&C control interface with EPDC RPC's will be a 5-v, 10-ma signal for on, 0-v grounded for off, and open circuit for automatic through DCM (if required).

4.1.4.3 Electrical Power Generation (EPG)

166

The EPDC interface with the EPG will be at the fuel cell, AC generator, and battery terminals. Electrical power characteristics at the interface will be:

REF.
KEY

1. Fuel cells: 29-v \pm 5-percent load range of 1.5 to 10 kw
2. AC generators: 120/208-v, 3-phase, load range of
0 to 30 kva, 400 \pm 20 Hz
3. Batteries: 27.55-v at 20 amp discharge with a TBD% SOC

166

The EPDC will nominally distribute power to the loads while maintaining power characteristics at the subsystem load interface as stated. The EPDC GCU will regulate the EPG AC generator voltage.

4.1.4.4 Electrical System Power Losses

166

The EPG will provide for EPDC power distribution conversion and control power losses as listed:

EQUIPMENT	POWER LOSS (watt)
DC distribution and control	108 w, plus 4 percent of DC load
AC distribution and control	66 w, plus 1.3 percent of AC load
Inverter distribution and control	26 w, plus 1 percent of inverter load
Inverter	25 percent of inverter load
Transformer-rectifier	17.6 percent of DC load
Interior lighting	275 w maximum
Exterior lighting, payload manipulation	800 w maximum
Exterior lighting, atmospheric running	275 w maximum
Exterior lighting, landing and taxi	3000 w maximum

4.1.4.5 Environmental Control/Life Support (ECLSS) Interface

166

EPDC equipment (except wire harnesses) and lighting will be located in the crew compartment - electronic equipment bay, near the

fuel cells and near the APU's. EPDC equipment is temperature-controlled by ECLSS to maintain the temperature limits listed below at the mounting surface while dissipating the power listed.

EQUIPMENT	LOCATION	NO. REG.	PER UNIT MAX. POWER LOSS (w)	TEMP. LIMITS (F°)
GCU	Near APU's	3	50	-65, +200
Inverter	Electronics bay	6	113	+40, +140
Battery charger	Electronics bay	1	40	-65, +150
Transformer rectifier	Electronics bay	3	740	-65, +150
Central dc distribution box	Electronics bay	2	60	-65, +200
Central ac distribtuion box	Near APU's	2	50	-65, +200
Inverter ac central distribution box	Electronics bay	2	10	-65, +200
Local Power distribution box	Forward crew Compartment	2	29	-65, +200
	D&C panel	2	40	-65, +200
	Airlock	2	5	-65, +200
	Electronics bay	2	98	-65, +200
	Near forward Cargo Bay	2	61	-65, +200
	Near Aft Cargo Bay	2	16	-65, +200
	Near APU's	2	165	-65, +200

4.1.4.6 Power Utilization Subsystems

166 The EPDC interface is at the using subsystem connector. Power characteristics as listed in Paragraph 4.1.4.3 is supplied to the interface for the loads. Power control and interconnecting wiring for all subsystems is provided by EPDC.

4.1.4.7 Support Equipment - GSE

166 The interface for ground electrical power to the orbiter will be through an external power umbilical connector located near the APU's. 120/208-v, 3-phase, 400-Hz power of 60-kva maximum can be furnished from the GSE to this interface.

4.1.4.8 Payload

166 An average of 1000-w DC (maximum 1.5 kw) power will be supplied by the orbiter to the payload power interface umbilical, located at the forward end of the cargo bay.

4.1.4.9 Space Station Interface

166 An average of 500-w DC (maximum 800 w) power will be supplied by the orbiter to the space station interface umbilical, located at the airlock docking port. The space station will be capable of supplying to the orbiter 7-kva maximum, 115/200-v, 3-phase, 400-Hz AC power through each of two umbilicals located at the airlock docking port.

4.1.5 Rationale for Assumptions

4.2 Mechanical Power

166

Auxiliary mechanical power is used by the shuttle vehicle for hydraulic operation of linear and rotary actuators, electrical power generation, shock dampers, and pressurization of tanks. Pressurization of fuel tanks is discussed in each section which has a requirement for individual fuel supply pressurization. Hydraulic power and generation of AC power is accomplished by Auxiliary Power Units (APU's) or the ABPS during ferry operations. Refer to Figure 4.2-1.

4.2.1 Auxiliary Power Units (APU)

166

Four independent 200 HP APU's provide power to a shaft driving an AC alternator, a lube pump, and three hydraulic pumps. The description of the AC alternator interface with the electrical power system is discussed in Paragraph 4.1.2. The lube pump supplies the APU and gearbox during operation. The hydraulic pumps provide the shuttle vehicle with primary hydraulic power for approximately 90 minutes during prelaunch, ascent, entry, and landing.

166

Electronic controls provide for speed control, turbine inlet temperature control, logic for APU startup and shutdown, instrumentation, and malfunction protection. Automatic shutdown of an APU will occur if turbine speed, turbine inlet temperature, and lube oil temperature or pressure exceed limits. Each APU is enclosed for both heat transfer reduction and fire protection. Redundant fire extinguishers are provided for each APU. Overheat sensors are provided to the caution and warning system.

166 A separate pressurization subsystem and elastomeric diaphragm tank assembly supply the hydrazine (N_2H_2) to each APU. Pressure modulation control is used to control the turbine speed and thereby frequency of the AC generator. The combustion of hydrazine is accomplished by a thermal decomposition chamber.

166 A period of ten minutes is required for preheating the decomposition chambers to ignition temperature. This period is compatible with prelaunch and entry timelines. Power requirements are 200 to 500 watts depending on the chamber configuration. While on-orbit, fuel temperature is maintained above 40° F using radiation heaters for fuel tanks and strip heaters for fuel lines.

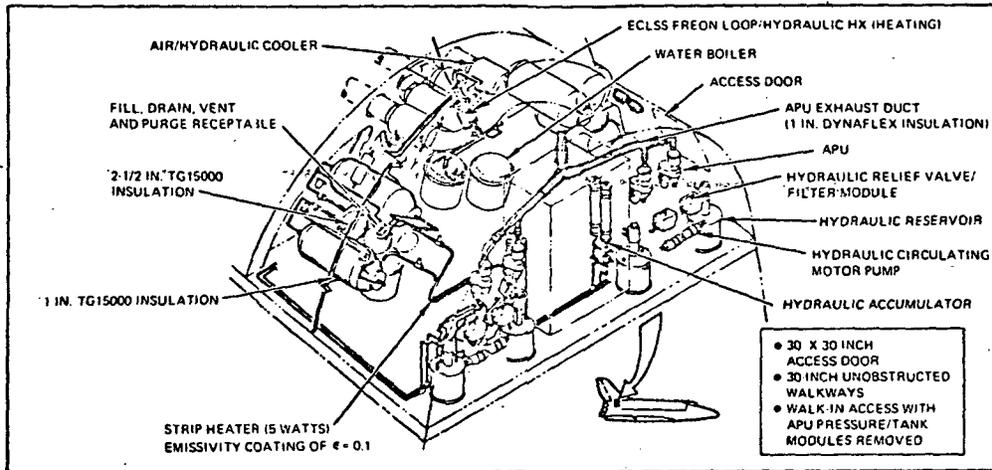

166 System cooling is provided by air coolers during prelaunch operations; by water boilers during boost, injection, and from start of entry to 20,000 feet; and by air coolers below 20,000 feet, including ferry operation. Ducted ram air is provided in flight, and electric-driven fans are used during ground operations. The use of air coolers below 20,000 feet instead of continuous water boiler operation maintains system temperatures below 275° F.

4.2.1.1 Rationale for Assumptions

Auxiliary Power Unit and Hydraulic Pumping Subsystems

APU Subsystem

FIGURE 4.2-1

4.2.2 Hydraulic Power System

166 The APU's drive multiple hydraulic pumps which provide supply redundancy. Check valves in the outlet lines of each pump prevent back flow to a failed pump. During atmospheric ferry flights, provision is made to provide hydraulic power from gear pumps on the ABES. During space operations when only light hydraulic power is required, electrical ~~AC-gear pumps will be used.~~ Refer to figure 4.2.2-1

166 Hydraulic power is used to drive the linear actuators of the thrust vector control system of both the orbital maneuvering engines and the main engines, retraction of the main engine nozzle, and main engine control valves. Hydraulic power is also used for deployment of the ABE and operation of the payload and ABE access doors, hydraulic motor and linear actuator. All landing gear functions of braking, door operation, steering, and gear extension/retraction are hydraulic functions.

166 Accumulators are provided for extending or retracting the landing gear without flow from the system. The main gear in addition has accumulators for the braking system sufficient for multiple braking operations even in the event of fluid loss from the main hydraulic unit system.

166 Circulation pumps are used to operate low power requirement loads, such as the payload bay doors while in orbit, and to prevent viscosity changes in the hydraulic fluid caused by low temperatures. Heat exchangers are provided to maintain the hydraulic oil within its operating limits.

166 Caution and Warning displays to the crew are provided for low-temperature, high-temperature, low-fluid level, and low-pressure.

REP. NO.

166 Distribution of power from the four independent hydraulic sub-
systems to the various flight control and utility subsystems is illustrated
in FIGURE 4.2.2-1. Use of four independent subsystems provides safe
flight and landing after a second failure regardless of the time of the
second occurrence. All utility functions are isolated from the pumping
source by valves which block the trunklines after each actuation. Four
independent hydraulic systems are powered by variable displacement pumps
driven by separate APU's. Bootstrap type reservoirs with air/oil separators
for self-bleeding capability ensure fluid stiffness and service life.

166 The hydraulic subsystem is designed for operation at a nominal pressure
of 3000 psi over a temperature range of -40°F to $+275^{\circ}\text{F}$. The system uses
MIL-H-83282 synthetic hydrocarbon fluid, thereby taking advantage of its
superior high-temperature, improved fire resistance, and reduced vacuum
vaporization characteristics.

166 Fluid cleanliness is maintained by 5-micron (nominal) filters
installed downstream of all case drain manifolds, all outlet manifolds, and
in the return port of each reservoir. Filters are also installed upstream of
all contamination-sensitive components such as servo valves.

Orbiter Hydraulic Subsystem Arrangement

APU Subsystem

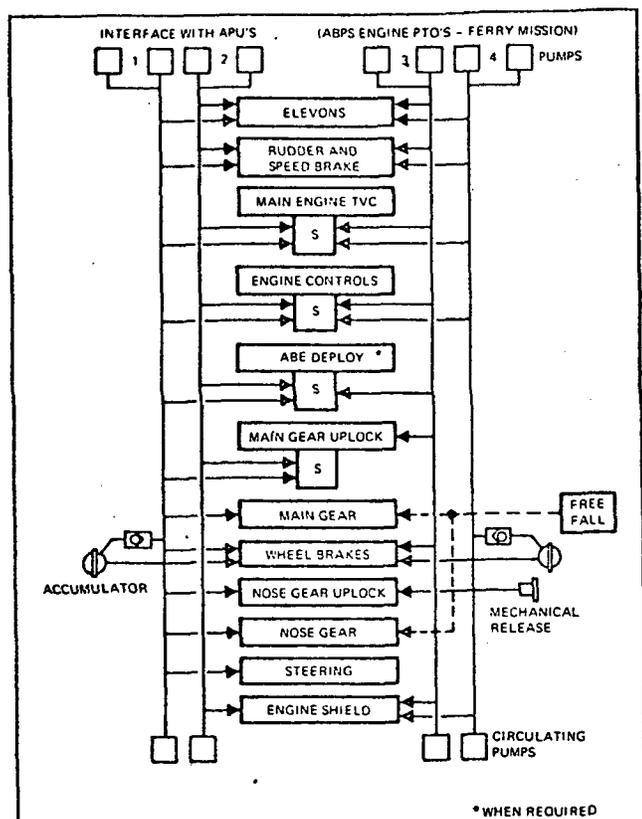

Figure 4.2.2-1 Hydraulic Subsystem Configuration

4.3 MAIN PROPULSION SUBSYSTEM (MPS)

166 The orbiter main propulsion subsystem (MPS), assisted by two booster solid rocket motors (SRM) during the initial phase of the ascent trajectory, provides the velocity increment and thrust vector control for insertion of the orbiter into a 50- by 100-nm orbit. MPS boost operation begins immediately before liftoff and terminates at orbit insertion.

166 The MPS consists of three liquid propellant rocket engines plus associated tankage, plumbing, valves, and controls. The engines operate on liquid oxygen and liquid hydrogen propellants contained in the orbiter external tank (ET), which is released following orbit insertion. The general arrangement of the mated MPS and ET is shown in Figure 4.3-1.

166 At normal power level (NPL), each engine operates nominally at a mixture ratio (LO_2/LH_2) of 6.0:1 and a chamber pressure of 3,000 psia to produce a vacuum thrust of 470,000 pounds with a fixed nozzle area ratio of 80:1. Nominal vacuum specific impulse (I_{sp}) for a single engine operating under these conditions is 455.2 seconds. Table 4.3-1 lists the total MPS propellant inventory for a 40,000 pound payload polar orbit. The same propellant loading will be used for reduced mission requirements or lighter payloads; however, in these cases the trajectory will be flown on a nonoptimum energy basis.

166 A schematic diagram of the integrated MPS and ET is presented in Figure 4.3-2. The ET contains three fuel and two oxidizer fluid lines interfacing with the orbiter at self-sealing disconnects on the bottom side of the orbiter aft fuselage. The three fuel disconnects are clustered on the left side mounted on a common carrier plate, and the two oxidizer disconnects are mounted on a similar carrier plate on the right side. The vehicle carrier plates are located

166 inside the vehicle moldline and are covered by flush closure doors following tank jettison to provide protection from heating during entry. The tank vent line disconnects each contain an integral safety relief valve that precludes tank overpressure when the tank-mounted disconnect is not engaged with the orbiter-mounted half. All other MPS fluid control valves, including tank vent and tank fill and drain valves, are located in the orbiter to minimize ET throwaway costs. Saturn S-II-type fluid line vibration damping mounts will be provided on the tank-mounted lines at critical locations. All tank-mounted fluid lines are designed for single mission (minimum weight and cost) application, whereas the orbiter-mounted fluid lines are designed for maximum reusability and employ vacuum jacket insulation. The installation arrangement of all orbiter-mounted fuel and oxidizer lines is portrayed in Figure 4.3-3.

166 The MPS fluid valves employ the same design concepts as the valves developed for the Saturn V program except for upgrading required to achieve the extended life (reusability) requirements of the orbiter. A 4,000 psi helium storage system with 750 psig regulation capability is provided in the orbiter for valve actuation and engine helium requirements. The schematic arrangement of the orbiter MPS helium system is included in Figure 4.3-3.

166 Propellant servicing is accomplished through fuel and oxidizer disconnects of eight-inch diameter located on the upper shoulder of the orbiter aft fuselage on the opposite sides of the vertical stabilizer. The eight-inch diameter fill and drain lines each contain two shutoff valves in series to assure closure at liftoff. LO₂ geysering in the ET feedline manifold is prevented during prelaunch operations by convection-induced flow of LO₂ from the insulated 17-inch diameter

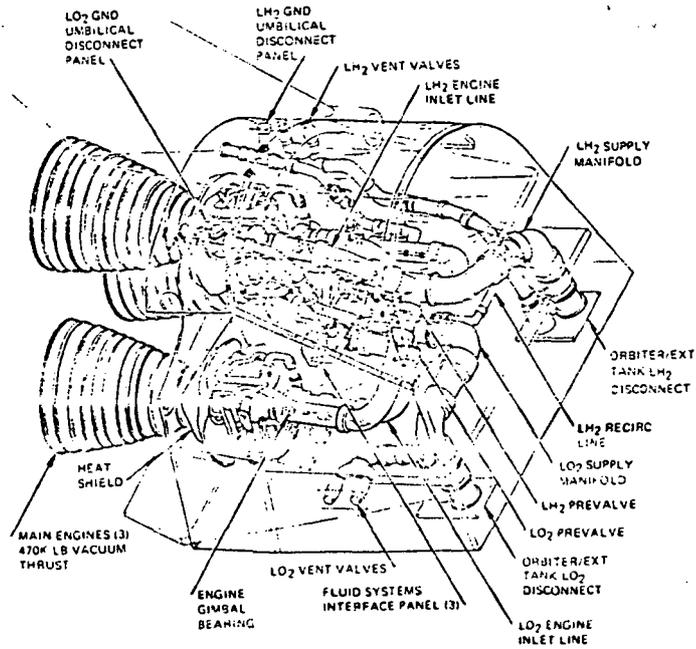

FIGURE 4.3-3

MAIN PROPULSION SUBSYSTEM INSTALLATION

166 manifold to the 4-inch diameter uninsulated antigeysering duct. Propellant loading is controlled by an orbiter-mounted signal conditioning unit supplying the ground loading equipment with signals from the ET-mounted warm wire point sensors. Differential pressure gauges installed in the orbiter between the propellant feed and vent lines provide intermediate loading level data between ~~point sensors for both the fuel and oxidizer subsystems.~~

166 Predicted propellant loading tolerances are within ± 0.6 percent for LO_2 and ± 0.7 percent for LH_2 . Tank manufacturing volumetric tolerances and repeatability of point sensor locations will be controlled to achieve the required flight-to-flight propellant loading accuracy. The propellant gauging system will be used for controlling tank loading operations and provides level indication. The in-flight engine mixture ratio control is preprogrammed before flight to a fixed value in the range of 5.8 to 6.2. The preprogrammed value for each flight will be based on predicted engine performance and predicted loading system tolerances to minimize the quantity of unused LO_2 . Incorporation of an LH_2 bias (1,500 pounds) to assure depletion of the heavier LO_2 propellant is effective in reducing the magnitude of the residual propellant mass.

The following functions are provided to assure satisfactory engine start:

1. Delivery of subcooled propellants to each engine inlet (3 lb/sec LO_2 , 1 lb/sec LH_2) to chill the engine to prescribed levels. This operation will start 15 minutes before engine start and terminates coincidentally with engine start command.
2. Ground prepressurization of tank ullage with helium (LO_2 at 20 to 22 psia, LH_2 at 35 to 37 psia). This operation will be completed approximately 60 seconds before liftoff.

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-37

REV.

BINGHAMTON, NEW YORK

REP. NO.

166 Subcooled LO₂ is maintained at the engine inlets by overboard bleed from the feedlines through the engines to ground disposal. During overboard bleed, LO₂ topping flow will be limited to a maximum temperature of 166° R to assure the presence of adequately subcooled propellant at the engine inlet. A comparable LH₂ overboard preconditioning system is not used because of the excessive pressure loss through the engines. Subcooled LH₂ is delivered to the engine inlets by electric-driven pumps which discharge conditioning flow downstream of closed prevalues through the engines and to the LH₂ tank via a recirculation manifold. During LH₂ recirculation, LH₂ topping flow is diverted to the recirculation return manifold to preclude warm LH₂ entering the pumps.

166 After completion of the engine conditioning cycle, the vehicle liftoff sequence begins by commanding engine start to NPL. When all three engines reach 50 percent power level and automatic self-check of engine operation is satisfactorily completed, ignition of the booster SRM occurs. When main engine thrust reaches approximately 90 percent, the vehicle thrust-to-weight ratio exceeds 1.0, and liftoff occurs. Throttling of engine thrust below 100 percent is commanded during orbiter ascent to limit vehicle acceleration to 3g. An emergency power level (EPL) of 109 percent may be commanded on the operating engines if premature thrust decay or engine shutdown is encountered on any of the three engines.

166 Tank prepressurization and hydrostatic head provide the required net positive suction pressure (NPSP) to the engine pump inlets during the starting transient. Following engine thrust buildup, tank ullage pressure is maintained by vaporized propellant pressurant extracted from the engines. An engine-supplied on-off control valve (controlled by redundant pressure switches sensing tank

166 ullage pressure) in parallel with a bypass orifice is used for in-flight tank
pressure control. Predicted tank pressurization performance is shown in
Figure 4.3-4.

166 The gimbal actuators and the engine control systems for the three engines
176 are supplied with hydraulic pressure from four redundant orbiter vehicle-
mounted APU-driven hydraulic systems. Thrust vector control during boost is
attained by gimbaling the MPS engines to the maximum pitch and yaw deflections
of ± 11 degrees. The engines are mounted in the orbiter aft fuselage in a
triangular pattern with an angle of 6 degrees between the upper and lower engine
centerlines in the pitch plane. The lower engines are installed with their
null position canted inboard 3.5 degrees in the yaw plane; however, all engines
are fired with parallel thrust vector alignment in the yaw plane. The engine
spacing of 104 inches in yaw and 100 inches in pitch allows adequate clearance
for maximum gimbal deflection on the two remaining engines after any one engine
has failed in its null position. The gimbal actuators are mechanized to drive
to a null position if two hydraulic systems are lost, if two hard-over servo
valve failures occur, or if two electrical signals are lost. The hydromechanical
logic circuit within the actuator assembly senses these failures and diverts
the remaining hydraulic pressure supply to drive the actuator to the null
position.

166 MPS engine control and data signals are processed through an engine
42 interface unit. The unit converts all engine control inputs (GN&C and manual)
to be compatible with the engine controller serial digital data system. Engine
serial data output is also appropriately converted for use by vehicle computer
systems and for dedicated displays. Engine data input to the PCM recorder and

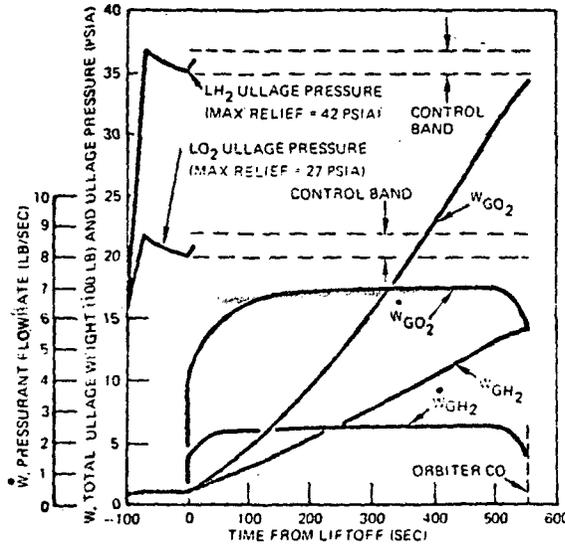

FIGURE 4.3-4

LO₂ AND LH₂ PRESSURIZATION REQUIREMENTS

to telemetry will be transmitted as direct data output through separate engine instrumentation connectors per the vehicle/engine ICD. The engine interface unit is further described in Section 4.3.2.

166 A pogo suppression accumulator will be incorporated in each LO₂ propellant feedline at the engine inlet.

166 Engine cutoff will normally be provided by a signal from the Guidance, Navigation, and Control (GN&C) subsystem when orbit injection velocity is attained. The Flight Performance Reserve (FPR) propellant (Table 4.3-1) provides a 317 foot per second (1 percent) ideal delta velocity margin to assure orbit injection. In those missions where the FPR is expended, engine cutoff will be initiated by an LO₂ depletion signal from a cluster of five point sensors located in the orbiter LO₂ feed manifold. In the event an off-nominal operation condition results in LH₂ depletion, a cluster of five point sensors located in the bottom of the LH₂ tank provides an engine cutoff signal to preclude engine damage after shutdown.

166 Propellant dumping and depressurization of the tanks to 5 to 15 psi before tank release will be manually controlled. Dumping of residual liquids and venting of residual gases will be accomplished through overboard fuel and oxidizer dump lines which discharge aft of the vehicle. Liquid propellant also will be dumped through the engines concurrent with dump system operation to provide sufficient thrust to settle the propellants remaining in the tanks. The total velocity increments introduced by dumping will be limited to 30 ft/sec. LO₂ dumping will be initiated first followed by LH₂ dumping. GH₂ and GO₂ will be vented concurrently through the dump lines.

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-41

REV.

BINGHAMTON, NEW YORK

REP. NO.

166 Propellant dumping through the engine will be a crew-controlled operation starting five seconds after main engine shutdown. Dumping will be initiated by opening the engine main valves and the vehicle prevalues. LH₂ and LO₂ will be dumped through both engines. The thrust obtained from dumping will retain propellants in the aft end of the propellant tanks and in the feed system. Dump cutoff control will be accomplished manually.

166 A short period after orbiter propellant dumping, the boiloff vent system is activated by opening the shutoff valves. Boiloff is vented overboard to maintain the ullage pressure within the 25.5- to 27.5-psia range. The redundant shutoff valve in series with the primary vent valve is left in the open position to permit emergency operation of the vent valve in the event of excess evaporation resulting from residual liquid splashing on hot structure. This redundant valve may be closed later in the mission when all of the residual liquid has been evaporated and/or the tank pressure decays at a level lower than the operating band of the boiloff vent system. The flow from the boiloff vent system is directed to the nonpropulsive vents.

166 Immediately following propellant dumping the engines are purged with helium, and the oxygen and hydrogen prevalues are closed. The engine main valves, closed in series with the vehicle valves, provide a double seal against tank leakage.

166 The AC electrical power and the hydraulic supply to the engines is discontinued two minutes after engine shutdown by stopping the APU and activating the cutoff circuits. At a convenient time following engine cutoff, all electrical power is removed from the engine interface to prevent overheating the engine control unit.

166 The main engine helium supply valve will also be closed if engine helium leakage continues after engine shutdown.

Figure 4.3-2 illustrates MPS controls and dedicated displays for critical performance parameters. Pilot override control capability is provided for critical MPS functions, e.g., engine shutdown and thrust level.

166 4.3.1 Engine

42 The orbiter main engine is a pump-fed, high chamber pressure engine utilizing a staged combustion concept and liquid hydrogen/liquid oxygen propellants. The 3,000-psi chamber pressure engine provides a vacuum thrust of 470,000 pounds with a nozzle expansion ratio of 80:1 and operates at an average propellant mixture ratio of 6:1.

166 The major components of the engine assembly consist of a main
42 chamber, nozzle, preburner, fuel and oxidizer turbopumps, and fixed low-pressure fuel and oxidizer boost pumps. Other components include an engine control unit, oxygen pressurant heat exchanger, fuel and oxidizer shutoff and control valves, a thrust mount, and a gimbal bearing block. Provisions also are included for a gaseous hydrogen pressurant bleed, fluid and electrical disconnect panels, and attachments for the TVC gimbal actuators.

166 During engine operation, propellants flow through the turbopumps, where
42 the propellants are pumped to high pressure for injection into the preburner and main combustion chamber. Prior to injection, the liquid hydrogen is used to cool the thrust chamber and preburner jackets. The preburner operates with propellants at a mixture ratio of approximately 1:1 to provide relatively cool fuel-rich combustion gases to drive the turbopumps. The fuel-rich turbine exhaust gases are injected into the main chamber with additional liquid oxygen to support main thrust chamber combustion.

4.3.2 Control/Monitor System

42 The control for engine start, main-stage, and shutdown is performed by sensing and monitoring engine performance, an electronic controller computes commands to modulate and sequence the values, and the integral spark ignition system. Refer to Figure 4.3.2-1. The engine monitoring function is provided to ensure the vehicle that the engine is functioning properly and to collect engine data for vehicle recording and post-flight engine maintenance analysis.

42 The sensors provide the engine data to the controller and vehicle for control, checkout and maintenance, and condition monitoring. Fifty-two engine parameters consisting of pressure, temperature, propellant volumetric flow, turbopump shaft speed, vibration, and position are measured. The sensor signal conditioning and analog-to-digital conversion electronics is located in the controller.

42 The controller performs the computations for engine control and sequencing, checkout, and monitoring. The computations are performed by digital computers within the controller assembly. The sensor signal conditioning and analog-to-digital conversion electronics are time shared among the sensors by multiplexing within the controller. The controller interfaces with the vehicle data bus, accepts and validates vehicle commands, and, with sensor data, computes propellant valve actuator commands for engine control. Controller output electronic circuitry transmits commands for positioning the valve actuators, switching hydraulic and pneumatic solenoid valves, and controlling spark ignition.

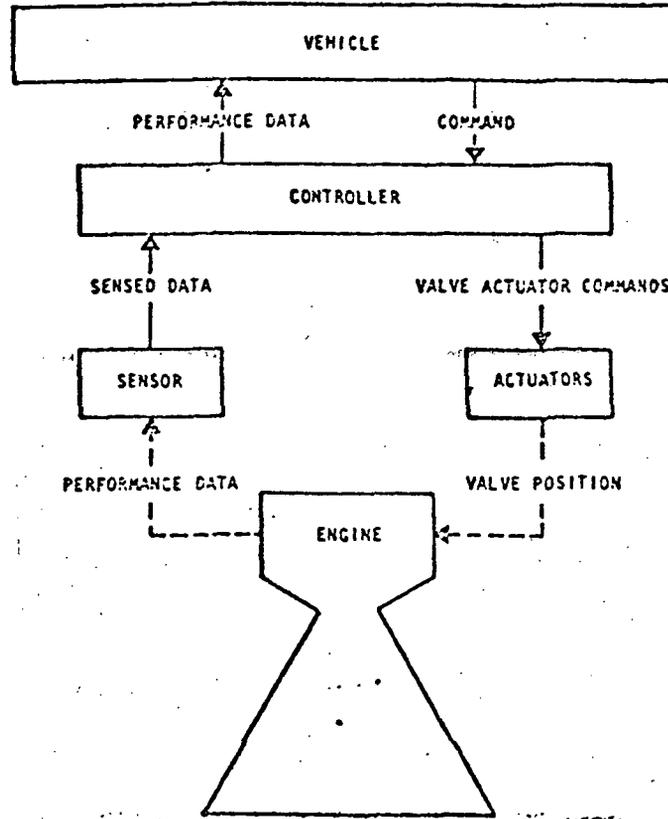

FIGURE 4.3.2-1

ENGINE CONTROL AND MONITOR

4.3.2.1 Engine Thrust/Mixture Ratio

42 To enable control of variable thrust and mixture ratio level, the system uses a simple two valve control. The control points selected have capability to fully control the engine thrust and mixture ratio over the full range of required engine operating conditions. The control modulates the areas of the oxidizer preburner oxidizer valve and the fuel preburner oxidizer valve to achieve independently the proper balance of propellant flows for thrust and mixture ratio control.

42 The control/monitor accepts data in flight and uses the data in the controller to compute the modulated control valve settings required to achieve vehicle commanded thrust and mixture ratio. This is achieved by the controller accepting vehicle thrust and mixture ratio commands and comparing them with monitored thrust and mixture ratio to determine a thrust and mixture ratio error. The thrust and mixture ratio errors determine the directions to change the two modulated control valve areas. The controller recomputes valve areas 50 times per second (every 20 msec). Each time the valve areas are adjusted the controller monitors engine performance and recomputes the error between vehicle commanded performance and engine monitored performance. When the error in performance reaches allowable limits the controller maintains the valves at those areas which achieved the desired level of performance. The process of comparing commanded performance and monitored performance and adjusting control valve setting is a closed loop control system.

42 Two performance control loops and one limit control loop are used in the engine control. Engine thrust is computed (as a percent of vacuum normal power level) in the controller from sensed main combustion chamber pressure and corrected for mixture ratio (and dump coolant on the orbiter). The vehicle

REP. NO.

commanded thrust is compared with the computed thrust to obtain an error signal. The thrust error signal is used to compute an area command for both the oxidizer preburner oxidizer valve and fuel preburner oxidizer valve to drive the thrust error to an allowable value.

42

Engine mixture ratio is computed in the controller from sensed propellant volumetric flows and corrected by propellant density computed from sensed propellant pressure and temperature. The vehicle commanded mixture ratio is compared with the computed mixture ratio to obtain an error signal. The mixture ratio error is used to compute a correction to position the fuel preburner oxidizer valve, which also drives the mixture ratio error to an allowable value.

42

Repeated computations of the thrust and mixture ratio control result in thrust and mixture ratio being controlled to within $\pm 5,920$ pounds (26,333.3 newtons) thrust and ± 0.82 percent mixture ratio precision which is below the requirement of $\pm 7,500$ pounds (33,361.5 newtons) and ± 1 percent.

42

Preburner temperature limiting control is provided for protection of the turbine power system from overtemperature. The preburner limit control functions by the controller computing an override command for the thrust control loop to decrease thrust whenever a sensed preburner temperature rapidly approaches or exceeds 2,200 R (1,222.2 K). The limit control normally affects system operation only during maximum thrust rate transients. As the preburner temperature stabilizes below 2,200 R (1,222.2 K), the temperature limit override is reduced, allowing control to revert to the thrust control loop, and the desired mainstage level is attained. This control logic aids in maintaining long-life operation of the high-pressure turbopumps.

42 Closed-loop control is used to achieve repeatability of thrust buildup to full mainstage power from a low power level (10 percent NPL) during start. For engine start the initial control valve sequences produce a low power level prior to thrust buildup. The same closed-loop control valves used for mainstage are used for thrust buildup control. Closed-loop mixture ratio control is initiated when thrust buildup to mainstage is completed.

42 In addition to the two valves used in closed-loop performance control, three other sequenced or scheduled valves control propellant flow during engine operation. These are:

1. The main oxidizer valve which is timed-positioned scheduled during startup and shutdown.
2. The main fuel valve, which is sequenced open and closed during startup and shutdown.
3. The combustion chamber coolant valve, which is scheduled with thrust level to optimize chamber cooling.

42 Engine shutdown can be initiated from any power level, during transient of steady-state operation. It is accomplished by reducing thrust under closed-loop control at a rate of 4,800 pounds (21,351.4 newtons) per 10 msec. After a low thrust level has been attained, propellant valves are sequenced closed for a fuel-rich shutdown. Shutdown performance and repeatability meet requirements by use of closed-loop control during a major portion of the transient.

42 4.3.2.2 Engine Monitoring

Vehicle and engine protection is ensured by engine condition monitoring performed by the system. Selected engine parameters are sensed and monitored by the controller. Controller digital computer programs compare the parameters against limits stored in memory. If an engine limit is exceeded and if the vehicle limit control enable command has been invoked by the vehicle, the controller

shuts the engine down. The vehicle also has a limit control inhibit command available to prevent against engine shutdown during critical periods of engine operation. This is done because the controller has no information with respect to the condition of the other booster engines, and it may be necessary to operate an engine above limits for a short time to ensure vehicle safety.

42 Parameters monitored for limit shutdown are fuel preburner over temperature, oxidizer preburner over-temperature, high-pressure fuel turbopump shaft overspeed, high-pressure oxidizer turbopump shaft over-speed, combustion chamber (high and low) pressure, and oxidizer heat exchanger failure.

42 If the safe limits stored in the controller memory are exceeded the controller automatically initiates a normal shutdown.

4.3.2.3 SSME CONTROLLER DATA FLOW

42 All data flow for the SSME (Figure 4.3.2.3-1) passes through the controller.

42 Data flow between the engine and vehicle consists of operational commands and data requests from the vehicle to the engine and data transmission from the engine to the vehicle. All vehicle data to the engine are received from the vehicle/engine data bus interface unit. The controller digital computer interface electronics route the data to or from the controller digital computers. Data flow in either direction is under vehicle control.

42 Included in the engine-to-vehicle data flow is engine status, other operational parameters, and maintenance data. The engine status includes engine operational phase, mode of operation, and self-test status. The operational parameters include actual thrust and mixture ratio. The data are transmitted in blocks of digital words at a maximum rate of 25 blocks of data per second and a maximum data bit rate of 10,000 bits/second.

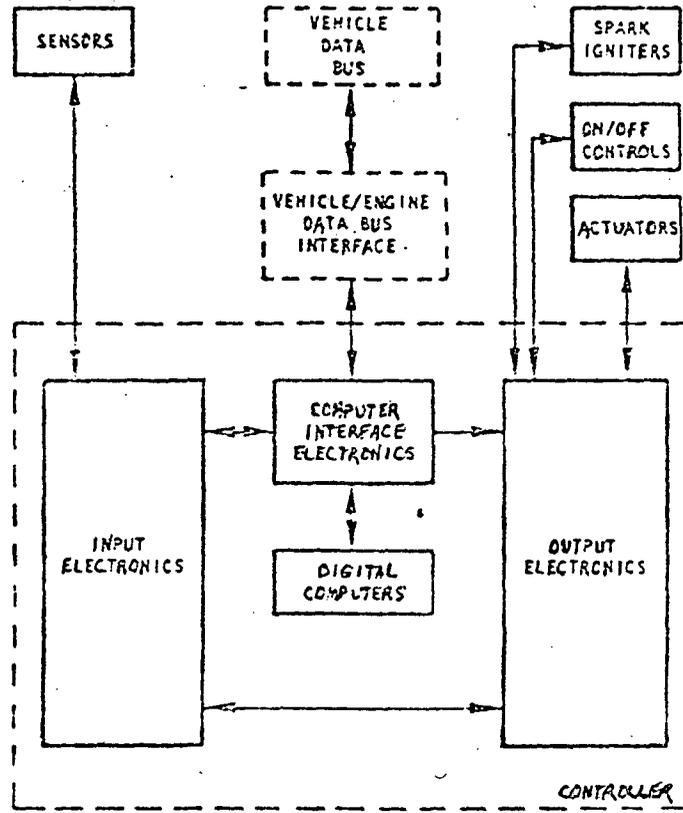

FIGURE 4.3.2.3-1

SSME DATA FLOW

42 Sensor data from 67 sensor assemblies (93 signals with redundant elements) for the control and monitor functions are sampled, signal conditioned, multiplexed, and converted from analog to digital form in the input electronics every 20 msec. These sensor data are routed by the digital computer interface electronics to the digital computers. During checkout, commands from the digital computer flow back through the digital computer interface electronics unit to activate sensor calibration circuits in the input electronics.

42 Data flow for sequencing the engine and controlling actuation devices is originated in the digital computers. Commands to initiate spark ignition, control solenoid valves, and modulate positions of valve actuators are computed in the digital computers. The digital interface electronics steer the data to the output electronics. The output electronics perform the digital-to-analog conversion and power amplification, and interface with the specific controlled devices. The commands are updated every 20 msec.

4.3.3 SSME Operation Details

4.3.3.1 SSME Sequence Schedule

4.3.3.1.1 Engine Start

42 Engine start operation is accomplished in two phases. The first phase of the start is the open-loop start normalization phase. The second phase is the closed-loop thrust buildup phase. Engine start to NPL is accomplished within 3.5 seconds. Simplicity and reliability of engine start control is obtained by accomplishing the start functions with the same control elements used for mainstage control and by establishing engine operation at a low power level prior to thrust buildup. Repeatability of thrust buildup is accomplished by bringing the system to full power under closed-loop control.

 The start sequence (Figure 4.3.3-1) is initiated by opening the main fuel valve to provide priming of the engine fuel system and to establish fuel flow

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-51

REV.

BINGHAMTON, NEW YORK

REP. NO.

with tank-head pressure. The main fuel valve is full open in 0.4 second. Spark igniter operation is initiated in all units and maintained for 3.5 seconds into the start.

42 Opening of the three oxidizer valves is initiated 100 milliseconds after start. The main oxidizer valve ramps to a 55 ± 2 per cent open position at a rate of 100 percent/sec. The fuel preburner oxidizer and oxidizer preburner oxidizer valves open to their initial opening of 2 percent of full area. Preburner ignition and main combustion chamber ignition follow in approximately 100 milliseconds. The four turbopumps are powered at a very low level by heated hydrogen until 0.5 second after start initiation. At 0.5 second, the fuel preburner oxidizer valve ramps to 12 percent open and thrust builds up to approximately 10 percent of NPL. This phase of engine start sequence is used to achieve approximately 10 percent NPL thrust to accommodate variations in the start transients due to tank pressures, booster-orbiter differences, environmental temperatures, etc. The positions of all valves are set to establish engine power at approximately 10 percent of NPL with an engine mixture ratio in the range of 1.0 to 2.0. Partial opening of the main oxidizer valve results in less oxidizer flow acceleration prior to main chamber priming, tends to increase preburner power level and temperature while at the low engine power levels, and reduces the pressure transients when the main chamber primes. When the main oxidizer injector primes, a thrust level of approximately 10 percent NPL is attained. During this phase when thrust is below 15 percent, the maximum thrust rate is approximately 13,000 pounds (57,826.6 newtons) per 10 msec period. This rate is the highest that has been experienced in simulation runs below 15 percent of NPL.

REV.

BINGHAMTON, NEW YORK

REP. NO.

42 The flexibility of dual preburners allows fuel preburner flow buildup to occur prior to oxidizer preburner flow buildup to ensure a fuel-rich start and to maintain a satisfactory fuel pump flow coefficient with the largest pump inlet pressure unbalance [(20 psia (13,79N/cm²)fuel, 225 psia (155.13 N/cm²) oxidizer] that can exist.

42 The second phase of the start is initiated at 1.7 seconds by activating closed-loop thrust control. The thrust control is allowed to stabilize at 10 percent of NPL of 0.30 second. The thrust control compensation is proportional at this time. Integral compensation is added in proportion to thrust level until MPL is attained, when integral gain is at the nominal MPL mainstage value. At 2.0 seconds, the main oxidizer valve is ramped open and the thrust command ramp initiated. The thrust command ramp is set at 4,800 pounds (21,351.4 newtons) per 10 millisecond rate to ensure the fastest practical thrust rate increase without exceeding the 7,000-pounds (31,137.4 newtons) per 10 millisecond maximum allowable rate. During start, open-loop mixture ratio control is accomplished by positioning the fuel preburner oxidizer valve from a thrust controller cross-feed signal. The cross-feed gain is selected so that the engine mixture ratio is in a high specific impulse range (2.0 to 4.0 main combustor mixture ratio) during a major portion of the thrust buildup and is at approximately the nominal value of 6.0 at mixture ratio control activation. This maximizes the specific impulse during the start transient and minimizes closed-loop control activation transients.

42 At 3.25 seconds, closed-loop mixture ratio control is activated. At that time: (1) cross-feed gain from thrust to mixture ratio control is changed to the mainstage value, and (2) the mixture ratio control compensation output

is initialized for a smooth transition from scheduled to closed-loop mixture ratio control. At 3.5 seconds, thrust and mixture ratio are within mainstage tolerance.

4.3.3.1.2 Engine Shutdown

42 Engine shutdown can be initiated from any power level during transient or steady-state operation. Shutdown repeatability is obtained with closed-loop control. Shutdown may be initiated by vehicle command or controller-generated limit shutdown signal.

42 Engine shutdown is accomplished in two operating phases, illustrated in Figure 4.3.3-2 . The initial phase is a controlled thrust rate of 4,800 pounds (21,351 newtons) decrease per 10-msec period. This effective rate minimizes both the shutdown time and shutdown impulse while keeping the transient thrust change rate within the 7,000 pounds (31,137 newtons) per 10-msec maximum allowable thrust decay rate. The closed-loop shutdown is predictable and repeatable from any mainstage level. Closed-loop mixture ratio control is active during this phase of shutdown.

42 The second phase of the shutdown sequence is initiated when the thrust reference decreases below MPL and sequenced closing of the propellant valves is initiated. At the start of this phase, a 0.85 second main oxidizer valve closing ramp is initiated. At 0.3 second into the phase, the oxidizer preburner oxidizer valve and the fuel preburner oxidizer valve are commanded full closed at 150 percent/sec. At 0.65 second into the phase, main fuel valve closing is initiated. The combustor coolant valve is ramped close when thrust decreases below MPL. All oxidizer valves are closed before the main fuel valve, ensuring fuel-rich shutdown. Total impulse and propellant consumed below MPS are more than 100,000 pound-sec (444,820 newton-sec) and less than 480 pounds (216,7 kilograms), respectively.

START PHASES

VALVE POSITION

SEQUENCE SIGNALS

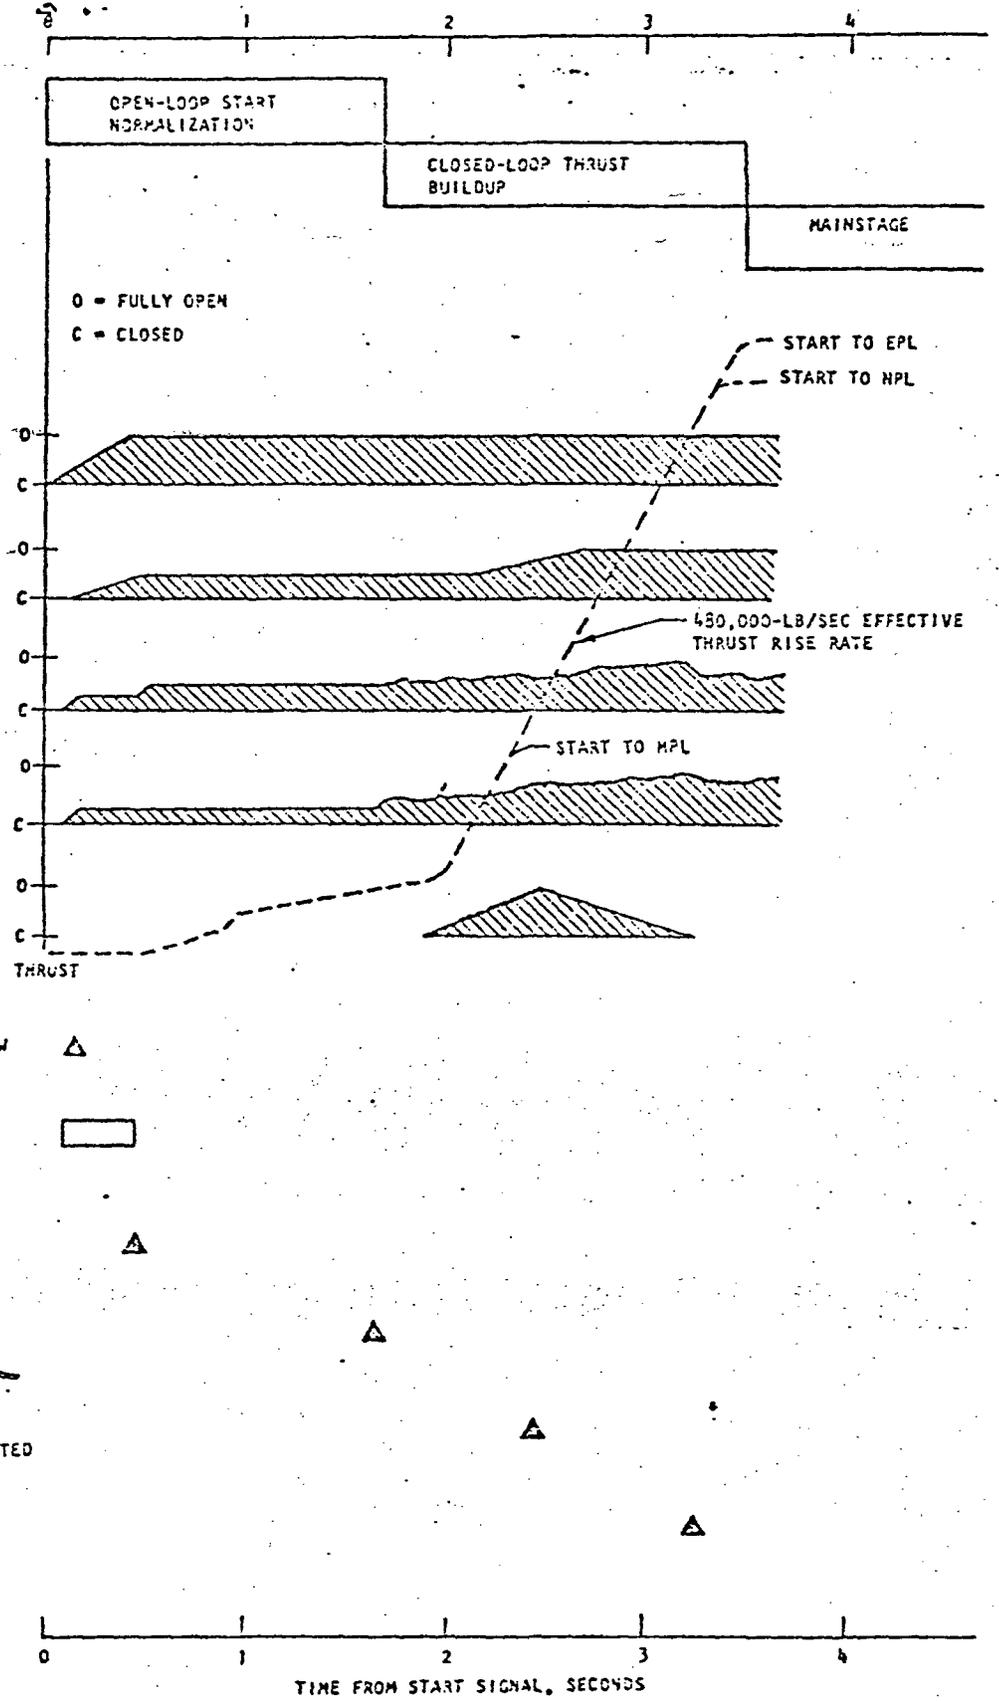

FIGURE 4.3.3-1

ENGINE START SEQUENCE

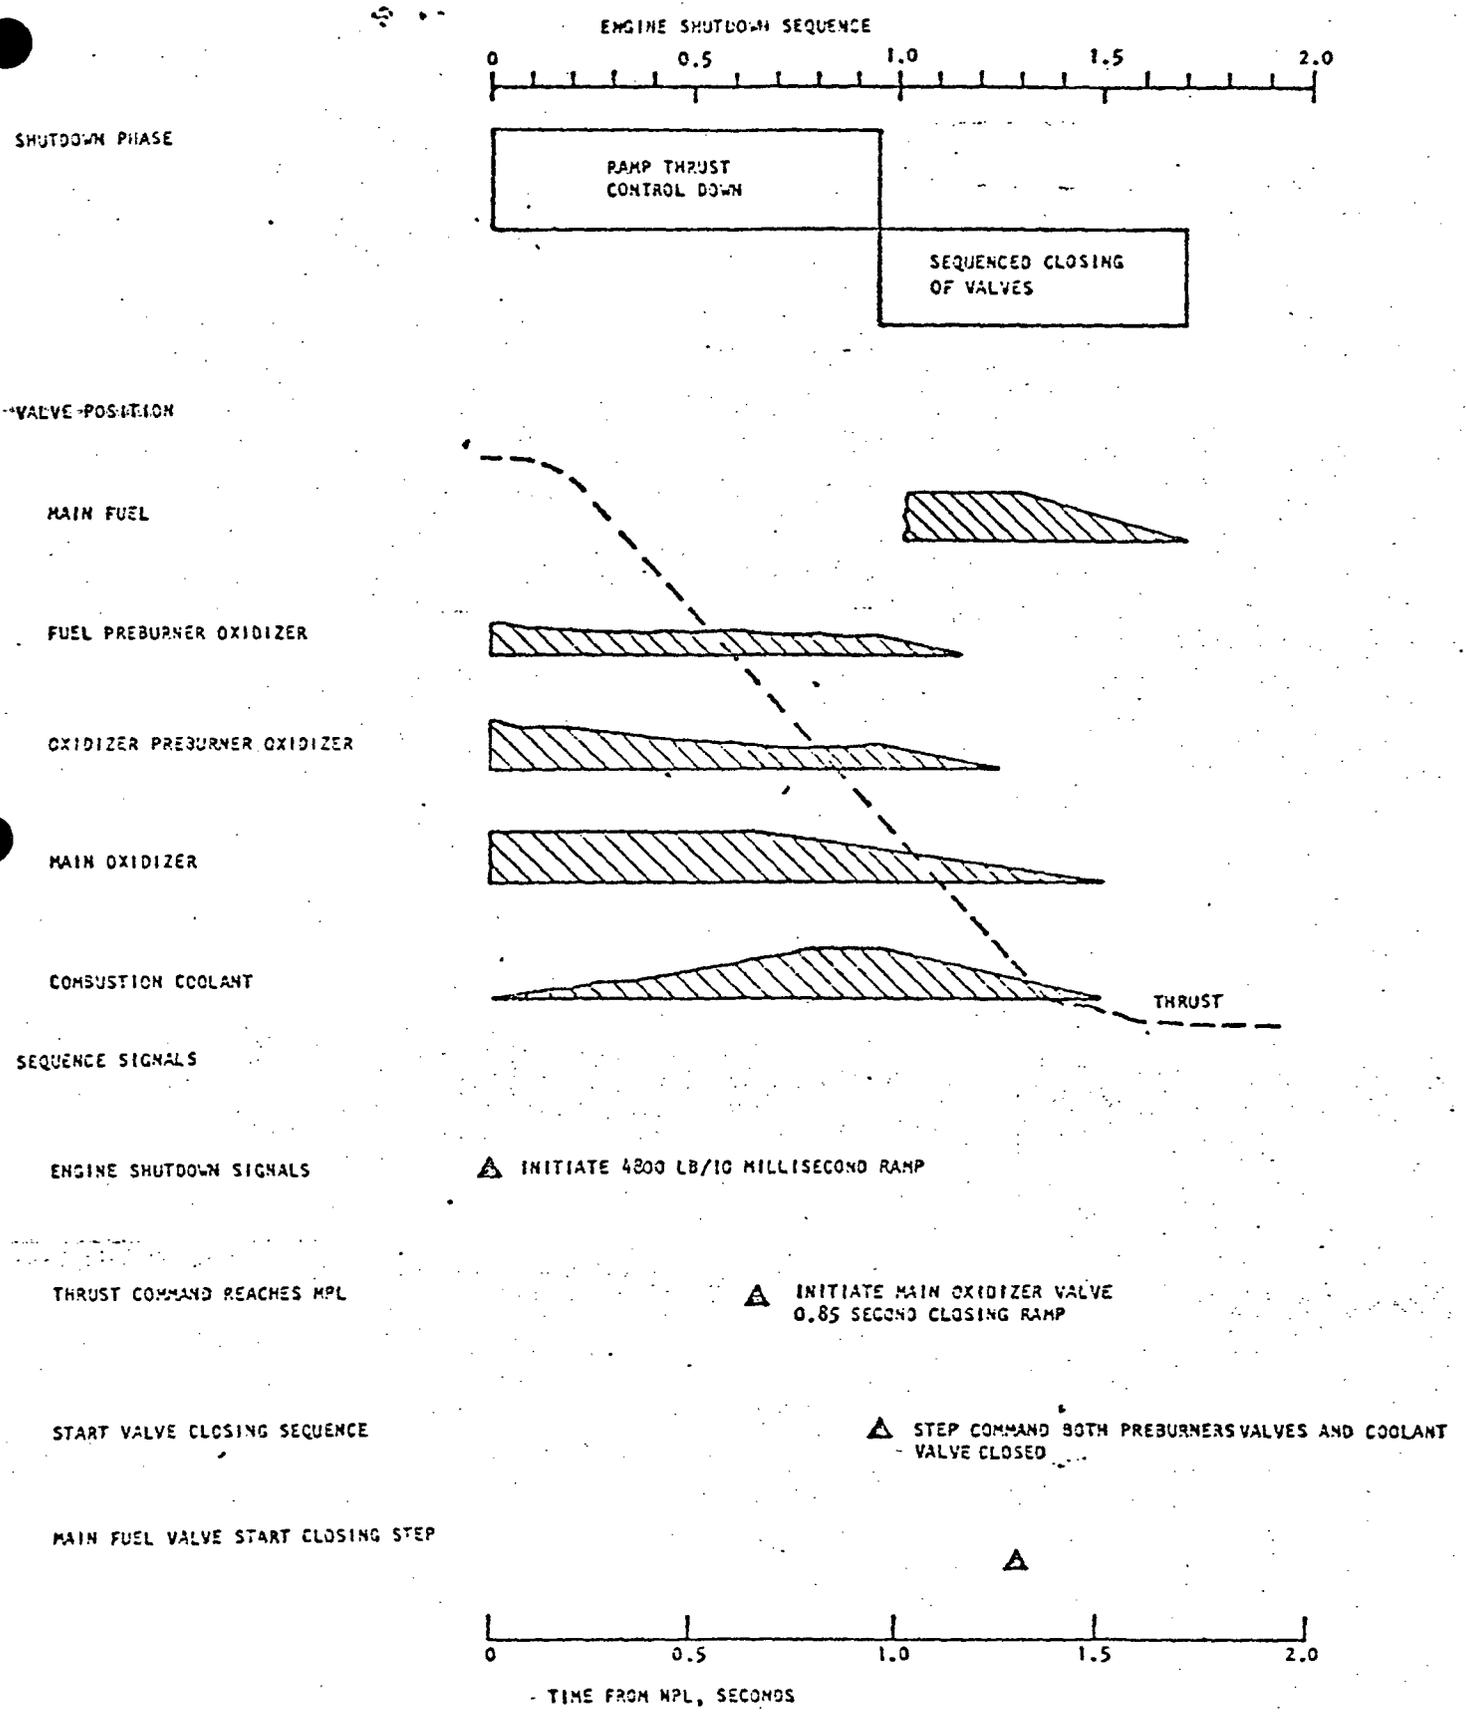

FIGURE 4.3.3-2
ENGINE SHUTDOWN SEQUENCE

42 The main fuel valve is full closed 1.05 seconds after thrust reference reaches MPL and all propellant flow has stopped except for residuals downstream of the main valves. Impulse from residuals will be approximately 15,000 lb/sec (66,723 newton-sec) and will have a duration of about 0.5 second.

4.3.3.2 SSME Flight Operations Monitoring

Continuous In-Flight Test

42 During engine operation, the controller continually performs a built-in test of the controller, sensors, and actuating devices. A summary of these built-in tests is provided in Table 4.3.3.2-1. During the start and shutdown sequences, the controller monitors the opening and closing sequencing of the propellant valve actuators and verifies that the power level of the engine increases and decreases in accordance with programmed limits. It also verifies proper timing of the ignition sequence.

42 As part of the shutdown sequence, the controller verifies that all control devices have been returned to a fail-safe condition and that the engine is safely shut down. Position sensors are monitored to verify retraction of the orbiter's extendible nozzle. The engine shutdown status is made available to the vehicle.

42 Additional monitoring during flight operation falls into five categories:

1. Performance Monitoring - Monitoring of engine thrust and mixture ratio to verify proper response to vehicle commands and to provide engine performance status to the vehicle.
2. Limit Control Override - Monitoring of preburner temperatures. If a temperature limit is exceeded, the controller throttles the engine power level to reduce temperature below the limit if limit control is enabled from the vehicle.

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-57

REV.

BINGHAMTON, NEW YORK

REP. NO.

3. Limit Control Shutdown - Detection of preburner over temperature, turbopump overspeed, main combustion chamber overpressure and underpressure and oxidizer heat exchanger failure. The controller uses the limit control shutdown measurements to determine if the engine has exceeded a safe operating limit or shutdown condition. If any of these parameters exceed a safe operating limit, the engine is shut down provided the limit control is enabled from the vehicle.

The preburner temperature limits used in limit control shutdown are higher than those used in limit control override. Table 4.3.3.2-2 summarizes the measurements and the limits which determine if the engine should be shut down.

4. Position Monitoring - Monitoring of actuator/valve positions for verification of proper operating sequences and interlocks.
5. Data Transmission - Transmitting engine status and performance data to the vehicle for recording of engine trends.

42 Propellant dumping through the engine may be sequenced during the post shutdown phase. The propellant valves are positioned by commands from the vehicle. The controller provides interlock logic to ensure oxidizer dumping prior to fuel dumping and to prevent both fuel and oxidizer valves from being open at the same time.

4.3.3.3 Data Transmission

42

The engine status and maintenance data available for transmission to the vehicle via the vehicle/engine data bus are listed in Table 4.3.3.3-1. The data rate in samples per second is indicated for each parameter versus the mission phases. Data are transmitted in bytes consisting of 8 binary bits. The data are arranged in blocks which are transmitted to the vehicle at a maximum rate of 25 times per second. Engine data which are obtained at sample rates higher than 25 samples per second are stored by the controller for transmission in the next block of data. For example, each block of data transmitted at 25 times per second contains 4 samples of each parameter which is sampled at 100 samples per second. The first byte normally transmitted with each block of data is the engine status byte defined by Table 4.3.3.3-2.

The engine status byte identifies to the vehicle:

1. The engine phase of operation (3 bits).
2. The mode within the phase (3 bits).
3. The self test status (2 bits).

2	5	1
010	101	01

Octal number

Binary equivalent

For example, the engine status byte indicates:

1. That the start preparation phase was entered.
2. That the modes were completed to a valid "engine ready".
3. That the engine is satisfactory (no failures).

Since the engine is in the start preparation phase, the data available to the vehicle is that listed under the column "Start Preparation" in Table 4.3.3.3-1. All bytes are arranged in blocks to fit within the 10,000 bit/second limit.

TABLE 4.3.3.3-1

DATA TRANSMITTED TO VEHICLE BY ENGINE MISSION PHASE

42 The order of transmission is fixed by the engine operating phase. The total data rates versus phase are listed in Table 4.3.3.3-5. Start and shutdown have the highest data rates.

42 Failure identification information is contained in data bytes 6 and 7 listed in Table 4.3.3.3-1. Table 4.3.3.3-4 is a list of failure modes and line replaceable units which will be identified to the vehicle. Byte number 51 in Table 4.3.3.3-1 is a timing pulse which is issued to correlate events with the time they occur.

4.3.3.4 Controller Built-in Test

42 The controller built-in-test is initiated by the executive program and is performed once in its entirety each time through the 20 msec major cycle of the executive program. It is performed continuously throughout all phases of ground and flight operation. The built-in-test starts with a complete checkout of the dual digital computers. Upon verification of the operability of the computer processors and memories, the checkout is expanded to the digital computer interface electronics, the input electronics, the output electronics, and the power supply electronics. The interrelationship of these major controller sections is shown in Figure 4.3.3.4-1. The input electronics conditions the sensor inputs and converts them to a digital format. The output interface electronics converts the digital computer outputs to the form required to drive output devices such as actuators, valves, and spark igniters. The computer interface electronics provides the interface between the dual digital computers and all computer inputs/outputs. The power supply electronics converts the electrical power supplied by the vehicle to the individual power supply voltages required by the controller.

4.3.3.4.1 Computer Checkout

42 The sample problem tests every instruction in the computer's repertoire and performs a complete test of every section of the processor and memory. Memory parity checking is used to check the data obtained from the memory. A parity bit is generated and stored during each memory write operation so that every word stored in memory including the parity bit has an odd number of ones. Upon each memory read operation, the parity of the word extracted from memory is verified to be odd.

42 The checkout of the memory is concluded by the testing of the parity hardware. Several known constants, some with odd and some with even parity, are fetched from the memory, and the parity checking hardware is monitored to verify that it can distinguish between odd and even parity. The parity-generating hardware is also checked by performing alternate store and fetch instructions using several constants.

42 During ground checkout, an additional test of the fixed portion of the memory is made by a memory sum check. This verifies the integrity of the computer program and assures that each location in fixed memory can be addressed.

4.3.3.4.2 Computer Interface Electronics Checkout

42 Upon successful completion of the total processor and memory checkout, the sample problem initiates the checkout of the computer interface electronics. Each of the dual digital computers has a dedicated set of computer interface electronics to perform the functions of:

TOTAL DATA RATE

1. Controlling flow of digital data to and from the computer, vehicle/engine data bus interface, and memory.
2. Monitoring computer operation to ensure fail safe computer monitoring and fail operational controller operation.
3. Providing a redundant time reference to the digital computer.

The control of digital data flow is through three separate electronic circuits:

1. Direct Memory Access Control - controls the direct data flow in and out of the memory.
2. Input Multiplexer Electronics - provides the data flow path between the controller inputs and the memory.
3. Data Bus Multiplexer Electronics - provides communication with the vehicle data bus.

42 These three circuits are checked out together with end-to-end test. Under direct memory access control, data are transferred via the direct memory access output into the data bus multiplexer electronics data register. This data are then transferred back into memory via the input multiplexer electronics. The input data are then compared to the initial data to verify the correct operation of the direct memory access control, data bus multiplexer electronics and the input multiplexer electronics. The interface between the data bus multiplexer electronics and the vehicle data bus is automatically checked every time a command from the vehicle is received and validated: the controller responds by transmitting engine status.

42 Two watchdog timers are used with each computer to ensure fail safe computer monitoring and fail operational controller operation upon a watchdog timer failure. The watchdog timers verify that each computer is

progressing through its program and is executing program instructions per a predetermined schedule. The watchdog timer is a simple timing circuit that checks the time it takes the computer to progress between checkpoints in the computer program. Imbedded within the program are instructions requiring the computer to reset each timer, at different points in the program's execution, in a sequential fashion. Each subroutine includes an instruction to reset only one of the watchdog timers, thus ensuring detection of a computer failure that prevents the computer from returning to the executive program on schedule. If either of the computers fails to reset either of its watchdog timers, the watchdog timer output switches to zero.

42 Each computer monitors the watchdog timer output of the other to determine operational status. This status is made available to the vehicle by the controlling computer (initially Channel 1 computer).

42 The output switch, which determines which computer is in control, is controlled by the Channel 1 computer watchdog timer output. Channel 1 computer maintains engine control as long as it remains failure free. Upon failure of Channel 1 computer, its watchdog timer output goes to zero, thus switching engine control to the Channel 2 computer.

42 All processor and memory failure modes cause the watchdog timer output of the corresponding computer to switch to zero. The watchdog timer output is used to command a HALT instruction in a failed computer. The HALT instruction prevents the computer processor from executing any further instructions to ensure that the failed computer does not output actuator commands or data to the vehicle data bus.

42 The proper operation of the watchdog timers is checked during ground checkout. The decay time of the watchdog timers is speeded up by switching in checkout circuitry. The watchdog timer output of each computer is monitored to verify that the watchdog timers will switch to zero if not reset within a specific time interval. All the failure modes of the watchdog timer test circuitry tend to shorten and not lengthen the timer delay times, thus ensuring a shutdown of the corresponding computer upon a failure.

42 Two real time clocks are used with each computer to provide fail-safe computer operation. During each controller test cycle, the two clocks are monitored to verify that they agree. If the clocks do not agree, the malfunction is detected and the corresponding computer channel is commanded to a HALT instruction. The watchdog timers run down causing control to switch if the failure is in Channel 1 computer. If both clocks are stopped but still agree, the failure is detected by the watchdog timer. In this case, the processor will not return to the executive program in time to reset one of the watchdog timers and the timer output will go to zero.

4.3.3.4.3 Input Electronics Checkout

42 Checkout of the input electronics is achieved by the sample problem program. The input electronics processes analog and pulse rate data from the engine-mounted sensors. These data are converted into a digital format for inputting to the digital computer memory via the computer interface electronics. The input electronics consists of low-level and high-level multiplexer gates, amplifiers, demodulators, pulse rate converters and analog to digital converters.

42 Internal reference voltages are applied at specific low- and high-level multiplexer input gates. These voltages have been incorporated to aid in checkout. The reference signals are monitored at the output of the analog to digital converters by the computers to verify operation of amplifiers and the analog to digital converters. These reference voltages are also used by the computers to measure bias and offsets in the input channels. This information is used by the computers to provide a continuous recalibration of the input channels by automatic software changes. The remaining portion of the input electronics checkout is accomplished during sensor input monitoring and processing discussed in 4.3.3.5.

4.3.3.4.4 Output Electronics Checkout

42 The output electronics converts the digital computer commands to voltages for controlling the valve actuators, solenoid valves, and igniters. All of the controller outputs are continuously verified by the computers. The controller output voltages are fed back to the input electronics and are processed through the multiplexer gates and analog to digital converters, in the same fashion as the sensor inputs, and are stored in memory. The controller output data are then compared to the commanded data and verified to be correct. This test provides a complete checkout of the output electronics. Upon detection of a malfunction of the controlling output channel, engine control is switched to the second output channel.

4.3.3.4.5 Power Supply Electronics Checkout

42 Built-in test circuits continuously monitor the controller supply electronics. Five internal controller power supplies, each capable of operating from either vehicle power bus, provide internal controller power distribution.

The five power supplies provide power to the triple redundant input electronics to the dual redundant digital computers/interface electronics, and to the dual redundant output electronics.

42

Each power supply includes circuitry in the regulators that monitor regulator performance and turn off the power supply upon detection of a malfunction. The operational status of all power supplies is continuously monitored as part of the controller self-test. The completion of the power supply electronics checkout completes the controller built-in test. The engine controller has been completely checked out during the controller built-in test with the exception of the sensor input multiplex gates which are checked as part of the sensor built-in test.

4.3.3.5 Sensor Built-in Test

42

Computer Channels 1 and 2 both conduct all tests. Computer Channel 2 conducts all tests, storing results in memory in case computer Channel 1 fails requiring computer Channel 2 to assume control.

4.3.3.5.1 Sensor Ground Checkout

42

All sensors except nonflight data sensors are functionally tested during the automatic ground checkout.

4.3.3.5.2 Sensor Inflight Monitoring

42

Three levels of sensor redundancy are used in the engine system:

1. Triple redundant sensors are used for performance control.
2. Dual redundant sensors are used for engine ready checks and limit control.
3. Nonredundant sensors are used for acquisition of maintenance data for transmission to the vehicle and recording.

42 Each of the triple redundant sensors used in performance control are initially checked for reasonableness by comparing their outputs with minimum and maximum limits. The sensors are designed so that a failure will cause the sensor output to fall outside of the reasonableness limits. The reasonableness limits for the seven performance control parameters are given in Table 4.3.3.5.2-1. As an illustration of a reasonableness test during mainstage engine operation, if the value of main combustion chamber pressure is not between 1280 psia (848.1 N/cm^2) and 3,450 psia (2378.7 N/cm^2), a reasonableness failure of the sensor is indicated.

42 After the reasonableness test, the triple redundant performance control signals are compared to each other. If all three channels have passed the reasonableness check and agree within a comparison failure limit stored in the computer memory, the average value of the three sensor channels is used to update the sensor information stored in memory.

42 Comparison failure limits for the seven performance control sensors are given in Table 4.3.3.5.2-1. The comparison limit that is used to detect a failed main combustion chamber pressure sensor is a difference between sensor signals of 4.0 percent of full scale. The engine control will still meet operational repeatability requirements if the differences are within this limit. The normal 3σ deviation that can be expected between good sensor channels is approximately 1 percent of full scale. Therefore, the probability of having nuisance failures using the 4 percent of full-scale failure limit for the main combustion chamber pressure sensor channels is negligible.

PAGE NO. 4-74

REV.

BINGHAMTON, NEW YORK

REP. NO.

42 If only two of the three sensor channels pass the above tests, the average value of the two agreeing channels is formed and this value is used to update the memory. If the same sensor channel does not pass the above tests three times in succession, it is assumed that the sensor channel has failed and that channel is not used in future processing. An alternate sensor value (computed from other sensed parameters, Table 4.3.3.5.2-2) is used to replace the failed sensor channel.

42 The performance control operates with two of the original sensors and an alternate computed sensor value as before. The sensor tests are continued with the new set of triple redundant sensor value as before. The sensor tests are continued with the new set of triple redundant sensors. Upon a second failure, the performance control continues to operate using the value of the good sensor and the alternate computed value. Thus a fail operational capability is provided for second failures of performance control sensors without an increase in sensor count.

42 A third sensor channel failure is detected either by the reasonableness tests or comparison failure limits test. A third failure results in computer Channel 1 being shut down. If the failure is in the sensors and not the signal conditioning electronics, computer Channel 2 will also have detected the failures and shut down. If the failure were in the signal conditioning electronics dedicated to Channel 1 computer, the Channel 2 computer will continue to operate and control the engine.

42 The dual redundant sensors used for engine ready and the engine limit control are checked for reasonableness by comparing their outputs with minimum and maximum limits similarly to the performance control sensors. If either

REP. NO.

sensor channel indicates that the engine is within operating limits, the engine is safe and is allowed to operate normally. If both outputs from a set of dual redundant sensors indicate that a limit has been exceeded in three successive samples, an engine failure is assumed and the engine is shutdown.

42 The nonredundant sensors used only for acquiring maintenance data are not tested in flight operation. These sensors are noncritical and do not affect control functions.

4.3.3.6 Actuator/Valve Built-in Test

42 The controller performs failure monitoring of the actuators and valves by use of actuator/valve position sensors. The modulating-type hydraulic actuators contain dual redundant servovalves to provide a fail operational/fail safe capability. A penumatic shutdown system provides actuator fail safety in case of loss of hydraulic power or loss of electronic control to the actuator. Pressure ladder-sequenced penumatic actuators and motors provide this shutdown capability to the valves and retraction capability to the orbiter nozzle. The controller contains provisions to detect failures and to switch out failed elements.

42 Monitoring of the actuators is accomplished by use of an analog electronic servovalve model. The model receives the same commands as the servovalve and electrically models the normal servovalve output spool position. The outputs of the servovalve and the electronic model are compared. If a servovalve failure is detected, the failed servovalve is isolated from the actuator and a redundant standby servovalve is switched in to control the actuator. Monitoring of the standby servovalve is accomplished in a similar manner.

CONTROL PARAMETER	REASONABLENESS FAILURE LIMITS*		COMPARISON FAILURE LIMITS
	MINIMUM	MAXIMUM

TABLE 4.3.3.5.2-2

ALTERNATE PERFORMANCE CONTROL SENSORS

42 The controller also compares the actuator position feedback signals with the actuator position command to detect actuator failures not detected by monitoring of the servovalves. Upon a failure of both servovalve channels, or a failure detected by monitoring actuator position, the pneumatic shutdown assumes control. This monitoring procedure is used during both ground and flight operation.

42 Built-in test of the pneumatic purge valves is provided by measurements of pneumatic pressure. Indicated failures are isolated by the electrical stimulation test of the pressure sensor to distinguish between sensor failures and valve failures.

4.3.3.7 Spark Igniter Built-in Test

42 Each igniter circuit provides an output which is monitored for spark rate and voltage level. This allows verification of igniter operation during both ground checkout and flight operation.

4.3.4 Instrumentation Parameter List

42 The engine is equipped with sensors to provide data acquisition during engine flight and non-flight operations. Dual sensing elements are provided for pressure, cryogenic temperature, flow and pump speed pickups.

42 Parameters for data acquisition are listed in Table 4.3.4-1. This list was developed from studies covering:

1. The dynamic simulation for selecting the control system.
2. Verification of the operational readiness condition of the engine through checkout.
3. Requirements for engine readiness prior to start.
4. Establishing performance and trend analysis of the engine and subsystems.

The table shows the usage of sensor outputs for achieving the following functions:

1. Performance Control.
2. Limit Control.
3. Position Indication.
4. Engine Ready.
5. In-flight Maintenance Recording.
6. Non-flight Data Acquisition.

The non-flight data are provided at a connector panel attached to the controller.

4.3.4.1 Alternate Performance Control Parameters

42

Alternate performance control sensors are listed in Table 4.3.4.4-1. Engine performance is maintained within specification requirements with the use of these alternate values after the first and second sensor output failure.

TABLE 4.3.4.1-1
ALTERNATE PERFORMANCE CONTROL SENSORS

4.3.5 Engine Actuator

176

The gimbaling of the main engine is accomplished by an electro-mechanical servo-actuator. The redundancy of components give the actuator fail operation capability after first failure and fail-safe after the second failure. In the fail safe mode, the actuator returns to neutral. With the triple redundant feature of the hydraulic servo valves, the actuator can accept three separate independent input signals. The servo actuator has a closed loop hydro-mechanical feedback loop. The developed force, direction and rate of position change of the actuator piston are determined by the electro-hydraulic servo valve.

176

The input hydraulic pressure is 3,000 psig, and the return pressure is nominally 45 psig. Using 3,000 psig fluid at $38 + 5 - 20^{\circ}$ C, the servo actuator has a piston rod maximum velocity of 5.25 inches per second with a load of 60,000 pounds.

176

The servo has a linear accuracy of 1 ma thru full stroke with a hysteresis of less than 1.5 ma. Threshold signal for piston movement is less than 0.5 ma. With no electrical signal to the servo and with 3,000 psig hydraulic supply, the position of the piston shall be within 0.055 in of the reference midstroke position.

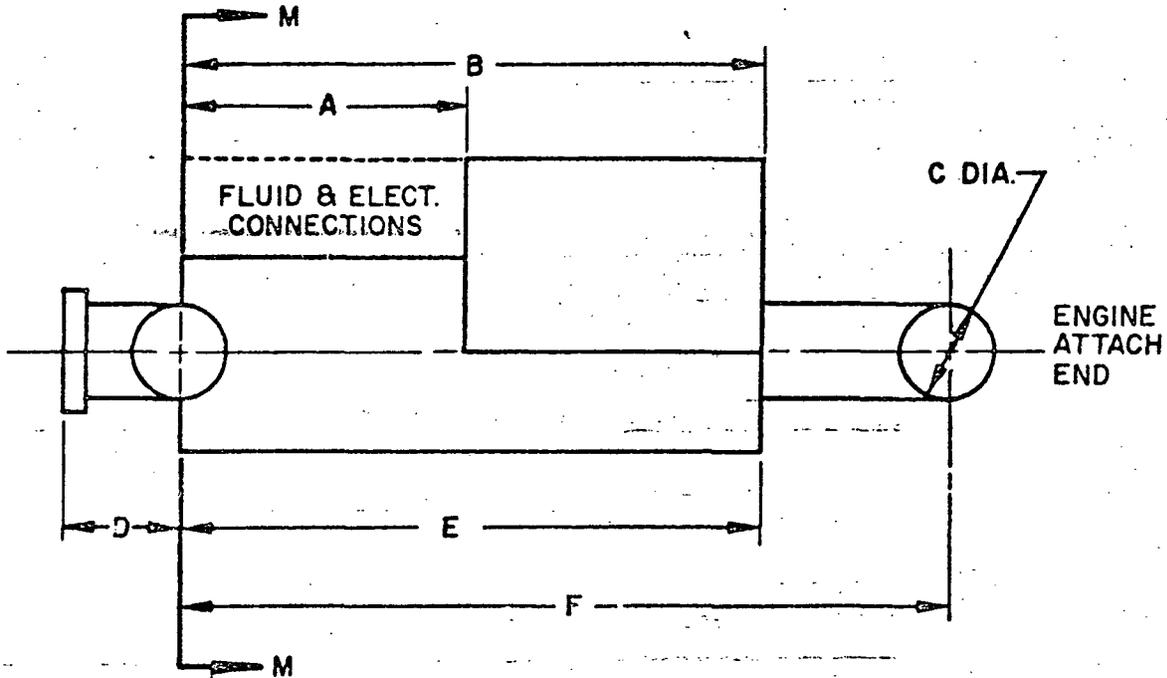

4.3.5.1 Operating Characteristics

176

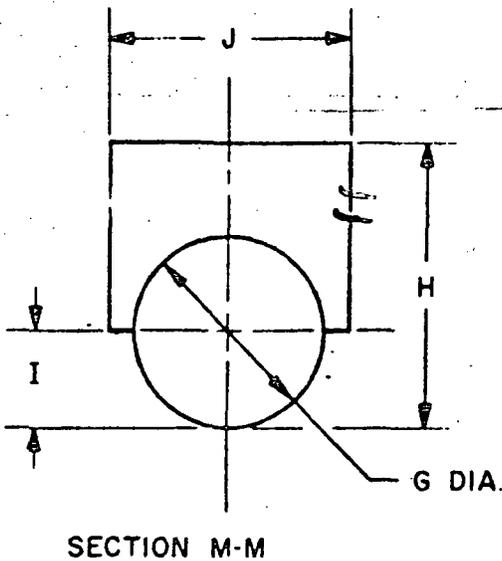

The servo system has the following general characteristics:

Frequency response - The system frequency response of amplitude ratio and phase shift is within the limits shown on Figure 4.3.5-3 and Figure 4.3.5-4. This is an engine position to current input ratio driven by a current source. The nominal phase shift at 1.0 Hz shall be 17° . This applies to inertia loads only.

ACTUATOR ENVELOPE-MAXIMUM DIMENSIONS

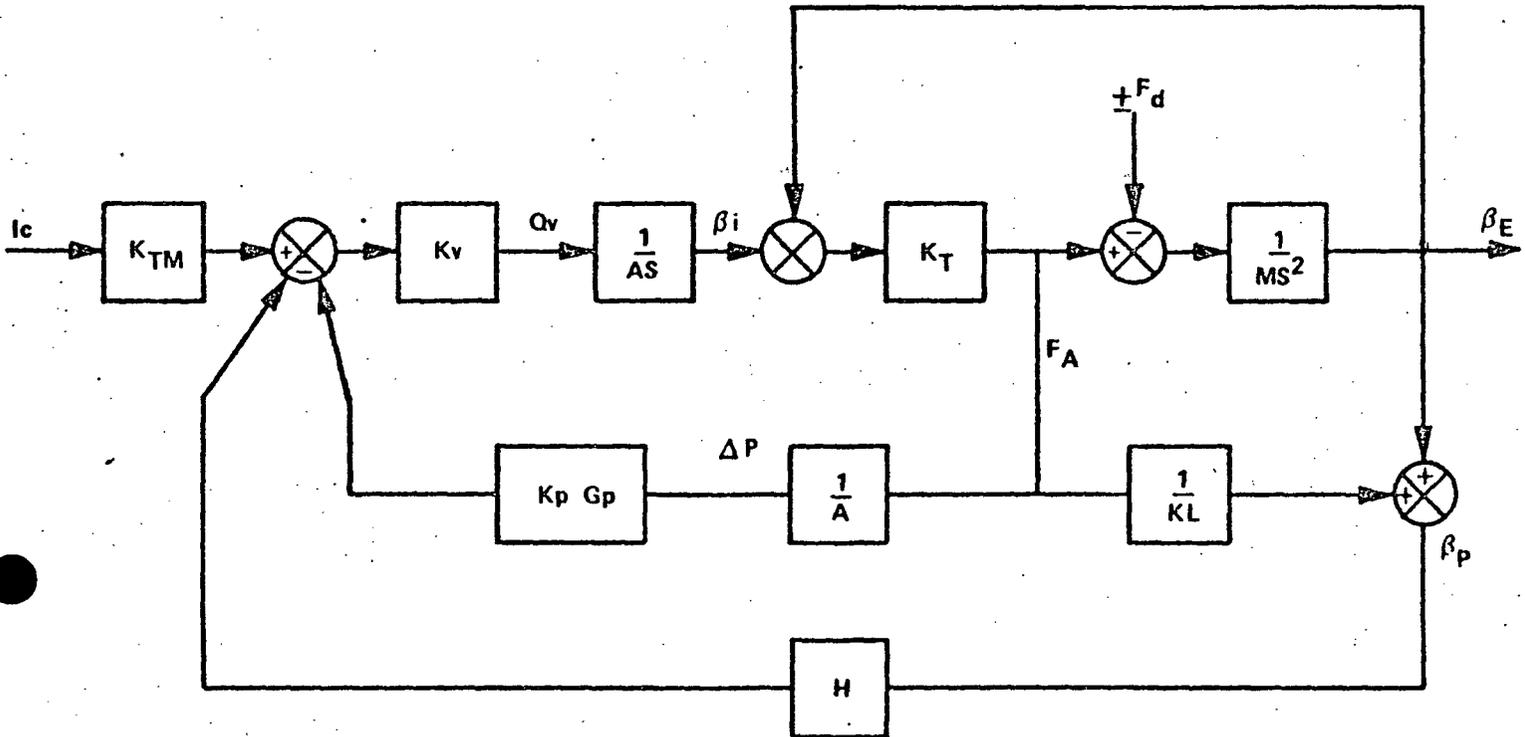

- NOTE:
 1. ACTUATOR SHOWN IN NULL POSITION
 2. ALL DIMENSIONS IN INCHES.

DIMENSIONS	
A	18.5
B	35.5
C	3.0
D	4.5
E	35.5
F	43.0
G	8.0
H	14.0
I	4.0
J	9.0

FIGURE 4.3.5-1

- 176 Transient response - The response of the load or engine position to input signals to the servoactuator as a function of time falls within the limits of Figure 4.3.5-5. There are no continuing oscillations, limit cycling, or hunting in the steady state condition. This requirement applies with inertia loads only.
- 176 System stability - With system characteristics as given in Figure 4.3.5-2, and the actuator bias loads from 0 to 60,000 pounds, the load does not have continuing oscillations, hunting or limit cycling in excess of 0.006 inch peak to peak position during a 10 second period. Hunting or long time drift during a one minute period does not exceed the threshold of 0.5 ma.
- 176 Position loop gain adjustment - Provisions shall be incorporated into the actuator to allow adjustment of the position open loop gain $\frac{(KvH)}{A}$ from 12 sec⁻¹ minimum to 22.3 sec⁻¹ maximum. This gain adjustment mechanism should be field serviceable and should not have to be returned to the vendor facility for installation.
- 176 Servo valve - The servo valves are of the flow control type utilizing mechanical feedback from the final stage to the first stage. External to the servo valve and removeable mechanics, hydraulic circuits are provided to stabilize the resonant load with bias loads up to 60,000 pounds as shown in Figure 4.3.5-2. Any additional steady state compliance due to these circuits is minimized.
- 176 Power consumption - The power used by the servo valve torque motor with 50 ma applied shall be no greater than 0.3 watts at 77 degrees F.
- 176 Actuator - The actuator is of the linear, double acting, equal area type with a net piston working area of 30 square inches.

REP. NO.

176 Length and stroke - The length of the actuator is as specified in Figure 4.3.5-1. The maximum stroke shall be ± 5.50 inches. ($10\frac{1}{2}$ deg). The design allows for a minimum stroke of ± 3.9 " ($\pm 7\frac{1}{2}^0$) by the installation of a stroke limiting mechanism internal to the actuator. This stroke limiting mechanism may be field installed.

176 Piston bypass valve - The piston bypass valve is manually operated, which when operated, relieves fluid locking of the piston. The valve is pressure actuated to close at a system pressure of 200 psig maximum.

176 Lock - A removable mechanical lock capable of holding the actuator rigidly in its midstroke position is provided. The lock when properly adjusted establishes the reference midstroke position.

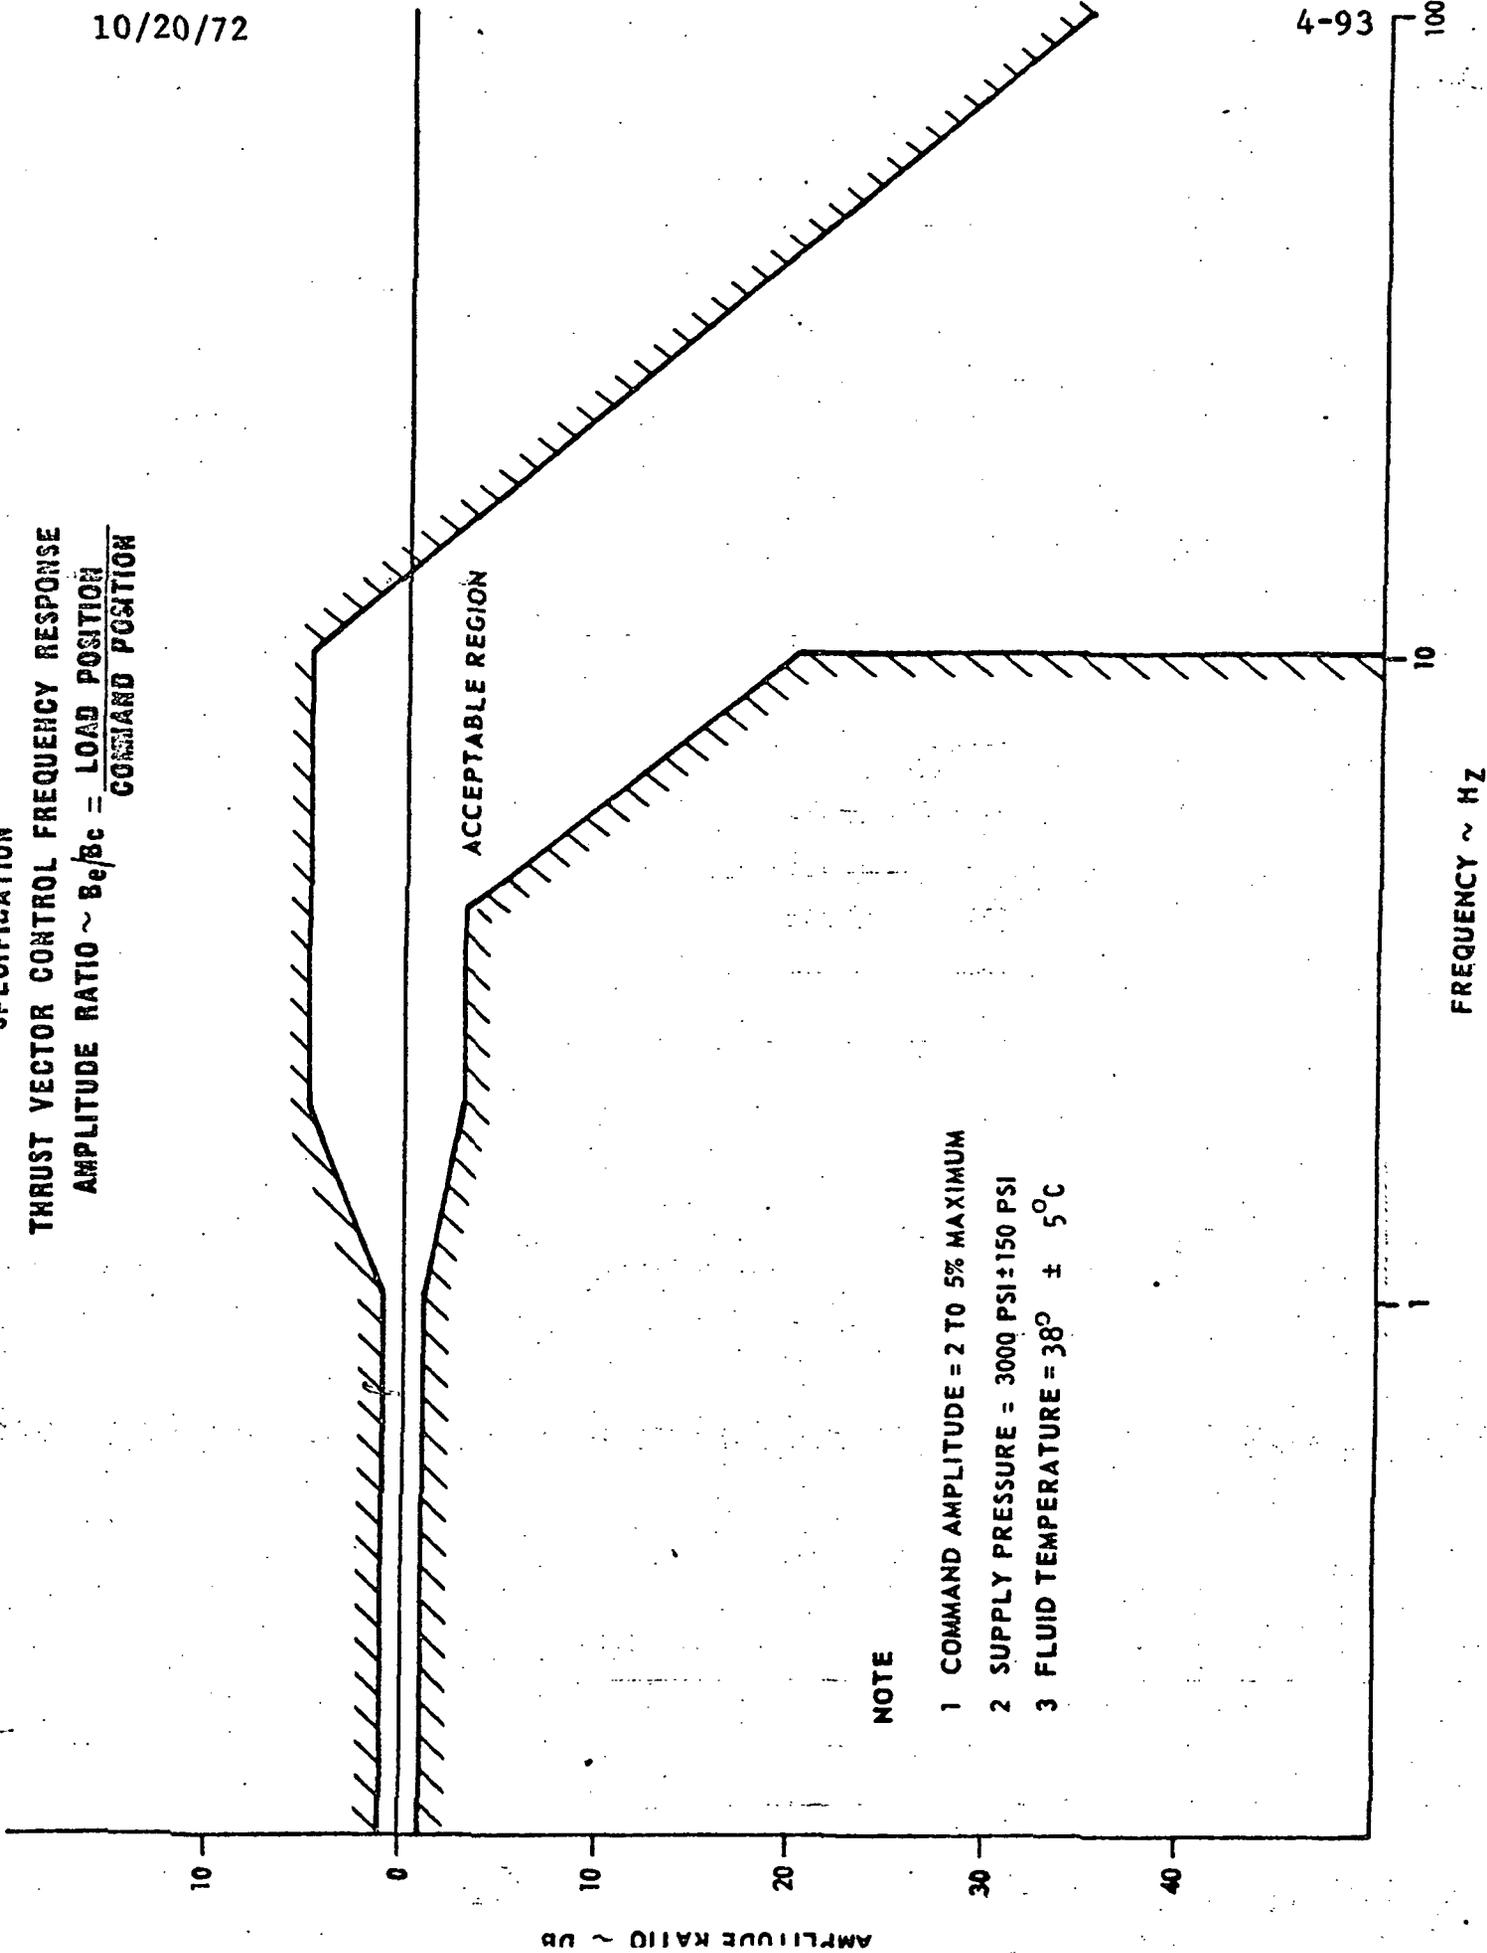

176 Potentiometer - A linear, dual element, potentiometer with center taps is provided for actuator piston position indication. The potentiometer is internally mounted, directly coupled to the actuator rod.

176 Stroke - The mechanical stroke of the potentiometer is 12.0 inches, including 0.025 inch of over travel at each end. The electrical stroke is 11.0 ± 0.02 inches.

176 Electrical characteristics - The electrical characteristics are as shown in Figure 4.3.5-6. The sum of the padding resistance, which is 500 ± 50 ohms, and the contact resistance is 575 ± 125 ohms for each element as measured between wiper and element. The resistance between the center tap and the element is 150 ohms maximum for each element.

176 Excitation - The excitation voltage of the potentiometer is 60 ± 0.25 vdc.

4.4 REACTION CONTROL SUBSYSTEM

166

The orbiter reaction control subsystem (RCS) consists of three self-contained monopropellant hydrazine propulsion subsystem modules installed as shown in FIGURE 4.4-1. The RCS provides attitude control and three-axis translational capability during both orbital and entry phases of the mission. The RCS may provide a backup for propellant acquisition during OMS engine operation.

4.4.1 CONFIGURATION

166

The RCS configuration employs 40 monopropellant thrusters operating at a rated vacuum thrust of 1000 pounds to provide a fail-operational/fail-safe attitude control and translation capability. Monopropellant hydrazine, stored in positive expulsion tanks, is used as the fuel. Tank pressurization is provided by regulated helium stored at ambient conditions. The RCS thrusters are installed in three independent removable modules located in the orbiter nose section and in each of the aft OMS pods. All thrusters, tanks, and components are completely interchangeable in all modules. The forward module contains 16 thrusters; each aft module located in the OMS pod contains 12 thrusters. Manifold isolation and purge valves provide multiple redundancy against loss of propellant in the event of a thruster valve open failure. Multiple redundant valves and regulators provide propellant tank pressure control.

166

During docking operations, the forward RCS module thruster deployment panel is reoriented 45 degrees toward the closed position to preclude exhaust plume impingement on either the space station or a deployed payload. This automatically disables the normally upward firing thrusters and modifies the functions of the downward and outward firing thrusters to then provide the required maneuvering forces. In this

manner, all forward module plume centerlines are maintained at a minimum of 45 degrees from any potentially sensitive surface.

166 The propellant storage and expulsion system uses the ethylene propylene terpolymer (EPT-10) diaphragm tank concept.

166 The polar mission propellant requirement defines RCS tank size and distribution between fore and aft modules. Propellant quantities for the three reference missions are shown in TABLE 4.4-1.

4.4.2- THRUSTER DESCRIPTION

166 The RCS thrust chamber assembly uses a stand-off tube to minimize heat soak-back to the propellant valve. This valve is a fuel-operated valve controlled by an electrically operated valve. A cavitating venturi is incorporated in the valve, thereby providing constant fuel flow to the thruster and permitting performance evaluation based on monitored chamber pressure variation. This concept minimizes catalyst bed overloading at each pulse, thereby minimizing cold start problems. The injector assembly consists of a body made of Hastelloy X with a low momentum Rigimesh injector design. The radial out-flow catalyst bed provides an increasing cross-sectional area to propellant flow, thereby minimizing the bed loading and decomposition gas velocities for maximum catalyst life. The inner section of the catalyst bed consists of 25 to 30 mesh Shell 405 catalyst to initiate the decomposition of the N_2H_4 . The outer section of the bed uses a coarse 14 to 18 mesh low-cost catalyst which improves the overall catalyst bed performance and life characteristics. The thrust chamber and nozzle are fabricated from a single Hastelloy B precision investment casting. An electrical heater (12 watts per thruster) is attached to the injector head and maintains a minimum catalyst bed temperature of 150° F to eliminate cold starts.

4.4.3 PROPELLANT TANKAGE

166 A usable propellant capacity of 3130 pounds is provided in the forward module tanks, and a usable capacity of 1878 pounds is available in each of the aft modules. Five tanks are located in the forward module, and three are contained in each of the aft modules. Propellant tankage and lines are maintained within the acceptable operating regime by module thermal control. This is accomplished by electrical heaters (on-orbit) and insulation (on-orbit and entry).

166 The propellant tankage system is designed to supply propellants to the thruster inlets at 290 psia minimum. Manual isolation valves are provided to isolate each tank assembly from the pressurization system if required. A manual disconnect is used to facilitate filling and draining the propellant tanks in each module.

166 The RCS EPT-10 tank diaphragm is used to provide positive fuel expulsion during all operating conditions including zero g and re-entry. A capillar barrier at the outlet prevents diaphragm damage or pulgging of the propellant outlet port and permits most of the propellant to be expelled in the event of diaphragm failure. Tank diaphragm failures can be detected during turnaround by individually pressurizing each tank, monitoring the flow from the propellant fill and drain dump fitting and sampling the helium pressurant.

4.4.4 PRESSURIZATION SUBSYSTEM

166 Four identical 4000 psi helium spheres provide the helium required for propellant tank pressurization. Two spheres are mounted in the forward RCS module, and one is contained in each of the two aft modules. The pressurization subsystem is designed to use primary and secondary regulators with operating bands of 310 to 325 and 320 to 335 psi, respectively, with a minimum 600 psia inlet pressure. Parallel pressure relief valves

designed to accommodate full helium flow (equivalent to four thrusters operating at steady-state conditions) are provided to limit propellant tank pressure to the design limit pressure of 435 psia. The pressure/volume/temperature (PVT) propellant gauging system developed and used successfully on the Apollo CSM RCS will be employed in the orbiter RCS.

166 Upon completion of RCS operations, purge isolation valves will be activated to provide a low-pressure helium purge to cool and decontaminate the thrusters. Post-landing operations will include thruster and valve assembly purge and drying with heated low-pressure nitrogen to ensure removal of residual propellants.

4.4.5 RCS OPERATION

166 The thruster engines receive firing commands from the Guidance, Navigation and Control computer or by indirect entry via manual translation or rotational hand controllers. Data from the RCS system is supplied to the onboard computer system for display to the crew of propellant and engine conditioning status. Electrical power and instrumentation conditioning for T/M is provided through redundant power systems. Manual crew controls are provided for control of activation and monitoring functions of the RCS operating system

KEY

4.5 ORBITAL MANEUVERING SUBSYSTEM (OMS)

166 The OMS provides the propulsive thrust to perform orbit circularization, orbit transfer, rendezvous, and deorbit. The OMS tankage is sized to provide propellant capacity for Mission 1, which retains a 65,000-pound payload throughout the mission.

166 The OMS is capable of burning all of its allocated propellant in either a single long burn or a series of multiple burns spread at random over the mission duration.

4.5.1 OMS CONFIGURATION

166 The propellant quantity required for the design mission will be provided in two pods, one located on each side of the aft fuselage. Each pod contains a high-pressure helium storage bottle, tank pressurization regulators and controls, a fuel tank, an oxidizer tank, and a pressure-fed rocket engine. The OMS employs nitrogen tetroxide (N_2O_4) as the oxidizer and monomethylhydrazine (MMH) as the fuel. Additional propellant storage is provided by three self-contained pressurant/propellant supply kits which may be located in the cargo bay. The OMS ΔV /payload capability and the number of auxiliary OMS kits required are shown in FIGURE 4.5.1 as a function of the booster-MPS liftoff capability for the three design mission inclinations.

166 Schematics of the basic subsystem and auxiliary subsystem are shown in FIGURE 4.5.1. Each pod system is fail-operational/fail-safe, except for the engine bipropellant valve, which is fail-safe. A pod crossfeed line, employed in conjunction with individual engine isolation valves, assures availability of all propellant for deorbit with the remaining single engine following a multiple failure in the bipropellant valve of one engine.

4.5.2 ENGINE

166

The OMS engine is a 5,000-pound thrust reusable pressure-fed rocket engine. The nominal characteristics for this engine are listed in FIGURE 4.5:1

166

The thrust chamber is regeneratively cooled using engine fuel flow with supplementary film-cooling. The coolant jacket extends aft from the injector to the radiation-cooled nozzle extension attach flange. The thrust chamber is fabricated of stainless steel. The injector is a flat-faced, nonbaffled design utilizing acoustic cavities to achieve dynamic combustion stability. The bipropellant engine valve is a series-parallel redundant valve with a pneumatic actuation package. The basic valve design is similar to that used in the Apollo CSM service propulsion subsystem engine valve, except for the use of a cam mechanism to lift the seals away from the ball prior to ball rotation, thus minimizing the amount of seal rubbing on the ball surface.

166

The design uses the basic gimbal technique employed on the Apollo CSM service propulsion subsystem engine. Electro-mechanical actuators incorporating redundant drive mechanisms will be employed.

4.5.3 TANKAGE

166

The propellant and helium tanks are fabricated from 6Al-4V titanium alloy. The fuel and oxidizer tanks are identical and contain a maximum usable propellant load of 12,200 pounds per pod. The helium tanks will be identical to the Apollo CSM service propulsion subsystem helium tanks with a nominal servicing pressure of 3200 psia at 70°F.

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-105

REV.

BINGHAMTON, NEW YORK

REP. NO.

166

Analysis indicates that lateral sloshing in the OMS tanks, which might occur during boost, does not represent a significant dynamic problem. Dynamic coupling of the sloshing forces and moments with the vehicle stabilization and flight controls can occur only at frequencies at which the disturbance torques generated are not significant. Therefore, the OMS propellant tanks do not have baffles.

166

Liquid propellant will be retained in the engine supply lines through use of screened retention reservoirs containing devices to prevent premature surface dip and vapor ingestion at the tank outlets at propellant depletion. The reservoirs refill by hydrostatic vapor expulsion during OMS firings and require no auxiliary settling thrust.

166

The auxiliary tankage and pressurization components located in the cargo bay are identical to hardware used in the OMS pods. Six propellant tanks (three oxidizer and three fuel) and three helium tanks may be installed. A single pressurization control assembly is employed for the auxiliary tankage. The auxiliary tankage kit is designed so that either one, two, or three sets of propellant and helium tanks can be installed as required by a particular mission.

166

Quantity gauging is provided during OMS engine firings by a set of 10 dual point sensor assemblies. Quantity indications between point sensors, necessary for OMS status assessment, are provided by an integrating unit similar to the Apollo CSM service propulsion subsystem backup gauging system, using engine burn time and nominal propellant flow rates. Low-level warning is provided in each tank by an independent point sensor assembly. Backup and zero-gravity gauging is provided by pressure/volume/temperature type

gauging through use of the on-board performance monitor and CRT display.

4.5.4 PRESSURIZATION

166 The fuel and oxidizer tanks are pressurized through parallel flowpaths, thus eliminating the possibility of mixing fuel and oxidizer vapors caused by leakage and/or diffusion through the isolation check valves in the helium pressurization lines. Check valves are employed to prevent liquid propellant migration.

4.5.5 INSTALLATION

166 The OMS is installed in two removable pods with propellant crossfeed lines that remain with the vehicle. The auxiliary tankage in the cargo bay also feeds propellant to the engines in each pod through the crossfeed lines.

4.5.6 ENVIRONMENTAL CONTROL

166 Thermal control for the OMS is provided by insulation and electric heaters to maintain the internal pod environment between 40° to 125°F on-orbit with a maximum of 150°F allowed as a result of entry heating. The insulation is installed to allow subsystem thermal isolation as a unit. This allows high heat capacitance elements to thermally stabilize the low mass elements.

4.5.7 MAINTENANCE

166 The engine propellant isolation valve located between the tanks and the engine propellant valves provide for engine removal without purging of the propellant tanks. The engine valves also can be checked out with the engine installed and the tanks fully loaded .

166 Manual shutoff valves installed upstream of the propellant tanks isolate the pressurization system from residual propellant vapor during ground operations. This valve also allows extensive checkout and replacement of pressurization system components without applying unnecessary pressure cycles

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-107

REV.

BINGHAMTON, NEW YORK

REP. NO.

to the propellant tanks. The propellant tanks will be purged only when maintenance or replacement of the tanks or associated components is required. The manual shutoff valve control will be designed so that the vent receptacle cover cannot be installed with the valve closed.

4.5.8 OPERATIONS

166 OMS preflight checkout and servicing is accomplished in the hypergolic servicing facility. Following propellant servicing, the helium storage tanks and propellant tanks are then pressurized to 1,000 and 50 psig, respectively, to meet safety standards for normal working areas. The loaded pods are subsequently mated to the orbiter, after which the electrical and instrumentation interface will be checked out with the tank and engine isolation valves closed. Final filling of the helium bottles will be accomplished at the launch pad. Auxiliary system checkout and servicing is identical to this procedure. An alternate capability will provide loading propellants at the launch pad after installation of the external pods and auxiliary system.

156 The OMS is capable of operation at any time after launch, including simultaneous operation with the MPS engines. During all operating modes, the engines are normally fired simultaneously with the TVC maintaining parallel thrust vectors. During single-engine operation, the RCS will provide roll control.

156 Auxiliary tankage propellant, when installed, will be consumed first. Propellant is retained in the pod tanks by closing the helium isolation valves in the pods. When a low-level warning is received from the auxiliary sump tank, the pod helium isolation valves are opened, and the auxiliary helium isolation, propellant isolation, and crossfeed valves are closed automatically.

BINGHAMTON, NEW YORK

REP. NO.

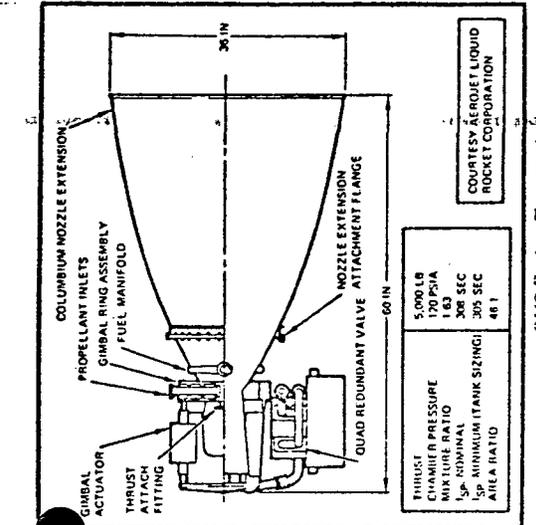

Following the deorbit burn, the engine propellant isolation valves are closed and the downstream propellant lines and engines are purged using residual helium. The engine valves remain open until just prior to reentry to vacuum-dry the purged assemblies and thereby remove remaining propellants and vapors. The engine valves are then closed to allow repressurization of the line upstream of the engine valves as a means of preventing air ingestion after entry.

166

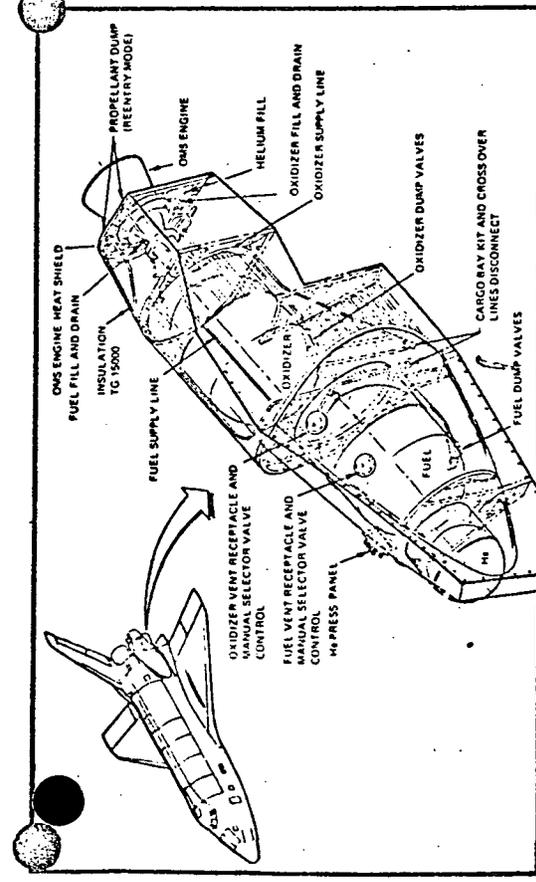

A dump system is provided for dumping OMS propellant in the horizontal flight condition. Residual propellants are dumped during entry following a normal mission; however, the system is sized to dump all OMS propellant in the pods prior to landing in the event of a low-altitude abort. For other abort modes, the OMS propellant will be burned through the engines.

REF. KEY 4.6 AIRBREATHING PROPULSION SUBSYSTEM (ABPS)

166

The ABPS primary purpose is to provide loiter flight capability upon return from a space mission. With modifications, the ABPS also provides self-ferry capability from alternate landing sites to the launch site. The self-ferry configuration is used to conduct the horizontal flight test program.

166

The orbital ABPS module, incorporating two engines, deployment mechanisms, a fuel tank, and supporting subsystems, may be installed in the aft section of the cargo bay. The weight of this module is charged against total payload capability; the module is removable for missions requiring maximum payload capability. The ferry system consists of the orbital module plus two additional engines, a ferry fuel tank, and supporting structure. A secondary electrical and hydraulic power generation system is included in the ferry system.

4.6.1 CONFIGURATION

166

The orbital ABPS module consists of the structural, the engine/nacelle/pylon, and the fuel tank assembly modules as shown in FIGURES 4.6.1. The vehicle scar weight associated with installation of the integrated module is that necessary for instrument and control wiring, vehicle structural "hard points," ferry mode vehicle power interface (hydraulic and electrical), and provisions for installation of the horizontal flight fuel fill and drain adapters. When the ABPS is installed, the two aft sections of the segmented cargo bay doors are removed.

166

The structural module includes provisions to accommodate the orbiter structural interface, nacelle thrust and airloads, nacelle deployment, tank

DATE 10/20/72

PAGE NO. 4-112

REV.

BINGHAMTON, NEW YORK

REP. NO.

166 mounting, and manipulator arm stowage. The nacelles are deployed by rotary motion about the nacelle pylon longitudinal axis using hydraulically driven power hinges. Segmented deployment doors actuated by linear hydraulic actuators remain closed throughout launch and orbital operations for environmental control purposes. The doors are automatically sequenced open during the deployment cycle and are then closed following engine deployment.

166 Each nacelle module houses an afterburner turbofan engine modified to accommodate the predicted launch and orbital environment. The engine is a derivative of the Pratt and Whitney F401-PW-400 engine now under development. Supporting subsystems include a dual element fire detection subsystem, a fire extinguishing subsystem (dual bottle/dual shot per nacelle), electric thrust control subsystem, an air start assist system, and a thermal control system. The electric thrust control subsystem is an adaptation from the concept being developed under the B-1 program with minor modifications required for engine and cockpit quadrant arrangement differences. A cartridge air start system is proposed with either cartridge or pneumatic capability provided for ground starts.

4.6.2 FUEL TANK

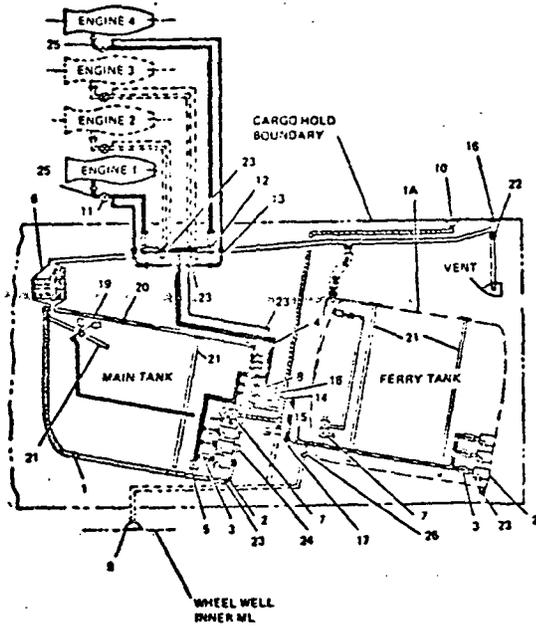

166 The fuel tank module includes a main fuel tank and the associated tank-mounted units of boost pumps, shutoff valves, vent valves, quantity gauging, and thermal control provisions. The tank may contain 22,565 pounds of fuel for the early orbital development flights. For operational flights with scientific payload, this tank will be off-loaded to the 13,681-pound quantity required for engine air-starting and 15 minutes of loiter flight at 10,000 feet.

166 Tank fuel flow is provided by three electrically driven "plug-in" type boost pumps supplying a common manifold that connects to both engine nacelles. An atmospheric air-venting system is provided that uses series/parallel vent valves to maintain on-orbit tank pressurization and fuel isolation. Refueling-defueling capability and capacitance gauging systems are provided for both the vertical and horizontal vehicle attitude. Dual level control valves are employed for capacity control in either attitude.

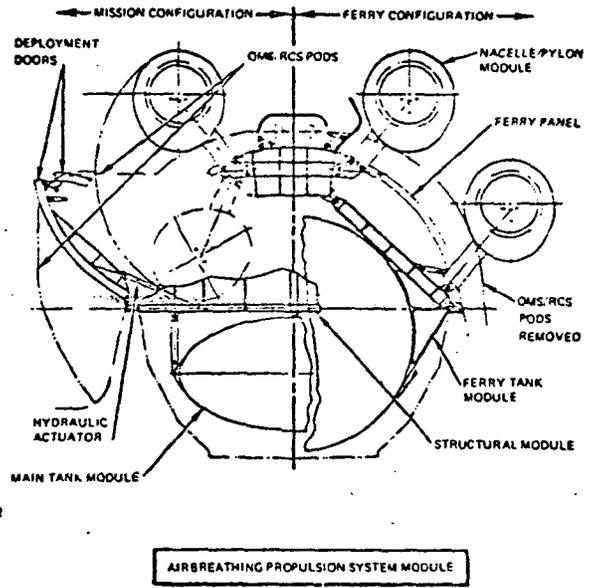

166 The thermal control subsystem employs electric heaters and insulation to maintain the bulk fuel, the engine, and support subsystems (starters, fire extinguishing, thrust control, lube oil, etc.) within design temperature limits. A steady-state temperature range of -65°F to 275°F is specified for the engine with a -350°F limit on transients; the lube oil in the storage tank is limited to -25°F minimum; and a range of -30°F to $+160^{\circ}\text{F}$ is stipulated for the fuel.

4.6.3 FERRY CONFIGURATION

166 To provide the required ferry thrust, two additional F401-PW-400 engine nacelle assemblies are installed in a fixed position on the ABPS structural module lower shoulder. The vehicle APU system will not be used for power generation during ferry or horizontal flight test operations; therefore, a secondary power generation kit providing hydraulic and 400-Hz electrical power capability will be installed and driven by each of the four engines. An uninsulated ferry tank will be installed aft of the orbital fuel tank to accommodate an additional 44,905 pounds of fuel. This capacity was selected to provide maximum fuel (67,470 pounds) for flight test up to

166 the vehicle gross weight limit of 232,000 pounds. Capacitance gauging and single point refueling provisions will be provided for the ferry tank in the horizontal attitude only. The ferry tank will be off-loaded to provide a total fuel loading of 52,000 pounds for the 400-nm ferry range capability.

4.6.4 OPERATION

166 The APES is purged of all fuel and lube oils prior to orbital flight. This is necessary since in orbit the engines encounter vacuum environment.

166 The vehicle uses pneumatic helium pressure for the main propellant and engine valve activation, engine pump seals, purging and inerting all propulsion lines, engines and fuel tank prepressurization.

166 Operationally, the ABPS remains inactive until reentry except for thermal control system functions. After entry, the nacelles are deployed, and the engine oil and fuel systems are primed. For early development flights, assisted air starts will be initiated at 40,000 feet- the upper limit of the air-start envelope. The design fuel load for operational flights is based on delaying air start initiation to 25,000 feet, which will provide sufficient time during descent for engine start and operational check prior to initiating the planned 15-minute loiter flight at 10,000 feet altitude.

AC The APES engine is provided with a manual power lever to control the engine thrust from IDLE to maximum. Below the IDLE position the power lever will actuate fuel cutoff valves.

C Control of all engine operations is initiated by crew members. Engine thrust level is governed by a fuel controller. The fuel controller combines input signals from the throttle lever position, engine RPM sensor, compressor

REP. NO.

inlet temperature and pressure sensors, and the compressor discharge pressure sensor to position the fuel metering valve.

B Instrumentation monitoring is required on fuel flow rates, temperatures, pressure; turbine inlet and exhaust temperatures; valve state; lubricating oil quantity, pressure and temperature; and burner pressure.

D The Caution and Warning System is provided inputs from the ABES system during ferry flights and the re-entry flight when activated by crew members.

4.6.5 RATIONAL for ASSUMPTIONS

A. Throttle controls for the APES are visible on instrument panel configurations, however, detailed descriptions are not yet available.

B. Reference 36, page 4-673 indicates APES instrumentation by quantity of measurements only. At present it is assumed these measurements pertain to standard turbofan parameters monitored in existing aircraft. Also since the engine is deployable, it is also assumed there are indications presented to the crew for the condition of engine deployed.

C. There is no reference detailed to the level of components of systems for the APES. It is assumed the APES is manually controlled, i.e. no computer throttle control and that the turbofan engine has a fuel controller similar to a standard aircraft.

D. There is no reference to date of interfaces of the Caution and Warning System, however, this interface is required for operation.

4.7 SOLID ROCKET MOTORS

66 The shuttle vehicle is equipped with 156" solid rocket motors (SRM) providing thrust forces for main vehicle liftoff, shuttle vehicle abort separation and external tank retro-deorbiting. Each of these engine groups is discussed in detail in the following paragraphs.

4.7.1 MAIN SRM

66 Two 156-inch diameter SRM's are attached to the orbiter external tank and burn in parallel with the orbiter MPS engines to provide ascent propulsive thrust up to staging. In addition to the rocket motors, the booster assembly contains an aft skirt launch support structure, forward skirt and external tank attach structure, separation rocket motors, recovery system, aerodynamic fairing, an electrical power and distribution system, and a malfunction detection instrumentation system.

66 The SRM assemblies transmit thrust through a structural skirt at the forward end of the motor into the external tank subsystem intertank structure. Total vehicle support on the launch pad is provided by structural skirts on the aft end of the motors. The motor nozzels are fixed at a cant angle of 11 degrees to the motor centerline in the yaw plane. Thrust termination ports are provided in the forward end of the motors for use under abort conditions. FIGURE 4.7.1.1 shows a baseline motor envelope, while preliminary motor characteristics are presented in FIGURE 4.7.1.2.

66 A segmented case design was selected to afford a maximum degree of flexibility in selecting a fabrication site and for ease of transportation

and handling. The motor nozzle uses a composite ablative inner liner and steel outer shell with provisions for attachment to the motor case aft closure.

66 Each SRM composed of polybutadiene acrylonitrile (PBAN) provides an initial sea-level thrust of approximately 3.52 million pounds. The motor ballistic provides a high initial thrust/weight with decreasing thrust to limit maximum g followed by an increasing thrust to minimize g loss while maintaining vehicle acceleration below the 3- g limit. Predicted ballistics for a motor using proven propellant grain geometries were used for trajectory analysis, FIGURE 4.7.1.2.

66 A conventional self-contained pyrogen ignition system with appropriate redundancies and safe and arm provisions will be utilized. Final selection of initiator type (exploding bridgewire versus hot wire) will be based on an assessment of overall Shuttle system ordinance requirements.

166 Thrust termination is provided for abort modes by means of two symmetrical blowout ports formed in each forward motor by the ignition of linear shaped charges (FIGURE 4.7.1.3). Exhaust stacks are provided to direct the gas discharge through the forward attach structure and away from the orbiter. The stacks also provide some gas expansion to achieve slightly higher thrust. The ports are sized to provide approximately 10 percent positive SRM net thrust throughout all phases of burning to enhance separation. A malfunction detection system is used in conjunction with the thrust termination system to provide an early warning of an impending catastrophic SRM failure. As a minimum, the system will contain pressure and temperature sensors to detect abnormal pressures and/or overheating conditions.

166 The SRM/external tank subsystem separation system (FIGURE 4.7.1.4)
171 operates in normal and abort modes at varying SRM residual thrust levels and oblique vehicle flight paths. The SRM separation system uses auxiliary rockets to provide relative separating motion between the SRM cases and the orbiter/tank. Forward and aft rocket thrusters provide the desired separation trajectory, while the aft thrusters are rotated to counter any SRM residual thrust. The thrusters are located to minimize plume impingement on the orbiter. This system prevents reaction loading on the external tank subsystem. Three rockets are located forward and three aft to provide safe separation with single rocket failure for normal staging ($F_{vac_{avg}} = 27K$ pounds, $t_{burn} = 2$ seconds). The aft separation rockets are installed at a greater angle than forward rockets to account for residual thrust of skewed main rocket nozzle.

REV.

BINGHAMTON, NEW YORK

REP. NO.

4.7.2 ABORT SOLID ROCKET MOTOR (ASRM)

166 The abort solid rocket motor subsystem, consisting of two solid rocket motors attached to the orbiter aft fuselage, provides the rapid start and high thrust necessary to successfully accomplish orbiter separation from the booster SRM's and external tank subsystem in the event of an abort between 0 and 30 seconds from liftoff.

66 In an aborted mission the abort rocket motors are fired simultaneously, reaching peak thrust in 600 milliseconds, and burn for approximately 21 seconds with an average thrust of 385,000 pounds. The predicted thrust-time history is shown in FIGURE 4.7.2.1 At ignition, a 2.45 thrust/weight ratio is provided to accelerate the orbiter (with 65,000 pounds payload) away from the booster and external tank. After burnout, at approximately 12,000-foot altitude, the abort solid rocket motors are jettisoned. In a normal mission, the motors are jettisoned unused 30 seconds from liftoff.

166 The ASRM's are separated during a nominal mission (unused) or following an abort firing (expended). The nominal separation is accomplished by placing the SRM's at the rear of the configuration so that a simple release mechanism allows the vehicle to accelerate away. The nominal acceleration at this point in this trajectory gives adequate separation safety margins. The ASRM's will land approximately two nm downrange. The more difficult ASRM separation problem occurs when the abort rockets have fired to separate and maneuver the orbiter away from the tank and booster. For orbiter stability reasons, the ASRM's are separated immediately after burnout with the orbiter and ASRM's experiencing deceleration forces.

166

The abort solid rocket motors require separation under two conditions of aerodynamic loading and mass. In a normal mission, the unused abort solid rocket motors are jettisoned at a dynamic pressure of 300 to 400 lb/ft², which provides separation forces in an upward and outward direction with respect to the orbiter. In an abort mode, the motor weight is 8,100 pounds at burnout and the dynamic pressure is 700 to 800 lb/ft². Relative acceleration studies indicate complete separation and clearance between the abort solid rocket motors and orbiter in less than 1 second. Bolt-on fittings are provided to meet orbiter maintenance time schedule. Separation occurs at the clamp thrust interface, leaving only the attachment fittings on the orbiter. These fittings will be structurally loaded during orbiter structural testing. A triple redundant explosive separation clamp sized for worse-case conditions will assure separation.

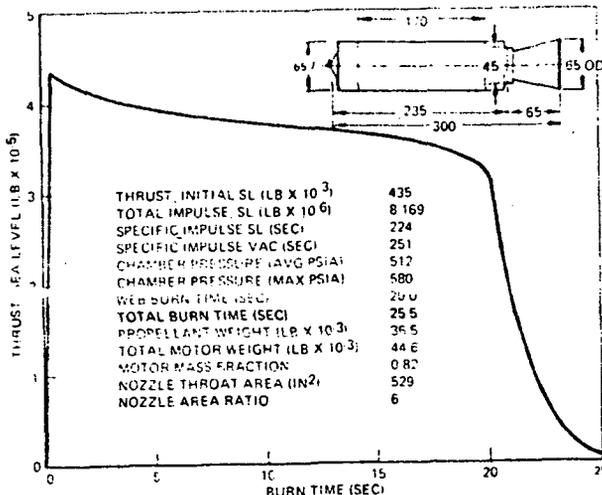

Figure 4.7.2-1 ASRM Thrust Time Profile and Characteristics

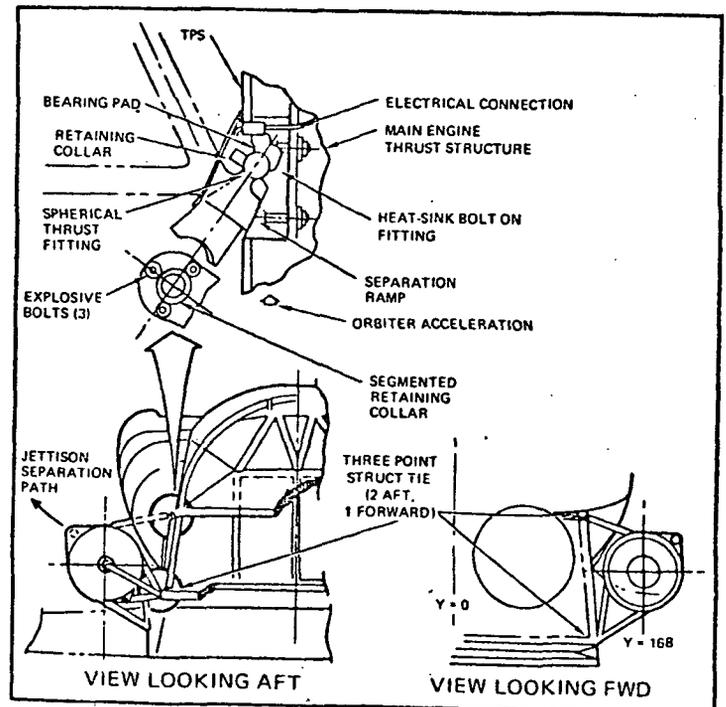

Figure 4.7.2-2 ASRM Installation and Separation System Concept

4.7.3 DEORBIT SRM FOR EXTERNAL TANK (ET)

Deorbit of the ET requires a 300-fps retrograde velocity increment to effect ET fragment impact in the prescribed footprint in the Indian Ocean. This ΔV is achieved with a forward-firing solid rocket motor installed in the ET forward fairing and firing through a fragile nose cap. The motor is armed and fired by the ET avionics battery/sequencer subsystem following ET-orbiter separation. The deorbit motor design, as dictated by the ΔV requirement, has an average vacuum thrust of 18,500 pounds and provides a total impulse of approximately 686,000 lb-sec during its 37-second burn time. The preliminary motor design is approximately 37 inches in diameter, 76 inches in length, and has a total loaded weight of 2,600 pounds. The configuration contains 2,400 pounds of propellant and is based upon the modification (5-percent increase in propellant quantity) of an existing spaceflight-qualified rocket motor.

10/20/72

allow a 15-percent-over-mission load condition on the landing system by increasing the main gear tire pressure to 250 psi and maintaining static tire deflection at 32 percent. The ferry/horizontal flight test condition provides the design criteria for the maximum tire load caused by the down-load due to elevon deflection for nose wheel liftoff. Main gear tire deflection at this condition is approximately 50 percent. The ferry condition also defines the criteria for turnover, spacing, and structural sideload caused by turns during taxiing. When designed to these conditions, the landing system is capable of drift landings with peak ground wind speeds to 35 knots from any azimuth.

Additional cost savings during the implementation and operational phases of the orbiter results from landing/deceleration system maintainability and servicing features. The main gear, nose gears, and deceleration chute are fully accessible for structural and system inspections and servicing by access through the gear doors and vertical stabilizer speed brake. Using standard access equipment, the main and nose gears can easily be inspected in the preventive maintenance apportionment time of 2.25 hours. With the speed brake open, deceleration parachute backup structure is exposed and can be inspected visually within 0.50 hour. In order to meet the allocated hours for servicing, the deceleration chute is a module package which, for installation, requires only mechanical and electrical connecting. Gear lubrication and main and nose gear shock strut service is also accomplished through the open gear doors. Jacking provisions are provided at each strut to accommodate wheel/tire replacement, without removal of other components, in 1.2 hours. The main gear brakes are replaceable as a unit, are open on the upper aft side for ease of inspection, and can be replaced within the allocated maintenance time.

Tow attachments to allow towing on slopes to 5 percent are provided on the front and rear of each gear, and are positioned to prevent towing equipment interference.

During the development of the landing and deceleration system, full consideration will be given to meeting the orbiter maintainability and turnaround time requirements, discussed further in Section 2.4.

SD will define, develop, certify, and deliver for the orbiter a landing and deceleration system which provides for all phases of shuttle operations. This results in the minimum launch weight impact and simplest, direct acting system, using existing equipment where possible to minimize cost and schedule time and risk.

The use of existing equipment requires on-orbit conditioning of the main and nose gear wheel wells to maintain the exposure temperature within -60°F to 275°F . This is accomplished by use of a combination of electric heaters and passive insulation, described in Section 3.1.3. Deceleration parachute thermal protection also is described. The landing/deceleration system will be developed and space-rated by conducting environmental testing where necessary. Certification by similarity to existing hardware will provide cost savings to the program. Thermal vacuum testing of nonmetallic components, such as tires and lubricants, is proposed. Landing gear simulators are proposed for the conduct of operational and endurance tests. Static ultimate load and fatigue tests will be conducted as part of the structural test program. Final qualification testing of the deceleration chute, nose gear steering, and brake systems will be accomplished during taxi as part of the horizontal flight test program. The landing system test requirements and program are discussed in detail in Volume 5.

The orbiter mission will expose landing system components to long-term space environment for the first time, requiring space rating of this equipment. SD will apply its Apollo CSM experience and analysis capability on long-term space environmental exposure affects to the development of certified equipment and to a reasonable certification program.

The landing/deceleration system proposed is based on the Phase B study. No problem areas not previously solved by SD on Apollo CSM or by NR on its many aircraft systems are anticipated.

3.1.3 THERMAL PROTECTION AND CONTROL (WBS 1.3.1.3)

The thermal protection and control system consists of two elements. One, the thermal protection system (TPS), is external to the primary structural shell of the vehicle. It maintains the airframe outer skin within acceptable temperature limits during the vehicle mission. Where internal vehicle special compartments or areas require additional thermal control, the external TPS is augmented by a second element; the internal thermal control system (TCS). Overall vehicle thermal design also is included in the ECLSS, discussed in Section 3.5, the purge and vent subsystem, discussed in Section 3.1.1.5; and other subsystems. TPS and TCS design, along with the increased vehicle thermal analysis, are discussed in this section.

SD 72-84-50-3

10/20/72

3.1.3.1 TPS DESCRIPTION AND FEATURES

The baseline TPS (FIGURE 3-25) consists of: (1) ceramic reusable surface insulation (CRSI) (ceramic panels with an external waterproof coating on a strain-isolation foam pad) directly bonded to the airframe in areas exposed to surface temperature between 650°F and 2500°F; (2) elastomeric reusable surface insulation (ERSI) directly bonded to the airframe in areas exposed to temperatures below 650°F, and (3) reinforced carbon-carbon (RCC) material in the wing leading edge and body nose cap in areas exposed to temperatures above 2500°F.

3.1.3.2 CERAMIC RSI.

Candidate ceramic insulation material systems basically consist of mullite or silica. SD's rationale supporting the use of mullite as the baseline TPS material is presented in the Discussion Item 2 response. SD plans to review the RSI material candidates after ATP and make the final selection by PRR. Four basic elements of the mullite CRSI system are reviewed as follows:

- Mullite panels — A low-density insulative composite material formed by coating a matrix of mullite fibers rigidized with an aluminum-boria silica refractory glass binder. The panel and pad (FIGURE 3-25) dimensions are determined by the thermal/structural analyses
- PD-200 pad — A chemically foamed methyl-phenyl silicone elastomeric material. This pad provides strain isolation of the CRSI from the aluminum structure and accommodates local surface irregularities. Its outer surface design temperature is 650°F, determined by the allowable bond temperature. The inner surface design temperature is 350°F. This temperature was selected to yield the lowest TPS and aluminum primary structural weight. Early analyses indicate that by increasing the bottom and chine pad thickness by 0.2 inch, the ablative characteristics will provide a ceramic panel loss fail safe entry. This will be substantiated by further analyses and tests.
- SR-2 coating — A waterproof ceramic coating fired at 2500°F on the top and sides of the panel. This coating is chemically compatible with and similar in expansion coefficient to the mullite insulation. The coating provides the necessary thermal control optical characteristics, rain erosion protection, and abrasion resistance for ground-

handling and atmospheric flight.

- RTV-560 adhesive — A silicone elastomer room-temperature-cured adhesive system used for both panel and pad bonding.

The RSI system is structurally sized considering the effects of airframe structure with a general thermal/structural analysis method for multi-material orthotropic elastic bodies. It is based on finite element, direct stiffness methods for computing displacement stresses and strains thru the substructure adhesive, pad, panel, and coating. This analytical technique has been verified and correlated with test results.

Panel-to-panel gaps (0.12 to 0.25 inch) are sized to avoid CRSI panel compressive loads at maximum expansion during entry. The gaps are partially filled with a low-density-quartz expandable gasket to thermally protect the substructure at the base of the joint. The height of the gasket is determined by thermal analysis to preclude material thermal degradation. A panel self-venting system is provided which allows venting to the boundary layer pressure through the panel gaps. It consists of a local interruption in the panel to PD-200 bond line (adjacent to the panel lower outer edge.) A silicone primer, applied to the lower panel surface, provides a water barrier while allowing venting of internal gases. This venting concept has been test-verified. Two CRSI test prototypes, mounted on simulated airframe structure and configured to two critical areas of the baseline system, have been successfully tested to withstand 100 orbiter thermal environment cycles. During the test series the prototypes were also subjected to a dynamic/acoustic energy spectrum of 163 db for the equivalent of 25 missions. See Section 2.2.4 for dynamic acoustic design requirements.

3.1.3.3 ELASTOMERIC RSI

An important feature is the use of an ERSI (ESM1004X) as the primary TPS on the orbiter upper surfaces where lower temperatures (<650°F) are experienced. Using an elastomer instead of a ceramic results in a TPS weight reduction of 3500 pounds. It is a flexible, open-cell structure material possessing good low-temperature flexural properties, and is attached to the airframe in coated sheets with RTV-560 bond. The ESM1004X is coated with an elastomeric silicone resin (for waterproofing) pigmented with titanium dioxide and carbon black (for thermal control). It is an impact-resistant, easily repairable material which will minimize the susceptibility to handling damage.

4.8 External Tank Subsystem (ET)

166 The ET is a single assembly with integrated LO₂ and LH₂ tankage and structure. The ET is mounted in parallel below the orbiter and between the two SRM boosters. The configuration consists of structure, thermal protection system, main propulsion system tankage components, avionics, and mechanical components (Figure 4.8-1).

4.8.1 Structure

166 The ET structural design is illustrated in Figure 4.8-1. Both propellant tanks are constructed of 2219 aluminum monocoque skins with support frames. The design employs explosive bulge forming to form the individual bulkhead/cone gores. The skins and frames are butt fusion-welded together to provide reliable sealed joints.

166 The LO₂ tank aft skirt and the LH₂ tank forward and aft skirts use 2024 integral machine-milled skin/stringer structure stabilized with attached hydro-formed and chem-milled frames.

166 The ET to orbiter structural attachment (Figure 4.8-2) consists of one forward and two rear connections, through truss structures mounted to the LH₂ tank support frames and longerons. The mechanical release components are installed in the orbiter. The attachment between the ET and each SRM booster consists of one forward ball joint connection at the intertank longeron/frame juncture plus two links and a slide at the LH₂ tank aft skirt frame.

166 A field joint is provided at the intertank skirts by circumferential tension bolts. This joint provides tank assembly and tank shipment benefits.

166 Doors in the forward fairing and the LO₂ tank aft skirt provide access to interior installed equipment. In addition, manhole doors in each tank

BINGHAMTON, NEW YORK

REP. NO.

166 provide manufacturing and field operations access for installing and maintaining equipment installed within the tank.

166 Saturn S-II type linear pyrotechnic explosive is installed along the sides of each tank for range safety propellant dispersion.

166 The ET is axially supported aft of the LO₂ tank by attachment of the canted SRM booster thrust cones to the ET ball joints on the intertank pitch axis.

4.8.2 Thermal Protection System (TPS)

166 Spray-on foam insulation (SOFI) is applied to the complete outer surface of the LH₂ tank, including the sidewalls and the end bulkheads. Sheet cork and the other high-density ablators are bonded directly to the outer surface of local structural areas (Figure 4.8-3). Sheet cork ablator is also bonded to a fiberglass substructure that is locally supported from the LH₂ tank aft bulkhead. The TPS coverage is minimized by using the heat sink provided by the ET sidewalls, SOFI, and propellants.

4.8.3 Deorbit Motor

166 Deorbit of the ET requires a 300-fps retrograde velocity increment to effect ET fragment impact in the prescribed footprint in the Indian Ocean. This ΔV is achieved with a forward-firing solid rocket motor installed in the ET forward fairing and firing through a frangible nose cap. The motor is armed and fired by the ET avionics battery/sequencer subsystem following ET/orbiter separation. The deorbit motor has an average vacuum thrust of 18,500 pounds and provides a total impulse of approximately 686,000 lb-sec during its 37-second burn time. The motor design is 37 inches in diameter, 76 inches in length, and has a total loaded weight of 2600 pounds. The configuration contains 2400 pounds of propellant.

4.8.4 Avionics

166 The ET installed avionics consist of two redundant primary batteries, sequencers and range safety receiver/decoders and antennas, development and operational flight instrumentation, and all interconnecting harnesses.

4.8.4.1 Instrumentation

166 The instrumentation used for propellant loading and tank pressure control during the mission consists of pressure transducers, temperature transducers, and liquid level sensors. Quad-redundant sensors are used throughout except for the optical type liquid level point sensors. The latter are mounted at the following volumetric levels at the walls in each tank: 2%, 3%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 97%, 98%, 99%, and 101% - with four sensors each located at the 1% and 100% levels. The 100% level is defined as the rated propellant load volume - exclusive of the 3% ullage volume. These sensors will be used during the fill operation to control the propellant fill rate. The liquid level sensors are used as part of the propellant utilization control system working in conjunction with engine controls.

Optical type liquid level point sensors located in the feed lines are used as control sensors during the LH₂ and LO₂ dump sequencing. These sensors are referred to as depletion sensors.

Tank pressure will be controlled to within ± 1.5 psi of the desired level during each phase of the mission by means of pressure control units located on the vehicle. After orbiter engine shutdown, these units will control the dumping of liquid residuals and will vent the tanks to 5 psi prior to separation.

4.8.4.2 SEPARATION

166

Since there is no communications link between orbiter and tank after separation, a simple combination timer, distance calculator, and attitude and attitude rate measuring unit is installed in the tank. This unit generates the signal to fire the retrorocket under normal operation mode and delays this signal in case of a malfunction where the distance/attitude condition for a normal firing time could create a hazard to the orbiter. It also generates the sequencing signals for the tumbling-enforcing jet system.

The geometric relations between orbiter and tank deploy tapes which remain attached to the orbiter during the separation maneuver and the relative velocity of their ejection from the tapereel tank provide for the direct determination of distances, attitude, and attitude rates.

The ET ordnance timing system performs the sequencing function which accomplishes retrorocket ignition. Prior to separation all power, control, and system monitor functions come from and are located in the orbiter. The post-separation system is fully autonomous (including its own power supply).

4.8.4.2.1 Electrical Power

166

No separate power system is required in the ET during operation up to separation. All power up to 2 sec prior to separation, and the power requirements for the ordnance system operation after separation are satisfied by its own batteries. The only additional requirement remaining after separation is for the operation of the timer/separation condition sensor unit. This low power requirement is provided by two dedicated batteries incorporated in the ET system.

- 166 Figure 4.8-4 illustrates the system to provide a separation sequence that accommodates both perpendicular and axial separation trajectories and meets all modes of separation from pad-abort to nominal mission orbital separation. Through use of the orbiter's existing ACPS (for orbital separation) and aerodynamic forces (for suborbital separation) no other active displacement system is required for ET separation anywhere in the mission.
- 4.8.4.2.2 Interface
- 166 Orbiter/ET interfaces requiring separation are grouped in two subsystems (LO_2 and LH_2) and three structural disconnect mechanisms. All of the subsystem's propellant transfer disconnects are composed of linear actuated poppet valves attached to umbilical plates on both the ET and orbiter sides of the interfaces. As the umbilical plates separate, the poppets are closed when the valves are disconnected. Because of differential motion between the ET, orbiter, and propellant lines resulting from thermal structural deflections, there is no rigid tie between the ET's umbilical and the ET. Retracting bungees are installed between the ET and its umbilical plates to retract and retain the ET's umbilical plates after release from the orbiter. Electrical plugs and receptacles are likewise attached to, and separated by, the orbiter and ET umbilical plates.
- 166 Three structural interfaces are arranged in a triangular pattern with two thrust interfaces aft. Side loads are reacted only at the left aft and forward attachments. All three interfaces react vertical loads. The geometry of the aft interfaces are such that the orbiter's MPS thrust forces are transferred to the ET by canted links approximately aligned with the MPS thrust axis. The forward structural attachment is comprised

DATE 10/20/72

BINGHAMTON, NEW YORK

REP. NO.

166

of an A-frame truss canting aft from the ET with its apex having a pivoted shallow probe engaging a socket within the orbiter's lower mold-line. A stud within the probe engages jaws of a restraining latch attached to the orbiter. The canted links provide controlled displacement of the orbiter away from the ET during pad-abort. Perpendicular (orbital and suborbital) ET separation is readily accommodated. Mechanically actuated doors will subsequently cover all of the orbiter's aft ET interfaces. The forward interface will have a heat-sink and therefore will not require a door cover.

4.9 Guidance, Navigation, and Control (less computer)

The shuttle flight control system, given guidance commands and data on vehicle dynamics from sensors, provides RCS firing commands, ØMS gimbal actuator commands, MPS gimbal actuator commands, and aerosurface actuator commands. The flight control system is divided into primary and backup control systems. The primary GN&C subsystem provides control for all flight phases, with both automatic and manual modes. The primary system is present in three redundant strings, interconnected only at IMU output and output force servos and jet drivers. During quiescent on-orbit periods, only one string is used. Flight control loops used with the main engine TVC, ØMS TVC, and the RCS are closed through the GN&C computer. Aerosurface control uses the computer and the Aerodynamic Stability Augmentation System. (ASAS) An additional manual aerodynamic control mode bypasses the computer and uses only the ASAS. The ASAS is an F-14 type conventional analog system which employs body mounted rate gyros and accelerometers. Gain scheduling is provided by inputs from an air data system. The entry and approach/landing primary control systems are illustrated on the following page:

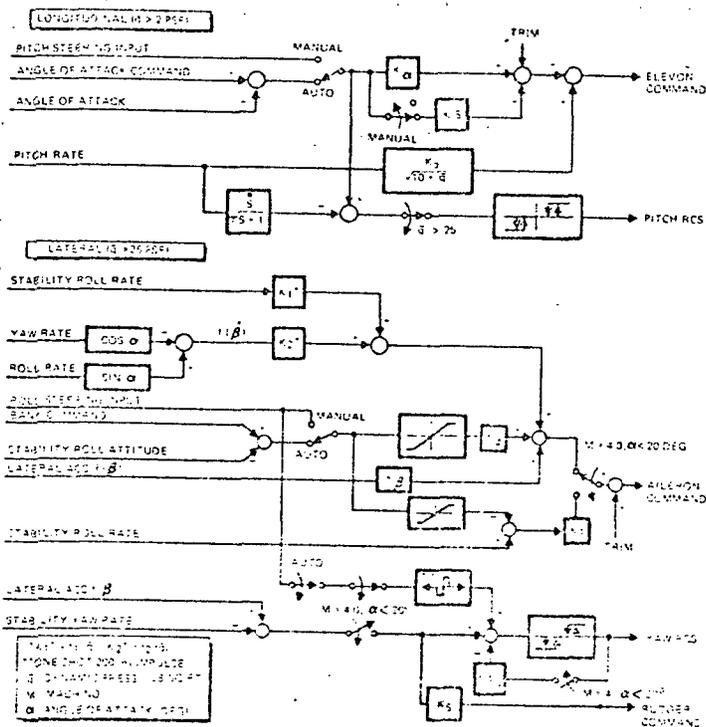

Figure 2-92. Entry Primary Flight Control System

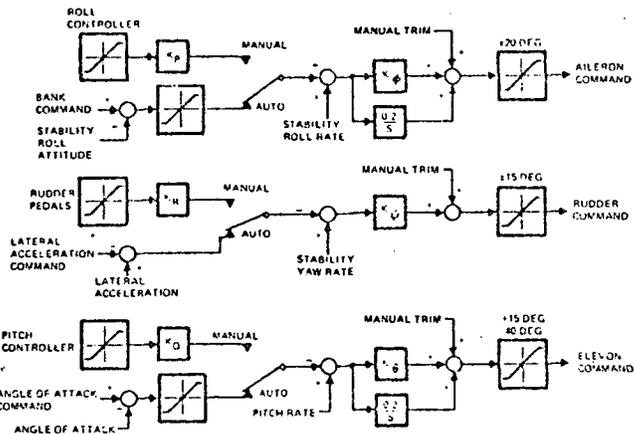

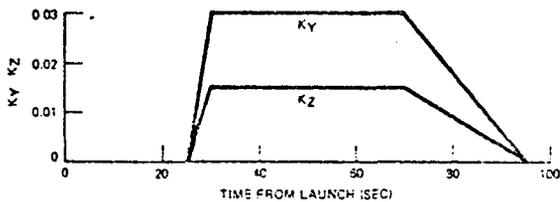

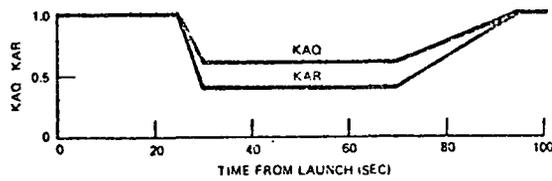

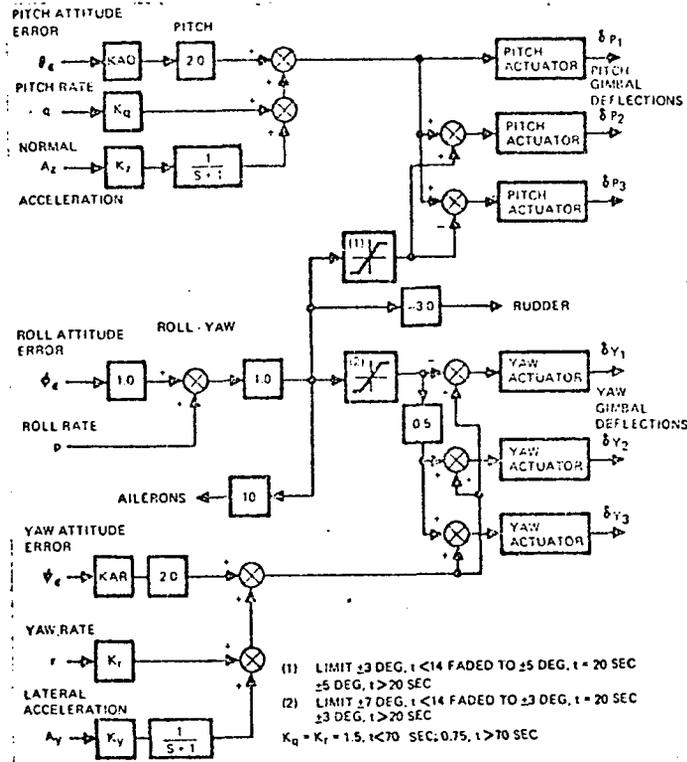

Figure 2-97. Approach/Landing Primary Flight Control

Ref
Key

4 The load relief control scheme used during periods of high dynamic pressure during boost uses both main engine TVC and aerosurface control. It is illustrated below:

Ref
Key

- 5 On-orbit (non-thrusting) flight control effects attitude and translation maneuvers using RCS jets. Cross-axis coupling is eliminated by RCS jet select logic. Key features are:
1. independently selectable three-axis hold capable of accepting guidance commands.
 2. independently selected three-axis translation control
 3. selectable attitude accuracies of ± 0.5 , ± 10 , and ± 45 degrees, and minimum attitude rate of $0.1 \frac{\text{deg}}{\text{sec}}$
 4. minimum overshoot response to commanded inputs provided by rate feedback, and RCS select logic providing minimum propellant consumption and inhibiting opposing jet firings.
- 6 Attitude control during \emptyset MS firing is achieved by gimbaling the \emptyset MS engines. In the case of single \emptyset MS engine operation, RCS will provide roll control.
- 7 A backup GN&C subsystem is provided, which provides safe return capability for all flight phases. It is separate from the primary subsystem, using dedicated sensors and electronics. Backup control inputs are manual. Control modes are summarized below:

Mode	Flight Phase	Characteristic
Command	• Boost/insertion (TVC) Orbital (\emptyset MS TVC, RCS), Entry, Aero, Landing	• Crew initiates guidance and control modes and monitors—control automatic through GN&C computer
Control stick steering	• Orbital (\emptyset MS TVC or RCS), Entry, Aero, Landing	• Manual control and guidance displays through GN&C computer • Rate command, attitude hold, and RCS minimum impulse; RCS translation—acceleration command
Manual	• Aerodynamic	• Manual control through ASAS Rate command and damp
Manual Backup	• Boost/insertion (TVC) Orbital (\emptyset MS TVC or RCS), Entry, Aero, Landing	• Backup sensors and computer, Rate command and damp Direct control

Ref
Key

1 Crew steering information is provided on a cockpit CRT. Display
8 information is processed through a Modular Display Electronics (MDE)
9 unit. The backup entry and approach/landing control uses a simple SAS rather than direct control to improve handling qualities. The scheme is shown below:

2,7 Provision is made throughout the system for failure recovery. Redundancy management and failure provision are summarized in the tables below:

Table 3-24. Phased Buildup and Redundancy Management Influence GN&C Packaging

Function	Unit Packaging	Rationale
Jet select logic and drivers	<ul style="list-style-type: none"> Logic in GN&C computer Drivers in 3 units, dual power supplies 	<ul style="list-style-type: none"> Allows flexibility for redundancy management for dual failure Provides spatial diversity, minimizes number of drivers to provide FO-FS
Backup GN&C	<ul style="list-style-type: none"> Dedicated gyro, accelerometer units Dedicated aero-control electronics units Dedicated RCS, TVC unit Separate computation in MDE processor 	<ul style="list-style-type: none"> Allows backup GN&C to be functionally independent Delays RCS/TVC implementation to first vertical flight. FHF qual integrity retained by avoiding rework for FVF Delays implementation to FVF Protection against primary system single point software failures
TVC gimbal drivers	<ul style="list-style-type: none"> Three units, dual supplies. Each drives one redundant actuator in each engine, primary or backup control 	<ul style="list-style-type: none"> No gimbal loss after two failures. Delays implementation to FVF
Aero-control electronics	<ul style="list-style-type: none"> Three units. Each dedicated to one level of redundant actuators on each surface, primary, or backup control 	<ul style="list-style-type: none"> Fail operational after one failure. Detection capability remains for transfer to backup. Delays driver avionics cost.

FVF—first vertical flight; MDE—modular display electronics; FHF—first horizontal flight

Table 3-26. GN&C Redundancy Management Considerations

Consideration	Trade Studies	Implementation and Solution
GN&C redundancy level	Redundancy level versus program costs (aborts, hardware, operations, weight, power, and cooling)	FO-FS best. Triplex primary system with unlike backup path
Hardover aerosurface/ TVC failures cause vehicle loss (allowable detect and correct times 0.5 sec, much less than pilot reaction capability)	Position sum actuators, operate-standby actuators, and force sum actuators	Use force sum actuators with simple pressure monitors to switch per conventional aircraft practice to "fail soft"
Protection against single-point GN&C software failure	Cost of exhaustive software C/O against cost of unlike separate 4th string	Use unlike "get home safe" GN&C 4th string
False failure detections caused by string command divergence from control law integrations and guidance sensitivities	Cross-strapping IMU's and computers or cross-strapping IMU's only	Cross-strap IMU; allows simple mechanization

Table 3-27. GN&C Failure Recovery Sequences

Detection and correction sequence

- A. Detection: Software compare in GN&C computers
Correction: Software midvalue select in GN&C computers
- B. Detection: Hardware compare in command monitor and in pressure-driver monitor
Correction: Manually disengage failed channel, or pressure-driver monitors automatically disengage failed channel
- C. Detection: Hardware compare in pressure-driver monitors
Correction: Fail-soft by force fight-automatically disengage failed channel
- D. Detection: Servo monitor (servo, CRT, backup guidance), BITE
Correction: None required for space since normally disengaged; auto disengage for aero
- E. Detection: Software compare in GN&C computers
Correction: Manual switch to backup automatic (software freeze on last inertial data point on discompare); if isolated by BITE, option to revert to primary
- F. Detection: Hardware compare in command monitor and in pressure-driver monitor
Correction: Manual switchover to backup GN&C, or pressure-driver monitors automatically switch to backup GN&C
- G. Detection: Hardware compare in pressure-driver monitor
Correction: Fail-soft by force fight and automatically engage backup channel; if isolated by BITE, option to revert to primary channel

Note: The detection and switching techniques used cover the different combinations of failures; the major failures are described above.

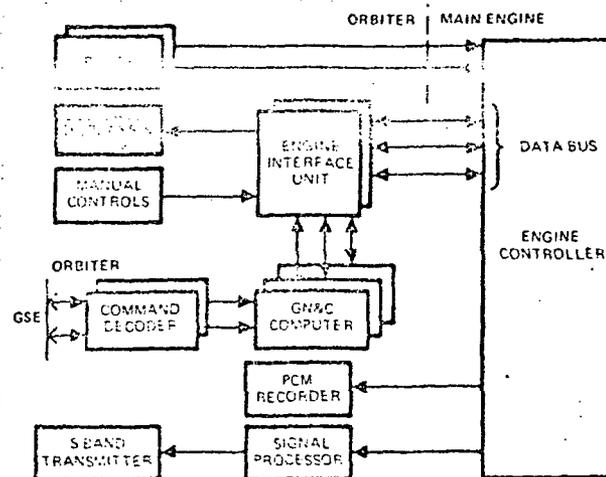

BITE: Built-in Test Equipment

Table 3-28. Redundancy Management Key Features

- Redundant strings interconnected only at IMU output and at the output force servos and jet drivers to maintain design simplicity. IMU interconnection prevents divergence in guidance computations and allows detection of slow degradation failures. Servo and jet driver interconnection (via monitor) required for "fail-soft."
- RCS engines divided into 3 groups electronically, each with dedicated GN&C computer and capable of doing all required maneuvers.
- Hydraulic pressure monitors in the main engine TVC and aerosurface actuators automatically disengage a failed channel for first failure and switch to backup for second. OMS TVC is not time-critical and does not require a monitor.
- When the backup system is engaged, there are no significant transients requiring initial corrective pilot inputs. Backup is rate command system that damps out failure transients automatically with rotational controller centered.
- Steering display command monitor detects guidance loop discrepancies for display; no automatic action is initiated by this monitor.
- Built-in test and self-test furnish LRU status to crew but are not used to automatically manage redundancy.
- After a second failure, if the failed string can be isolated using BITE, control may be restored to the remaining good string at crew option.

Ref
Key

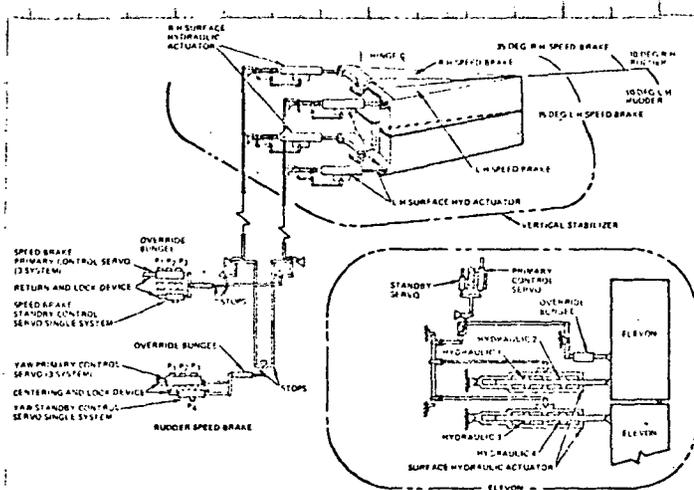

- 12 Main engine control signals are processed through the Engine Interface Unit, described in 4.3.2. Main engine gimbal actuators are mechanized to drive to a null position if two hydraulic systems are lost, two hard-over servo valve failures occur, or if two electrical signals are lost. Hydraulic pressure monitors in the main engine TVC actuators automatically disengage a failed channel upon the first failure and switch to backup upon the second. Main engine control interface is illustrated below (one per engine):

- 6 ØMS basic gimbal design technique is the same as that employed on the Apollo CSM. It employs electro-mechanical actuators incorporating redundant drive mechanisms. RCS thrusters will be activated by a fuel
- 14 operated valve, controlled by an electrically operated valve. RCS engines are electronically divided into three groups, each with dedicated
- 2 GN&C computer and capable of doing all required maneuvers.

Ref
Key

- 15 The aero-surface control system receives its input from the three-channel primary control servo and a single-channel backup servo. These inputs are summed mechanically and coupled by linkage to the power actuator. Load limiting/override bungees are provided to prevent excessive loads in this linkage system for both power-on and the power-off droop condition. Two dual tandem irreversible surface actuators are connected to each of the pinned together elevons. The rudder panels serve dual functions being used for aero-control and speed brakes. Two dual tandem actuators are connected to each side of the rudder panel to provide this control. Hydraulic power for actuation is provided by the four independent vehicle systems to individual sections of the dual tandem actuator. Aero-surface hinge moment and rate requirements for reentry and landing are provided with any two hydraulic power sources operating.
- 2 Hydraulic pressure monitors in the aerosurface actuators automatically disengage a failed channel upon the first failure, and switch to backup upon the second. The aero-surface control mechanisms are illustrated below:
- 16

Ref
Key

17 Elevon deflection ranges from -40° to $+15^\circ$ (negative is trailing edge up). Rudder deflection is $\pm 15^\circ$, while speed brake deflection ranges up to 70° . Sensor LRU's, excepting those covered in section 4.10., are:

- IMU (including power supply)
- Star Sensor
- Horizon Sensor Assembly
- Rate Sensor Package
- Accelerometer Package
- Air Data Package
- Angle of Attack Transducer
- Gyro/Accel Package
- Backup Optical Unit

18,7 Three Inertial Measurement Units (IMU's) will be carried. The IMU's will be all-attitude, forced air cooled, gimballed devices, each weighing 47 lbs., and requiring 120 watts of power. IMU outputs are cross-strapped, feeding each IMU output to each computer. Each IMU will output inertial acceleration and attitude. IMU error sources are tabulated below:

Component	Characteristic	Equipment Capability	Error Budget (1 σ)
Accelerometer	Bias (g)	25	100
	Scale factor (%)	0.0025	0.0150
	Input/Output axis misalign (sec)	10	40
Gyro	Scale factor (%)	0.04	0.10
	G-insens drift ($^\circ$ /hr)	0.03	0.05
	Mass unbalance input axis ($^\circ$ /hr/g)	0.1	0.1
	Mass unbalance spin axis ($^\circ$ /hr/g)	0.03	0.10
	Anisoeastic ($^\circ$ /hr/g 2)	0.003	0.100
gimbal	Feedback (two speed) (sec)	25	72

1,7.20 IMU's will be capable of fine alignment using star trackers and/or horizon sensors, and coarse alignment using the backup optical unit. Fine alignment accuracy will be within 1 arc-minute. Three star trackers will be carried. Star trackers will use image-dissector type detectors hard mounted to the spacecraft structure. They will be capable of observations within a fixed field of view; about 17° by 17° . Line-of-sight

7 motion within the field of view will be electronically tracked.

7 Capability to track sunlit or beacon lit rendezvous targets will be included to provide rendezvous bearing. Star tracker on-axis random error and bias will be within 30 arc-seconds (1σ). Three horizon sensors will be carried. Angular error (limited by horizon definition) will be within 6 arc-minutes (1σ). A Crewman Optical Alignment Sight (COAS) 1,18,21 will be included. It is a manual sighting device mounted in the left window, oriented along the spacecraft +x axis. It will be capable of repeated removal, stowage, and remount without elaborate calibration. Sufficient accuracy will be provided to allow backup rendezvous tracking, IMU coarse alignment, and backup system alignment. The device will be similar to the Apollo and Gemini instruments. Instrument, alignment, 7 and limit cycle error is expected to be within 11 arc-minutes (1σ).

7,18 Three body-mounted rate gyros will be employed in each of the three GN&C Strings. Rate sensors will be conventional spring-restrained, single degree of freedom rate gyros. Individual rate gyro operational and status monitor signals will be transmitted for each gyro. These gyros will provide body rate data for normal control purposes, and will be located in the best location (s) to aid in suppressing body-bending deflections and load alleviation. Two body mounted accelerometers, mounted one each in the yaw and pitch axes, will be employed in each of the three GN&C Strings. These instruments will be of a spring-loaded, seismic mass type. Air data is provided by vehicle nose pressure 1 ports at high altitude and by redundant probes deployed at lower altitudes.

4.10 Communications and Tracking

There are three general systems to be used in conjunction with the Shuttle Mission. These are the Spacecraft Data and Tracking Network (STDN), the Space Ground Link System (SGLS), and the FAA Air Traffic Control Network (ATC).

Primarily the communication system uses existing equipment. The equipment of the STDN network is compatible to the equipment installed in the SGLS network. The SGLS network will provide secure voice and data networks for classified missions. The ATC equipment gives the shuttle landing capability at almost any large airport.

The Shuttle orbiter vehicle contains transponders for tracking and navigation, telemetry television command, and voice. Tracking, telemetry command and voice link (TTCV), television transmission, and payload data/voice channels are compatible to the Spacecraft Tracking Data Network in current operation. S-band equipment is provided for the Satellite Control Facility (SCF) TTCV by the Space-Ground Link System (SGLS). In addition, S-band equipment is provided for voice and data crypts and normal payload data and voice relay to ground. Navigation, tracking/landing aids, and communication equipment is provided for flight which is compatible to the Air Traffic Control (ATC) system currently in operation.

The communications system also controls antenna selection, audio and video processing equipment, and signal distribution controls. The subsystem flow diagram, showing general functional requirements and functional redundancy is shown in Figure 4.10.2-1.

10/20/72

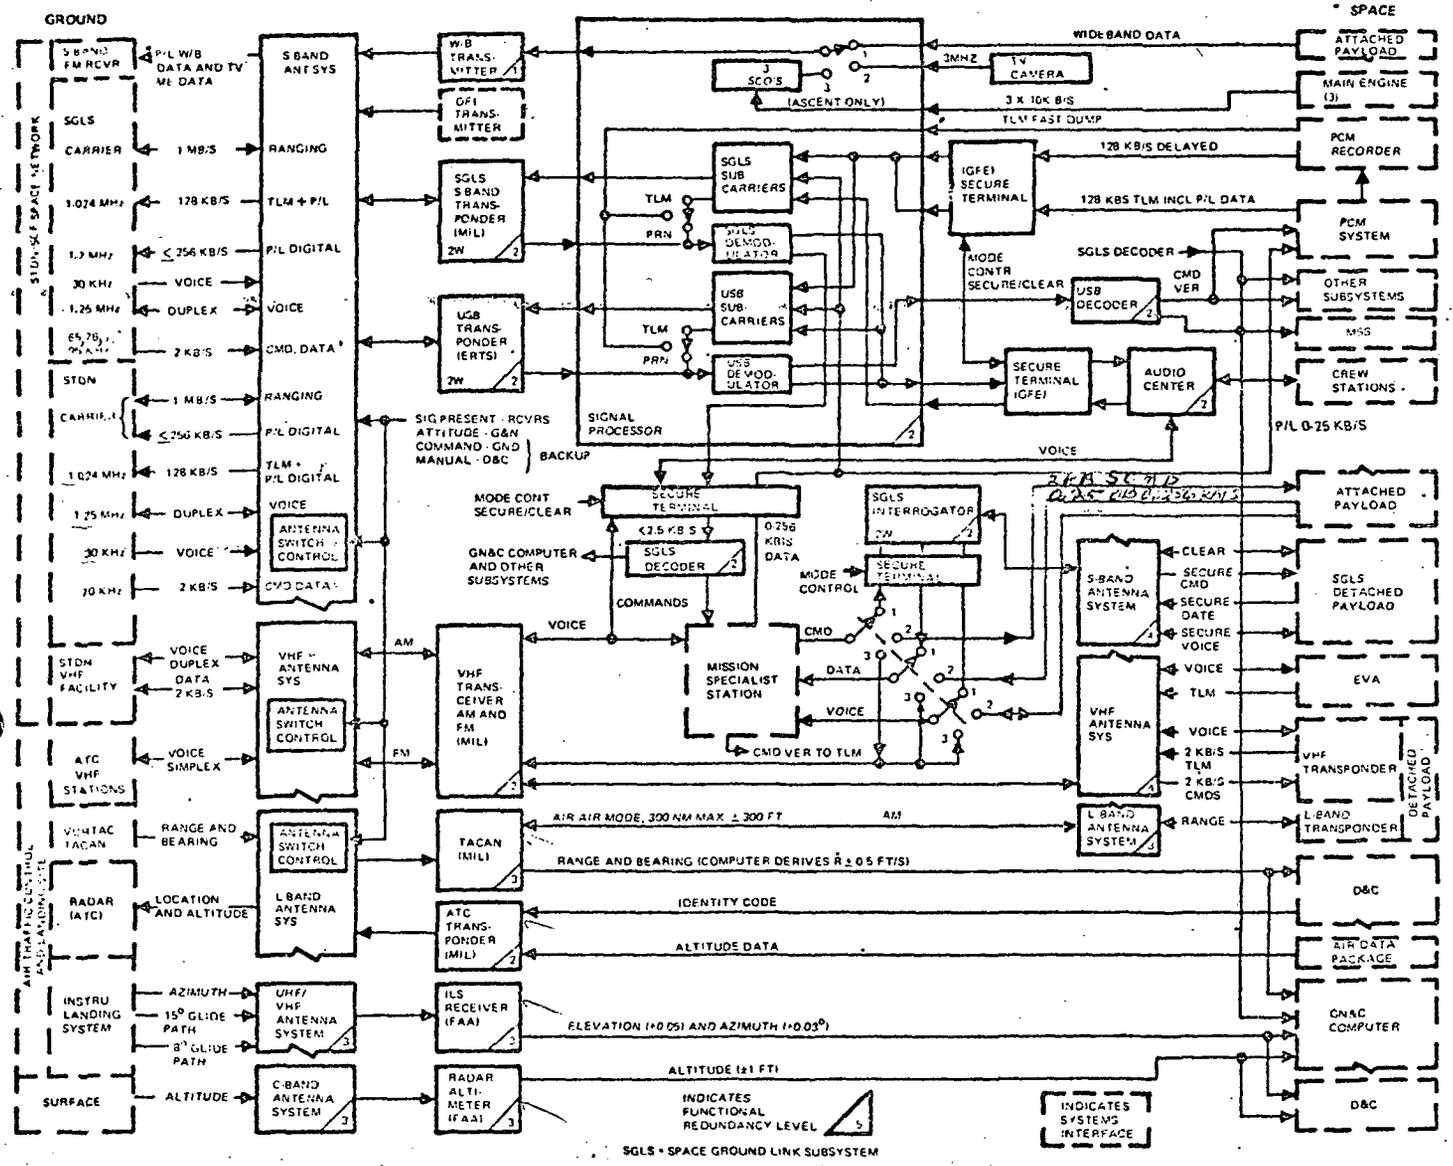

FIGURE 4.10.2-1

COMMUNICATION AND TRACKING SIGNAL FLOW

The only major change required for any currently operational communication system is to the glide slope transmitter located at the primary and alternate landing sites following a space operations.

The orbiter vehicle is equipped with antenna systems oriented for communication coverage at specific vehicle attitudes. Selectable antennas are used for increased geometric pattern coverage where required. Figure 4.10.2-2 shows the relative location of the antennas and the type (polarization) of the patterns. Attenuation of the radiated patterns is modified by body geometry as shown for each frequency band. Selection of the strongest signal/antenna is accomplished by automatic switching logic.

4.10.1. S-Band

The Shuttle vehicle uses three S-band frequencies for communication. There are two transmission frequencies (air to ground) of 2272.5 (+2.5) MHz and 2287.5 (+2.5) MHz. The receiving frequency is 2106.4 (+2) MHz.

The on-board receivers have a nominal receiver sensitivity of 97 db. On-board transmission line losses are estimated at -10 db from the receiver/transmitter to the antenna. The on-board transmitters have a TBD watt power capability. With this power the air-to-ground link has complete coverage with no signal attenuation where line-of-sight between the ground station and shuttle exists.

S-Band OMNI Antennas

There are four right hand circularly polarized, flush mounted helix antennas, located at intervals about the circumference of the orbiter. The omni antennas provide near-earth communications. The antennas are utilized individually and are selected by S-Band Antenna

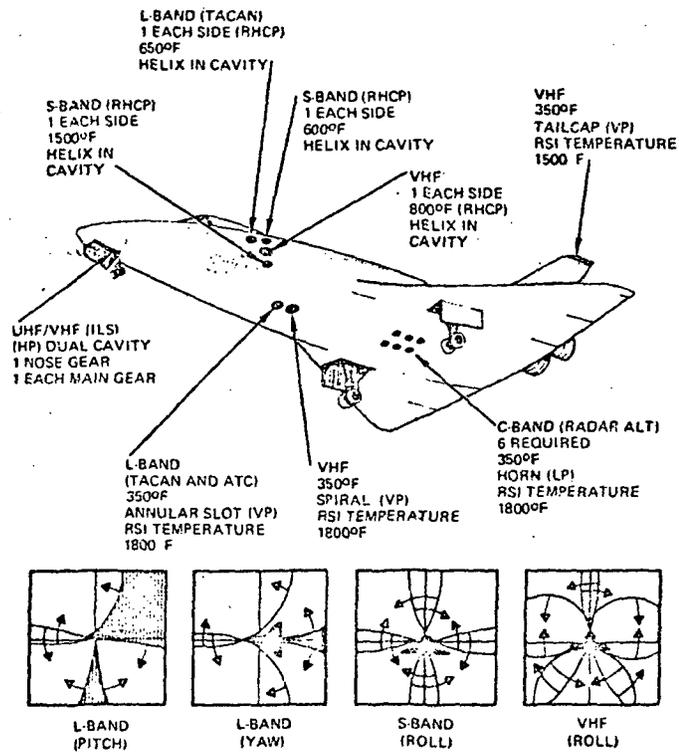

FIGURE 4.10.2-2

COMMUNICATION COVERAGE in all ATTITUDES

switches. Figure 4.10.2.1-1 is a typical antenna pattern for any one of the 4 OMNI antennas.

MSFN Unified S-Band Stations

Table 4.10.2.1-1 gives the Call Letters, Names, and Lat.-Long. locations of the S-Band ground stations. Goldstone, Madrid, and Canberra stations are equipped with 85 foot "Dish" antennas with 51 db gain. The remaining stations have 30 foot antennas, with 43 db gain. Power output of all the stations is variable from 1 to 10KW.

4.10.1.1 S-Band Voice

Duplex (simultaneous two-way) voice operated relay (VOX) voice communication is provided for crew members headsets. Normal voice duplex communication is provided by transmission of a phase modulated 2287.5 mc carrier -1250 kc subcarrier, and reception of a phase modulated 2106.4 mc carrier -30 KC subcarrier. Backup voice communication for down voice is provided by transmission of a direct phase modulated 2287.5 mc carrier. Backup voice communication for up voice is provided by using the up-data 70 kc subcarrier of the 2106.4 mc carrier.

4.10.1.2 S-Band T/M

Digital telemetry data will be by pulse code modulation (PCM). The high data bit rate of ≤ 256 Kbs is provided by direct phase modulation of the 2287.5 mc carrier. The low data rate of 128 Kbs is provided by transmission of a 2287.5 mc carrier-phase modulated by a 1024 kc subcarrier.

Analog data transmission is provided by a 2272.5 mc carrier using sub-carrier frequencies of 65, 76, and 95 Khz. All data for these subcarriers undergoes crypto secure processing prior to multiplexing.

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-157

REV.

BINGHAMTON, NEW YORK

REP. NO.

On-board data recorders are provided for PCM data for later transmission to a ground receiving station.

4.10.1.3 Command Data

The Shuttle has provisions for accepting digital encoded commands. The up-data link for this use has a maximum data rate of 2 Kbs using the 2106.4 mc carrier, phase modulated by a 70 kc subcarrier.

4.10.1.4 Video

Television transmission is provided by an analog video signal directly frequency modulating a 2272.5 mc carrier.

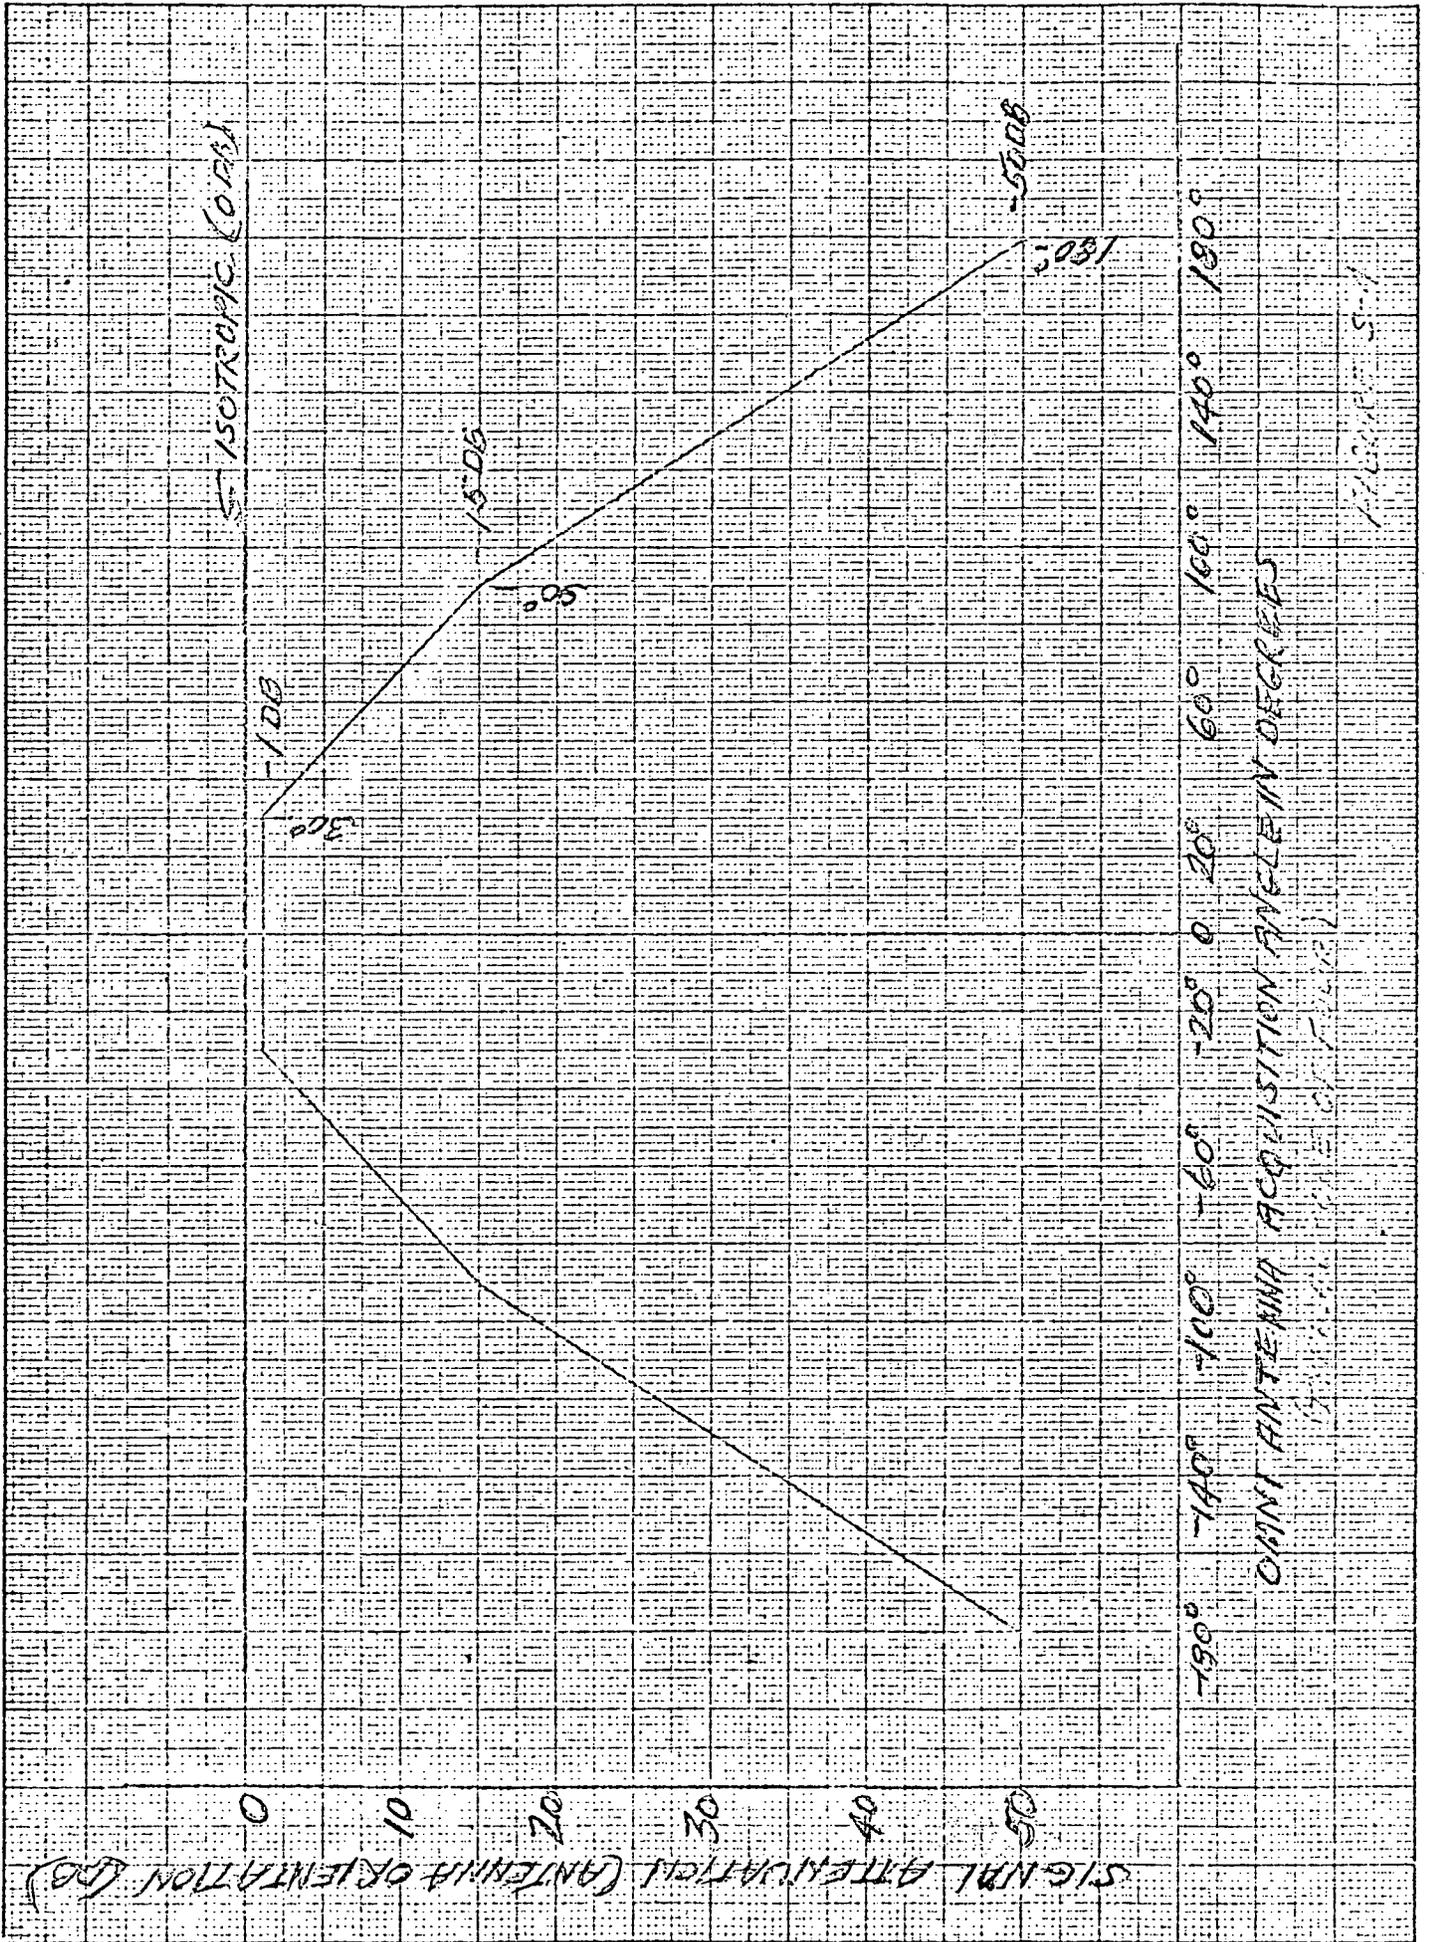

4.10.1.5 Wide Band Data Link

A wide band transmission link is provided for payload or main engine data (as applicable) in lieu of the video channel. Note: Lower response payload data will be transmitted as a part of the standard T/M data.

4.10.1.6 Range Measurement

The S-band equipment provides the capability for Doppler tracking and pseudo random noise (PRN) ranging by receiving and transmitting in phase coherence on the 2106.4 mc carrier.

REP. NO.

4.10.1.7 Rationale

The system described in Reference 166 uses basically the same system as the Apollo Command Module Communication and Instrumentation System.

4.10.1.8 Reference

166 Pages 3-109 to 3-113

1. Communication and Data System - Spec
North American Aviation MC901-0712
29 Jan. 1968
2. CMS-SU-21-Section A Apollo Master
Command Module Simulator, Communication
and Instrumentation System Specifications

4.10.2 VHF System

- 166 The Shuttle Orbiter has two VHF amplitude modulated carriers of 296.8 mc
1 and 259.7 mc. Transmission or reception on either frequency is provided
2 by using two receivers and two transmitters. Four antennas are provided
for selection by automatic switching logic. Vertical polarized antennas
are provided at the orbiter tailcap and belly. Right Hand Circular
Polarized (RHCP) RF patterns are provided on each side of the fuselage
by helix cavity antennas.
- 166 The system provides a duplex loop suitable for simultaneous voice commun-
ication and also provides a low rate data transmission and command link
of 2 Kbs for detached payload communication.
- 166 The orbiter vehicle has two VHF transceivers that are frequency modulated.
1 The channel frequency is selectable for use of voice communication with
2 Air Traffic Controllers during approach and landings. This system shares
the same antennas as the duplex system. A triplexer functions to allow
simultaneous operation of three transmitters or receivers off of a common
antenna. RF losses by the triplexer are less than 1.5 db.
- 166 Each of the STDN stations has a VHF system using directable narrow-beam
1 antennas fed from the main dish. This system gives air-to-ground commun-
2 ication at orbital altitudes under any vehicle attitude when line-of-
sight conditions exist.
- 166 The ATC system uses the VHF band for control of air traffic during the
orbiter re-entry. The orbiter-ground link for ATC is established

following re-entry. Prior to this time, the vehicle will not be in line-of-sight, is blacked out from re-entry heat, or is out of range/reception because of distance.

4.10.2.1 Rationale

The system described in Ref. 166 uses basically the same system as the Apollo Command Module Communication and Instrumentation System.

4.10.2.2 Reference

166 Pages 3-109 to 3-113

Command Module Simulator, Communications
and Instrumentation System Specifications

4.10.3 UHF System

166 A UHF transponder gives the orbiter voice communication capability with the Ground Controlled Approach (GCA) of the airport for low visibility landings. The transponder has selectable channels that are preset prior to takeoff. This system has a maximum operational range of 50 miles. The orbiter antenna system is located in the three-wheel wells. The ground-based system uses an omni-directional antenna such as a corner reflector discone or top-hat antenna.

4.10.3.1 Rationale

The system described in Ref. 166 uses basically the same system as the Apollo Command Module Communication and Instrumentation System.

4.10.3.2 Reference

166 Pages 3-109 to 3-113

4.10.4 Audio Control Center

166 Each crew station has audio control equipment to accomplish audio
1 signal amplification and switching to select intercommunication between
the crew station, to select communication RF links, to select recording
equipment, to relay audio signals received. Each station has provisions
for connecting a second headset for emergency operations. Automatic
volume control is provided to balance the output for strong/weak signals.
Standard Push-to-Talk (PTT) and voice-operated relay (VOX) mike circuits
will actuate the transmitters to a "Transmit" condition.

166 Two communication panels provide redundant controls over the power
1 system-communication system interface. Access to the channel selector
controls is provided between the pilot-copilot positions. Access to
the crypto secure terminals is provided at the crew station aft positions.

4.10.4.1 Rationale

The system described in Ref. 166 uses basically the same system as the
Apollo Command Module Communication and Instrumentation System.

4.10.5 TACAN

116 TACAN is a phase measuring high speed rotating ground based beacon providing
4 highly accurate azimuth determination in combination with a ground based
21 transponder providing distance measuring. TACAN covers the frequency range
1 of 962 megahertz to 1213 megahertz, with 1 megahertz channel spacing. Bearing
information (aircraft to station) is accomplished by a phase comparison of
two equal frequencies. One frequency is fixed in phase aligned to true north
while the other is rotated. The phase difference at the aircraft position
establishes the relative bearing to the station. The Distance Measuring
Equipment (DME) has two modes of operation. The airborne interrogator pulses
at a relatively high frequency in search mode. Once lock-on is achieved with
the ground based transponder, the pulse repetition frequency is reduced.
Identification messages are transmitted each 30 seconds in morse. The ability
to communicate between the aircraft and the ground station is a function of
line-of-sight range and altitude. Accuracy of bearing information is within
 $\pm 1.5^\circ$. Accuracy of the DME is ± 0.2 percent of the distance measured. A
"cone of confusion" exists directly over the station for bearing information
but does not exist for the DME. The system will provide range and bearing
information to the Guidance, Navigation, and Control subsystem and to the
Display and Control subsystem. The TACAN will operate in the L-Band of the
radio frequency spectrum. A self test feature will provide a visual indica-
tion of "GO/NO-GO" status of the functional units. An aural identification
signal will be provided to the intercom equipment. Controls will be provided
to allow the crew to select the desired channel. All modes will be simulated
including multiple location of ground stations and search prior to lock-on.
Radiation patterns of the ground station will be simulated including the
radio horizon, maximum range, and cone of confusion. Accuracy bounds will

approximate those of the real-world equipment with resolution and update rates which will cause no noticeable discontinuities in either the displays or the on-board computer.

For in-orbit use, the TACAN system will be employed as a range and range-rate system. This will be accomplished by installing a TACAN ground transponder in the vehicle to be tracked or to which rendezvous is being made. This usage of TACAN will be very similar to its current use in air-to-air refueling operations.

166 pp. 3-109 to 3-113

4.10.6 Radar Altimeter

166 The radar altimeter system measures altitude relative to the local ground. The system operates in the C-Band of the radio frequency spectrum and is used in the range 0 to (TBD) feet. Outputs of the system are to the Guidance, Navigation, and Control computer and to the Control and Display Subsystem. A model of the ground terrain is required with highly accurate models of the prime landing sites nominal approaches. Off-nominal and secondary landing sites will be approximations requiring lower accuracy.

4.10.6.1 Rationale

Not required.

REP. NO.

4.10.7 ATC Transponder

The Air Traffic Control (ATC) transponder will be used to identify and track the orbiter during post-entry phases of the mission. The ground control station will transmit interrogation signals to the transponder in the orbiter which will respond in the L-Band with altitude and identification signals to the ground station. The transponder will be compatible with continental United States and international operations requirements. The L-Band antenna switch will control interface of the ATC transponder and TACAN with one of the two antennas. Signal attenuation presents a non-linear altitude versus range limitation in the L-Band. The ATC transponder altitude limitation should be programmed as a variable similar to the TACAN coverage. The radio horizon can be represented as:

$$r = r_0 \frac{\cos \alpha}{\cos (\alpha + \theta)}$$

r = radio horizon for a given Nav-aid measured from the earth's center.

r_0 = earth radius

α = elevation angle constraints (default value of zero)

θ = central angle between Nav-aid position and shuttle positions

$$\theta = \sin^{-1}(\bar{U}_R \text{ shuttle} \times \bar{U}_R \text{ Nav-Aid})$$

The test for visibility with respect to the radio horizon between shuttle and the Nav-aid is:

$r < r \text{ shuttle} \rightarrow \text{visible}$

$r > r \text{ shuttle} \rightarrow \text{not visible}$

The index of refraction in the lower atmosphere (to about 10 miles) decreases with height. Radio frequencies above 200 mhz. follow curved paths slightly bent toward the earth. By replacing the real earth radius with one of $4/3$ the true radius (5284 miles) the coverage can be considered straight lines.

REV.

BINGHAMTON, NEW YORK

REP. NO.

4.10.8 Instrument Landing System (ILS)

4 . The ILS system is a fixed directional beacon with a directional (localizer)
21 and elevation (glideslope) beam about a reference path in the plane of the
166 runway centerline. The DME is used in conjunction with ILS to provide range
to go information. The localizer coverage is approximately $\pm 35^\circ$ at 25 N.M.
ground range and $\pm 360^\circ$ for 10 N.M. ground range. The glideslope coverage
is $\pm 10^\circ$. Elevation coverage is approximately 20° for both localizer and
glideslope. The coverage range is 25 N.M. slant range for the localizer
and 10 N.M. slant range for the glideslope. The beam is considered linear
in a $\pm 4^\circ$ range for the localizer and $\pm 0.8^\circ$ range for the glideslope with
respect to the reference path. The display is a "fly-to" error presentation.
The localizer has a single null while the glideslope contains multiple nulls.
The simulation will provide two glide slopes with each independently adjust-
able. The steep slope will be typically 13° centered with ground intercept
at 5000 ft. from the end of the runway and the shallow will be typically 3°
centered with the ground intercept at 1000 ft. from the end of the runway.
Both the localizer and glide slope will be independently adjustable and
located at the landing site. False nulls in the glide slope will be simulated.
The ILS system will be used for horizontal flight test only.

4.10.9 GCA Radar

166 Each major airport in the continental U.S. is equipped with a Ground Control Approach (GCA) radar system. This radar is a skin-track pulse system which provides cross track, distance from touchdown, and height above glidepath to the GCA operator. The operator, using the UHF communication system, can direct aircraft down through overcast conditions to a Category II landing. GCA radar will control the final approach from 4 to 7 N miles to touchdown.

4.10.9.1 Rationale

All commercial and military aircraft use GCA for Cat. II landing in overcast conditions.

4.10.9.2 References

Instrument Flying Handbook, AC 61-27A,

Administration

166 Pages 3-109 to 3-113

4.10.10 Air Route Surveillance Radar

166 The FAA within continental U.S. has a series of overlapping radar systems that provides a map-like presentation of all aircraft within a defined zone. The radar system is composed of many skin-tracking radar installations or sectors. Each installation has a maximum range of 200 miles or less dependent on aircraft altitude (line of sight). These many installations are united into one control center for all traffic control. By means of electronically generated range marks and azimuth indicators, the controller can locate each radar target with respect to the radar installation, or can locate one radar target with respect to another. From direct reading counters on the controller's display panel, the controller determines the bearing and range of one aircraft target with respect to another. A video presentation not only gives him aircraft position, but their relation to other runways, navigation aids, and hazardous ground points in the area.

4.10.10.1 Rationale

FAA will control all air traffic into commercial or military air terminals.

REP. NO.

4.10.11 Precision Ranging System (PRS)

158 The PRS system may be used by the shuttle from post-blankout at an
166 altitude of approximately 140,000 ft. to touchdown. The system consists
of a shuttle based interrogator and multiple transponder beacons located
at ground stations. As many as 10 PRS beacons could be interrogated by
the shuttle during the approach and landing sequence.

158 This navigation system is based on using an inertial measurement unit
166 (IMU) and a precision ranging system (PRS) as the primary sensors. The
IMU measures changes in vehicle velocity due to non-gravitational forces
on the vehicle. The PRS provides measurements of range and range rate
from the vehicle to ground transponders. Range measurements are made
twice per second using a phase comparison of frequencies. Range rate is
measured at the same time using Doppler Shift. This system of touchdown
has an accuracy of approximately 12 ft. altitude, 24 ft. crosstrack, 13 ft.
down range, .6 ft./sec. altitude, 1.2 ft./sec. crosstrack, .9 ft./sec.
down range.

4.10.11.1 Rationale

Not required.

4.10.11.2 References

158 All of the Document.

166 Pages 3-109 to 3-113

4.10.12 Microwave Landing System (MLS)

157 The MLS will be used during approach and landing for range, azimuth, and elevation angle information with respect to the runway. The MLS is a sophisticated landing NavAid being developed jointly by DOD, DOT, and NASA and is scheduled for limited production in 1976. The system uses the Ku band. The airborne antennas will provide azimuth coverage of ± 45 degrees, and elevation coverage of ± 30 degrees referenced to the Orbiter longitudinal axis. Four transmitter antennae will be used in the MLS. The range, azimuth, and long range elevation will operate in the C band while the flare elevation antenna will operate in the Ku band. The C band transmits data in a 20 N.M. range by 60° azimuth by 20° elevation angle. The Ku band flare antenna transmits elevation data in a 2 N.M. range by 8° azimuth by 8° elevation.

Accuracy of the system is estimated at 1 ft. altitude, 7 ft. in cross-track, .5 ft./sec. altitude rate, and .6 ft./sec. in crosstrack. These estimates are based on using a measurement update every 4 seconds.

REP. NO.

REF. KEY 4.11 Operational Instrumentation

166 The orbiter vehicle is equipped with two types of instrumentation dependent on the mission objectives. Development Flight Instrumentation (DFI) will provide the required data for in-flight and post-flight evaluation for the initial flights. Once the developmental flights have been completed, the instrumentation system will be converted to the Operational Flight Instrumentation (OFI).

166 The data collected from sensors is conditioned for display and monitoring on-board the vehicle, provided to computers for CRT display, recorded, telemetered to the ground, and also provided to group support before and after launch.

166 Table 4.11-1 shows the division of measurements per system for both OFI and DFI usage. Figure 4.11-1 shows the general concept of the data interface requirements in both flight phases. Table 4.11-2 gives the OFI and DFI sample rate.

4.11.1 Recorders

166 There are five categories of recorders on-board the vehicle. These are the maintenance recorder, a short-burst (5 min.) loop recorder, a wide-band data recorder, a crash (FAA) recorder, and a voice playback unit. The recorder functions are straightforward with the following special features. The playback of the maintenance recorder is not required for flight crew training. This recorder is played back following a mission landing. The loop recorder is a cued recorder which is controlled manually or automatically by GN&C or C&W systems. This recorder will be used by the crew in problem analysis during flight. There is no requirement for the wide-band recorder. The crash recorder is not required for simulation. This

166 is outside of crew training requirements. The voice recorder is required. The system should provide near real world simulation interfacing with all active voice or T/M (simulated) lines.

4.11.2 Sensors and Signal Conditioning

166 The types of signal sensors are indicated in Table 4.11-1 Table 4.11-2 indicates the sample rate for PCM inputs. The data rate (maximum) is 256 kbs and is programmable in 4 formats. Inputs to the signal conditioning units is 0-5 volt and 0-20 millivolt full scale. Dedicated spacecraft instruments use dual 0-5 volt inputs. Total error for instrumentation is distributed as follows:

Sensors	3.0%
Signal Conditioners	1.0%
Noise	0.6%
PCM	0.4%

4.11.3 Ground Support Equipment PCM Links

66 There is no requirement for simulation of preflight GSE activity occurring prior to the crew boarding the vehicle. GSE maintenance/monitoring must be complete prior to that time. By the same ground rule, there is no requirement for preventive maintenance simulation for main engine performance evaluation.

4.11.4 Caution and Warning System

66 A Instrumentation sensors are provided for 200 major critical flight parameters. Parallel systems are provided to display the problem to the crew and to provide input data to the GNC computer where required.

TABLE 4.11-2 OFI and DFI Rates

A Redundant caution and warning indicator display light units are provided in the orbiter crew station. Klaxon horns, intercom speakers, and headset tone signals provide audio cues for alert. The audio tones are coded by frequency and pulse duration for easy recognition by the crew.

A The tone signals used from the Skylab Mission will also be used for the shuttle. A siren signal will indicate Fire Emergency. A 1000 cps tone modulated by a square wave of 1.25 cps will indicate Warning, and a continuous 1000 cps tone will indicate Caution conditions. A rapid loss of pressure (Emergency) will be represented by an interrupted buzzer signal. Stall (Emergency) will be represented by an intermittent horn while gear down and locked (coupled to a low power level) will be represented by a continuous horn. A single pulse will represent a crew alert for incoming crypto message.

A Other crew alert tones will be present when crossing the Tacan Outer Marker
B (400 Hz modulated once every two seconds), Middle Marker (1300 Hz with alternate dots and dashes), and the Boundary Marker (3000 Hz dots @ two per second).

A Redundant sensors provide input parameters to two C/W units. Each unit is equipped with redundant power supplies. Caution, Warning, Emergency, and Crew Alerts provide inputs to set the Master Alarm units. Master Alarm is visually indicated on a telelight switch. Depress the switch with an alarm on will silence the alarm. Reoccurrence of the condition will re-trigger the alarm circuit.

A The C/W system provides a means of disabling malfunctioning sensors through the use of inhibit switches. In the Inhibit position, the sensor input is not fed into the C/W system.

A. A Memory feature provides the crew with the capability to recall an alert signal that triggered the C/W circuit. Memory may be cleared by depressing the CLEAR switch.

4.11.5 Rationale

A. The Caution and Warning System will be similar in logic and performance to the Skylab C&W System. Refer to Saturn Workshop Systems Handbook, DC-5 July 11, 1972.

B. It is assumed that the C/W tones used for shuttle will be very similar to existing commercial aircraft warnings.

166 Pages 3-111- 3-113

4.12 Environmental Control and Life Support Subsystem

166

The environmental control and life support subsystem (ECLSS) provides atmospheric revitalization, life support, and thermal control (Figure 4.12-1) with subsystem assemblies as shown in Figure 4.12-2. The atmospheric revitalization subsystem furnishes a shirt-sleeve environment for the four-man crew for a seven-day mission and a 96-hour contingency by controlling CO₂, humidity, odor, pressure, oxygen/nitrogen cabin atmosphere, and cabin temperature. Six additional crewmen can be accommodated for a short duration. Expendable capacity is supplied for 42 man-days. The mission can be extended up to 30 days by adding expendables in the payload. The life support subsystems provide for food and waste management, fire control, and extravehicular/intravehicular activities. The thermal control subsystem affords active thermal control for avionics and mechanical equipment, dissipates the heat from the crew compartment, and provides for water management. The fluid and energy interchange functions performed by the ECLSS and interfacing vehicle systems are shown in Figure 4.12-3.

4.12.1 Atmospheric Revitalization

4.12.1.1 Pressure Control

166

A two-gas atmosphere, oxygen/nitrogen at a nominal pressure of 14.7 psia, is used to reduce fire hazard potential and to provide compatibility with payload module experiments and proposed space station environments. The oxygen stored in a supercritical state, is acquired from the electrical power generation reactant storage system. The nitrogen is stored at 3,000 psi in two carbon filament storage tanks. Normal gas usage and losses as a result of venting and seal leakage are shown in Table 4.12-1. The subsystem includes provisions for a 10-minute emergency

REP. NO.

166 high oxygen gas flow of 55 pounds per hour. An alarm to the Caution and Warning system is initiated after a time delay if the oxygen flow exceeds three pounds per hour. Additional quantities of oxygen and nitrogen, stored at 3,000 psia, are connected to the primary system for one cabin repressurization at a flow of 150 pounds per hour, offering the four-man crew a 96-hour contingency, or seven airlock operations.

166 Gas flow into the cabin is controlled by the cabin pressure regulator, which sets the N_2 flow based upon the cabin O_2 partial pressure of 3.0 to 3.2 psia. The partial pressure control opens when the O_2 partial pressure is 3.2 psia or above, permitting only nitrogen to flow into the cabin. Nitrogen will continue to flow until a total cabin pressure of 14.7 psia is reached. When the O_2 partial pressure drops to 3.0 psia, the partial pressure control closes to permit only O_2 to flow into the cabin.

166 Cabin overboard pressure relief valves are located in the cabin area and in the avionics bays. A differential pressure relief valve is provided between the cabin and each avionics bay to maintain the avionics bay pressure at approximately 0.4 psi below cabin pressure. A total of two pounds per day for three avionics bays is bled overboard to maintain bay pressure below cabin pressure. During times of airlock repressurization or emergency fire extinguishing operation in the avionics bays, the pressure in the bays may be as much as 0.6 psi higher than in the crew cabin. Gas flow into the crew cabin is prevented by check valves in the differential pressure regulator and the sealed avionics bay door design.

166 Portable face masks and emergency oxygen assemblies are designed to furnish a ten-minute supply of oxygen to each crew member and passenger. Provisions are also available to connect these assemblies to the oxygen system.

4.12.1.2 Cabin Humidity, CO₂, Odor and Temperature Control

166

A condensing heat exchanger for humidity control and cabin temperature, lithium hydroxide for controlling CO₂ level, and activated charcoal for controlling air odors are used because of their proven performance in the CSM environmental control system. The system is comprised of three two-speed fans, two lithium hydroxide (LiOH) canisters, a condensing heat exchanger, and an air bypass valve. Air volume through the system is governed by the cabin temperature control range of 65° to 80° F, selectable to ±2° F. The fans can operate at maximum flow for high heat load flight conditions or at reduced flow for station keeping operations. Figure 4.12-2 shows system performance for the four-man design condition. With 10 men and maximum heat load, the cabin temperature will approach 75° F. A payload heat exchanger is included in the cargo bay with a capacity of 5,200 Btu/hr. Additional heat dissipation from operation of the mission specialists station of 1,000 Btu/hr is absorbed by the cabin atmosphere heat exchanger plus 2,000 Btu/hr from equipment in the avionics bay. The LiOH canisters are installed in two parallel flow paths. Each canister will be installed in the system for 24 hours, based on a seven-day, four-man mission. The canisters will be replaced more frequently when 10 people are carried. Each canister also contains activated charcoal for trace contaminate control. Low toxicity outgassing materials in the cabin design are used to reduce contaminant problems. The condensing heat exchanger removes the cabin sensible and latent heat load. Water is removed from the heat exchanger by water separators and transferred to the waste water system for storage. A replaceable, disposable filter is

166 provided at the inlet to the fans for particulate control. A coldwall configuration has coolant flow passages attached to the cabin wall to control the wall temperature to prevent condensation in orbit and excessive cabin temperature during and after entry. All surfaces normally in contact with the crew will not exceed 113⁰ F.

4.12.2 Life Support

4.12.2.1 Food Management

166 The food management system consists of a galley area offering a food preparation center for food and equipment storage, hot and cold water dispensers, and waste storage. The GFE food concept assumed includes the use of protective canisters for storing food serving cans, dehydratables, and drink packages. Foods are categorized as thermostabilized, rehydratables, wafers, and beverages. Some foods are ready to eat, and others require chilling or heating in the galley oven. Rehydratables are prepared by injecting hot or cold water and mixing. A freezer can be installed in the galley for extended missions by moving stored food to other areas of the vehicle.

166 Simulation of the food management system outputs/inputs such as electrical loads, water usage, heat absorbtion/rejection is required.

4.12.2.2 Waste Management

166 The waste management subsystem accumulates solid waste and collects, transfers, and stores liquid wastes. Urine and urinal rinse are collected, separated from air, and stored for return to earth. The commode uses a slinger and vacuum drive concept for feces storage. The bactericide for bacteria control in the urine is stored in a bladder tank. Air flow

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-188

REV.

BINGHAMTON, NEW YORK

REP. NO.

leaving the urinal and commode passes through bacteria filters and charcoal canisters before reentering the cabin. This process provides odor and bacteria control to the entire vehicle.

166 Simulation of the electrical loads, heat rejection/absorbtion, and water usage is required.

4.12.2.3 Personal Hygiene

166 For the seven-day mission, personal hygiene provisions will be a GFE kit stored in the waste management compartment. Space is available above the waste management system for installation of a hand wash basin and a more extensive personal hygiene system for extended missions.

166 Simulation of the electrical loads, heat rejection/absorbtion, and water usage is required.

4.12.2.4 Fire Detection and Extinguishing

166 The fire control subsystem is located in the avionics bay and flight deck. The detection system consists of a light source, a gas filter interferometer, and a detection and localization logic similar to the Skylab system. Several gases can be monitored at once, and it can localize incipient fires or toxic elements. This system simultaneously serves as a fire detector and as a contaminant detector. It detects a problem before it represents a hazard to the crew.

166 Different types of fire extinguishing systems are provided for the three avionics bays and for the crew compartment. The avionics bays are isolated and differential pressure regulators normally maintain the bays 0.4 psig below cabin pressure. If a fire occurs in the avionics bay, a high N₂ purge flow is introduced to reduce the O₂ partial pressure below 1.0 psia, extinguishing the fire in less than one minute. Operation of avionics

166 bay fans will effectively mix all the gases to give the minimum reaction time. The high gas flow into the bay will be vented overboard by the individual bay vent valve. The vent valve will operate between 14.7 to 15.0 psia.

166 The crew compartment will use four hand-operated portable, foam fire extinguishers. Each extinguisher is identical to that used in the CSM.

4.12.2.5 Extravehicular/Intravehicular Service and Recharge Station and Airlock

166 Two portable life support systems (PLSS) service stations are provided for two-man operations. Each station has provisions for water (for recharging the suit sublimator cooling system), oxygen and battery recharge, and oxygen open-loop prebreathing. To recharge the PLSS, a pump boosts the 900-psia oxygen supply to the 1500-psia PLSS oxygen storage tanks. The airlock will normally be repressurized from the cabin gas in less than five minutes by opening the airlock pressurization valve. Expendables are supplied for seven airlock repressurizations and PLSS recharges.

4.12.3 Thermal Control

4.12.3.1 Coolant Loops

166 Figure 4-12.2 presents the coolant loops and design performance data. Water is used to cool the cabin because it is nontoxic. Freon 21 cools the unpressurized areas because it has a low freezing point and viscosity. Thermal integration is accomplished in the Freon loop through interfaces with the environmental control subsystem, fuel cells, and

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-190

REV.

BINGHAMTON, NEW YORK

REP. NO.

hydraulic systems. Up to 15,000 Btu/hr of Freon system heat transfers to the hydraulic fluid to maintain its temperature. Electrical heaters provide thermal control of other passive systems in space. Refer to Figure 4,12-3.

166

Thermal control of the three avionics compartments (located in the crew compartment) is accomplished by pinfin coldplates and by air cooling systems of one of two parallel fans operating with a heat exchanger in each bay. The CSM-developed coldplates will be improved in durability by increasing the faceplate material thickness to reduce potential damage during normal maintenance procedures.

4.12.3.2 Heat Sinks

166

Space radiators are the primary heat sink and can reject the maximum heat load without attitude constraints during all space operations. The water sublimator is the normal heat sink for boost and before and during reentry to 100,000 feet altitude, with system thermal lag absorbing heat between that altitude and the cruise condition. During atmospheric cruise (below 30,000 feet), vapor-compression cycle refrigeration systems reject the heat to ram air-cooled heat exchangers. Heat is rejected during ground operations through GSE heat exchangers or the vapor-cycled systems. The radiator is a two-sided, deployable radiator consisting of eight modular panels stowable in the cargo bay and enclosing the cargo space as a door. The radiator is in turn provided with a thermal protection cover or outer door during ascent, reentry, and recover conditions. The panels are constructed from aluminum, and the top panels are thermally isolated from the bottom panels. Figure 4.12-4 shows one side open,

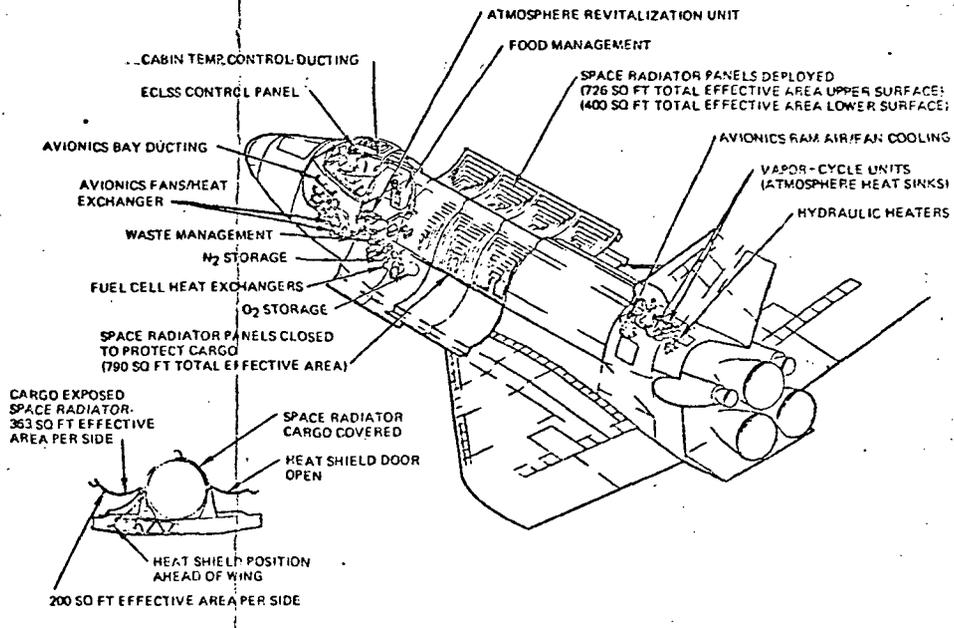

FIGURE 4.12-4
RADIATOR CONFIGURATION

exposing the cargo bay, and the other closed, protecting the cargo. In the open position the radiator has 726 square feet of effective area on the bottom side. The radiator is most efficient when in the deployed position, for heat can be rejected from both sides without supplemental cooling for all orbital mission phases and without attitude constraints.

166

When the radiator is in the stowed position, the effective radiator area is 790 square feet and supplemental cooling will be required, using excess fuel cell water in the sublimator for the worst-case mission heat load and radiator attitude. The radiator coating has a solar absorptivity of 0.2 and an infrared emissivity of 0.92.

4.12.3.3 Water Management

166

The water management system stores, distributes, and disposes of potable water and collects and stores waste water. Potable water is stored in two tanks, each having a capacity of 100 pounds. It is supplied to the galley at temperatures of 150° and 45° f. When the potable storage tanks are fully charged, the system pressure will rise to 20 psi above cabin pressure. With continued fuel cell flow, the tanks will become full and normal disposal is accomplished by the water sublimator. For emergency, the water will be dumped overboard through two heated nozzles. Bacteria are controlled by processing potable water through silver ion generators. In the event the water from one of the fuel cells should become contaminated, the water can be dumped directly overboard to bypass the potable system. Waste water condensate from the humidity control heat exchanger is stored in three tanks, each of 100 pounds capacity and normal operating pressure of 14.7 psia.

4.12.4 Fault Detection Management

166

The fault detection subsystem allows continuous monitoring of critical paths of the subsystems during flight and minimizes ground checkout procedures. The instrumentation will permit determination of redundant paths in flight and status of each line replaceable unit within the subsystems during ground checkout. Controls will isolate units or groups of units when an out-of-tolerance condition is detected. Notification of out-of-tolerance conditions will activate Caution and Warning system alarms and displays.

4.12.5 Ground and Launch Operations

166

Postlanding cooling of the avionics equipment and cabin will be supplied by the ECLSS. System heat will be transferred to the GSE heat exchanger, which will be activated by connecting the ground coolant lines and electric power to the service connections. With ground power available to the vehicle, the vapor-cycle system will serve as a standby cooling system if the GSE coolant system is not operating or if it is not available. Prelaunch cooling will be provided by the GSE system through the upper swing arm to T-25. Subsequent to T-25 the vapor-cycle system will provide system cooling.

4.12.6 Cabin Noise Level

166

Special provisions have been incorporated in the design of the cabin systems to control noise level. The avionics bay doors and the noise-producing avionics equipment, such as the inverters and fans, are sound insulated. The cabin fan and water pump assemblies have been remotely

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-194

REV.

BINGHAMTON, NEW YORK

REP. NO.

166 located under the lower compartment floor away from living areas. The pump and fan incorporate local sound insulation and the duct system design contains sound absorbing baffles. Audio cues for these devices are not required.

4.12.7 Corrosion and Contamination Control

166 A program for corrosion and particulate contamination control will be employed for all ECLSS fluid systems. Stainless steel tubing and components will be used in the water system loop and the potable and waste water system to reduce corrosion. The Freon system will be made of aluminum.

4.12.8 Rationale

4.13 Payload Accommodation System

4.13.1 Structural/Mechanical Interfaces

4.13.1.1 General Structural Attachment

The payload attachment mechanism Figure 4.13.1.1-1 consists of easily moved attachment fittings that can be placed at 14 locations along the length of the bay. This design provides flexibility for payload changes between missions. Alignment of the payloads within 0.5 degrees of the orbiter's reference system is maintained by this system.

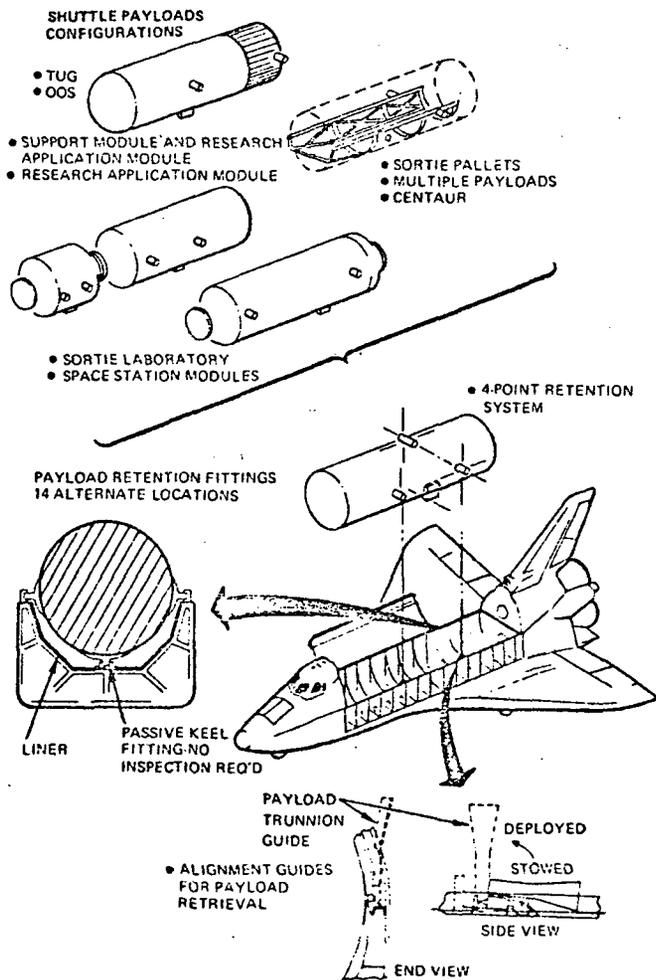

FIGURE 4.13.1.1-1 PAYLOAD RETENTION

4.13.1.2 Payload Deployment/Retrieval

166

Deployment and retrieval of payloads is provided by the general purpose remote manipulator system (RMS) illustrated in FIGURE 4.13.1.2-1. The system is adaptable for various payloads to perform multiple payload deployment, retrieval on a single orbit mission, and the docking/retrieval of light mass payloads.

A payload is retrieved in three basic steps: (1) transmission of commands for stabilization, orientation for manipulator attachment, retracting solar arrays, antenna, etc.; (2) manipulator engagement, translation, and securing in the payload bay; and (3) connection of payload utilities, (e.g., caution/warning, power, data, and fluid/gas venting when required)..

These utilities are connected without EVA by the standard interface connections provided at the docking port and the payload bay access hatch.

For multiple payloads having propulsive stages, actuation of interface connections remotely controlled from the payload handling station will be provided by kits.

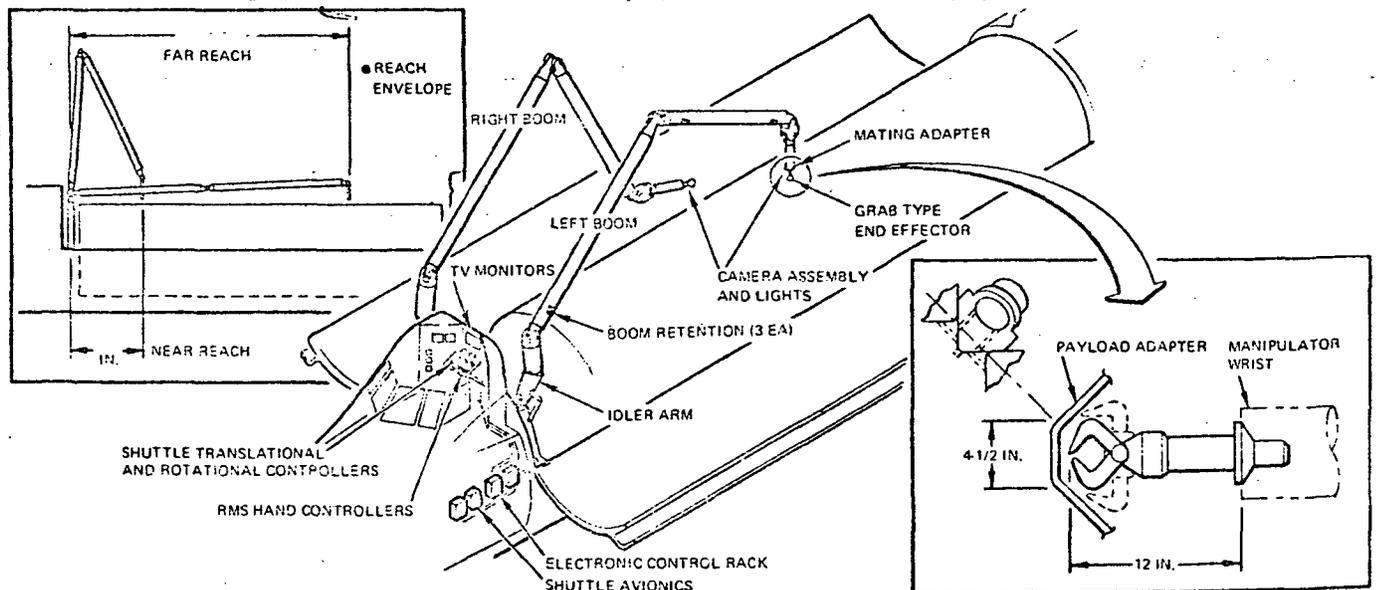

FIGURE 4.13.1.2-1

Manipulator Arms Adaptable to Multiple Payload Deployment and Retrieval

DATE 10/20/72

THE SINGER COMPANY
SIMULATION PRODUCTS DIVISION

PAGE NO. 4-197

REV.

BINGHAMTON, NEW YORK

REP. NO.

1, 2,
3 Shuttle orbital payload deployment and retrieval will be
accomplished by two remotely controlled manipulator arms. The two identical
50 foot long arms each possess shoulder, elbow, and wrist joints. The
shoulder, located at the attachment point of the arm to the orbiter,
possesses two rotational joints (pitch and yaw). The elbow, connected
4 to the shoulder by a 23½ foot long rigid tubular beam, possesses two
rotational joints (roll and yaw). The wrist, connected to the elbow by
a 23½ foot long beam "forearm," possesses three rotational joints (yaw,
pitch, and roll). The terminal device is connected to the wrist by a
3 foot long beam. The standard terminal device will be a hand-type
5 grasping mechanism, but special devices may be attached for particular
6 mission. Each arm will weigh about 1000 pounds. Each arm is attached
7 to the fuselage near the forward bulkhead of the payload bay. During
8 launch and entry, the arms are stowed along the top of the payload bay.
Each arm is extended, and attached at seven points to one of the payload
1 doors, near the mating line between the doors. Each arm is attached to
a different door. When stowed, each arm occupies a cylindrical envelope.
50 feet in length by 8 inches in diameter. The attachments must be
released before opening the payload doors, and, the arms are ordinarily
locked in them shortly after closing the doors. After the payload doors
1 are opened, an arm deployment mechanism is actuated which raises the
shoulders out of the payload bay and opens a 20 foot separation distance
between them. The deployment mechanism must be retracted in order to

2, 9, close the doors. Electric motors and gear reducers located at each of
10
11 the seven rotational joints, plus the terminal device, provide torque
1 to move the arm and terminal device. The selected motors have a maximum
shaft power of 28 watts. Each joint uses two motors. If one motor
1 fails, the joint can still be moved with full speed and torque capability.
Each rotational joint has a brake, which is locked up whenever power
to that joint is off (not powered up, or power failure). Each rotational
joint also contains a potentiometer to measure angular position and a
tachometer to measure angular rate.

Control of the manipulator arm may be either automatic or
13 manual. The on-board computer will be able to execute certain basic
14 arm maneuvers itself. Manual control will be effected through a force-
reflecting system. To provide both the coarse control helpful for
positioning the arm in the approximate attitude desired, and the fine
13 control necessary for delicate maneuvers, a variable-gain system was
chosen. For coarse control, angles transcribed by the manipulator arm
and the controller will be equal. For fine control, angles transcribed
by the controller will be 18 times as large as those transcribed by the
manipulator arm. Interface between the controller and the manipulator
arm will take place through the on-board computer, which will calculate
the necessary transformations.

8 A checkout system is provided to verify the condition of
arm motors, tachometers, and potentiometers, before power is applied
to the system. Upon selecting the desired device to be evaluated, a
predetermined voltage is applied to it. The actual voltage accepted and
returned is then available for display. Ordinarily, no motion will

result, since brakes are locked when the system is powered down. In case of certain failures, the checkout system may be used to move a joint independently. A switch will be provided to release the brake on a joint, thereby moving the joint when the checkout system applies electrical power.

Sensory inputs to the crewman controlling the manipulator arm are provided by the force-reflecting controller, a window through which the operator can see into the payload bay, and three TV monitors. Four TV cameras are mounted in the payload bay - the operator chooses which three he wishes to monitor. Two floodlights are attached to each camera. One camera is mounted near the end of each arm (after wrist yaw and pitch joints, before wrist roll). Another TV camera is mounted at the base between the two manipulator arms. This camera can be used to automatically track the terminal device. Iris and focus control is provided for all cameras, as is a power switch. Both the fore and aft payload bay cameras can be zoomed as well. Both the aft and forward (when in manual mode - not automatic terminal device track) can be panned and tilted by the operator. Brightness, contrast, and test controls are provided on the crew station monitors. Resolution of at least 300 scan lines is provided by the TV system.

In case of certain arm failures which would prevent closing of the payload doors, an explosive device will separate the failed manipulator arm from the vehicle, allowing the orbiter to be flown away from the derelict arm.

Efficient manipulator arm design requires certain limitations on arm dynamics. Rotational joint design requires limitations on angular

travel at each joint. Each joint is also torque limited to prevent damage to the manipulator arm. Travel limits and torque capability (based on 10 pounds maximum tip force) are:

		Angular Travel	Torque (ft-lb)
Shoulder	Pitch	$\pm 200^{\circ}$	500
	yaw	$\pm 130^{\circ}$	500
Elbow	roll	$\pm 200^{\circ}$	350
	yaw	$\pm 155^{\circ}$	350
Wrist	yaw	$\pm 120^{\circ}$	150
	pitch	$\pm 120^{\circ}$	150
	roll	$\pm 200^{\circ}$	65

Travel limits are enforced by mechanical stops and/or microswitches. Joints and the control system are designed so that maximum tip position error is ± 2 inches and maximum tip velocity error is $\pm .05$ ft/sec. (excluding structural deflection under load). This requires an angular position accuracy of $\pm .113^{\circ}$ and an angular rate accuracy of $\pm .033 \frac{\text{deg}}{\text{sec}}$ at each joint. This places requirements on the precision and frequency of arm control inputs received from the on-board computer. Angular position information will be exchanged between the computer and the arms in 13 bits, every 20 to 40 milliseconds.

Structural deflection at maximum (10 pounds) tip force will not exceed 1 inch.

The arm electric torque motors, controller torque motors, and TV camera operate off 28 vdc. Floodlights will operate off 110 vac. The largest electrical load is expected during payload unload and deploy. An average power demand of 1.008 KW is anticipated for a period of ten minutes during this process.

4.13.1.3 Payload Control/Display Panels

- 166 Payload services such as electrical power, fluid and gases filling, venting, and draining, etc., are provided by replacing blank panels with payload-unique panel kits. These panels will be located adjacent to orbiter service panels of a similar nature to aid mission preparations and operations.

4.13.2 Propulsive Fluid System Interfaces

- 166 For propulsive stages using LH₂ and LO₂ propellants, a fill, drain, dump and vent system interfacing with the MPS will furnish payload fuel requirements. Payload kits provide the interface connections from the payloads to the orbiter's plumbing.

Propulsive payloads that utilize storage propellants will have interface panels and connecting lines for propellant dump but are independent of the orbiter propulsion system lines.

4.13.3 Electrical/Instrumentation Interfaces

- 166 Standard connectors are provided for all hardwired electrical interfaces for payload power, monitoring, communications, navigational data, and caution/warning located in the payload bay, docking port, at the payload handling stations and the mission specialist station (MSS).

Payload electrical loads of 50 kwh of electrical energy from the orbiter's EPS is sufficient for the majority of payloads; Therefore, mission-to-mission changes to the base power system will not normally be required. For payloads requiring more energy, provisions have been incorporated to allow additional reactants and tankage to be installed in the payload box.

166 The baseline orbiter's time phased average power profile for a typical mission given in the EPS loading includes the specified payload requirement of 1000 watts average (1.5 kw peak) during all mission phases except the orbital operations phase where excess capability exists. This power is supplied to the payload bay and to the docking port in the form of regulated dc.

4.13.4 Payload Avionics Signal Interface

166 The baseline configuration accommodated the majority of payload and has sufficient flexibility that between-flight changes will be required only for infrequent special missions. This flexibility is provided by simple design extensions of the basic avionics subsystems, and simplifies crew procedures, flight preparations, and payload adaptation.

166 The orbiter communication system and the payload signal interface that is common to all payloads is shown in Figure 4.13.4-1. Except for the safety of flight signals (critical displays and safing discretes) which are routed to the forward flight station and the MSS, the individual selection, routing, and switching of payload signals is accomplished at the payload control panel of the MSS. Payload data communication flexibility is provided by multiple recorders, multiple transmission channels, general purpose alphanumeric displays, and alterable memory computers. The junction and switches shown are repeated for simultaneous accommodation of up to five payloads. Digital commands from ground stations are encoded, and a payload data interleaver combines payload data for inclusion with the normal 128 kilobits per second operational flight instrumentation OFI (Mode 1) transmission. When orbiter OFI is not transmitting (Mode 2), up to 256 kilobits per second payload digital data can be accommodated.

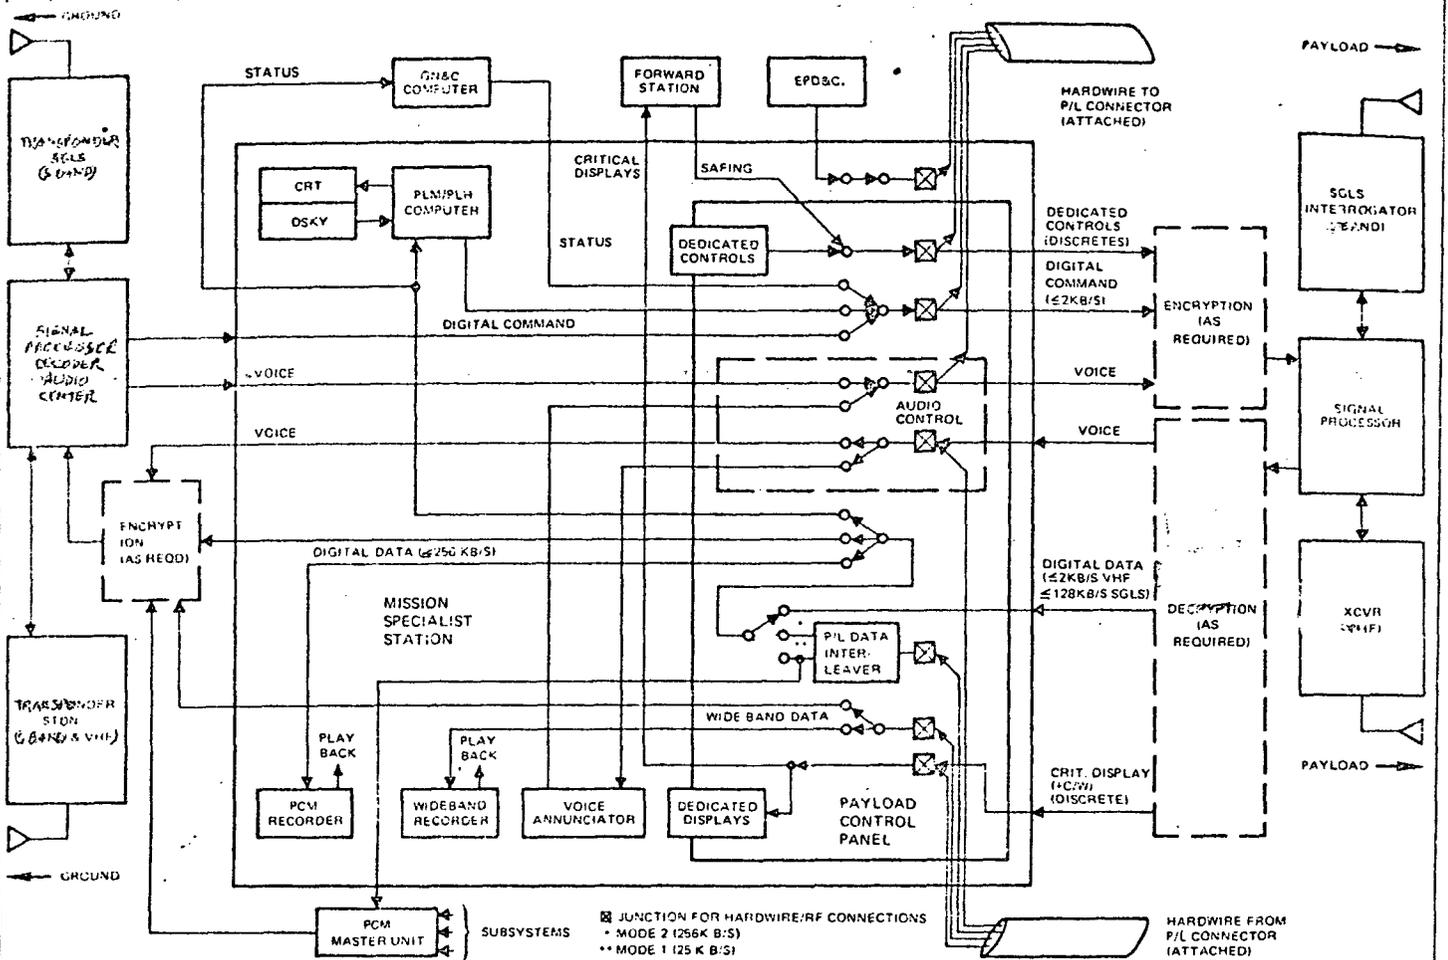

FIGURE 4.13.4-1 Payload Interface Signal Flow

166 The MSS provides for managing orbiter/payload interfaces and supporting operation of active payloads. The console houses most of the payload signal support equipment. The MSS caution and warning system annunciates payload critical malfunctions and is interconnected with the flight deck performance monitor during periods when the payload computer is not operating or the MSS is not manned.

The computational support system is required for status determination, control, limited onboard checkout, initialization, data display, and gross verification of proper data transmission for all payloads, and to support the manipulator arm control. The read-only tape memory enables the MDE to operate in either the payload signal processing or manipulator control mode, and provides for payload variation and program growth needs. Either of the payload data

Area	Payload Bay Environment
Acoustics	145-db interior overall sound pressure level
Pressure	Air vents control pressure to differential ± 2.0 psi
Humidity	Nitrogen purge by GSE - dew point - 65°F
Contamination:	
Ground	Payload bay liner, GSE purge
On-orbit:	
H ₂ O	Hold for 2 days and dump*
Waste	Hold for 7 days
Propellant	RCS thrusters do not impinge on payload bay
Material outgassing	Material selection and design criteria per NASA guidelines (QSSF Handbook 8060.1)

*Ice particles decay time due to drag and sublimation ≈ 3 hr

Table 4.13.5-1 Payload Bay Environment

Mission Phase	Low-Temperature Limit	Baseline Design	High-Temperature Limit	Baseline Design
Pre-launch	+40°F	GSE purge gas conditions bay to 75°F $\pm 10^\circ$ F for extreme 95% cold atmospheric temperatures (i.e., KSC: 44°F; WTR: 39°F)	+120°F	GSE purge gas conditions bay to 75°F $\pm 10^\circ$ F for extreme 95% hot atmospheric temperatures (i.e., KSC: 89°F; WTR: 88°F).
Launch	+40°F	Adiabatic payload bay wall will remain near pre-launch temperature	+150°F	Entry designs TPS; during launch, bay wall temperature rises a maximum of 18°F (i.e., 103°F maximum)
On-orbit (doors closed)	-100°F	Insulation and radiators maintain temperature above minimum.	+150°F	Extensive multidimensional analysis shows maximum temperatures less than 120°F
Entry and post landing	-100°F	Same as on-orbit minimum temperature	+200°F	Payload bay insulation designed to meet entry temperature requirements. Repressurization air cooled to less than 200°F by air vent heat sinks. Post-landing ground purge connection incorporated.

Table 4.13.5-2 Payload Bay Thermal Environment

166 recorders can be controlled at the payload control panel to play back data for ground transmission, subject to the bandwidth limitations of the ground RF link. In addition to the installed equipment which can accommodate most payloads, the MSS incorporates space and modular installation provisions for additional unique displays and controls provided with special payloads.

166 A three-way conference voice is available, as are dedicated digital data channels and a time-shared (with orbiter TV) wide band ground downlink. Also, payload access to orbiter antennas is provided for ground checkout of transmission functions.

4.13.5 Payload Environment Control

166 The orbiter incorporates a payload heat exchanger in the ECLSS Freon loop to provide a minimum cooling capability to the payload of 5200 Btu/hr. This exchanger is located near the payload bay service panel for convenient access for hookup during payload changes.

166 Provisions within the orbiter ECLSS distribution system permit the installation of payload-supplied fans and ducting for atmosphere revitalization of pressurized payload modules.

166 The characteristics of the environmental conditions in the payload bay are presented in TABLE 4.13.5-1. Thermal control provisions are presented in TABLE 4.13.5-2. In addition, the air vents provided for pressure control use heat sinks to cool incoming air during re-entry to 200°F.

4.13.6 Payload Bay Door Mechanisms

The door mechanism rotates axially while maintaining contour control between door segments. Each co-linked segment is independently hinged to the fuselage longeron at three places and contains three latches on the door centerline edge. Latches also are located at the forward and aft cargo bay bulkheads. The latches first grasp and pull the door edges together against thermal distortions and the peripheral door-to-fuselage seals holding the door shut. To avoid large latch reaches, each latch actuates upon contact with its mating pin via a proximity sensor signal. The latches have a zip-fastener action, initiating at the point of first contact; i.e., each latch will pull the next adjacent latch into contact. This will continue even if one latch on each segment is failed or tripped.

Each door segment is supported by either three idler hinges or two idler hinges and one powered hinge. There are four powered hinges on each side of the orbiter. The four powered hinges are driven by a common torque shaft with redundant electric motors at each end of the shaft. Intermediate stopping, provided through sequencing proximity switches, provides manipulator positioning and deployment and retrieval. The powered hinges are driven by

reversible jackscrew linear actuators. The reversible jackscrews are used so horizontal payload loading can be accomplished by simply disconnecting the gear boxes from the drive torque shaft, allowing the remaining system connected to the door to free-wheel as the doors are opened through use of GSE. Reliability is designed into the system through the use of independent drive systems at each end of the drive torque shaft. A drive system is automatically declutched from the torque shaft in the event of failures resulting in its loss.

The potentiometers and tachometers mounted on the manipulator joints can also be utilized as rendezvous and docking sensors. Normally, they provide angular position and velocity of each joint to the on-board computer to close the force-feedback control loop. The on-board computer can calculate the exact position and velocity of the terminal device at any time with this information. After payload capture by the manipulator arm, knowing the position and velocity of the terminal device fixes the position and velocity of the target vehicle.

4.13.8 Payload Dedicated RecordersA.
166

Two recorders are provided for payload wideband data and PCM data. The dedicated recorders and interface equipment will be installed as required as specialized units at the mission specialist station. Additional recorders may be transcribed or replaced during servicing of payloads. On board reduction of these records is not required; however, the recordings may be mounted and transmitted to the ground via the orbiter communication system.

4.13.8.1 Rationale

There may be specialized recorders on the payload.

4.13.9 Payload Handling Station

The payload handling station is equipped with five closed circuit television cameras (CCTV) and two monitors. In addition, the handler will have visual contact. Two CCTV cameras are located on the ends of the manipulator arms which insure a close image of the final mating target. Two TV cameras are mounted in the payload bay to provide remote viewing of the payload attachment, release, and stowage operations. The fifth TV camera is used to help the operator align the payload during manipulator controlled docking operations.

REF.
KEY4.1 6 Miscellaneous Systems

This section includes those subsystems which are not described elsewhere in this document.

4.1 6.1 Purge and Vent System

166 The orbiter requires a controlled venting and purging throughout the vehicle because of hazardous fluids and gases, thermal heat dissipation, and air frame delta pressure limitation.

166 The large quantities of on-board hazardous fluids and combustible gases dictate the use of an inert gas dilutant for purging airframe cavities. On the launch pad, prior to fueling, the vehicle undergoes an air purge furnished by GSE. When the vehicle is loaded, the airframe is then purged with GN₂. Internal to the vehicle, the compartments are isolated to avoid gas mixing and are provided with independent non-propulsive vent ports.

166 The vent ports are sized for maximum flow rate during the boost phase of flight. A two-position mechanically controlled non-propulsive vent port having lanyard-type pull out plugs will be used to give the two stage orifice control required.

166 Two feeders (top fuselage and bottom fuselage) are provided from the aft located GN₂ tanks for the purge system. This system will be manually controlled by the crew.

166 Pages 3-22

REF.
KEY4.16.2 Landing/Braking System

- 167 The orbiter vehicle is equipped with a conventional tricycle landing gear system. Each set of gears is a dual wheel having hydraulic retraction and hydraulic/free-fall extension. The two main gears and nose gear have the same material construction and components as conventional commercial aircraft. Each wheel has a folding drag brace, a gear activation system, up/down locks, and position indication system. The nose gear is equipped with a combination shimmy damper and steering system. Nose wheel limits are $\pm 30^\circ$ either side of center. Turning radius of the vehicle is 116 feet. The main gear has an anti-skid brake system with locked-wheel protection at touchdown. Brakes and nose gear steering are electrically control-hydraulic activators. Accumulators in the hydraulic system provide stored energy for towing and braking.
- 167 Emergency fail-safe free-fall capability is provided without hydraulic power.
- 167 The nose gear uses two 32x8.8 type VII tires at 200psi pressure. The main gear uses four 44.5x16 type 21 tires at 220 psi pressure. For ferry missions the main gear tire pressure will be increased to 250 psi.
- 167 The braking system and the drogue parachute provide the capability to stop the vehicle within 6,000 feet on a dry runway and 10,000 feet on a wet runway.
- 167 The brake assembly is a carbon-on-carbon surface. The brakes are sized to provide five normal stops or to stop an orbiter during aborted takeoff without overheating.

REF.
KEY

167 The drogue chute assembly is basically a B52 main chute and an Apollo pilot chute and mortar assembly.

167 For ferry flight, the static tire deflection is 32% of full travel. Maximum tire loading occurs during the horizontal takeoff roll when the elevon deflection causes nose gear liftoff. Main gear deflection at this condition is 50% of maximum travel.

167 For cross-wind landing, the gear is designed for a maximum ground wind speed of 35 knots.

167 During in-orbit flight, the landing gear system and the drogue chute system will be thermally protected by passive insulation and electric heater blankets. The design limit of the gear system is -60°F to 275°F.

167 The nose gear is equipped with ground tow attachments. Simulation of the tow system is not required.

4.16.3 Glide Brake System

167 The orbiter vehicle employs an integral split rudder design which provides aerodynamic drag forces. The design is manually controlled and may be adjusted for the amount of braking force required. X

167 The glide brake (or speed brake) system is normally deployed at 250 knots airspeed at approximately 41,000 ft. During the landing glide and approach, the split rudder glide brake is deployed and modulated to control airspeed and glide range.

167 The nominal glide brake setting is 40°. This setting may be varied to increase range/speed by closing the brake or to decrease range/speed by opening the brake further.

4.1 6.4 Ejection Seat Mechanism

166

Orbiters 1 and 2 will be equipped with two ejection seats for the Horizontal Flight Test phase and the first six manned orbital flight tests.

166

The ejection seat will operate at dynamic pressures from zero to a maximum of 650 psf. Existing ejection seats which have zero altitude/zero velocity performance capability will be used.

166

The ejection sequence will separate the canopy hatch and remove it from the ejection path. The crew member will automatically be positioned for safe ejection. The seat will then be ejected by a rocket-catapult blast through the canopy hatch.

166

The ejection seat mechanism will be removed from the operational vehicle.

4.16.5 Docking Mechanism

The orbiter docking mechanism employs a neuter docking concept. Figure 4.16.5-1 schematically illustrates this concept. It presents the orbiter assembly and the corresponding docking element assembly. During the mission, the neuter active assembly is installed with its extendible tunnel retracted into the air lock. The tunnel extension provides the clearance for the docking operation. All docking elements will provide a passive assembly that interfaces with the orbiter docking assemblies.

The seals and latches are designed to accommodate relatively large tolerances accumulated from manufacturing, thermal, and pressurization distortions. The arrangement provides the capability for inspection and unscheduled maintenance and interface connector engagement in a shirtsleeve atmosphere after a docking has been accomplished. The total neuter assembly is contained within an 80-inch-diameter clear passage. Attenuation of docking forces is obtained by using a 10-inch stroke hydraulic shock unit. The standard utilities interface connectors are located around the 40-inch diameter clear opening. This arrangement provides the flexibility for replacement and for mission configuration changes. Visual alignment aids and displays assist the crew in aligning the docking element within the accuracy required for mating. The passive docking assembly with an outward opening hatch for the baseline orbiter configuration provides the capability to attach a payload to the docking port by utilizing the payload handling manipulator or to dock with other orbiting elements or an orbiter

vehicle. This tunnel assembly provides a minimum 36-inch clearance between the docking element and the orbiter and eliminates need of a loose docking adapter. Separation and jettison provisions provide positive separation of the docking assembly for emergency or contingency conditions.

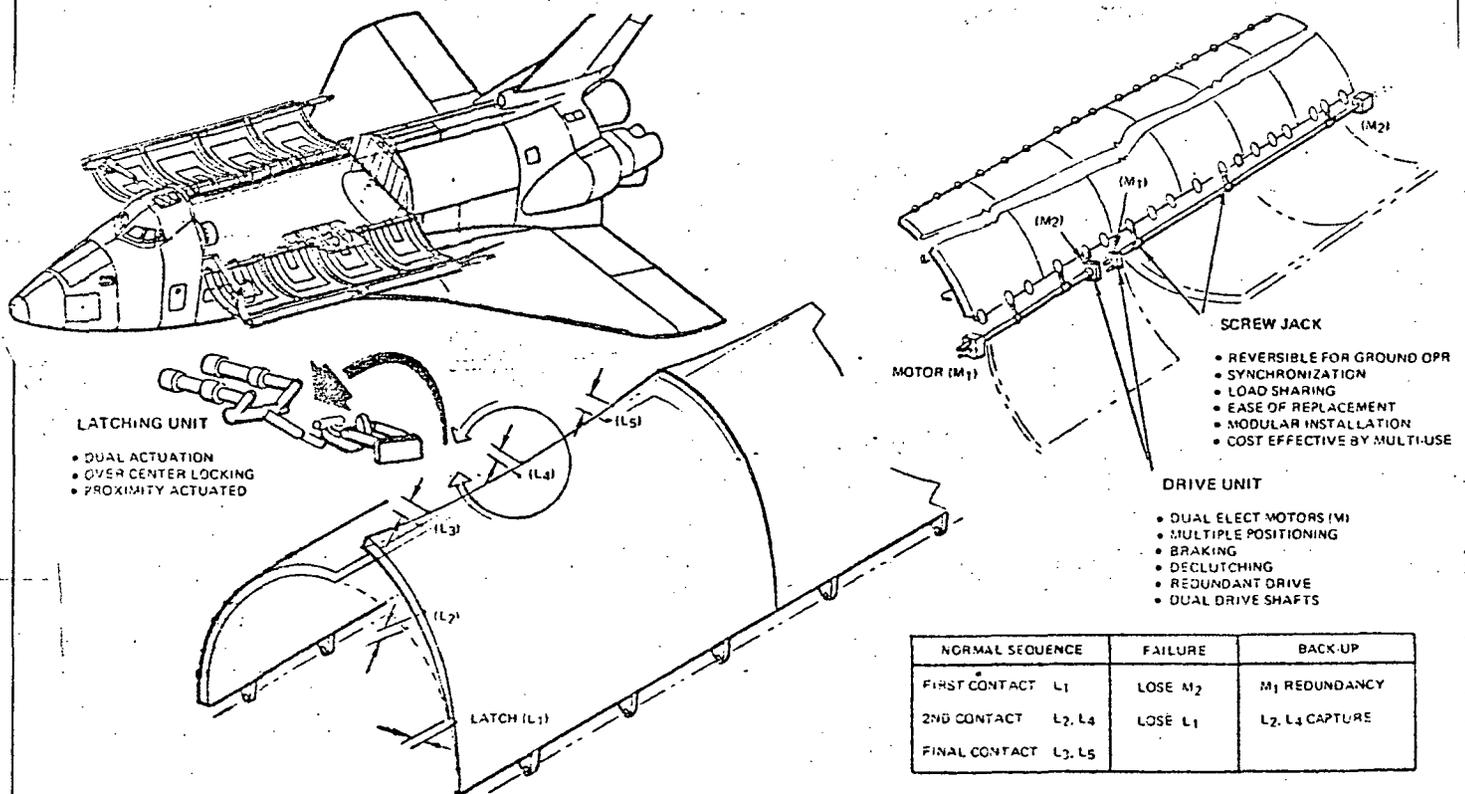

Figure 4.16.5-1
PAYLOAD DOOR ACTUATION AND LATCHING

4.17 On-Board Computer System

The Shuttle Vehicle on-board Computer System is functionally divided into four semi-autonomous federated systems: the GN&C, the Performance Monitor, the Payload system, and the Main Engine Controllers.

Key features of the on-board computer system are:

166

- Computation tasks grouped and allocated for manageability, separation of high development activity, isolation of high traffic data from flight critical functions and ease of integration.
- Display, keyboard and non GN&C computation functions mechanized in a single type, small computer augmented by tape mass memory, enables low development and equipment costs to satisfy redundancy requirements.
- No direct exchange of data between computers performing redundant functions (multiple cross switching but no cross strapping), low data rate and non-interrupt transfer of data, memory protection.

166

A block diagram of the on-board computer system is shown in Figure 4.17-1.

166

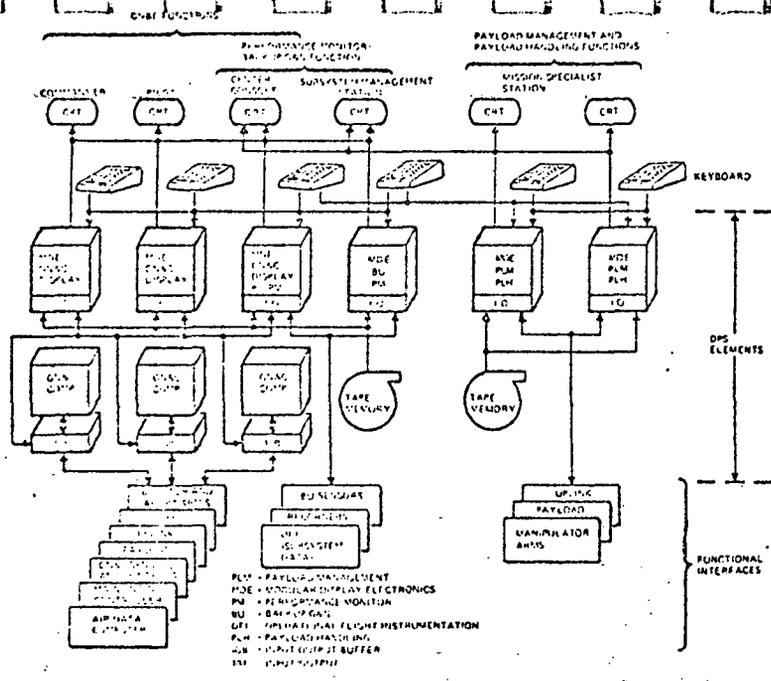

Figure 4.17-1. Shuttle Vehicle On-Board Computer System and Interfaces

166

The input/output (I/O) interface between the computers and the other vehicle subsystems is implemented using a modular design concept to provide the flexibility to accommodate changing requirements and permit early computer design. The modular display electronics I/O, computing, and display subassemblies are combined into a single unit, which permits a simple design and is feasible because the identified I/O channel requirements are primarily multiplexed, serial digital. The I/O to the GN&C computers is significantly more complex, and subject to change; therefore, these functions have been grouped into a separate unit identified as the GN&C I/O buffer. The I/O buffer provides the functions of signal conversion, multiplexing, and transfer of data to and from the computer memory. The transfer functions are accomplished by using a direct memory access (DMA) channel which operates independently of the CPU, except for initialization. Modifications to the I/O buffer capabilities are accomplished by exchange of available standard modules and/or where necessary exchanging custom I/O modules. The transmission of commands and data to and from the Main Engine Controllers will be via a dedicated serial interface

61
&
42

with DMA interface to controller computers.

41 Guidance, Navigation, and Control (GN&C) System

The primary GN&C system consists of three 64K 32-bit word computers dedicated to the solution and status of the Orbiter guidance, navigation, and control functions. The computers contain identical programs to allow a triple redundant computer system mode of operation.

Data will be routed to each computer to allow program vote, average, or compare on input data.

Output data will be voted, or compared, at the actuators rather than at the computer.

41 &
166

The Performance Monitor System Modular Display Electronics (PM MDE's) will contain backup G&N programs so that a "get me home" capability is available for all flight phases in the event of a generic software error or other critical system failures. Separate dedicated sensors and electronics are used with this system.

41

Display data for crew observation of the GN&C system performance and status is provided by the GN&C Modular Display Electronics (MDE) processors which are connected to CRT displays and keyboards.

166

The CRT's can operate in tabular alphanumeric, or graphic mode and contain an interactive selection feature for rapid indexing and data selection. Major display mode selection and manual data entry are accomplished via an associated keyboard. Switching is provided to permit several modes of CRT/MDE interconnection for flexibility of access to different display generation programs which may be accommodated among the MDE's.

Performance Monitor (PM) System

41

The PM system consists of two MDE processors dedicated to the monitor and display of non-GN & C systems status or to the solution and display of the backup guidance and navigation function. One of the PM MDE processors capabilities is obtained by time sharing the center console GN & C MDE, between the GN & C display functions, the PM function, and the backup G & N functions. Reload of the MDE memory for a change of functions will be provided by a tape read-only memory under control of the crew.

41

Payload (PL) System

The PL system consists of two MDE processors dedicated to the status, control, checkout, initialization, and display of payload data. The PL computers which contain

identical programs will both be active but only one will be in control. The PL system will not be required to process onboard experiment data which will be either recorded onboard or transmitted to the ground for processing. Data transmission and recording will not require the PL computer participation. Memory growth capability for the PL computer system is provided by a dedicated read-only tape memory unit.

42

Main Engine Controller

The controller is a single integral electronics package mounted directly on each of the three main engines. The controller contains electronics for interfacing with the engine and the Vehicle with double and triple redundancy. The controller also contains two independent 16 bit HDC-601 Digital Computers, each of which performs the computations necessary for full-authority closed-loop control of the engine thrust and mixture ratio in response to commands from the Vehicle and data from the engine sensors.

Normally, Computer No. 1 is in control and Computer No. 2 is in operational standby. In the event of a failure, control is automatically transferred to Computer No. 2 without impairing engine operation.

4.18 GN&C On-Board Computer & Interface Systems

4.18.1 GN&C General Functional Description

The GN&C subsystem (Figure 4.18.1-1) provides (1) automatic and manual control capability for all mission phases except docking, which is manual only; (2) guidance commands that drive control loops and provide steering displays for the crew; and (3) inertial navigation updated by star and horizon sensors for autonomous orbital flight and by RF navigation aids for rendezvous, approach, and landing. Three independent redundant strings and a backup provide FO/FS redundancy. The equipment is divided into three subsystems: the aerodynamic stability augmentation (ASAS); the primary GN&C; and the backup GN&C. Sensor requirements are found in table 4.18.1-2. Section 4.9 discusses overall GN&C subsystem functional requirements. The various system control modes are summarized in Table 4.18.1-1.

The basic aerodynamic stability of the orbiter is augmented by using the ASAS, an F-14 type conventional system that employs body mounted rate gyros and accelerometers. Gain scheduling is provided by inputs from a DC-10 type digital air data computer and deployable probes. Side stick rotation controllers, rudder pedals, and trim controls allow manual control, and the GN&C computer provides commands to the aerodynamic stability augmentation subsystem for automatic flight control functions, such as automatic landing.

Manual (backup)	.Boost/insertion(IVC) Orbital (OMS TVC or RCS), Entry, Aero, Landing	.Backup sensors and computer, Rate command and damp .Direct RCS jet

Table 4.18-1-1 Control Modes

The primary GN&C provides guidance, navigation, and control for all flight phases with both automatic (command) and manual (control stick steering) modes. The flight control loops used with the main engine and orbital maneuver subsystem (OMS) thrust vector controls, and the reaction control subsystem (RCS) are closed through the GN&C computer; aerosurface control uses the computer and the ASAS. An additional manual mode for aerodynamic flight control bypasses the computer and uses only the ASAS. Rate gyros and accelerometers provide sensing for damping and load relief. Attitude information is obtained from the inertial measurement unit (IMU). Air data is provided by vehicle nose pressure ports at high altitudes, and by redundant probes deployed at lower altitudes.

The backup GN&C subsystem provides a safe return capability for all flight phases. It is separate from the primary subsystem and uses dedicated sensors and electronics. Backup flight control is manual; rotation controller and rudder pedals inputs are used. The change from tip pods to body-mounted RCS jets eliminates severe control cross-coupling and allows direct RCS control on-orbit as additional backup. Steering information for ascent, entry, and terminal area energy management is provided through visual interpretation of the backup G&N data on a cockpit cathode-ray tube (CRT). Backup system alignment is accomplished by an optical sighting device, much like the CSM crewman's optical alignment sight.

Currently, a gimbaled IMU provides the navigation reference with horizon and star sensors for autonomous alignment and state vector update. During active rendezvous, TACAN is used for range much as it is used in military air-to-air refueling operations. Range rate is derived from the range data in the GN&C computer. A star sensor acquires a target light to provide bearing. Rendezvous with a passive target employs ground tracking of the target combined with orbiter on-board navigation and, when required, range, range rate, and angle data from rendezvous sensors (considered part of the payload). TACAN update is used to assure approach and landing path intercept above 10,000 feet altitude.

Automatic landing is accomplished via a computed flight path generated in the GN&C computer using the inertial navigation system for reference with continuous updates from TACAN and instrument landing system (ILS). Radar altimeter updates are used near touchdown. The two segment (15-and3-degree) glide slope approach requires separate ground ILS transmitters for each segment. Rollout control similarly uses the GN&C computer and inertial navigation system with continuous ILS localizer updates.

For all critical mission phases where automatic switching (i.e., allowable recovery times exceed pilot capability) is required, the three independent strings are operated in parallel

4.18.2 GN&C System Elements & Interfaces

This section provides detailed descriptions of the least replaceable units (LRU's) included in the GN&C system.

The size and weight of the individual LRU's are included in Table 4.18.2-1. This table does not include the various displays, controls and navigational aids which interface directly with the primary GN&C equipment. Table 4.18.2-2 contains a tabulation of the individual LRU power requirements by mission phase. Individual detailed LRU descriptions follow.

<u>LRU</u>	<u>Qty.</u>	<u>Weight Lb/LRU</u>	<u>Volume Ft³/LRU</u>	<u>Total Wt.-Lbs.</u>	<u>Total Vol-Ft³</u>
Air Data Package	3	25	0.52	75	1.56

4.18.2.1 Air Data Equipment

The Air Data Equipment for shuttle has been selected for maximum use of existing equipment and permits a phased development program.

For the Mark I Orbiter, the horizontal flight control system requires only the computation of dynamic pressure for gain scheduling of the stability augmentation system; displayed parameters include altitude, altitude rate, mach number, and airspeed. These parameters are computed by the Air Data Package from input probe pressure signals corresponding to static and total pressures.

The selection for Air Data Package is a modified version of the Honeywell Digital Air Data System designed for the DC-10. Utilizing a computer (7 CPU cards, 1 memory card), this device converts pressure signals to digital format, computes flight parameters, and produces both analog and parallel digital output to displays and to the aerodynamic control electronics.

Updating the Air Data System for the Mark II vehicle requires the addition of an Angle of Attack Transducer package, which produces digital outputs permitting computation of angle of attack by the GN&C computer. This device consists of two differential pressure-to-electrical signal transducers and utilizes module building blocks in converting to the required digital outputs.

Three each of the Air Data and Angle Transducer units are required in each system, for single-string redundancy in a spatially diverse vehicle layout.

4.18.2.2 Rate and Accelerometer Sensors

Sensors for both the orbiter and booster vehicle GN&C systems include both body rate gyros and accelerometers for control loop stabilization.

The hardware elements for both rate and acceleration sensors are based on existing equipment in current production by Honeywell for the Grumman F-14 flight control system. Available configurations include both dual and triple redundant single-axis packages utilizing heaterless GNAT gyros, and triple accelerometer packages. In applying the single-string system criterion of spatial diversity to the redundant gyros and accelerometers, subassemblies and circuits of the F-14 units will be handled as building blocks in repackaged sensors of four types: roll, yaw, and pitch body rate packages, and a 2-axis accelerometer package; each LRU includes the inertial sensor, plus loop electronics and power supply. Separating rate sensors by axis is assumed to be required to permit locating the sensors at different airframe body stations because of vehicle bending mode variation by axis.

4.18.2.3 IMU

Each IMU consists of two LRU's; the platform and the power supply. Both are shown in Figure 4.18.2-1.

The platform has four gimbals with appropriate synchros, resolvers and torque motors for each gimbal. The angular sequence starting with the inner gimbal is pitch, roll, and yaw with the fourth gimbal providing redundant roll. The stable element (inner member) con-

tains two 2DOF gyros with SRA's directed along the pitch and yaw gimbal axes, respectively. One gyro controls the roll and yaw platform gimbals while the other controls the pitch gimbal axis. The platform baseline is typified by a Kearfott KT-70.

The accelerometers, also mounted on the stable member, consist of a two axis accelerometer, measuring accelerations in the X and Z axis and a single axis accelerometer measuring Y axis accelerations. This definition applies when the gimbal angles are driven to zero in all axis with respect to the vehicle body axis system. The coordinate system X, Y, Z, defined in the conventional sense, corresponds to the roll, pitch, and yaw axes of the vehicle. The gimbal torquing electronics and the accelerometer rebalance electronics are located in the platform assembly.

4.18.2.4 Star Tracker System

The star tracker is a strapped down optical sensor using electronic gimbaling to determine star positions within the eight degree diameter field-of-view (FOV). Usage of the tracker is extended to include acquiring and tracking a space station light beacon. The acquisition mode, results in a scan of the entire FOV after which the brightness object is selected. The tracker then enters a tracking mode in which the selected object is scanned over a very small FOV on the order of 16 arc-minutes. The position of the object is measured in two axes with respect to the boresight of the tracker.

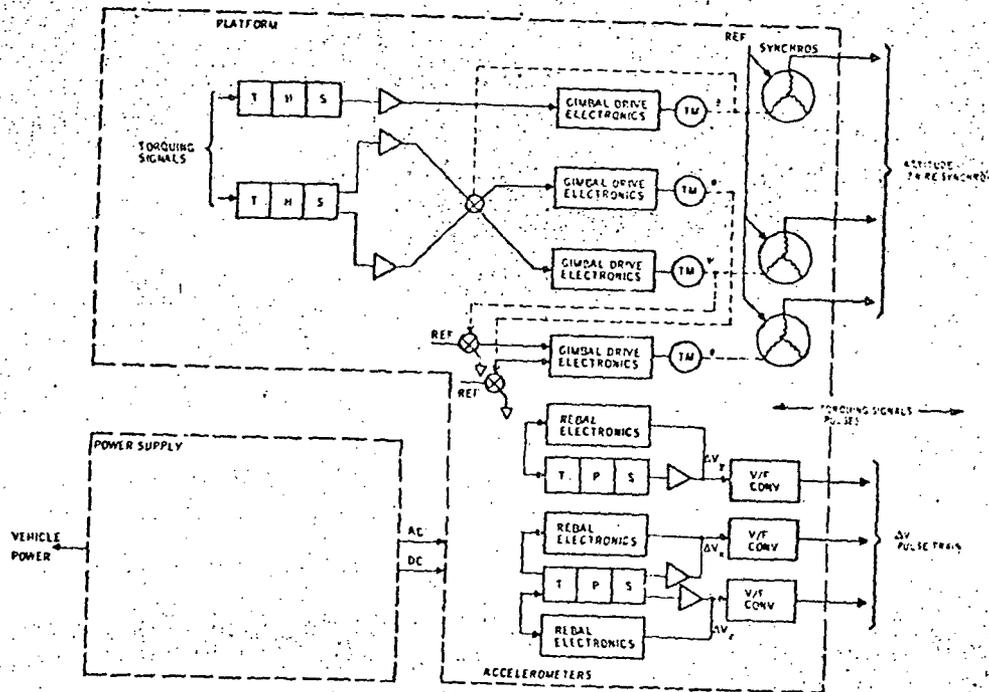

Figure 4.18.2-1 IMU Block Diagram

The star tracker (baseline is typified by the ITT Dual Mode Star Tracker) consists of an optical lens system, photosensor and electronic circuitry as shown in Figure 4.18.2-2. The lens gathers and brings to focus the radiant energy from the source at the photo cathode of the multiplier phototube. The photo cathode surface forms an electron image of the focused light source. An accelerating voltage applied between the photo cathode and a limiting aperture causes electrons from a particular area of the photo cathode (instantaneous photo cathode area) to pass through the aperture. This then defines an instantaneous FOV of a small region in space. A multiplier section behind the aperture amplifies the signal.

Deflection coils placed around the image section of the phototube provide a means of deflecting the electron image. A search sweep generator and a track sweep generator provide deflection signals to the coil to cause the electron image to sweep across the aperture during the acquisition and track modes, respectively. The search sweep generator is used to scan the entire tracker FOV whereas the track sweep generator scans a small preselected area.

The video amplifier and star selection circuits amplify the star presence signal, and set a reference level corresponding to the largest signal encountered in the FOV. On receipt of a tracking signal from mode control, the tracker scans the FOV and stops when the brightest star enters the instantaneous FOV. Once this happens, the tracker enters the tracking mode. The tracking loop circuits develop an analog

error signal which is used to control the deflection-coil signals so that the fine scan is centered on the star image. The output error amplifiers sample the deflection coil signal and provide output error signals to the computer.

The power supply requires both plus and minus 27 vdc input power.

The star tracker system is comprised of 3 LRU's:

Star Tracker/Shuttler

Sun/Shield/Sun Sensor/Shutter Assembly

Control Unit

4.18.2.5 Horizon Sensor

The horizon sensor, used operationally during navigation is of the conical scan variety. The sensor approach uses two horizon sensing heads interfacing with a signal processing box. A block diagram of the sensing system is shown in Figure 4.18.2-3.

Each head contains an optics section with a motor driven rotating mirror. A bolometer/amplifier provides a signal indicating the level of radiance received through the rotating FOV. A marked change in radiance levels indicates a horizon crossing. Under normal operation, two horizon sensor crossings per scan are received by each head. A motor packoff provides a reference timing signal which locates the center of each scan pattern.

Within the processor box, pitch information from each head is derived from the horizon crossing signals and the reference pulse.

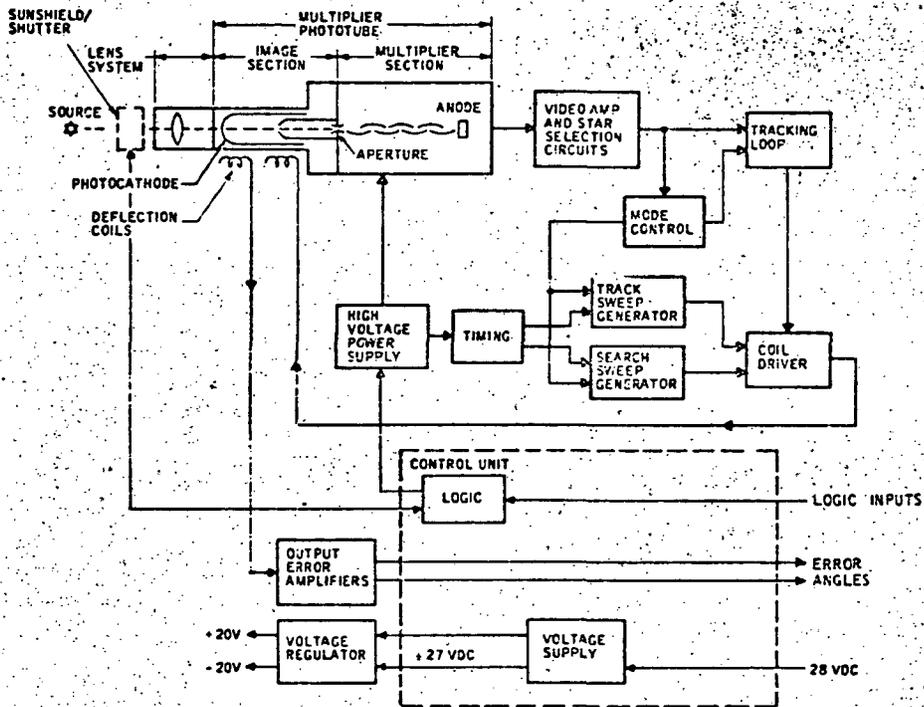

Figure 4.18.2-2 Star Tracker Block Diagram

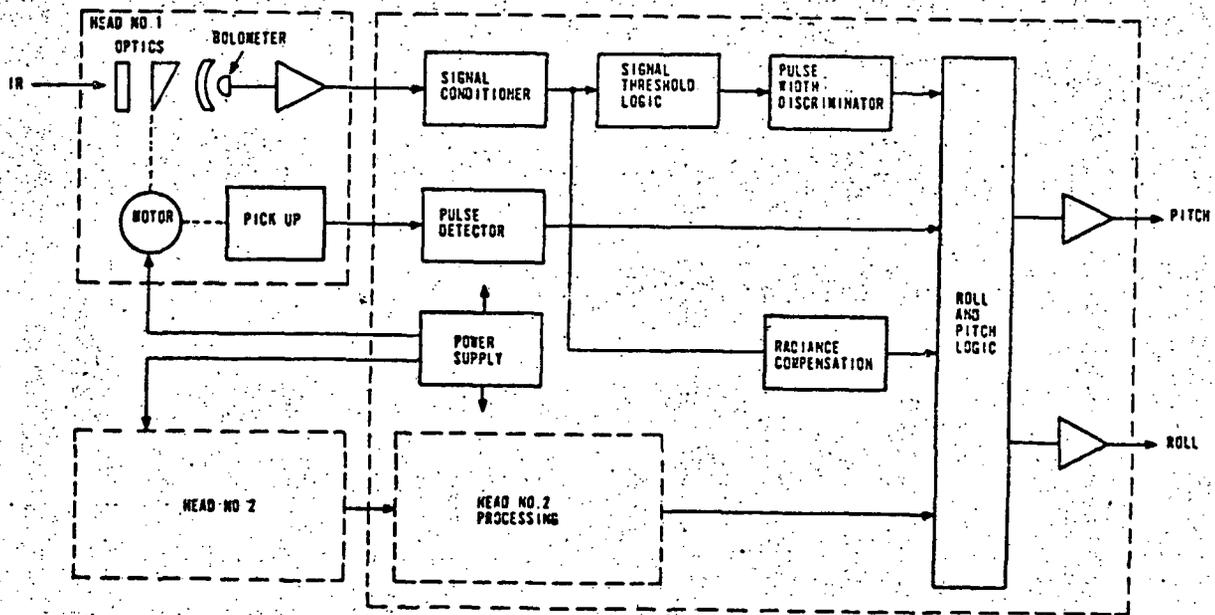

Figure 4.18.2-3 Horizon Sensor Block Diagram

The pitch information from each head is averaged to obtain a pitch angle output signal. A roll output signal is obtained by comparing the period of "Earth crossing" pulse from each head.

Radiance compensation circuitry is provided to suppress the effects of horizon anomalies on the output performance of the horizon sensor.

The horizon sensor, typified by the Barnes 13-156 Conical Scan Horizon Sensor System, provides a highly accurate, long life, local vertical reference over a wide range of altitudes (80 - 6000 nautical miles). The optics are designed to view the CO₂ special band (15 microns) which is the optimum spectral band for minimizing horizon variations. The output error angle signals are linear over a ± 5 degree region saturating at 10 degrees. A sun presence signal, detected in the short wavelength spectral band, inhibits the signal output thus preventing corruption of the navigation processing with erroneous updates.

4.18.2.6 Analog SAS

The selection of an analog SAS shown in Figure 4.18.2-4 as opposed to a digital SAS was based on the fact that there are several flight proven and operational fail operative and fail safe analog flight control systems in use today. All aircraft currently flying employ this method of control. There is no production digital stability augmentation other than Apollo. Therefore, analog is tentatively selected as the conventional off-the-shelf approach in order to minimize risk and be available for horizontal flight.

Analog aerodynamic flight control electronics are packaged in three identical 3-axis LRU's in adherence to the spatial diversity concept of redundant hardware independence. In each, the pitch, roll and yaw control channels receive control commands from the GN&C computer and provide crossed commands to the elevon control surface actuators, and in yaw channel from transducers in pedals. Capability also exists in the roll and pitch channels to provide surface actuation signals in response to analog manual input commands from transducers on the center control stick. Vehicle body rate and lateral and normal acceleration feedback signals are introduced for axis stabilization and a dynamic pressure signal from the air data system is used in each axis for gain scheduling.

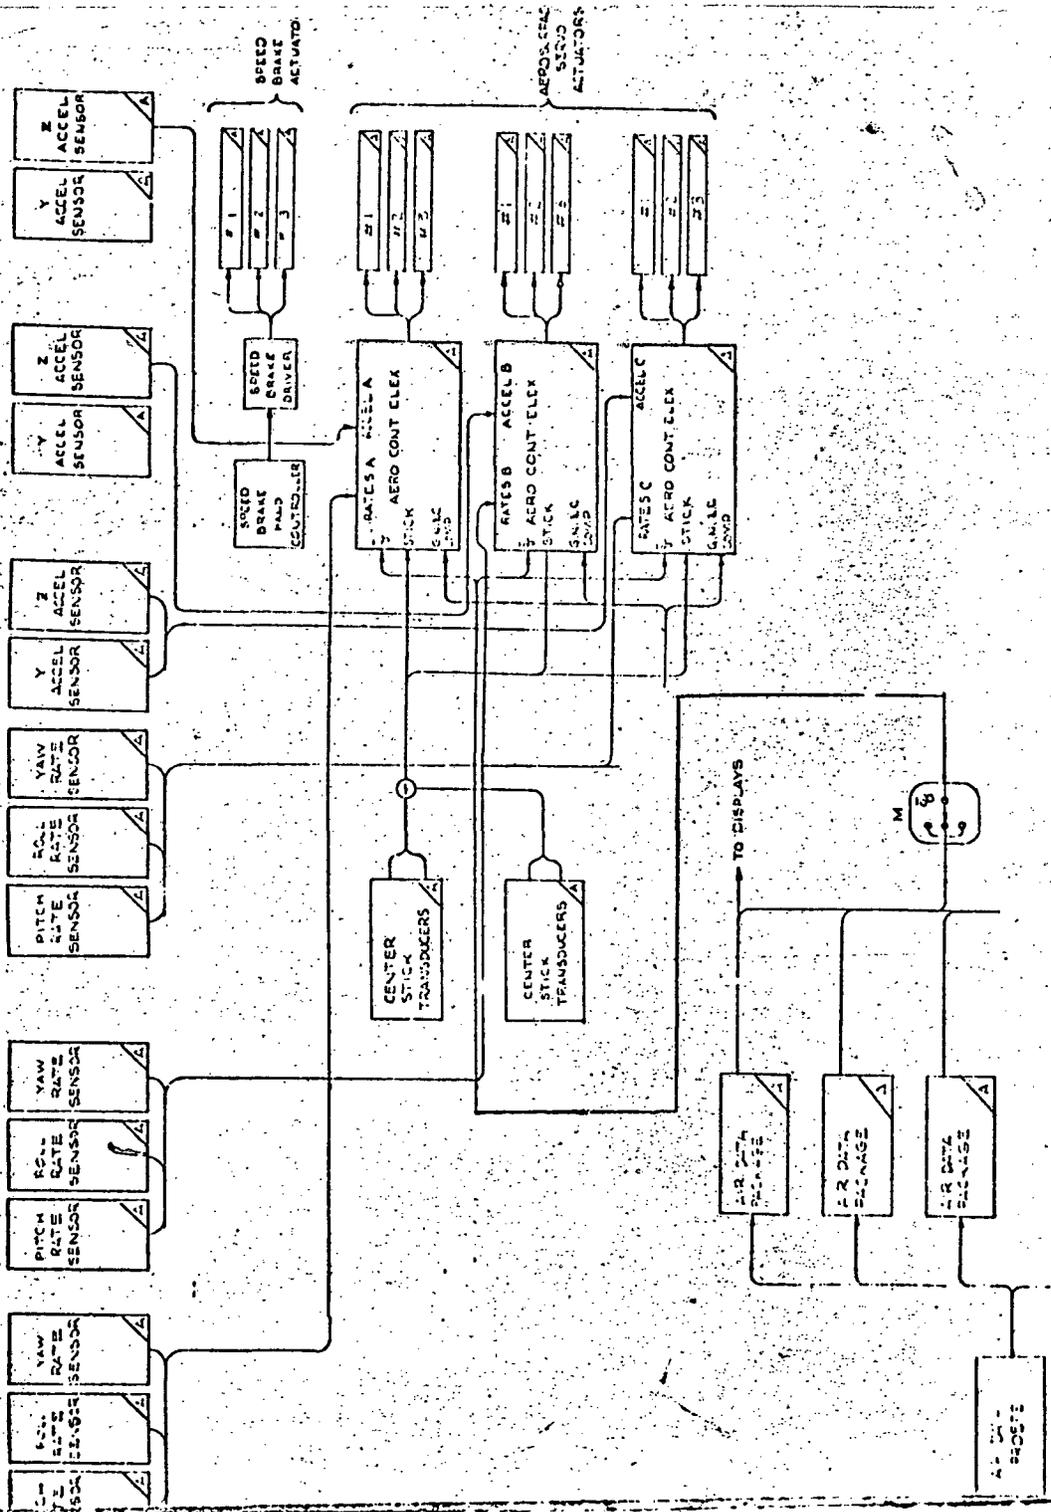

In addition to the control electronics and actuator servo amplifiers, each LRU includes an independent set of middle-select comparators and the required power supplies. In packaging of the aero control electronics, extensive use will be made of existing aircraft flight control hardware and packaging techniques. Plug-in circuit boards will be modified from C-5 and F-14 hardware; wire-wrap interconnecting base plate and fabricated aluminum enclosure are adapted from the existing F-15 aircraft flight control electronics hardware.

4.18.2.7 TVC Electronics

Hardware for thrust vector control is packaged in four LRUs" 3 identical TVC gimbal servo driver units and one manual TVC electronics box.

Each of the TVC gimbal servo driver units contains 8 servo

Figure 4.18.2-4 Analog SAS

amplifier circuits, middle select level detectors for redundancy management, and bias supplies, and represents a single layer of redundant drivers for the 8 engine gimbal actuators. Gimbal command inputs are accepted from either the GN&C computer in automatic control mode, or upon manual switchover to manual TVC, from the MTVC electronics in a backup mode.

The MTVC electronics unit accepts 3-axis commands from the two rotation hand controllers and body rate signals. Stick and rate inputs are amplified, and summed in an integrating amplifier; the resultant command signal outputs are fed to the appropriate gimbal servo drivers in each of the three TVC driver LRU's. All of the TVC electronics hardware is new design, with circuits based on Apollo BG286 MTVC and BG288 servo amp background experience. Packaging will utilize plug-in circuit boards, wire wrap interconnecting matrix, and non-hermetic aircraft-grade enclosure design of fabricated aluminum sheet, with thermal design based on convection cooling.

4.18.2.8 APS Logic/Driver Unit

Control of the ACPS thruster valve solenoids and of OMS engine ignition is handled by two APS Logic/Driver Units. Based on the existing Apollo Reaction Jet/Engine on-off control, this device accepts ACPS thrust commands from either the GN&C computer or from the Translation Hand Controller; it contains the logic necessary to select the appropriate thruster in response to the commanded rotation or translation maneuver, and provides the switching circuits necessary for controlling

current to the thruster valve solenoids. This device also includes the necessary transient suppression and bias supply circuits, and circuits for OMS engine ignition and cutoff control.

The unit will utilize the BG287 chassis as well as the basic existing welded matrix and cordwood module configuration. Growth space is adequate to accommodate revisions necessary to tailor the existing jet select logic to shuttle ACPS system requirements, add one 2-jet driver module to the existing 16-jet control capability, and modify the SPS engine ignition timing and logic to meet shuttle OMS needs.

4.18.2.9 GN&C Computer Interface

The GN&C computational facilities consist of three, single thread, dedicated data acquisition strings and computers. At the present time, no provisions are being made to permit the transfer of data between computers. Figure 4.18.2-5 presents a simplified block diagram of the selected concept.

During the quiescent on-orbit periods, where the consequences of a hard failure are minimal, only one GN&C string is used. In Table 4.18 are the key features of the redundancy configuration. The failure recovery scheme is shown in FIGURE 4.18.1-1 and TABLE 4.18.1-3.

Table 4.18.2-2

Redundancy Management Key Features

- Redundant strings interconnected only at IMU output and at the output force servos and jet drivers to maintain design simplicity. IMU interconnection prevents divergence in guidance computations and allows detection of slow degradation failures. Servo and jet driver interconnection (via monitor) required for "fail-soft."
- RCS engines divided into 3 groups electronically, each with dedicated GN&C computer and capable of doing all required maneuvers.
- Hydraulic pressure monitors in the main engine TVC and aerosurface actuators automatically disengage a failed channel for first failure and switch to backup for second. *GIS TVC is not time-critical and does not require a monitor.*
- When the backup system is engaged, there are no significant transients requiring initial corrective pilot inputs. Backup is rate command system that damps out failure transients automatically with rotational controller centered.
- Steering display command monitor detects guidance loop discrepancies for display; no automatic action is initiated by this monitor.
- Built-in test and self-test furnish LRU status to crew but are not used to automatically manage redundancy.
- After a second failure, if the failed string can be isolated using BITE, control may be restored to the remaining good string at crew option.

DSKY (PILOT)

4.18.2.9.1 GN&C I/O Buffer

The input/output I/O interface between the computers and the other vehicle subsystems is implemented using a modular design concept to provide the flexibility to accommodate changing requirements and permit early computer design. The modular display electronics I/O, computing, and display subassemblies are combined into a single unit, which permits a simple design and is feasible because the identified I/O channel requirements are primarily multiplexed, serial digital. The I/O to the GN&C computers is significantly more complex, and subject to change; therefore, these functions have been grouped into a separate unit identified as the GN&C I/O buffer. The I/O buffer provides the functions of signal conversion, multiplexing, and transfer of data to and from the computer memory. The transfer functions are accomplished by using a direct memory access channel which operates independently of the CPU, except for initialization. Modifications to the I/O buffer capabilities are accomplished by exchange of available standard modules and/or where necessary exchanging custom I/O modules. The feasibility of this approach has been verified by detailed I/O interface studies summarized in Table 4.18.2-3.

Table 4.18.2-3

Input/Output Buffer Subsystem Interface Summary

Interfacing Subsystem	Signal Type	Type of Interface	Interface Device	Number	Rate	Typical Signal Names	Use
GN&C	Discrete	Hardware	Standard	291	25 s/s	Status and control	GN&C performs monitor and equipment control
	AC analog	Hardware	Custom	9	1 and 25 s/s	Gimbaled angles	Guidance and flight control computations
	Pulse	Hardware	Custom	23	1 and 25 s/s	Accelerometers, rate, gyros	Guidance and flight control computations
	DC analog	Hardware	Standard	47	1 and 25 s/s	Star angles, vertical errors, air data, commands	Navigation and guidance computations, flight control
	Serial	Hardware	Semi custom	5	25 s/s	Air data	Flight control computations
Booster	Discrete	Hardware	Standard	3	25 s/s	Status and control	Booster status and discrete control
	Serial	Hardware	Semi custom	1	25 s/s	Main engine	Main engine control and monitor
Communication	Discrete	Hardware	Standard	65	1 and 25 s/s	Status, control, antenna switching commands	Status, equipment control and switching
	Serial	MUX	Semi custom	2	2 Kb/s	Up data	Ground data load
	Parallel	Hardware	Custom	6	1 s/s	Range, bearing	Aero-navigation guidance; orbital rendezvous
	DC analog	Hardware	Standard	3	25 s/s	Altitude; glide slope	Autoland
D&C	Serial	MUX	Semi custom	10	2.8 kb/s	Altitude/transition commands	Flight control
OFI	Discrete	Hardware	Standard	4	1 s/s	Status and control	Status, equipment control
	Serial	MUX	Semi custom	1	2 Kb/s	Computed data	Telemetry
	Serial	Hardware	Semi custom	1	1 s/s	Time	Mission/event sequencing, navigation updates
Computer/computer	Serial	MUX	Semi custom	12	256 Kb/s	Intercomputer data transfer	Indirect transfer of data between computers for reinitialization, support information, data exchange, and GN&C display data (CRT and annunciator)

s/s—sample per second Kb/s—kilobits per second; MUX—multiplexed

The GN&C I/O Buffer consists of two standard remote multiplexers and input buffer, and an output decoder. Data collected via the multiplexer/buffer will be, with very limited exceptions, already conditioned to a specified DC level. The decoder will be custom designed to meet subsystem interface requirements.

After signal conditioning has been performed, data from the various subsystems is distributed to one of the two multiplexers.

The input data is multiplexed and routed to the buffer units of the computers. Each multiplexer accepts: (1) 96 discrettes, (2) 1 serial data channel, (3) 80 high level analogs, and (4) 50 differential analog signals. The multiplexer's sample rate is under internal control; its output is 8-bit plus parity serial data.

The buffer units accept input data from the multiplexer at the bit rate programmed by the multiplexer programmable read only memory. The buffer stores the input data in an internal memory. Each multiplexer input has a separate starting address. Two multiplexer channels are stored simultaneously (16 bits).

The buffers used in conjunction with the G&N computers receive data from the various subsystems via the multiplexers described above. Using input data and the stored program, the computer system performs the required G&N functions. Computer outputs are obtained either under direct software control or under decoder control via direct memory address through the parallel channel. Nominal decoder output capacity is as follows: (1) 15 serial signals, (2) 100 analog signals, and (3) 200 discrettes.

4.18.2.9.2 Remote Multiplexing Unit (RMU)

The selected multiplexer is typified by an off-the-shelf Teledyne Remote Multiplexer Unit (RMU) Model DS-704 with minor modifications. The RMU is the device which interfaces the user subsystems to the GN&C computers, via the appropriate Buffer Unit. It consists of a time division multiplexer, A/D converter, programmable read only

memory, and the necessary control/timing logic and modulator circuitry required to output multiplexed subsystem data into a PCM format for transmission to the Buffer Units. The modification required is the addition of a serial digital input channel(s).

The following is a description of the functional capabilities of the RMU:

Inputs:

- . High level (00 to +5 VDC) analog: 80 single ended channels
- . Low/High Level Analog: 50 differential channels
- . Discretes: 96 points
- . Serial Digital: Total input capability is limited to 142 equivalent 8 bit words, i.e., Analog Input = 1-8 bit word, 8 discrete inputs = 1-8 bit word. The number of serial digital 8 bit words inputted to the RMU will subtract from the existing analog/discrete capability, i.e., - 1 serial digital word block consisting of 142-8 bit words would delete any analog/discrete input capability for that RMU.
- . Format Select: Two lines specifying one of four formats to be read from the programmable read only memory.
- . Power: +28 \pm 10% VDC @ 400 ma.

Outputs:

- . Data Output: 9 bit (8 bit + parity) words being transmitted at approximately 30 Kbps with Bi-phase - L Modulation.

Functional Operation The RMU will operate according to the mode stored in the programmable read only memory and selected by the Format Select lines. Figure 4.18.2-6 presents a simplified functional block diagram of the RMU. One of four modes can be externally selected which specify: output bit rate, input channel selection, output modulation, output word length, and gain selection for the differential analog input channels. The RMU will then scan the appropriate input channels, perform the required A/D conversion for formatting, add the necessary parity, modulate the resulting serial data stream, and output this data stream for transmission to the appropriate Buffer Unit.

Functional Configuration Two functional RMU's are provided within one case. These RMU's may be used redundantly by external crossstrapping or to expand the total number of input channels.

Physical Characteristics (for Dual RMU's)

Power: 20 Watts (both units ON)

Weight: 10 lbs.

Dimensions: 8.5 H x 4.5 W x 3.5 L (Preliminary est.)

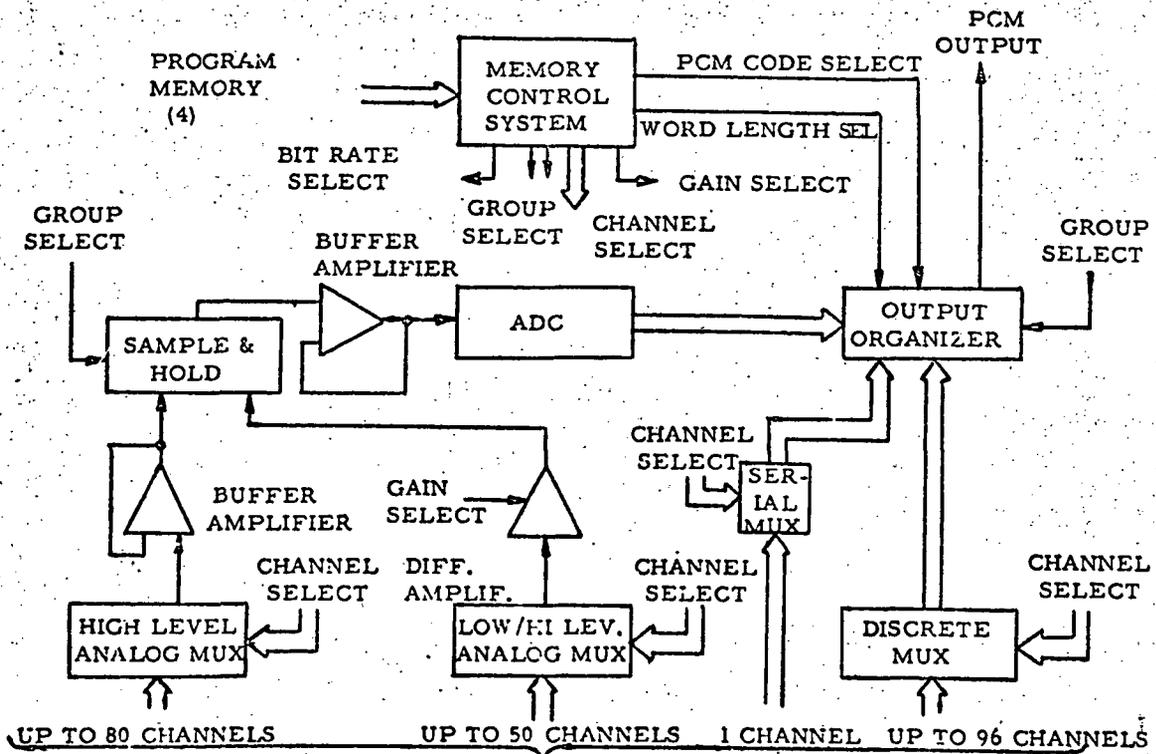

Volume: 0.08 cu. ft.

4.18.2.9.3 Input Buffer

The input buffer contains all of the circuitry and storage necessary to accept, decommutate, and store the inputs from four multiplexers which are outputting serial data streams. In the baseline system only two will be used. The multiplexers are free running and

Figure 2.18.2-6

- SIMPLIFIED BLOCK DIAGRAM, REMOTE MULTIPLEXER
(TELEDYNE DS-704)

operating asynchronously. As each pair of words of data are received, from a multiplexer channel, the data will be transferred to a pre-determined location of core storage in the buffer unit, or the computer.

In addition to the four PCM input channels, provisions will be made to custom interface, on an exception basis, those specific inputs where significant cost savings may accrue. Typical candidates for consideration are data inputs from TACAN and Up-Data Link equipments.

The input buffer for the GN&C computers will have a buffer-computer interface compatible with the computer parallel Direct Memory Access (DMA) channel. The computers will initiate data fetches from the buffer under control of software. By use of an I/O call, a starting buffer address and word count will be transferred and then sequential fetches of up to 24 locations will begin. Transfers from the buffer core to main memory will take place via DMA.

A simplified block diagram of the input buffer is shown in Figure 4.18.2-7.

Physical Characteristics

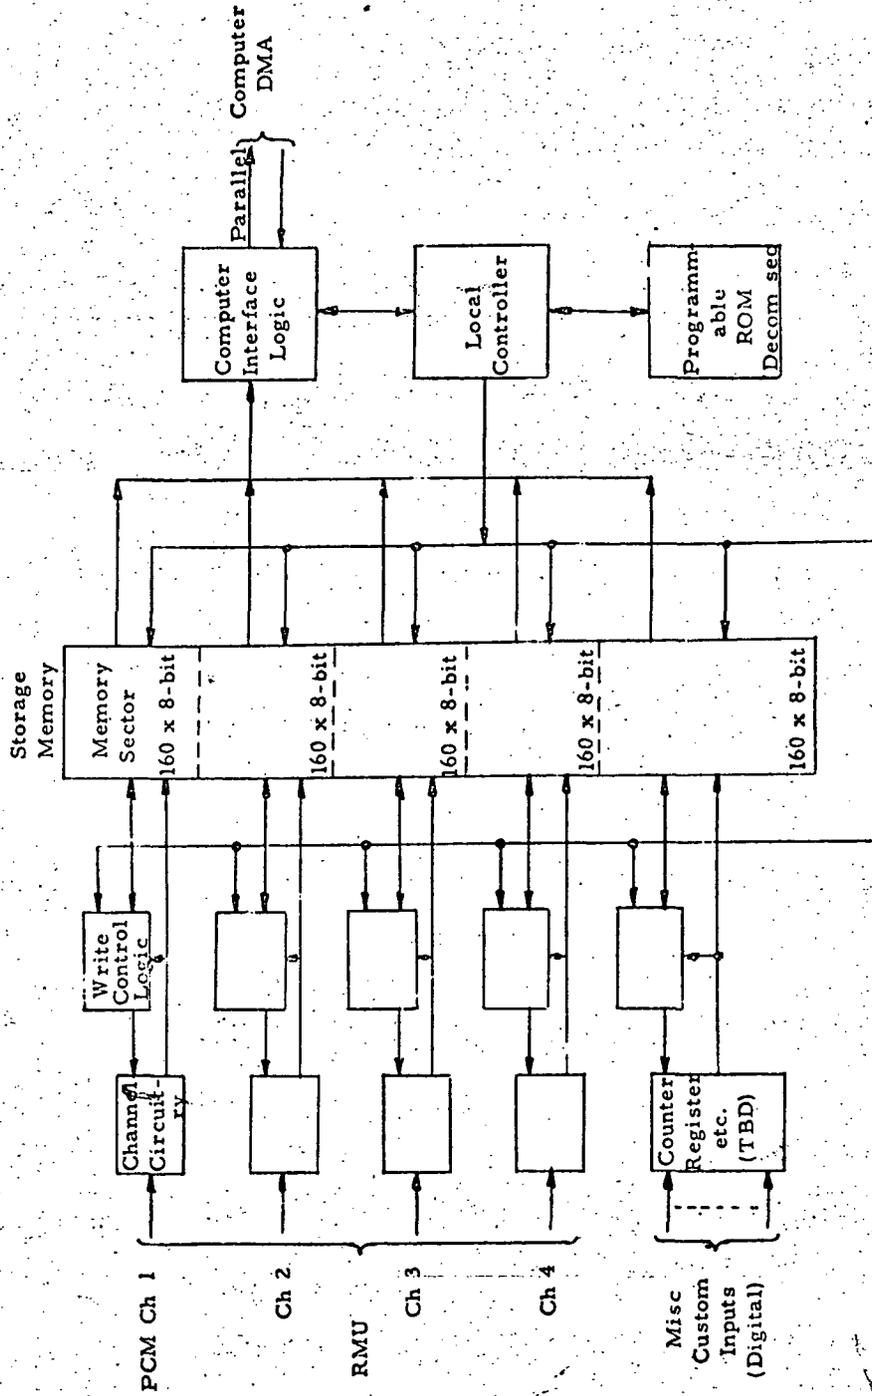

Weight 24 lbs.

Dimensions: 4.1 H x 10.1 W x 15.5D

Volume: 0.25

Power: 100 watts

Figure 4.18.2-7 Block Diagram Input Buffer

4.18.2.9.4 Output Decoder

The output decoder provides a means of distributing and/or formatting the G&N computer output. The output decoder has the following capabilities.

- . 16 independent serial channels - each serial channel is loaded via a direct I/O instruction
- . 128 discrettes (0 - 5^v) - four fixed main memory locations are fetched via the DMA at selected intervals and their contents are used to update the discrete outputs.
- . 64 DC analogs (0 - 5^v @ 8 bit accuracy) - 16 fixed main memory locations (4 outputs per location) are fetched via the DMA at selected intervals and their contents are used to update the digital to analog converters.
- . Gyro Pulse Torque Commands to gyro - a three-channel gyro pulse torquer converts command signals from the computer to precise binary torque pulses which may be used to drive the gyro packages. Each pulse delivered to the gyro represents an increment of angle at the gyro input axis.
- . 48 bit register to telemetry - one and one half fixed memory locations are fetched via the DMA at software controlled intervals and their contents are used to reload the 48 bit register. The register is made available for periodic sampling by the telemetry data acquisition system.

The Output Decoder interfaces with the parallel DMA channel of the computer. The DMA facilities of the computer are shared with the Input Buffer.

Figure 4.18.2-8 depicts a simplified block diagram of typical functional paths which may be provided by the Output Decoder.

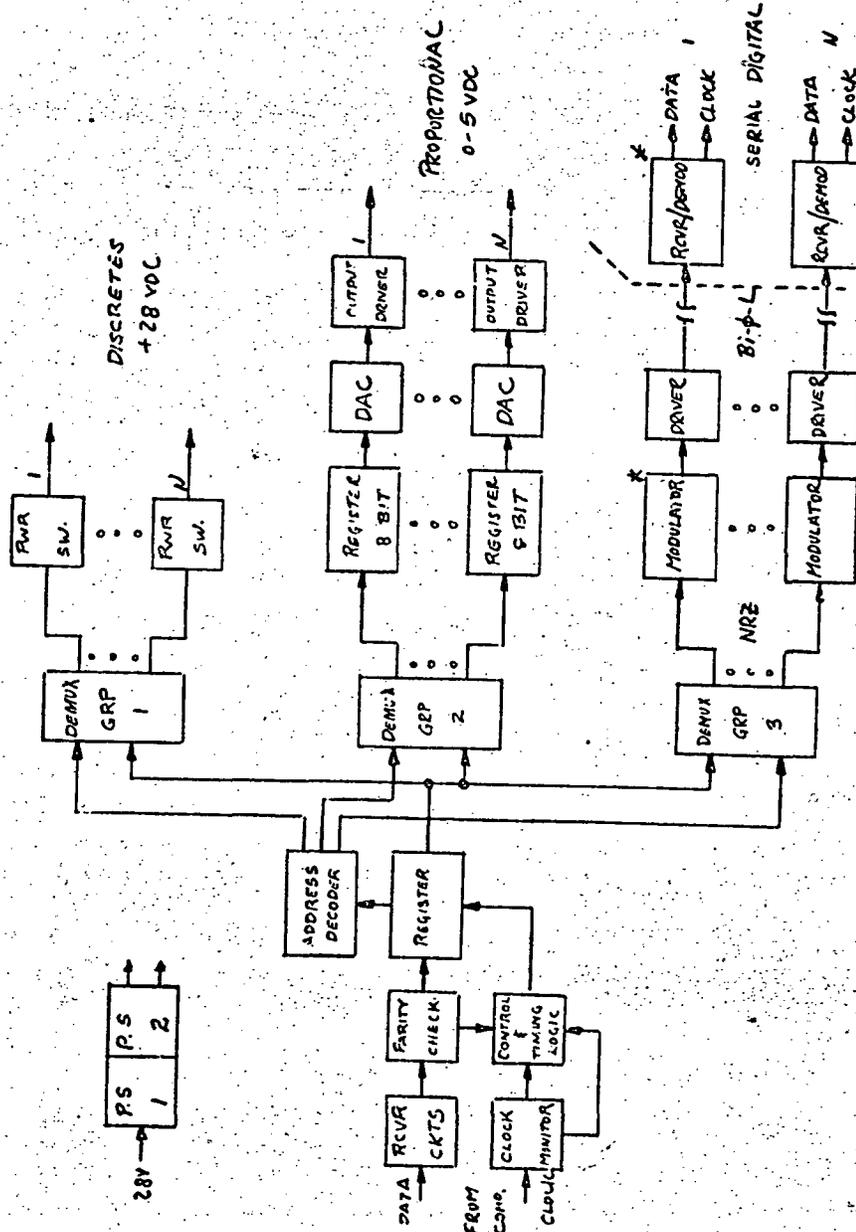

Physical Characteristics

Weight: 27 lbs.

Dimensions: 4.1 H x 10.1 W x 15.5 D

Volume: 0.25

Power: 80 watts

4.18.3 GN&C Computer System

The GN&C system consists of three 64K 32-bit word computers dedicated to the solution and status of the Orbiter guidance, navigation, and control functions. The computers contain identical programs to allow a triple redundant computer system mode of operation. The computer clocks will be phase locked to the master timing unit to provide an inherent computer synchronization capability.

The GN&C program also provides navigation and guidance data to the Booster control computer and provides the control program for the manipulator arms.

Although the final choice for the GN&C computer has not yet been made, there are at present two candidates for the GN&C computer for the Orbiter. One is the Model AP-1 (designated AP-101 for the Space Shuttle) manufactured by IBM Corporation. The other candidate is the SKC-2000 manufactured by the Kearfott Division of The Singer Company.

The Model AP-1 Computer

The IBM System/4Pi, Model AP-1 computer is a medium-sized, high-speed, general-purpose computer for real-time space and military control use. A standardized parallel channel and AGE interfaces permit the AP-1 to be integrated into an optimum system design with other Advanced System/4Pi computers. A summary of AP-1 characteristics follows.

The AP-1 has a full parallel 32-bit word machine organization. Data transfers to and from main storage and the I/O are handled on a fullword basis as well. The architecture provides addressing of each 16-bit storage halfword, thus allowing both 16-bit and 32-bit operands to be processed. This, together with the short and long format instructions (16 and 32 bits), significantly increases the overall storage efficiency of the AP-1 computer. It further expands the applicability of the AP-1 to a wide range of problems, since most uses require only 16-bit precision in the operands. Navigation and similar high precision computations are effectively addressed using 32-bit operands. The short format instruction, 16 bits, provides a similar advantage, because more than 70% of the instructions in a typical application program may be of the short format.

AP-1 Functional Characteristics

Machine Organization

Type	General purpose, stored program, parallel
Organization	Binary, fixed point, fractional
Data Flow	32-bit parallel
Data Word Length	32 bits
Instruction Word Length	16 and 32 bits
Average Instruction Execution Rate	450,000 operations/second to 550,000
General Registers	Two selectable sets of eight 32-bit hardware registers

Main Storage

Type	Random access, nonvolatile, destructive readout core
Capacity	16,384; 32,768; or 49,152 18-bit halfwords (including 1 parity bit and 1 store-protect (optional) bit)
Modularity	8,192 18-bit halfwords per pluggable page

I/O

Serial Channels	Four channels; transformer coupled, two-way party line, 15 devices per channel; 1-MHz bit rate; 45,000 16-bit halfwords per second per channel
Parallel Channel (option)	One channel; multiple devices; 16 bits transfer; 150,000 to 750,000 halfwords/second
Interrupts	16 internal and external interrupts; 9 levels of priority; maskable
Discretes	12 DC-coupled inputs; 9 DC-coupled and 3 relay-controlled outputs

Logic Circuits

Class	Monolithic integrated
Type	TTL and MSI
Package	Flatpacks; 14, 16, and 24 leads

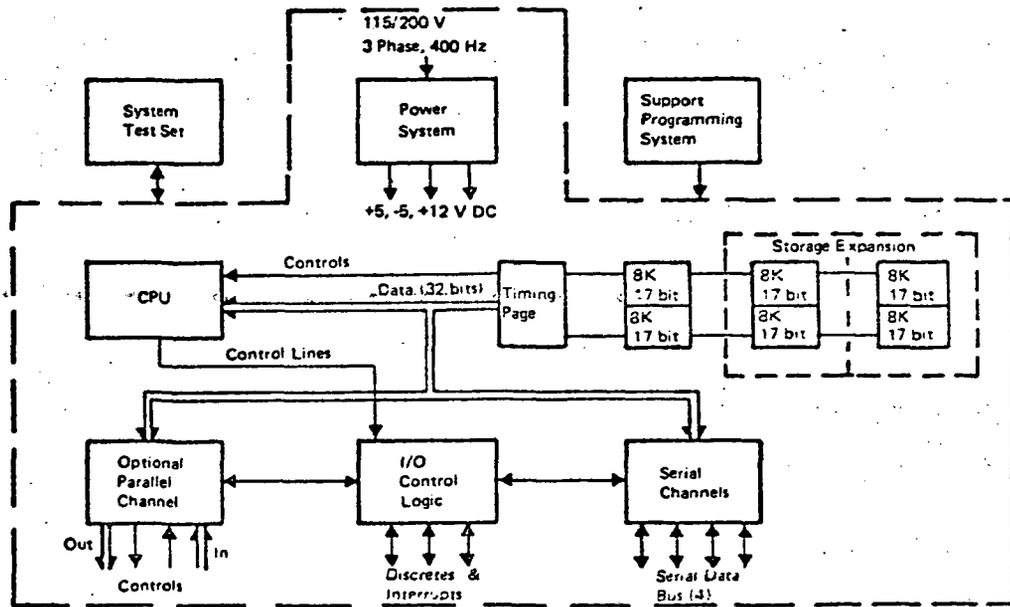

Power System

Primary Power	115/200 V AC, 3 phase, 400 Hz OR 28 VDC
Power	250 W (32 K halfword main storage)
Features	Overvoltage and overcurrent protection; transient protection; power sequencing

Physical

Volume	0.87 ft ³
Weight	40 lb (32 K halfword main storage)
Environment	Meets or exceeds MIL-E-5400, Class 2X

A block diagram of the AP-1 computer is shown below.

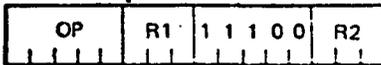

4.18.3-1 AP-1 Functional Block Diagram

CPU Characteristics

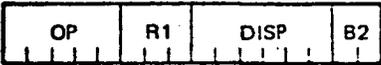

Type	General-purpose, stored program, simplex - 4 SETS OF GENERAL REGISTERS		
Number system	Binary, fixed-point, two's complement, fractional		
Operation	Full parallel		
Data word length	32 bit fullword, including sign		
Instruction word length	16 or 32 bits		
Instruction set	42 short (16 bits) and 41 long (32 bits)		AP-101 ≈ 117 instr.
Typical execution times	Storage to Register (μs)		Register to Register (μs)
	Add	2.0 1.6	1.2
	Multiply	6.6 5.4	6.0
	Divide	10.6 8.6	10.0
Average instruction execution rate	Over 450,000 instructions per second using typical instruction mix (68% add or equivalent, 18% branch, 5% multiply, 1% divide, 8% miscellaneous) (AP-101 550,000)		
General registers	Two selectable sets of eight 32-bit hardware registers; in each set, all are usable as accumulators, seven are usable as index registers, and four are usable as base registers		

Instructions

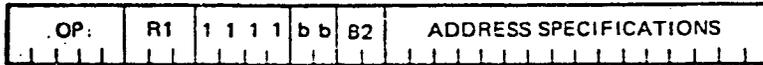

The five basic instruction formats shown below allow most operations to be coded in either a halfword or fullword instruction. The halfword format instructions not only provide increased throughput, by means of the instruction-look-ahead feature of the AP-1, but significantly improve the storage efficiency of the computer. Improved storage efficiency means decreased storage capacity requirements for operational programs, since typical applications have consistently demonstrated that the short format (16-bit) instructions account for over 70% of the instructions used. The AP-1 Assembler program automatically optimizes the object program by selecting the short format instruction whenever feasible.

RR (Register to Register)

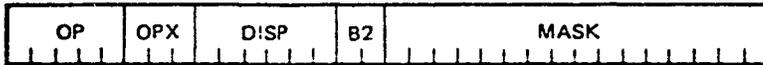

SRS (Short Register to Storage)

LRX (Long Indexable Register to Storage)

SSS (Short Storage to Storage)

LSS (Long Storage to Storage)

- OP and OPX Operation code and operation code extension
- R General register designation
- DISP Displacement field
- B Base register designation
- bb Addressing mode

The AP-1 general-purpose computer features an efficient instruction set, resulting in low main storage overhead and high throughput. A comprehensive set of halfword and full-word instructions are provided for arithmetic, logical, bit manipulating, data formatting, and input/output operations. Extended mnemonics for the Branch-on-Condition instruction aid in simplifying programmer source coding.

		AP-1 Instruction Set					
Instruction Type	Basic Instruction	Typical Execution Time (SRS) (μ s)	Format				
			RR	SRS	LRX	SSS	LSS
Arithmetic	Add	2.00 (1.6)	X	X	X		
	Compare	2.00	X	X	X		
	Divide	10.75 (8.6)	X	X	X		
	Load	2.00	X	X	X		
	Modify Storage	3.12					X
	Multiply	6.75 (5.4)	X	X	X		
	Store	2.00		X	X		
	Subtract	2.00 <i>AP-1cl</i>	X	X	X		
	Tally Down	3.12 <i>examples</i>				X	
Logical	AND	2.00	X	X	X		
	Exclusive OR	2.00	X	X	X		
	OR	2.00	X	X	X		
	OR Bits	3.12					X
	OR Halfword	3.12				X	
	Test Bits	2.75					X
	Test Halfword	2.75				X	
	Zero Bits	3.12					X
Branch	Branch and Link	1.37	X	X	X		
	Branch on Condition	1.37	X	X	X		
	Branch on Count	1.62	X	X	X		
	Branch on Overflow & Carry	1.37	X	X	X		
	Shift	Normalize and Count	$1.32 + n/4$	X			
Shift Left Single & Double Logical		$1.87 + n/4$		X			
Shift Right Single & Double Arithmetic & Logical		$1.87 + n/4$		X			
Input/Output		In	1.87			X	
	Load AGE	2.00		X	X		
	Out	2.12			X		
System Instruc- tions	Load Multiple	10.37		X	X		
	Load PSW	2.25		X	X		
	Load System Mask	2.25	X	X	X		
	Store Multiple	10.12		X	X		

Organization

The organization of the AP-1 computer offers very versatile addressing. The addressing technique accommodates 65,536 halfword addresses in the main storage. The generation of Storage Operand Effective Address is a function of the instruction format; and offers short or extended displacement addressing, direct and indirect indexed address, and immediate operands.

The AP-1 computer contains two selectable sets of eight 32-bit general registers, which may be used as accumulators for fractional binary arithmetic; for logical and shifting operations; or as base registers, index registers, or temporary storage.

Interrupt handling normally requires a put-away routine and a storage area to save the general registers whenever an interrupt servicing routine is entered; then the registers must be restored at the end of the interrupt routine. Assigning one set of the general registers to interrupt (executive) routines and the other set to the problem programs gives an improvement in throughput and storage efficiency. Alternatively, in a multiprogramming environment, assignment of the general register sets among the problem programs may produce even greater throughput.

Main Storage

Main Storage Features

Type	Ferrite magnetic core, nonvolatile, random access, destructive read-out
Capacity	Choice of 16,384; 32,768; or 49,152 18-bit halfwords, including 1 parity bit and 1 store protect bit, for the optional store protect feature, within the existing structure. A slightly larger structure will accommodate 65,536 halfwords
Modularity	8192 18-bit words
Cycle time	1 μ s write or read/restore \rightarrow 900 ns AP-101
Access time	450 ns
Electronics	Monolithic
Special features	Power transient protection, separate sense winding, 2-1/2D Organization, temperature compensation

A militarized, 1- μ s core storage array organized in a 2-1/2D addressing scheme forms the basis for the AP-1 main storage, which is implemented primarily with monolithic circuits on two unique page types: an 8 K X 18-bit storage page and a timing page. The storage page contains 8/13 mil,* wide-temperature-range, ferrite cores with self-contained, temperature-compensated voltage regulators, address drivers, sense amplifiers, and a storage data register. A single timing page can handle up to eight storage pages, providing 8 K X 18-bit modularity up to a maximum of 64 K halfwords of storage. No adjustments are required to provide complete interchangeability of the pluggable modules.

Input/Output

High-speed internal operations, coupled with a versatile serial and/or parallel input/output, provide for excellent throughput. The four-channel multiplex serial I/O services up to 15 peripheral devices per channel at a data rate of 1 megabit per second. The data-handling capacity of each transformer-coupled, party-line, serial data bus may be up to 45,000 half-words per second, depending on the amount of data blocking.

I/O Characteristics

Serial channel	Direct memory access; four multiplexed I/O channels; up to 15 devices per channel
Data interface	Serial, 1 MHz, transformer-coupled (70-ft lines)
Maximum data transfer rate	45,000 halfwords per second per channel 180,000 halfwords per second for 4 channels
Parallel channel (Option)	Direct memory access, externally controlled, 750,000 halfwords per second, maximum Buffered I/O, externally controlled, 480,000 halfwords per second, maximum Direct I/O, program controlled, 240,000 halfwords per second, maximum
Data interface	16 bits plus address and control, single-ended TTL interface
Maximum data transfer rate	240,000 to 750,000 data words per second
Features	Channel-to-channel interface Externally specified channel-control-word chaining on buffered I/O
Discrete inputs (typical)	12, DC coupled
Discrete outputs (typical)	12: 3 relay controlled; 9 DC coupled
Program loadable/readable counters	Two 6-second counters with 100- μ s resolution; one 3-second counter with 50- μ s resolution
Interrupts (typical)	12 internal and 4 external; 9 levels of priority with program mask control

Transformer coupling and the sinusoidal Manchester phase-coded signals provide data transmission reliability not possible with direct-coupled DC lines. The AP-1 transmission lines can withstand a short or an open without affecting data transmission. This is particularly desirable in a party-line I/O system. An unterminated line design allows removing units without disrupting operation of the line.

Each serial channel is initialized separately by a program instruction. Facilities exist to permit block transfer of data words and to provide for chaining blocks of data. Data and control words are transferred to and from the CPU general registers or main storage. ~~Peripherals respond only when a select code commands a response.~~

An optional multiplex interface module (MIM) can provide a compatible interface between an I/O device and the serial channel. One version of the MIM (shown in the serial I/O application diagram) features a back-up channel for improved I/O reliability, parity checking and generation, peripheral unit selection logic, parallel-to-serial data formatting, and automatic gain control to assure uniform data amplitude during transmission.

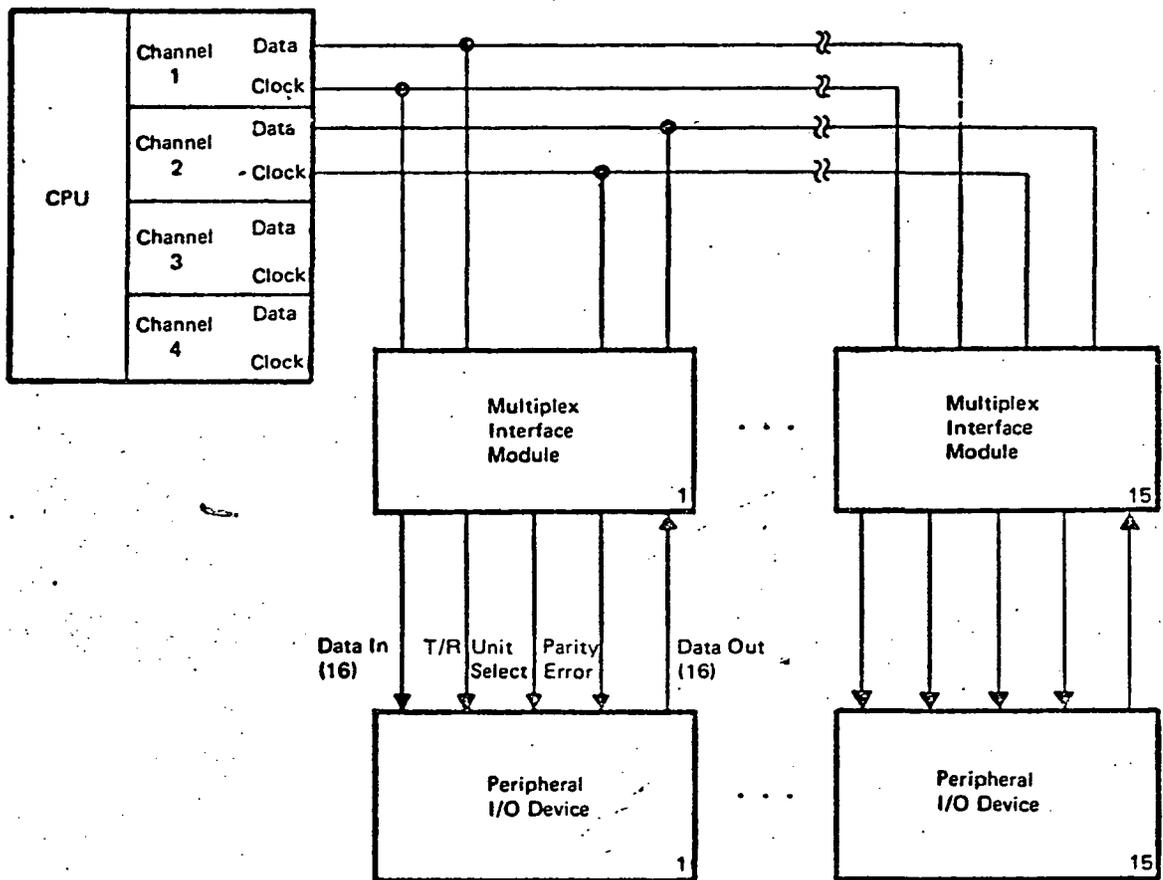

Figure 4.18.3-2

Typical serial channel application shown for channel 1 primary and channel 2 backup. Four channels are available.

Designed for inclusion in each peripheral I/O device, the MIM connects the serial bus interface to a parallel TTL interface, and includes the control lines necessary to service most I/O devices.

The I/O capacity of the AP-1 may be increased by adding an optional high-speed parallel channel. This parallel channel may be used with, or in place of the serial channel in applications requiring support of such high-speed I/O devices as the IBM System/4 Pi Drum Mass Memory,

Input and output data busses provide transfer of data unidirectionally to the peripheral devices. The parallel channel interface has been standardized to assure I/O compatibility with other computers of the Advanced System/4 Pi family, such as the SP-1.

The parallel channel can support four devices, each of which may be an I/O unit, such as a drum or magnetic tape unit, or a control unit. Each control unit may interface with as many as 127 I/O devices, giving the AP-1 excellent and versatile I/O support potential.

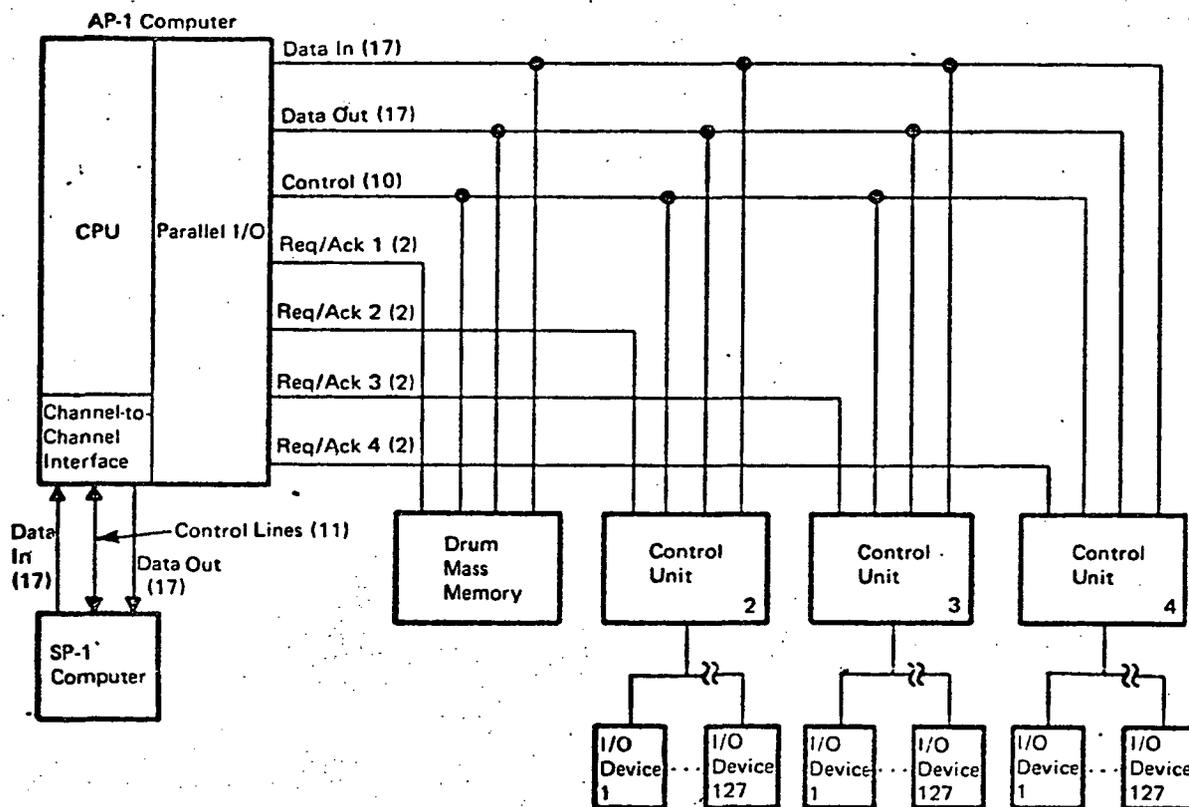

Figure 4.18.3-3

Typical parallel channel application, showing direct device attachment (drum) and control units with maximum number of peripherals attached.

Three I/O modes are provided for transfer of data and command functions between the AP-1 computer and peripheral equipment:

- 1) **Direct Memory Access (DMA) I/O** — The I/O device supplies a 16-bit main storage address, and 16 bits of data are written into or read from the storage location. DMA I/O is device initiated. A CPU lockout feature significantly increases the data rate to a maximum of 750,000 halfwords per second.
- 2) **Buffered I/O** — The I/O device provides an "address tag", used to access a channel control word (CCW) containing count and address; a single word or a block of data words are written into or read from main storage. Buffered I/O is device initiated. A maximum data rate of 480,000 halfwords per second may be reached when the CPU is locked out.
- 3) **Direct I/O** — Under control of the CPU instruction stream, a command is sent to an I/O device, and one word (16-bits) of data is written into or read from the device. Direct I/O is program initiated. The data rate is a function of the operation following the transfer and may be as high as 240,000 halfwords per second.

In addition to high speed, the AP-1 parallel channel provides several features for expanded performance. Most significant is the channel-to-channel interface, which permits the AP-1 to transfer data to or from another member of the advanced System/4 Pi family, such as the SP-1 or another AP-1. The AP-1 channel, although faster than the SP-1 channel due to the higher main storage speed, is compatible with the SP-1, thereby permitting communication between the AP-1 and the SP-1.

Being able to externally chain two channel-control words while in the Buffered I/O mode increases the length of the data block that may be transferred. Provisions for an expanded control word for Direct I/O enhance the number of different I/O functions or transfers that may be performed.

A priority interrupt system is implemented with full masking capability for nine levels. Four external interrupts and 12 internal interrupts automatically store the current program status word in an assigned main storage location and begin an interrupt servicing routine. The internal interrupts include arithmetic conditions, time, machine errors, and I/O termination interrupts.

Three program-loadable/readable counters are provided in the I/O logic of the AP-1. One of these is used principally to implement I/O time out monitoring. The other two may be used in any countdown application. All three issue an interrupt when the countdown reaches zero.

The I/O serial and parallel channel interfaces are shown on the following page. Four serial channels are available as standard I/O on the AP-1. Each consists of a clock line and a two-way serial data bus. On the parallel channel each device has unique Service Request and Service Acknowledge lines. Four pairs of these lines are built into the parallel channel. In addition, the I/O implementation includes an interchannel interface that interacts with the data out and/or data in bus of another AP-1 or SP-1 computer.

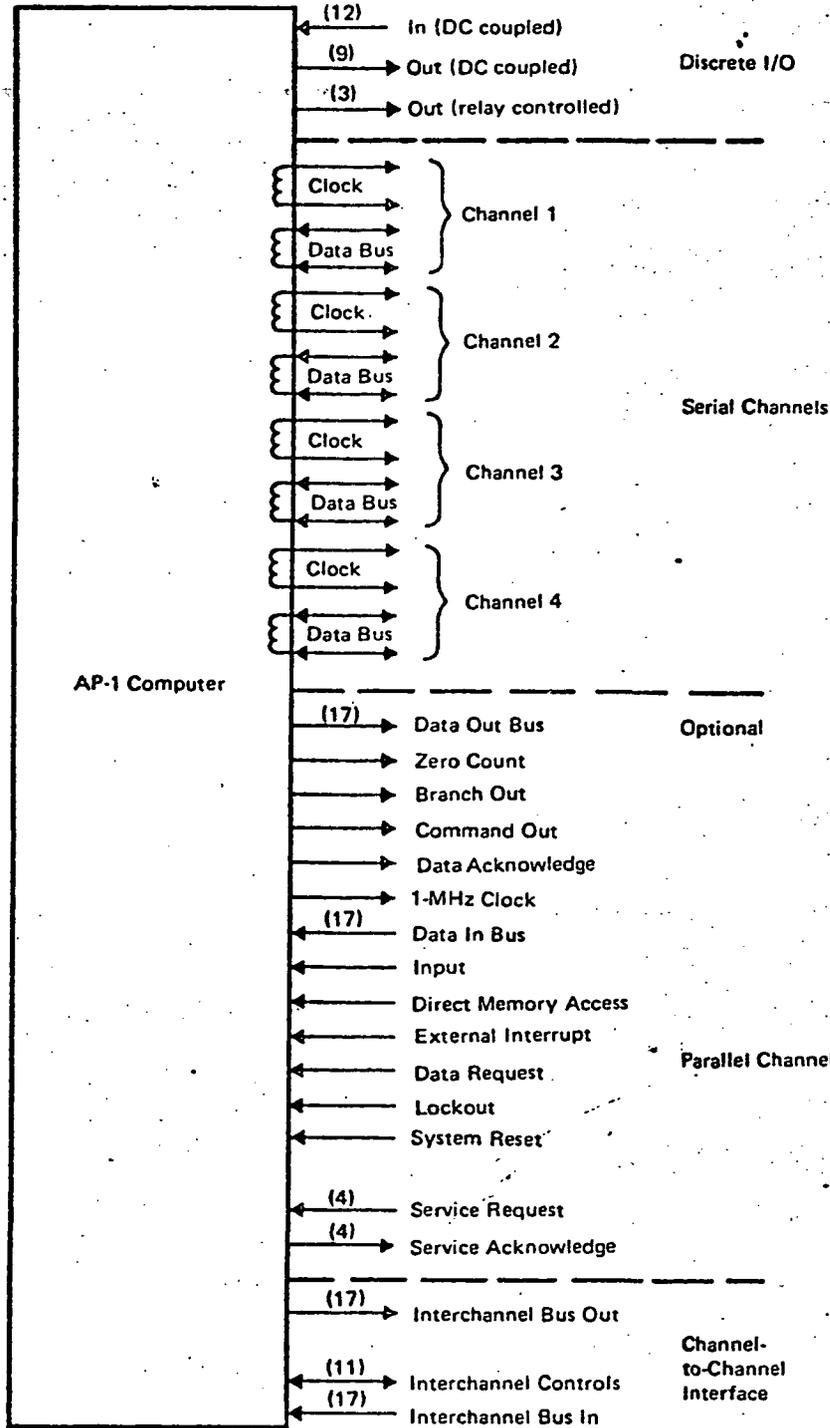

Figure 4.18.3-4 I/O Interface

Options

Nine major options are available for extending the capability of the AP-1 to meet specific application requirements. These options are summarized below:

- 1) Expanded Main Storage — The minimum configuration AP-1 has a 16-K halfword main storage. This may be expanded in 16-K increments to 48 K halfwords by inserting pairs of main storage pages (plus replacing the timing page with a new timing page for a 48-K storage). This modification is field installable.
- 2) 64-K Main Storage — An expansion to a 64-K halfword main storage may be done without any changes to the architecture and organization of the computer. A slightly larger structure to accommodate the additional main storage pages is the only other requirement in addition to that listed for a 48-K halfword main storage.
- 3) Main Storage Extension — Additional 64-K halfword modules of external main storage may be attached to the AP-1 computer. A factory modification, this feature permits a memory extension to 256-K halfwords directly addressable by the CPU through storage interface logic (SIL). The interface is implemented on an additional SIL page pluggable module working with the external main storage extension packages.
- 4) Parallel Channel — A high-speed parallel channel with support for four devices (four pairs of unique request and acknowledge lines) is available. Featuring a channel-to-channel interface and compatibility with other Advanced System/4 Pi computers, this channel provides both general register and direct memory access data transfers. The parallel channel option is field installable. Details for the parallel channel are described in the I/O section of this document.
- 5) Store Protect Feature — A store protect option, which prevents the accidental overwrite of protected halfwords, is available as a factory modification. The store protect bit is set on the selected halfwords during the memory load through the AGE interface. It is not program resettable, assuring maximum integrity of the protected data. If an attempt is made to write in a protected area, an interrupt will be issued and serviced by the interrupt routine. Each MCM-1 main storage page is populated with the necessary store protect bits.
- 6) Maintenance Library Program — An optional software feature, the MLP is used to test and debug operational programs on the AP-1 computer. Used in conjunction with an external data adapter and peripheral equipment such as a keyboard, CRT display, and tape drives, the MLP simplifies the task of operational program checkout and maintenance.
- 7) Floating Point — This option allows floating-point operations for extended range applications. A factory modification, the floating-point feature provides both long and short fraction operands. The floating-point operands consist of a 2's complement, signed integer exponent, and a 2's complement fraction. General registers 4 and 5 serve as the floating-point register first operand during floating-point operations.

AP-101 FORMATS
8/24 + 8/40

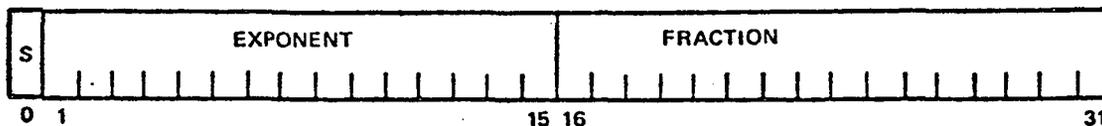

8 BIT EXPONENT
WILL BE HEXADECIMAL

- 8) Field Programming System (FPS) – The FPS is an AP-1 software option that provides for generating and testing operational software directly on the AP-1 computer using the computer test set, paper tape reader, paper tape punch, and a typewriter.
- 9) Compiler – A compiler may be provided to extend the AP-1 language translation facilities to include a higher order language (HOL) such as JOVIAL, FORTRAN IV, HAL, ETC. Translation of the HOL by the compiler to AP-1 macro assembler language simplifies implementation of this option.

Floating-Point Arithmetic (Optional)

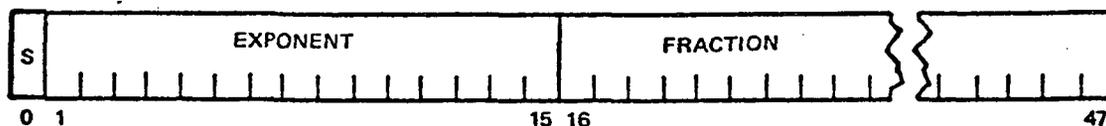

Floating-point data occupy a fixed-length format, which may be either a fullword short format or a three-halfword long format.

Short Operand

AP-101
8/24

Long Operand

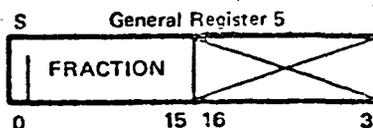

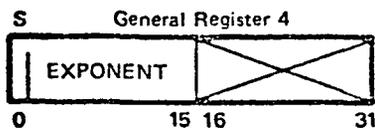

8/40

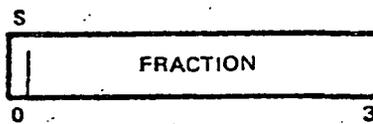

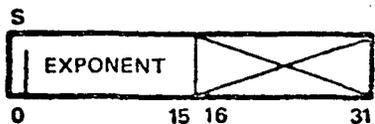

Note: The sign of the normalized fraction is unlike the first binary fraction digit.

The first operand is contained in a pair of general registers. General register 4 contains the exponent of the first operand in bits 0 through 15. Bits 16 through 31 are ignored. General register 5 contains the fraction of the first operand. The fraction of a short floating-point number is contained in bits 0 through 15 of general register 5. The fraction of a long floating-point number is contained in bits 0 through 31 of general register 5.

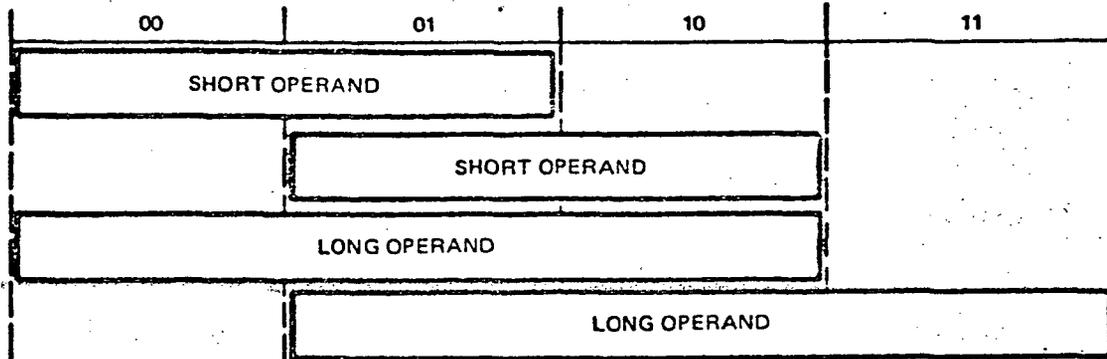

Short Operand

Long Operand

The floating-point second operand may start at any halfword address. The figure below illustrates floating-point data placement in main storage.

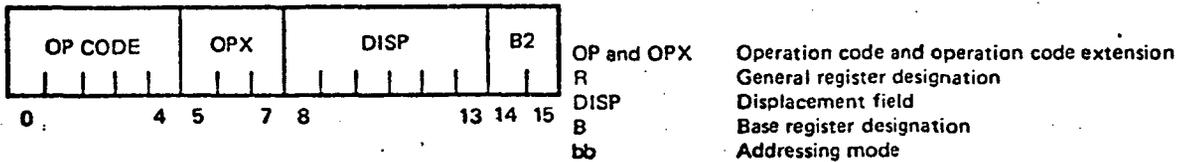

Floating-Point Data Placement in Main Storage

Floating-Point Exceptions

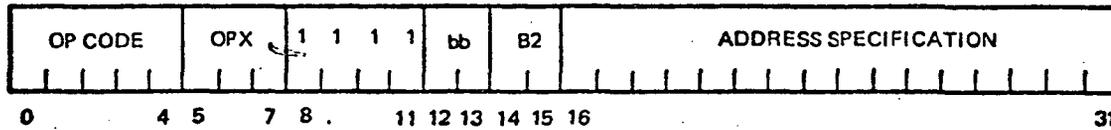

The operand incompatibility interrupt, exponent overflow interrupt, and the floating-point divide interrupt are the three floating-point exceptions. A bit in the program status word (PSW) may be used to mask and hold these pending until the PSW bit is reset to zero. The exception is then honored by a PSW swap. The interrupt code in the "old" PSW identifies the particular exception.

The instruction formats are:

Short Format

Long Format

These formats are identical in form and addressing modules to the SRS and LRX instruction formats.

Floating-Point Features

Data	Exponent: 16 bits Fraction: Short 16 bits Long 32 bits Range: 10^{-9864} to 10^{+9864} (approx)	AP-101 8 BITS - HEX 24 BITS 40 BITS
Instruction Length	Short: 16 bits Long: 32 bits	
Repertoire	Add; Add Long Subtract; Subtract Long Multiply; Multiply Long Divide; Divide Long Load; Load Long Store; Store Long Convert to Floating Point Convert to Fixed Point	
Average Execution Times	Add 4.00 μ s Multiply 9.50 μ s Divide 13.50 μ s	AP-101 → 2.6 μ SEC.

Field Programming System (Optional)

The AP-1 FPS provides the programmer with the facilities to

- 1) Generate and edit source input tapes
- 2) Assemble the source program modules from the generated tapes
- 3) Link the program modules into an executable program
- 4) Control program checkout through entry and display of data during program execution

The AP-1 FPS consists of the following program components:

- 1) Tape Generation and Edit (TGE) program
- 2) Assembler
- 3) Linkage editor
- 4) Program verification package.

The TGE module gives the problem programmer a tool for placing the source program module on punched tape, modifying that tape module before assembly, and listing the contents of the source tape.

The FPS assembler provides programmers with a convenient means of writing operational programs to be run on the AP-1 computer. The assembler accepts as input a symbolic source program module written in the assembler language, and produces as output an object program module. The module is ready for subsequent processing by the FPS linkage editor. The assembler language is upward compatible with AP-1 macro assembler, which operates on the IBM System/360. Programs written in the FPS assembler language may be assembled on either the System/360 or the AP-1.

The FPS linkage editor, like the System/360 AP-1 linkage editor, accepts as input independently produced object modules generated by the assembler. The linkage editor links these modules together into a single AP-1 executable program.

The program verification package (PVP) helps the user check out his program by providing dynamic control over the program while it is being executed on the AP-1. The user may control program debug by entering commands to the PVP directly through the typewriter or indirectly through a user-written test information program.

Compiler (Optional)

A compiler can be provided to extend the AP-1 language translation facilities to include a higher order language. The compiler translates programs written in HOL JOVIAL to the AP-1 macro-assembler language.

The selective use of a HOL for military computer applications has been demonstrated to be cost- and schedule-effective. In addition, HOL programming addresses the military need for software commonality and maintainability.

With the compiler, the AP-1 application programmer has at his disposal three languages to express his problem:

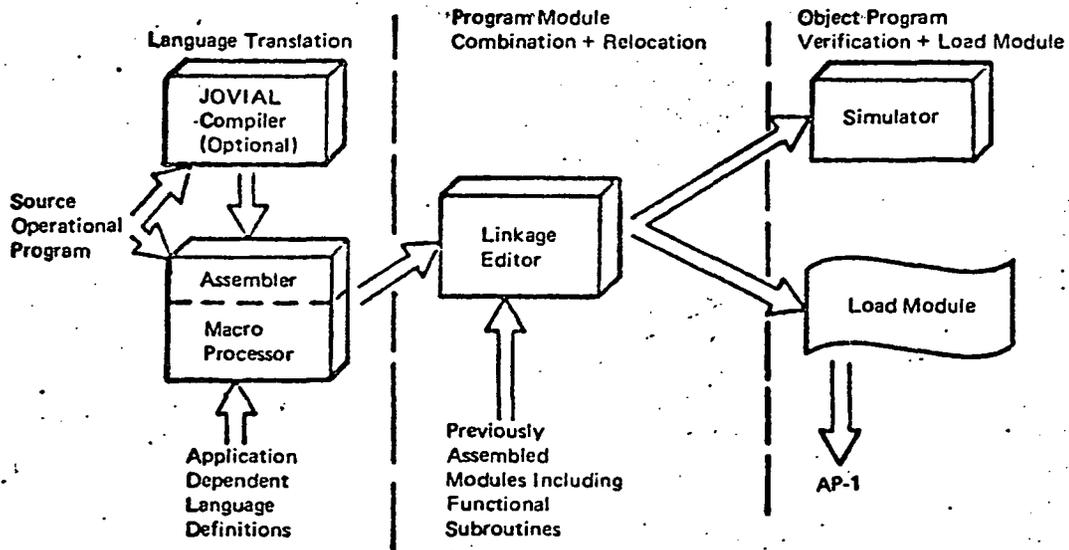

- 1) JOVIAL
- 2) Macro
- 3) Assembler.

To augment this capability, the subroutine library may be called by any one of the above languages. The programmer may intermix the use of these languages in any combination to achieve an optimum program for the AP-1 application.

For example, the HOL is well suited for the major and primary mission tasks. The macro language is ideal for defining unique application functions, including input/output, and the assembler language best handles time-critical and bit-handling operations.

AP-1 Computer Support Software

The AP-1 Support Programming System (SPS) provides the application programmer with a flexible set of aids designed to effectively reduce the time required to develop application programs to support program modification and maintenance. Continuing a field-proven concept, the AP-1 SPS, operating on System/360 under OS control, gives the user an assembler, a linkage editor, a simulator, a subroutine library, and an optional compiler. The program generation process is shown in the following illustration. An optional Field Programming System (FPS) permits generating and testing programs directly on the AP-1 computer.

AP-1 Support Software Program Generation Process

Macro-Assembler

The AP-1 assembler provides the programmer with a symbolic source language that produces storage-efficient, high-throughput programs using the effective instruction set defined by the computer's architecture. An excellent macro capability combined with mathematical subroutines significantly reduces the repetitive coding required of the application programmer.

Identical in most respects to the widespread, well-known System/360 assembler language, the AP-1 assembler requires minimum retraining of experienced programmers and provides early on-line release of new trainees, thus significantly reducing training costs. High-quality user and programmer manuals assist the programmers in the effective use of the AP-1 assembler language. Programming rules and techniques, such as modular programming (C-sects, D-sects, etc.), syntax, macro generation, symbols and labels, source instructions, comments and combinations, and subroutine linkage, are in most cases identical to System/360 operations.

Linkage Editor

The AP-1 linkage editor accepts as input independently produced object modules generated by the AP-1 assembler. The linkage editor combines and relocates these modules, resolves module linkages, and generates an executable load module suitable for AP-1 execution or simulation. This load module is available on paper and magnetic tapes for loading the AP-1 memory. Corrections can be made to the object modules at linkage edit time. The AP-1 linkage editor also produces a symbolic listing of the relocated load module complete with operation mnemonics, labels, and absolute addresses.

Simulator

The AP-1 simulator dynamically analyzes the executable load module produced by the AP-1 linkage editor for programming errors and unusual conditions. The user has complete control of portions of code to be simulated and of stopping conditions. In addition, the user can choose several types of debug outputs, including full or partial dumps; instruction-by-instruction traces, complete with location symbols; and location snaps. He may, if he desires, devise his own format for simulation control inputs through entries that are available to attach simulated I/O devices.

The AP-1 simulator program consists of a series of subroutines. To form an executable simulation capability, these subroutines are combined with a user-written control program. This control program reads the control input and passes control information to the simulator through subroutine calls.

Subroutine calls are made through a screening interface, which detects syntax errors, if any, in the call; then passes information to the appropriate subroutine.

The actual simulation is done interpretatively, with an execute table of interpretative instructions being built and changed dynamically during simulation. Corrections to the load module to be simulated can be made at any time during the simulation.

Functional Subroutine Library

The AP-1 functional subroutines consist of the elementary trigonometric, vector, and conversion routines. The linkage editor selectively includes these in AP-1 application programs as needed.

AP-1 Support Software

Assembler	<ul style="list-style-type: none"> Efficient symbolic language Modular programming and testing Assembles relocatable programs Selects instruction length for the AP-1 machine instructions Provides syntax error detection and identification Allows macro-processing and conditional assembly Produces listed output

The SKC-2000 Computer

A general purpose, high performance digital computer, the SKC-2000 bases its modular design upon a single data and control bus interconnecting all modules with a standard interface to provide true modularity and maximum flexibility. Modular flexibility is further augmented by asynchronous module operation, a complete spectrum of input output capabilities, and contemporary mechanical design utilizing sandwich construction which is easily expandable.

SKC-2000 modules' strict compliance with asynchronous modularity concepts permits module

mixing or matching, and growth by adding modules or through replacement with modules using newer technologies.

SKC-2000 modules can be used, for example, to form a simplex central computer, a multi-computer, or a multi-processor installation with equal ease. Modules for a simplex computer typically include a central processor module, one or more memory modules, a power supply module, and an input/output module. Because individual modules are relatively small, they are packaged most efficiently as part of the larger SKC-2000 computer.

SKC-2000 FEATURES

Type General purpose, parallel, asynchronous module, high speed data/control bus
 Military Specifications MIL-E-5400 Class 2, MIL-E-16400

PARALLEL CENTRAL PROCESSOR MODULES

Number Systems	Binary, floating point and two's complement fixed point		
Data Words, Floating Point	24 bit mantissa, 8 bit exponents		
Data Words, Fixed Point	32 bits including sign		
Instruction Words	16 bits short and 32 bits long		
Instructions	99 total long and short		
Address Modes	direct, indirect, relative, immediate		
Indexing 1st Level Registers	7	} 4 groups for a total of 88	
Indexing 2nd Level Registers	15		
Execution Times, Average for:	1.9 μ sec Memory	1.9 μ sec Memory with LSI	ROM Program Store & LSI Scratchpad

Options	Fast shift matrix, $\frac{1}{2}$ word arithmetic		

MEMORY MODULES

Standard Type	20 MIL DRO lithium ferrite core, coincident current 3 wire, 3D
Optional Types	Plated wire, 1.2 μ sec 2 $\frac{1}{2}$ D core, solid state LSI scratchpad, solid state ROM
Module Size	4K, 8K words by 32 bits
Access Time, LSI	0.25 μ sec
Access Time, 1.9 μ sec Core	<1.00 μ sec
Protected Program Storage	2 AGE and/or program controlled subsets
Contents Protection	Over-voltage; under-voltage; over-temperature; erroneous input signals
Special Techniques	Selection currents controlled by single thermal sensor; strobe timing slaved to selection current amplitude
Electronic Technology	MSI/TTL, Hybrid
Power, Long Term Average	85 watts typical, 1.9 μ sec cycle core
Voltages	\pm 5 volts \pm 5%; \pm 12.5 volts \pm 2%
Weight	6 pounds including structure

INPUT/OUTPUT CAPABILITY

Program Interrupts	16 priority levels — expandable (7 preassigned including power failure, BITE, Control Console)
Direct Memory Access I/O	16 priority levels (2 preassigned)
Data Bus	32 bit parallel — 4 MHz
Data Flow, 1.9 μ sec Memory	500,000 words/sec
Data Flow LSI Memory	1,000,000 words/sec
Programmed I/O	To/From Memory; To/From CPU, command or data designation, with or without acknowledge
Channel Device Codes	61 directly addressable; 14 are useable for DMA
Discretes (Input Switch Type)	8 directly interrogated and branched upon

PHYSICAL FEATURES

Packaging	$\frac{1}{2}$ ATR cross section, variable length
Cooling	Forced air or cold plate
Circuit Cards	X-Y

Baseline SKC-2000	Parallel CPU, 8K x 32 bits 1.9 μ sec cycle memory, 3 card I/O and power post-regulators
Size	15.33 in. long \times 7.50 in. wide \times 4.88 in. high
Power	245 watts including regulator loss
Weight	19.7 pounds

The order set of 99 was derived by detailed consideration of aerospace computer programming requirements and is a balanced set providing an optimum combination for computation and programming ease. Inclusion of many big-machine features facilitates transition to the SKC-2000 by the programmer who is familiar with large commercial computers.

Instructions having short and long formats, 16 and 32 bits respectively, enhance efficient memory usage. Experience shows that 80% to 90% of the instructions will be in short format form. Typically, instructions use the greater part of memory. Hence, packing two instructions per memory word results either in appreciable reduction in memory size or a greatly increased number of instructions

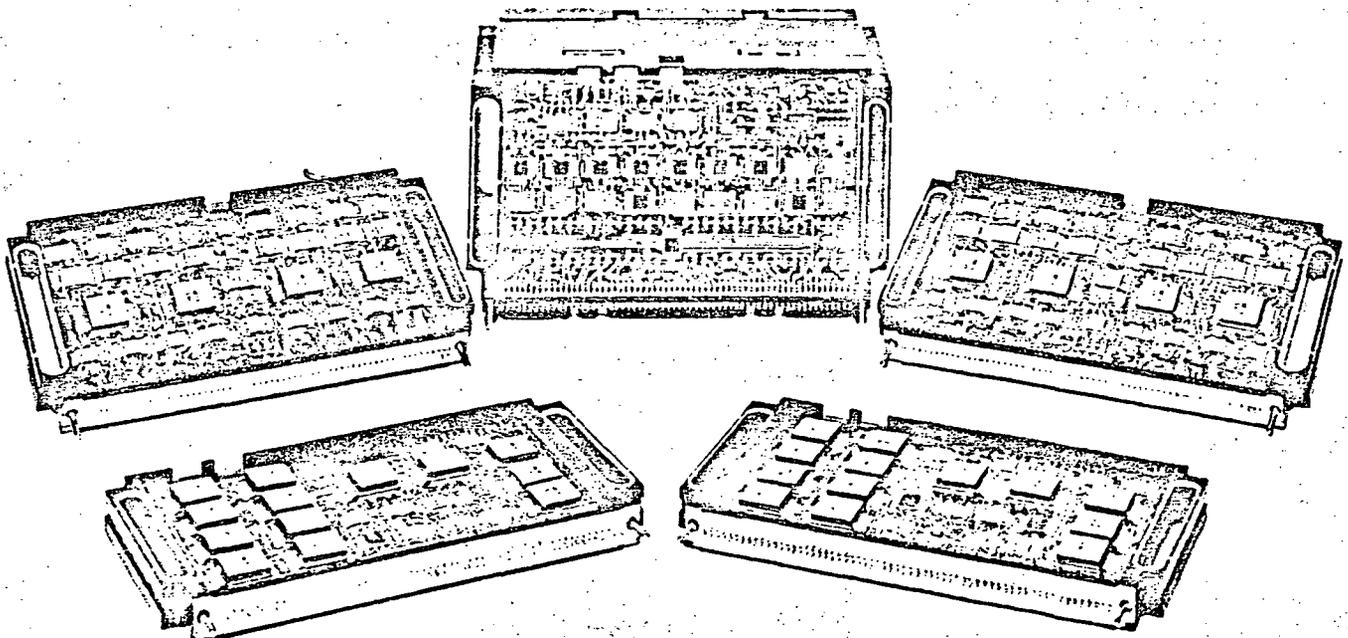

for a given memory size. An 8192-word memory module provides approximately 10,000 instructions and 2,000 words of scratch pad, making it the equivalent of a 12,000-word memory.

Addressing modes include: (1) direct, for operand location at the address specified by the instruction; (2) indirect, for operand location at the address specified by the instruction (up to 16 levels); (3) relative, for operand location at the effective instruction address plus first and second level index registers; and (4) immediate, for operand location in the address portion of the instruction. Relative addressing may be combined with either direct or indirect addressing.

MEMORY MODULES

Designed as independent, asynchronous modules of 4K or 8K words by 32 bits, standard ferrite core memory modules have 1.9 microseconds cycle time. Asynchronous modules operate independently of the 4 MHz computer clock and use an initiate

pulse from the requesting processor or device to start the memory cycle and issue a "data available" signal at the cycle's completion. Thus, asynchronous operation allows use of any memory cycle time while maintaining full compatibility with other modules.

Optional memory modules include LSI read only, LSI read/write, plated wire, and 1.2 μ sec 2½ D core.

Standard core memories use MSI, TTL, and hybrid circuits to provide high reliability and small size. A novel circuit using a single precision alloy resistor mounted on the core stack to sense temperature and to control X and Y currents for both read and write, precisely slaves read and write currents to each other.

Another unique circuit slaves strobe timing to selection current amplitude and rise time, assuring interrogation at the output signal's optimum point.

Memory modules provide program storage protection against inadvertent write cycles, the protected portion being adjustable by program control or during manufacture to fit system requirements. Another design feature is the inclusion of memory address latches within each module.

Protection against over-voltage, under-voltage, over-temperature and erroneous input signals is built into the memory module. Resulting signals force the computer into a shut-down routine and are transmitted to the system's built-in test equipment (BITE).

INPUT/OUTPUT MODULE

Extensive input/output capabilities of the SKC-2000 facilitate design of an application-oriented

I/O module and provide direct communication with external units. I/O capabilities of the computer include:

1. Data Transfer
 - a) Program Controlled; "A" Register, Memory
 - b) Direct Memory Access
2. Priority Interrupts
3. Discrettes (switches)

Program-controlled I/O utilizes programmed instructions to transfer information to and from the computer "A" register or to and from the computer memory. These instructions may request an acknowledgement and may designate the information being transmitted either as data or as a command. All combinations of input/output, acknowledgement, and data/command give 16 types of program-controlled transfers for each of 61 directly addressable devices. Program-controlled I/O instructions are long or short instruction formats for global and non-global addressing with indirect addressing applicable to global addressing.

Direct memory access (DMA) by other computers or devices allows high speed data transfer to and from SKC-2000 memory modules independent of central processor module operation. Access to the memory is accomplished via the bus system allocated to various users on a priority basis. Use of DMA facilities permits an external device to insert or extract words almost arbitrarily from the computer memory, bypassing all program control logic. DMA transfer is particularly well suited to devices transferring large amounts of data in block form such as tapes, drums and disks, for information exchange between computers, or for sensors generating or requiring large amounts of data.

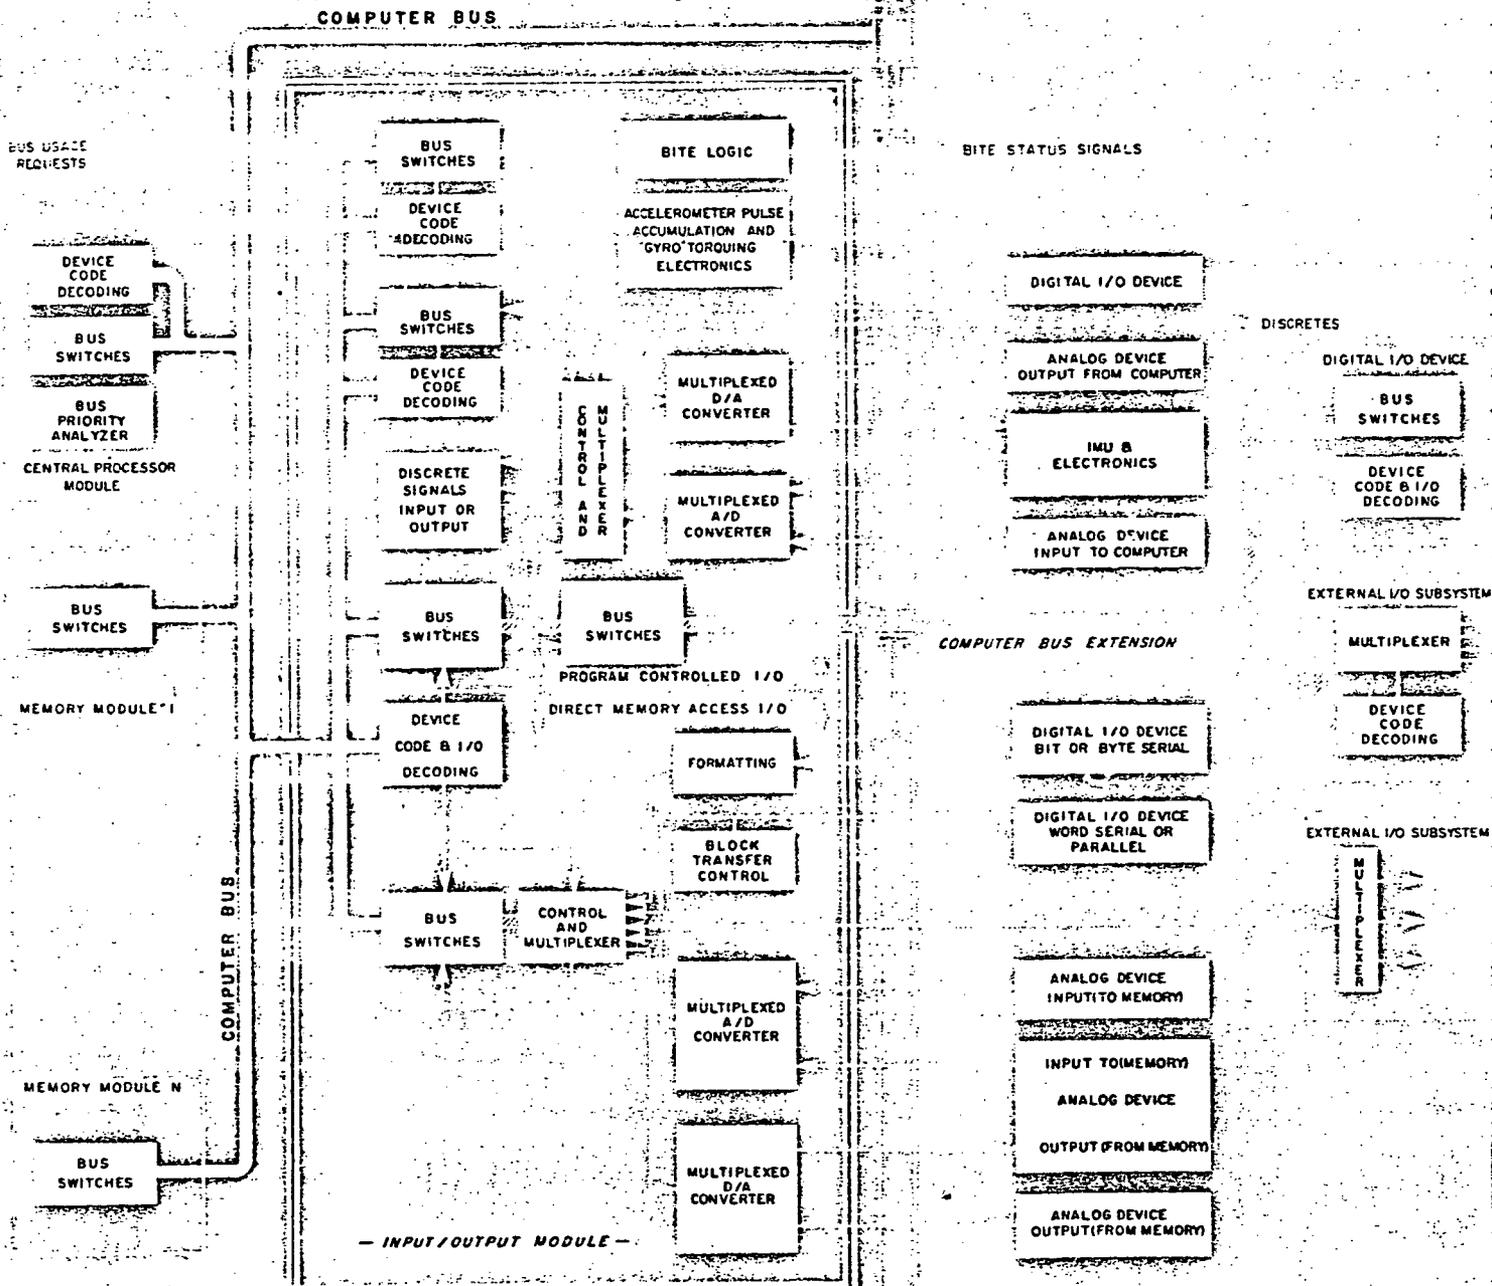

Program interrupts are signals having preassigned priority which divert the program to assigned locations in memory. Jump commands in each of these locations direct the computer to the interrupt sub-program. The program counter value at the time of the interrupt is stored for use when returning to the main program. Of the 16 interrupts provided in the basic computer, 7 are preassigned, leaving

9 for other system uses. Unlimited interrupt expandability may be provided in the input/output section.

8 discrete (switch) inputs which are directly accessible to the program via the "Jump on Switch i" order are accepted by the SKC-2000. Additional discrettes may be handled by conventionally programmed I/O techniques.

- SKC-2000 COMPUTER -

8 DISCRETES DIRECT TO CPU AGE CONNECTOR

TYPICAL INPUT/OUTPUT CAPABILITIES

Typical I/O channel capabilities include serial channels with I/O bit rates up to 4 megabits/second. Channel control can be by direct program control, by an I/O processor operating independent of the program, or by an I/O processor which operates independently but is directed by software. Similarly, parallel channels operating at up to 16 megabits per second are available.

A block transfer channel for communication with standard peripherals in byte format is also available. This channel is started under program control by setting a register with the starting address and number of words to be transferred. The transfer is then automatically controlled by the block transfer channel which stops when the correct number of words have been transferred.

Analog to digital and digital to analog converters built into the SKC-2000 digital computer's input/output module are compact, high accuracy, high reliability circuit board-mounted units demonstrating high-speed conversion compatible with high

speed computers. Self-checking capabilities assure operational precision.

BITE SUBMODULE

A comprehensive combination of software and hardware built in test equipment provides efficient self-test features for error detection and program protection and is integral to computer design. The BITE submodule is located in the I/O module.

In operation, the combination —

- determines computer performance
- protects hardware from damage
- protects memory against information loss
- isolates faults for maintenance and traceability
- processes and traces errors

Software is provided to check program storage (memory sum), check the computer's central processor, end around check the I/O channels etc., and to process the BITE priority interrupt.

BITE priority interrupt is based on the following signals:

SIGNAL	FUNCTION
Memory Power Fail	Out-of-specification memory input power levels detected
BITE Memory One	Protected storage alteration attempted by program
Memory Over-Temperature	Memory temperature exceeds specified value
Bus Priority Time Out	User failed to generate memory release signals
Indirect Addressing Fail	Indirect addressing exceeded 16 levels
Time-Out Alarm	Time-out counter improperly reset by CPM
T ₁ Time-Out Alarm	CPM reset time exceeded time allotted
Master Clock Pulse Fail	Master clock failure detected
Primary Power Fail Interrupt	120 μ sec warning signal to CPM
4 Spare Signals	Available per application requirements

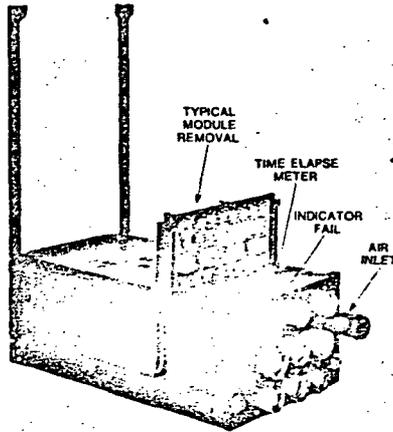

POWER SUPPLY MODULE

Power supply modules for the computer system vary depending upon the type of memory modules chosen and input/output module design. The power supply typically operates from 115 volts 400 Hz or from 28 volts DC prime power. Each power supply module is equipped with a high efficiency switching regulator designed in accordance with MIL-STD-704A, and has over-voltage, over-load, and short circuit protection. In addition to providing line conditioning and RFI attenuation, continuous fault monitoring (BITE) operates to assure orderly shutdown in the event of out-of-tolerance conditions. Internal energy storage is sufficient to complete the current instruction and store the contents of status and CPU registers. This

orderly shutdown is followed by deactivation of the memory circuits.

PACKAGING

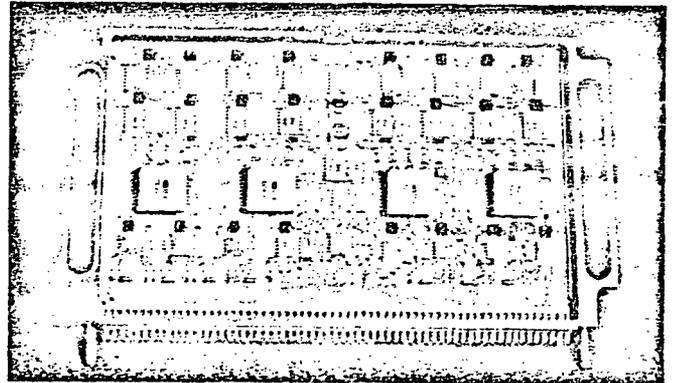

SKC-2000 packaging employs a stacked and clamped card mounting technique in which the cards form an integral "box-like" structure for the overall assembly. Four longitudinal members (straps) are used to clamp the cards between a front connector panel and rear support panel. Lower straps form a subchassis by providing the structure for retaining the female connector plate motherboard assemblies and for card keying and guiding. Card removal is effected by loosening four front bolts and lifting the two upper straps.

Circuit card construction used throughout incorporates several unique features which provide efficient methods of flatpack interconnection and heat removal while reducing electromagnetic interference. A glass-filled epoxy double-sided laminate 0.008 inch thick provides electrical insulation and serves as a base for the conductors. These are routed in the X direction on the outer surface and the Y direction on the inner surface. Interconnection between X and Y conductors is accomplished by plated-through holes, a type of construction which achieves a significant increase in reliability and producibility over multilayer boards.

Designed to be hard-mounted to eliminate the need for vibration isolators, the computer has been subjected to extensive vibration tests without any failures. A thorough dynamic analysis shows that all stress levels are well below fatigue limits.

SKC-2000 computers are designed to be easily maintained, having conveniently located and readily accessible test points which contribute to a short mean time to repair. The design includes separate external AGE and test connectors and accessible test points on individual cards.

SKC-2000 COMPUTER PROGRAMMING AND SOFTWARE

The SKC-2000 computer is significantly easier to program than previous military computers. Features that facilitate programming are:

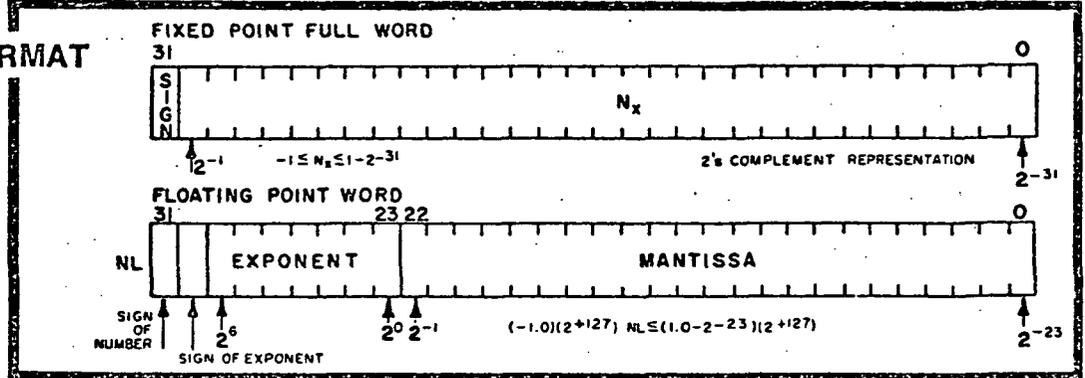

- Floating point arithmetic eliminates scaling
- 88 index registers eliminate memory boundaries
- Dual level index registers simplify reentrant subroutines
- Incremental addressing in branch instructions for relocatable subroutines
- Trap instructions provide for special instructions
- Large instruction repertoire for minimizing computation time

In addition to hardware designed for the programmer, a powerful software package is available to complement machine language programming. It includes an assembler, a loader, an arithmetic simulator, an interpretive simulator, utility routines, and diagnostic routines.

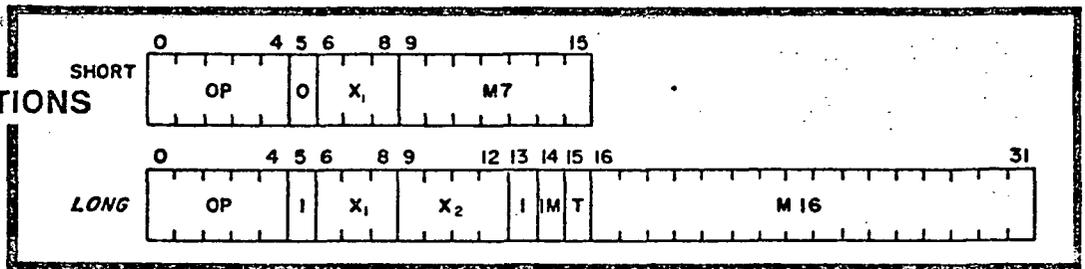

The assembler/loader is designed to allow the user great flexibility and utility in his coding. Features include relocatability, reentrancy, addressing via index register modification, availability of common (blank or labelled) and globally defined symbols. An assembly language, FOCAP, has been developed and documented for the assembler/loader.

SKC-2000 simulators operate on a host machine via the host machine's assembler. They simulate execution of a user program written for the SKC-2000 as if the user program were actually running on the SKC-2000. The arithmetic simulator reproduces the arithmetic of the SKC-2000 in the manner most expeditious in the host machine. An interpretive simulator accepts the binary pattern used in the SKC-2000 and interprets each instruction, performing each operation exactly as in the SKC-2000. The arithmetic simulator runs much faster and is useful for much of the program checkout. The interpretive simulator is a very desirable tool where real-time and I/O problems do not lend themselves to hands-on debugging.

- NOTES: 1. Times are average, based upon use of the 2.0 μs memory initiation pulse and include memory access. Individual times vary dependent on machine operational state.
2. Reductions in execution times are available through memory overlap operation.
3. Each indirect operation adds one memory cycle time to the execution time.
4. One level indexing does not increase execution time. Two levels add 0.5 μsec.

4.18.4 Orbiter GN&C Operational Flight Computer Program

The operational flight program for the Shuttle on-board GN&C computer consists of an executive and a set of "mission" modules (see Figure 4.18.4-1 which can be assembled to build up an operational program to accommodate all Shuttle baseline missions. The computer program for the GN&C computer will be devoted to the solution, display and performance monitoring of the Guidance, Navigation and Control problems of the Shuttle Orbiter. Peripheral support such as displays and performance monitoring of non-GN&C orbiter subsystems will be provided by dedicated MDE processors which are divorced from the GN&C processors.

The GN&C Operational Flight computer program description covers the operational software functions for the orbiter from prelaunch through landing. The GN&C software functions include Guidance, Navigation, Control, Attitude reference, Executive, and in conjunction with the MDE computer, Display Processing and status monitoring. The defined functions within the above functions for all mission phases are:

- Guidance

- Prelaunch Targeting

- Atmospheric guidance during boost

- Orbit injection guidance

- Prethrust targeting for rendezvous and deorbit

- Cross-product steering

- Entry guidance

- Approach guidance

In addition, the software functions include sequencing and interfacing with the MDE computer and systems other than GN&C.

The overall control of the operational program is provided by the executive sub-program. The Executive sub-program provides for the flow of information between programs and the external environment and provides for standardization of interfaces in the presence of a variety of modules and for management of the program resources to assure the response required by the system. In addition, the executive program will provide an internal environment which will permit application programs to be constructed and executed independently of one another and allow a modular program structure which emphasizes operational flexibility, ease of modification, and capability for growth.

All computer program instructions will reside in protected memory locations while all computer variable data will reside in unprotected memory locations. Protected memory is defined as read-only memory while unprotected memory is defined as read-write memory. The protected and unprotected memory locations are predetermined during the program development process and will not change during a mission time span. All unused memory locations will be assigned as protected memory. If any program attempts to write into protected memory, the computer will enter a fail state.

Individual program will be responsible for all internal program calculation scaling and arithmetic manipulations in order to attain sufficient accuracy as required for the Shuttle Orbiter configuration for all mission phases. Extended precision arithmetic functions will be used as required. The fixed point scaling must be sufficient to accommodate the maximum expected values and maintain the required parameter resolution.

Software Elements

The following paragraphs describe design concepts for the on-board Shuttle GN&C Flight Program.

a. On-board Executive System. This section describes the on-board executive control system.

1. Basic Structure. The executive structure will be based on a timer interrupt, fixed schedule, time slice mode of operation. In effect, this type of executive does not require, nor allow, instantaneous

response to external interrupts.

The timer interrupt interval will be under program control and will provide the initialization and reference for the basic executive time structure. When the executive detects a timer interrupt, it will process its schedule tables to determine which set of program jobs are to be executed during the next program interval.

All program intervals will be approximately equal in execution time. This will be accomplished by predetermining the time required for the longest path in each job and shuffling jobs to balance the time intervals. Each time interval will contain portions of various rate jobs as required to satisfy the time and rate constraints.

The program intervals occur 25 times per second, based on the maximum system sample rate. Each interval contains all 25 per second jobs, every other interval contains 25 and 12.5 per second jobs, every fourth interval contains 25 and 6.25 per second data, etc.

2. Job Schedule. The Job Schedule function manages the sequence in which programs are executed. System considerations determine the priority of the routines driven by the schedule function. The job schedule function is designed to respond quickly to execution requests on a predetermined priority basis.

All external interrupts are treated by the schedule as discrete inputs (ON-OFF). The scheduler will mask the interrupt and sample the interrupt status on a periodic basis. An interrupt detected as ON will result in the scheduler modifying its scheduled jobs or

setting a flag to be used by one of the sub-programs.

Internal interrupts such as the Internal Timer or Machine Error interrupts will be handled as true interrupts, as follows:

(a) Internal Timer Interrupt - This interrupt will occur when a pre-set timer counts down. The program will set the time to count down in 40 milliseconds (based on accepted maximum sample rate of 25 per second). This interrupt will cause the program to exit its present scheduled job and return to the basic scheduler entry point. The program structure will be designed so that this interrupt will always occur during a low priority (background) job or during an idle state.

(b) Machine Error Interrupt - This interrupt indicates that the computer circuitry has detected a problem in the computer hardware. This interrupt will force the program into an error detection self test mode. Verification of the machine error will cause the computer to be shut down. One of the redundant computer systems will take over control of the orbiter vehicle by manual or automatic means.

3. Input/Output Supervision. The input/output supervision function controls all the operations associated with the input/output buffer device. Effectively, the input/output supervisor will input data at interval n to be used in calculations in interval $n + 1$. The output data at interval n is for data calculated during interval $n-1$. For time critical functions, the input-calculation-output process will be optimized to satisfy the required time constraints.

The input and output data is normally a function of mission phase, sequencing, control panel selection, job scheduling, etc.; as such, the data set is variable and is a function of the jobs schedule by the executive.

The input/output data will be transmitted to or received from the input/output buffer utilizing predetermined unprotected main memory locations.

4. Systems Services. Systems services provides the function of system and applications program interface with the operator of the system. This function will sample all input control media such as control panel switch positions at a predetermined and constant rate, nominally 6 samples per second. If the panel switch inputs are in a changed state for two or more successive samples, the services facility will either change the job schedule to satisfy the inputs or set a flag for usage by the subsystems program.

5. Systems Clocks. This facility will provide the capability of maintaining unique clock facilities for system usage. The clock facility will be utilized for display functions, sequencing, or subsystem usage. System clock accuracy and update rate will be consistent with accuracy constraints on the onboard system. The clock facilities will include Time From Launch, GMT, Launch Local Time, Time to Go to Event, and Time in Mission Phase. Maximum clock update rate for a minimum number of time bases will be 25 per second. Nominal clock update rate will be 1 per second. The basic time information for

calibrating the Software clocks shall be provided by the Master Timing Unit or the Display Keyboard.

6. Common Subroutines. This service facility will contain all common subroutines to be used by the various subprograms. Included in the common subroutines are the standard mathematical functions to determine sine, cosine, tangent, square root, root mean square, matrix inversion, etc. In addition to the standard set of subroutines, this facility will contain other routines that are used by more than one subprogram. The subprograms will branch to the appropriate subroutine as necessary; exit from the subroutine will be to the using subprogram.

7. Common Data Blocks. The Executive program will maintain common data blocks of unprotected memory. The Common Data Blocks will be available for usage by all programs, subprograms or routines. Inclusion of data in the Common Data Blocks implies that data is used across program interfaces. Data that is unique to individual programs such as scratch pad memory, constants, etc., will be maintained in individual local program data blocks which are not accessible to other programs.

8. Self Test. The Self Test function will be executed on a minor cycle basis to determine and verify the operational state of the GN&C computer. This function will be designed to execute a maximum number of computer program instructions and to compare results of mathematical manipulations against a predetermined result. Failure of the Self Test function in a particular computer will result in a shutdown of that computer.

9. Systems Tables. The executive program structure will be designed to maximize the usage of System Tables in conjunction with simple subroutines for execution of the System Table data. The System Table concept simplifies the programming, checkout and validation of the GN&C Flight Program in addition to providing a relatively simple means of incorporating program changes and updates.

b. Guidance, Navigation, and Control Programs. The GN&C software consists of the operational software functions from prelaunch through landing. The GN&C software functions include Guidance, Navigation, Control, attitude reference, Executive, Display processing, and status monitoring. These functions are required for both the orbiter and the booster of the flyback (LOX/RP) configuration.

However, a pressure fed booster which is controlled by the orbiter and which is towed to the launch site after a free fall return would not require any software functions: the orbiter GN&C computer would be augmented to provide the pressure fed booster control during the mated boost phase.

The LOX/RP booster configuration contains its own GN&C computer with the same functions as the orbiter during prelaunch, mated boost, and separation. A period of booster coast and return to atmospheric flight requires computer Guidance, Navigation and ACPS control. These functions are performed by the computer until the pilot initiates manual control.

Table 4.18.4-1 summarizes the orbiter GN&C program functions by mission phase.

REV.

BINGHAMTON, NEW YORK

REP. NO.

Baseline GN&C computer sizing estimates are based on well-understood requirements from previous programs, are therefore relatively accurate, and are not expected to grow beyond the 100-percent reserve provided. If added functions during the definition phase cause growth beyond the reserve, available access channels will accommodate mass memory. The performance monitor (PM) and payload (PL) functions are not as well defined, and the use of tape mass memory allows expansion and the sharing of functions to minimize the number of computers. Tape memory was selected for the modular display electronics functions, which are not time critical, based on availability and low power, weight, and cost. The payload data processing requirement of 10,000 32-bit words is satisfied by the use of a modular display electronics unit with an equivalent of 8000 32-bit words in the main memory and the tape mass memory. (Preliminary analysis indicates a 4000-word resident memory augmented with incremental 2000pword tape loads is adequate.)

Hardware floating point arithmetic is implemented in the GN&C computer to reduce the problem of scaling errors and provide the lowest program cost for the primarily arithmetic GN&C software. Hardware floating point is not provided in the modular display electronics; the added cost to provide this capability for the primarily data handling and logic functions of the modular display electronics, which do not involve a large amount of scaling, is not justified by offsetting software savings.

Table 4.18.4-2 illustrates the assignment of programs and requirements to the functionally dedicated GN&C computers and MDE's and identifies the memory size, speed estimates, and capabilities. These values were derived by analyses of vehicle requirements, modeling, and coding of selected functions. The results of this process compared within 5 percent with equivalent programs from Apollo RTCC and Saturn IU.

Data pool, subroutines, input/output, sequencing, scheduling, tables	(13.8)	(0.5)	Subroutines, input/output, data pool, tables	(0.5)	(5.0)	Subroutines, input/output, data pool, tables	(2.5)	(2.5)
System status	2200		System status	900		System status	*2000	1400
Redundancy management, GN&C system performance monitor, ground checkout	(25.5)		Non-GN&C system performance monitor, annunciator lights, self-check	(20.0)		Performance monitor, analog, discrete, serial limit checks		
Flight crew displays	450	3600	Crew station displays	3900		Crew displays	500	500
GN&C system status, procedures	(0.4)	(5.6)	Input/output conversions, formats, tables, display services, time share GN&C, P/M, and backup GN&C	(5.6)		Input/output conversions, formats, tables, display services	(5.6)	(5.6)
Navigation	5850		Backup GN&C		2950	Payload checkout	*2000	
State vector, attitude reference	(2.1)		Steer to displays, get-home guidance and navigation		(33.1)	Minimal on-board checkout, no experiment processing	(3.0)	
Guidance	7500					PLH control program		1000
Steering commands, engine control, abort	(39.5)					Closed-loop control of attitude, rate, and position		(36.3)
Targeting	4200					PLH constraint tables		1000
Flight control	2950					Deployment and retrieval trajectories, payload dependent tables		
TVC, RCS, digital outer loop, boost blending	(20.1)					Program loader	150	150
Program services	2700					Tape memory load on request		
Uplink, PCM, preflight, system align and calibration, interfaces (booster, payload, main engine controller, GSE interface)	(5.0)							
Unmanned orbiter	500		Program loader	150	150			
Sequencing, calculation for autonomous flight	(2.5)		Tape memory load on crew request					
Program loader		100						
Peak memory loading	30300	4050		5350	3500		3550	4950
	(128.2)	(6.1)		(26.1)	(38.1)		(13.1)	(44.9)
Machine capability main memory	65536	8192			8192			8192
	(380.0)	(256.0)			(256.0)			(256.0)
Tape memory		256 K			256 K			256 K

Note: Sizing is in terms of equivalent 32-bit words. Most GN&C computer instructions are 16 bits. MDE computers are all 16 bits. Floating point data are 32 or 48 bits and other data are 16 or 32 bits. Speed in KADS.
MDE—modular display electronics P/M—performance monitor PLM—payload management PLH—payload handling

*Mutually exclusive, tape memory load

4.18.5 Rationale

Not applicable.

4.18.6 Assumptions

None.

4.18.7 Data References
