16. Abstract

A FORTRAN IV computer program for the calculation of the thermodynamic and transport properties of complex mixtures is described. The program has the capability of performing calculations such as (1) chemical equilibrium for assigned thermodynamic states, (2) theoretical rocket performance for both equilibrium and frozen compositions during expansion, (3) incident and reflected shock properties, and (4) Chapman-Jouguet detonation properties. Condensed species, as well as gaseous species, are considered in the thermodynamic calculations; but only the gaseous species are considered in the transport calculations. Further information on obtaining the program may be had from the authors.

FORTRAN IV COMPUTER PROGRAM FOR CALCULATION OF THERMODYNAMIC AND TRANSPORT PROPERTIES OF COMPLEX CHEMICAL SYSTEMS

by Roger A. Svehla and Bonnie J. McBride

Lewis Research Center

SUMMARY

A FORTRAN IV computer program for the calculation of the thermodynamic and transport properties of complex mixtures is described. This program (TRAN72) was developed by combining a program for the transport properties calculation with another program (CEC71), published in NASA SP-273, for the thermodynamic properties calculation.

Equations for the calculation of the transport properties are given and explained. Equations for the calculation of the thermodynamic properties can be found in NASA SP-273. Input data, included with the program, are explained.

The program has the capability of performing calculations such as (1) chemical equilibrium for assigned thermodynamic states, (2) theoretical rocket performance for both equilibrium and frozen compositions during expansion, (3) incident and reflected shock properties, and (4) Chapman-Jouguet detonation properties. Condensed species, as well as gaseous species, are considered in the thermodynamic calculations. However, only gaseous species are considered in the transport property calculations.

The program is available for external distribution. Further information on obtaining the program may be had from the authors.

INTRODUCTION

Many processes in existence today involve complex chemical mixtures, frequently at high temperatures. Some of these mixtures result from combustion processes such as occur in automobiles, aircraft, and rockets. Others occur in processing equipment in the chemical, petroleum, and natural-gas industries. Research equipment, such as shock tubes, also involves high-temperature gas mixtures.

The need frequently arises for the thermodynamic and transport properties of these mixtures, particularly for use in heat- and mass-transfer calculations. Usually, the temperatures of the gases involved are quite high, too high for the properties to be measured directly. Consequently, the properties are calculated. As a result, a number of different computer programs have been written for the property calculations. In general, most of the programs now in existence are designed to calculate either the thermodynamic properties or the transport properties, but not both. These programs are not reviewed herein. References 1 to 4 are a starting point for a review of the programs for calculating the thermodynamic properties. Some programs have also been written for calculating the transport properties (refs. 5 to 9); however, each has its limitations. Some of these programs use approximate equations (refs. 5 to 8). One is limited in the choice of the intermolecular potential energy function (ref. 7). Two programs are designed primarily for ionized gases (refs. 8 and 9).

We have developed a computer program which is designed to avoid these limitations. Rigorous equations are used in the transport calculations, and the transport cross sections are not restricted to any specific potential energy form. The program is a general one, capable of handling any chemical system. However, it does not include ionization, although it is capable of handling incipient ionization. Other important features of this program include simplicity of input, storage of all thermodynamic and transport property data on a master tape, and elimination of any need for advance knowledge of which species will be important. The program is a combination of the NASA Lewis Research Center Chemical Equilibrium Calculations Program (ref. 1) with additional routines to do the transport property calculations. The program will handle a variety of problems. It has the capability for doing calculations such as (1) chemical equilibrium for assigned thermodynamic states (T,P), (H,P), (S,P), (T,V), (U,V), or (S,V); (2) theoretical rocket performance for both equilibrium and frozen compositions during expansion; (3) incident and reflected shock properties; and (4) Chapman-Jouguet detonation properties.

The thermodynamic properties which are tabulated include pressure, temperature, density, enthalpy, entropy, molecular weight, $(\partial \ln V/\partial \ln P)_T$, $(\partial \ln V/\partial \ln T)_P$, specific heat at constant pressure, isentropic exponent, sonic velocity, and composition. The calculated transport properties are viscosity and thermal conductivity. Specific heat and thermal conductivity are calculated for both frozen and equilibrium conditions. Prandtl and Lewis numbers are included. Other properties which are characteristic of the type of problem being run are also calculated. (See the sample problems in appendix D.)

The present report does not cover the equations and numerical techniques used for the calculation of the thermodynamic properties. These are given in NASA SP-273 (ref. 1), which discusses the details of the thermodynamic calculations. The present report does give the equations used in the transport calculations, however. These are

covered in the section TRANSPORT PROPERTY EQUATIONS. Sources of the transport data are given in the section SOURCES OF TRANSPORT AND RELAXATION DATA. Symbols are defined in appendix A. Variables, indices, and constants used in the transport subroutines are given in appendix B. A listing of the entire program is shown in appendix C, and sample problems are shown in appendix D. The sample problems were selected to illustrate many of the various capabilities of the program. Flow charts of some routines are included.

COMPUTER PROGRAM

The TRAN72 computer program was written in FORTRAN IV. At the Lewis Research Center it was checked out on an IBM 7094II/7044 Direct Couple System. It has been used to generate both thermodynamic and transport properties of a number of chemical systems for internal use at Lewis.

The source program is available to other organizations. Thermodynamic and transport data are provided with the program. However, these data are updated periodically; as a result, the answers for the sample problems in appendix D may change somewhat from time to time.

Further information on obtaining the program may be had from the authors.

ASSUMPTIONS AND CAPABILITIES

The program is designed to provide both thermodynamic and transport properties for a wide range of scientific and engineering applications and for a range of independent variables. Thermodynamic data for a large number of ideal gases and condensed species are provided with the program for a temperature range of 300 to 5000 K. Transport data are provided over a wider range in many cases. See the section SOURCES OF TRANSPORT AND RELAXATION DATA for the temperature range for each interaction.

The range of applicability of the thermodynamic calculations is approximately described by the limits of applicability of the ideal-gas law. A reduced-state plot of the thermodynamic properties might give the user an idea of the limits of temperature and pressure. The lower limit for temperature in the transport calculations occurs when ternary and higher order molecular collisions become important. This also defines the upper pressure limit for the transport property calculations. The upper limit for temperature occurs when ionization becomes appreciable. However, incipient ionization can be included in the calculations. But, for increasing ionization, higher approximations are needed in the transport calculations (refs. 10 and 11). Additional comments on this may be found in the discussion of the transport property equations. The lower pressure

limit is given by the onset of the free molecular flow regime, which occurs when the mean-free-path length is of the same order of magnitude as the dimensions of the container. Under these conditions the equations for the transport properties are no longer applicable.

In the computation of the thermodynamic properties the NASA Lewis Research Center CEC71 program (ref. 1) is used. The usual equations for the conservation of mass, momentum, and energy are applied (ref. 1, eqs. (93) to (95)) and the ideal-gas law is assumed. The free energy is minimized by using a Newton-Raphson iteration technique. Composition and properties are calculated for equilibrium conditions and, for some situations, for frozen conditions (sometimes called nonreacting). The effects of chemical kinetics, or finite reaction rates, are not included. TRAN72 handles the same types of problems as does CEC71, including normal shock waves, Chapman-Jouguet detonations, rocket expansion problems, and properties at assigned thermodynamic states. The additional assumptions for each type of problem are as follows:

(1) Shock waves are of negligible thickness and normal to the direction of flow. One-dimensional flow is assumed.

(2) For Chapman-Jouguet detonations the Mach number of the wave front, based on the speed of sound in the burned gas, is unity. The assumptions mentioned previously for shock waves also apply.

(3) For rocket combustion problems, it is assumed that there is complete mixing in the chamber, adiabatic combustion at constant pressure, isentropic expansion with complete mixing, and frictionless one-dimensional flow. It is also assumed that the chamber is large enough that the velocity in the chamber is negligible.

Because of storage limitations on the IBM 7094, the maximum allowable number of species is 100 and the maximum number of elements is 10. This applies to the thermodynamic property calculations and includes gases, liquids, and solids. In doing the transport calculations, no more than 20 of the species are used. First the composition obtained from the thermodynamic calculations is searched for the 20 gaseous species with the largest concentrations. However, all gaseous species with mole fractions of less than 10^{-7} are omitted. Then this gaseous composition is normalized by summing the concentrations of these 20 species and dividing each concentration by the sum. The mole fractions obtained by this normalization procedure are the ones used in the transport property calculations.

DESCRIPTION OF PROGRAM INPUT

The procedure for operating the program is relatively simple and is almost identical to that for operating the CEC71 program (ref. 1).

The input specifies the type of problem to be run, the chemical system of interest, the mixture ratio, and the range of variables. Considerable flexibility is available in specifying the variables. For example, in a rocket combustion problem, nozzle expansion points can be specified as pressure ratios, area ratios, or a combination of both. In addition, a number of options are available, such as the following:

(1) The calculated thermodynamic and transport properties may be obtained on punched cards, as well as printed output.

(2) For rocket and shock problems, both equilibrium and frozen properties are available. In particular, for rocket expansion problems, freezing can be made to occur at the chamber, the throat, or any supersonic point in the nozzle. For this type of problem, equilibrium flow is assumed from the chamber to a previously designated station in the nozzle. After that station is reached, the composition is frozen.

(3) Input can be specified in a number of different units. For instance, pressure can be given in mm Hg, atmospheres, psia, or newtons/meter^2.

(4) Species may be omitted from consideration in the calculations through the use of OMIT cards. Also, certain condensed phases may be included in the initial composition through the use of INSERT cards. Otherwise, only gases are considered initially, which may lead to convergence difficulties.

(5) Thermodynamic property calculations can be obtained without including transport property calculations. If this option is used, the program is essentially the same as the CEC71 program. The opposite is not possible. Transport properties cannot be calculated without first doing the thermodynamic property calculations, since the results of the thermodynamic calculations are needed in the transport calculations.

The input data are discussed under four categories. Three of the categories are required and one is optional. The three required categories and the code names by which they are referred to herein are

(1) Library of thermodynamic and transport data for reaction products (THERMO and TRANSPORT data library)

(2) Data pertaining to reactants (REACTANTS cards)

(3) Namelist data, which include the type of problem, required schedules, and options (NAMELISTS input)

The optional category of data is the list of chemical formulas of species which are singled out for special purposes (OMIT and INSERT cards).

Each category of data is discussed in this report. Many of the details are summarized in tables I to VI. Both input and output for 10 sample cases are given in appendix D. These cases are identified by the numbers 51, 52, 122, 123, 679, 950, 1207, 1565, 5612, and 6666. The order of the input is indicated in table II.

THERMO and TRANSPORT Data Library

A library of thermodynamic and transport data is included with each program distributed. The thermodynamic data for reaction products are in the functional form discussed in the section THERMODYNAMIC DATA. The transport data are in a tabular form. The order and format of the THERMO and TRANSPORT data are detailed in table I.

THERMO and TRANSPORT data may be read either from cards or from tape. If the data are read from cards, the program will write these data on logical tape 4. However, a permanent tape or disk containing the data may be made during any run by using the required type of control cards preceding the operating deck. When the data are read from cards, the data are preceded by a code card which has the word THERMO punched in columns 1 to 6. The sample cases in appendix D assume a permanent tape is available. Thus, the THERMO code card and the data are omitted and the input data all start with the REACTANTS cards described in the next section. When data for various species are added, removed, or changed on the tape, the whole set of THERMO and TRANSPORT data cards must be included in the input for making a new tape.

These TRANSPORT data follow immediately after the END card for the THERMO data. No general identification card is needed to indicate the beginning of the TRANSPORT data.

During a computer run, the appropriate reaction-product data consistent with each new set of REACTANTS cards will be automatically selected from the data on tape 4 and stored in core.

REACTANTS Cards

This set of cards is required for all problems. The first card in the set contains the word REACTANTS punched in card columns 1 to 9. The last card in the set is blank. In between the first and last cards may be any number of cards to a maximum of 15, one for each reactant species being considered. The cards for each reactant must give the chemical formula and the relative amount of the reactant. For some problems, enthalpy values are required. The format and contents of the cards are summarized in table III. A list of some REACTANTS cards is given in table IV.

Relative amounts of reactants. - The relative amounts of reactants may be specified in several ways. They may be specified in terms of moles, mole fraction, or mole percent (by keypunching M in card column 53) or in terms of weight, weight fraction, or weight percent (blank in column 53). For example, in appendix E, cases 679 and 1207 specify reactants in terms of moles and case 51 specifies them in terms of weight.

For these cases, the relative amounts of the reactants are completely specified by the values on the REACTANTS cards. However, there are optional variables which may be set in namelist INPT2 that indicate relative amounts of total fuel to total oxidants. (See table V and section NAMELISTS input.) For this situation, each reactant must be specified as a fuel or an oxidizer by keypunching an F or O, respectively, in column 72 of the REACTANTS card. The amounts given on the REACTANTS cards are relative to total fuel or total oxidant rather than to total reactant.

Tables V, VI, and VII describe the namelists. Referring to table V, there are four options in INPT2 for indicating relative amounts of total fuel to total oxidant. They include

(1) Equivalence ratio, r (ERATIO is TRUE)

(2) Oxidant-to-fuel weight ratio, O/F (OF is TRUE)

(3) Fuel percent by weight, %F (FPCT is TRUE)

(4) Fuel-to-air or fuel-to-oxidant weight ratio, F/A (FA is TRUE)

For each option, the values are given in the MIX array of INPT2. This feature is illustrated by cases 52, 122, 950, 5612, and 6666 in appendix D. Cases 52 and 950 show where ERATIO is TRUE (ERATIO = T), and the reactants are identified as fuel or oxidant in card column 72. Since these cases involve just one fuel and one oxidant, the amounts of each (as given in columns 46 to 52) are shown as 100. This means that the oxidizer is 100 percent of the total oxidizers and the fuel is 100 percent of the total fuels. Cases 122 and 5612 are examples which have more than one fuel. Case 122 shows that each fuel is 50 percent (by weight) of the total fuels and the one oxidizer is 100 percent of the total oxidizer.

The purpose of the previous namelist variables is to permit using one set of reactant cards with any number of values (maximum, 15) of a variable. Case 950, for example, specifies three values of equivalence ratio (ERATIO = T).

Reactant enthalpy. - Assigned enthalpy values for initial conditions are required for assigned enthalpy and pressure (HP), rocket (RKT), detonation (DETN), and shock (SHOCK) problems. An assigned internal energy is required for the assigned internal energy and volume (UV) problem. These assigned values for the total reactant are calculated automatically by the program from the enthalpies or internal energies of the individual reactants. The enthalpy values for the individual reactants are either keypunched on the REACTANTS cards or calculated from the THERMO data. The choice varies according to the type of problem as follows:

(1) RKT, UV, and HP problems: Enthalpies or internal energies are taken from the REACTANTS cards unless zeros are punched in card columns 37 and 38. For each REACTANTS card with the "00" code, an enthalpy will be calculated for the species from the THERMO data for the temperature given in card columns 64 to 71. See MgO(s) in case 51, appendix D.

(2) SHOCK problems: Enthalpies for all the reactants are calculated from the THERMO data for the temperatures in the T schedule of namelist INPT2 (table V). If enthalpy values are punched in card columns 64 to 71 (table III), they will be ignored. It is not necessary to punch zeros in card columns 37 and 38.

(3) DETN problems: If no T schedule is given in namelist INPT2, the option for calculating reactant enthalpies is the same as for RKT, UV, and HP problems. However, if a T schedule is given in INPT2, the enthalpies will be calculated from the THERMO data for the temperatures in the T schedule, the same as for the SHOCK problem.

When the program is calculating the individual reactant enthalpy or internal energy values from the THERMO data, the following two conditions are required:

(1) The reactant must also be one of the species in the set of THERMO data. For example, $NH_3(g)$ is in the set of THERMO data but $NH_3(\ell)$ is not. Therefore, if $NH_3(g)$ is used as a reactant, its enthalpy could be calculated automatically but that of $NH_3(\ell)$ could not be.

(2) The temperature T must be in the range $T_{low}/1.2 \leq T \leq T_{high} \times 1.2$, where T_{low} to T_{high} is the temperature range of the THERMO data.

NAMELISTS Input

As indicated in table II, the NAMELISTS code card precedes the NAMELISTS input. The card has the word NAMELISTS punched in card columns 1 to 9. All problems require an INPT2 input. Rocket and shock problems each require an additional set, namely RKTINP or SHKINP. The additional set simply follows INPT2 directly.

The variables in each namelist are listed in tables II, V, VI, and VII. Table II indicates which variables are required and which are optional for the various types of problems. Tables V, VI, and VII give a brief definition of each variable. Some additional information about some of these variables follows:

Pressure units. - The program assumes the pressure in the P schedule to be in units of atmospheres unless either PSIA = T, NSQM = T, or MMHG = T.

Relative amounts of fuel (or fuels) and oxidizer (or oxidizers). - These quantities may be specified by assigning 1 to 15 values for either O/F, %F, F/A, or r. If no value is assigned for any of these options, the program assumes the relative amounts of fuel (or fuels) and oxidizer (or oxidizers) to be those specified on the REACTANTS cards. (See discussion in section REACTANTS Cards.)

Printing mole fractions of trace species. - The program normally prints only the compositions of those species with mole fractions greater than 5×10^{-6} in F-format for all problems except SHOCK. The TRACE option permits printing smaller mole fractions. If the variable TRACE is set to some positive value, mole fractions greater than or equal

to this value will be printed. When this option is used, a special E-format for mole fraction output is used automatically. A TRACE value of 1.E-38 is the lowest value allowed by the program. (See case 1565 in appendix E.)

For SHOCK problems, mole fractions of trace species are often desired. Thus, for SHOCK problems, the program will set TRACE to 5.E-9 automatically, and the E-format for output is always used. This value may be changed by using the TRACE option in INPT2 namelist input. (See case 1207 in appendix E.)

TP, HP, SP, TV, UV, or SV problems. - In these problems, from 1 to 52 values of T, and from 1 to 26 values of P or V (or RHO) may be assigned. However, only one value of entropy S0 may be assigned in INPT2 for the SP or SV problem. Only one value of enthalpy is permitted for the HP problem, and only one value of internal energy is permitted for the UV problem. However, these values of enthalpy and internal energy are not assigned in INPT2 but are calculated by the program. In a TP problem, if 52 values of T and 26 values of P are assigned in INPT2, properties will be calculated for the 1352 possible P and T combinations. Similarly, as many as 1352 combinations can be calculated for a TV problem.

DETN problem. - Calculations will be made for all combinations of initial pressure P and initial temperature T. Initial temperatures may be specified in INPT2 namelist or on the REACTANTS card.

RKT problem. - At least one chamber pressure value P is required in INPT2, although as many as 26 chamber pressures may be assigned. A complete set of calculations will be made for each chamber pressure. The RKT problem requires a second namelist for input, RKTINP, which is discussed in the next section.

RKTINP namelist (RKT problem only). - This namelist is required for RKT problems. It follows the INPT2 namelist. A list of variables and definitions is given in table VI. Even though this namelist is required, all variables are optional. If no variables are assigned, only the chamber and throat conditions will be calculated. Usually, a pressure ratio schedule (PCP), an area ratio schedule (SUBAR or SUPAR), or some combination of these schedules will be assigned.

Pressure ratio and area ratio schedules must not include values for the chamber and throat, inasmuch as these values are calculated automatically by the program. If both a pressure ratio schedule and an area ratio schedule are given in RKTINP, the pressure ratios will be calculated first. If both schedules are omitted, only chamber and throat conditions will be calculated.

The program will calculate both equilibrium and frozen performance, unless RKTINP has the logical variable FROZ set equal to FALSE (FROZ = F) or the logical variable EQL set equal to FALSE (EQL = F). If FROZ = F, only equilibrium performance will be calculated. If EQL = F, only frozen performance will be calculated.

If a frozen expansion is being calculated, it is possible to specify the freezing point by using the variable NFZ. For instance, to freeze immediately after the fifth point, set

NFZ = 5. If NFZ is not specified in the RKTINP namelist, the program assigns NFZ = 1 (freezing in the chamber). If NFZ = 1 or 2 (NFZ = 2 corresponds to the throat), 22 additional stations may be assigned in the expansion. If NFZ > 2, the program will allow only 11 additional stations. Freezing is permitted in the chamber, the throat, or any supersonic station but not at a subsonic station.

SHOCK problem. - The program requires a P and T schedule in INPT2, and a schedule of either initial velocities (U1) or Mach numbers (MACH1) in a second namelist, SHKINP (see table VII). These values of P, T, and either U1 or MACH1 all refer to the unshocked gas and must correspond one-to-one with each other. Case 1207 in appendix D is a shock problem. The pressure and temperature schedules are limited to 13 values for SHOCK problems only. This corresponds to the 13-value limit for U1 or MACH1 schedules.

REACTANTS cards must be only for gaseous reactants that are also included as reaction species in the THERMO data. This permits the program to calculate enthalpy and specific-heat values of the reactants from the THERMO data.

SHKINP namelist (SHOCK problem only). - A list of variables and definitions is given in table VII. SHKINP must include from one to 13 values of either U1 or MACH1 of the unshocked gas. The program will calculate incident shock parameters that assume both equilibrium and frozen composition unless SHKINP has the logical variable INCDEQ set equal to FALSE (INCDEQ = F) or the logical variable INCDFZ set equal to FALSE (INCDFZ = F). If INCDEQ = F, only frozen composition will be used. If INCDFZ = F, only equilibrium composition will be used. In addition, there are options for calculating reflected shock parameters. For each incident condition called for, reflected shock parameters will be calculated that assume either a frozen composition (REFLFZ = T), an equilibrium composition (REFLEQ = T), or both (REFLFZ = T, REFLEQ = T).

OMIT and INSERT Cards

As indicated in table II, OMIT and/or INSERT cards may follow the REACTANTS cards. Their inclusion is optional. They contain the names of particular species in the library of thermodynamic data for the specific purposes to be discussed. Each card contains the word OMIT (in card columns 1 to 4) or INSERT (in card columns 1 to 6) and the names of from one to four species starting in columns 16, 31, 46, and 61. The names must be exactly the same as they appear in the first 12 columns of the THERMO data cards (see table I).

OMIT cards. - Occasionally, it may be desired to specifically omit one or more species from consideration as possible species. This omission may be accomplished by means of OMIT cards containing these species names. See appendix D, cases 51 and 950.

If OMIT cards are not used, the program will consider as possible species all those species in the THERMO data which are consistent with the chemical system being considered.

INSERT cards. - These cards contain the names of condensed species only. They have been included as options for the following two reasons:

The first and more important reason for including the INSERT card option is that, in rare instances, it is impossible to obtain convergence for assigned enthalpy problems (HP or RKT) without the use of an INSERT card. This occurs because the temperature sometimes becomes extremely low (several kelvin) when only gases are considered. In these rare cases, the use of an INSERT card containing the name of the required condensed species will eliminate this kind of convergence difficulty. When this difficulty occurs, the following message is printed by the program: "LOW TEMPERATURE IMPLIES CONDENSED SPECIES SHOULD HAVE BEEN INCLUDED ON AN INSERT CARD."

The second and less important reason is for efficiency of computation. If it is known that certain condensed species will be present among the final equilibrium compositions for the first assigned point, a small amount of computer time can be saved by using an INSERT card. The inserted condensed species will then be considered by the program during the initial iterations for the first assigned point. If the INSERT card were not used, only gaseous species would be considered during the initial iterations. However, after convergence, the program would automatically insert the appropriate condensed species and reconverge. For all other assigned points the inclusion of condensed species is handled automatically by the program. Therefore, it usually is immaterial whether or not INSERT cards are used for the purpose of saving computer time.

DESCRIPTION OF PROGRAM OUTPUT

The program prints four kinds of output: input data used to do the calculations, information concerning iteration convergence, tables of results, and optional intermediate output.

Input Data

Input data have been previously described. The general procedure used in this program is to list the input as they are read in and before they are processed by the program. The purpose is to show, in as clear a way as possible, what is actually on the input cards. All problems list the following input data:

(1) The word REACTANTS

(2) Reactant data

(3) INSERT and/or OMIT card data

(4) The word NAMELISTS

(5) All data in namelist INPT2 given in table V (P and RHO use same storage)

Following the INPT2 data is the statement "SPECIES BEING CONSIDERED IN THIS SYSTEM." Each species in the list is preceded by some identification, such as J12/65. The J refers to JANAF data (JANAF Thermochemical Tables, see ref. 1). The letter L refers to unpublished data calculated at the Lewis Research Center. The number refers to the month and the year the data were published or calculated (12/65 is December 1965).

For a rocket problem, the namelist RKTINP data given in table VI are listed. For a shock problem, the namelist SHKINP data given in table VII are listed.

Following the list of chemical species (or RKTINP or SHKINP data, if any) is the current value of O/F. This is followed by a listing of the enthalpies or internal energies of the total fuel and oxidant and of the total reactant. Following this is a list of the kilogram-atom per kilogram of each element in the total fuel and oxidant in the total reactant.

Tables of Thermodynamic Results

The final output of the program is in the form of tables that are designed to be self-explanatory. Tabulated properties include pressure P, temperature T, density ρ, enthalpy h, entropy s, molecular weight M, two partial derivatives $(\partial \ln V/\partial \ln P)_T$ and $(\partial \ln V/\partial \ln T)_P$, specific heat c_p, isentropic exponent γ_S, and velocity of sound a. (An option is available to punch these values on cards. See table V and case 123 in appendix D.) Compositions are also included and given in terms of mole fractions. In addition, rocket, shock, and detonation problems each list additional calculated properties which are pertinent to each type of problem.

Tables of Transport Results

The printed output consists of calculated results in tabular form. Punched-card output is also available as an option. With the exception of the heading at the top, the output for the transport calculations is the same for all types of problems. Viscosities, thermal conductivities, specific heats, Prandtl numbers, and Lewis numbers are calculated and listed for the same conditions as shown in the results of the thermodynamic calculations.

Both frozen and equilibrium values are shown for the thermal conductivity, specific heat, and Prandtl number. The difference between frozen and equilibrium can be described in the following way: Consider a system of reactive species initially in chemical

equilibrium. If heat is then either added or removed, the temperature and pressure will change. If the composition does not change from the initial state, the system is said to be frozen. If the composition adjusts to the equilibrium composition of the new temperature and pressure, the system is said to be in equilibrium. But, if the final composition is neither of these two conditions, the effects of chemical kinetics must be considered. As stated previously, however, the effects of chemical kinetics are not included in the program.

The specific heats shown in the transport properties table are usually identical with those shown in the thermodynamic properties table. However, differences do frequently occur for perfectly valid reasons. These are explained in the section TRANSPORT PROPERTY EQUATIONS.

At this point it is worth explaining why the calculation of the specific heat is repeated in the transport property calculations, with condensed phases omitted. The reason is that it enables the calculation of internally consistent Prandtl and Lewis numbers, numbers derived from properties which are all based on the same gaseous composition. These may be preferable for use in heat- and mass-transfer calculations.

Error Messages

The only other printed output which can occur comes from any one of a number of programmed error messages. Most of these are in the subroutines which do the thermodynamic property calculations. These are explained in detail in reference 1. Four programmed error messages occur in the transport property subroutines. Two are in subroutine TRANSP and the other two are in subroutine INPUT. These messages are explained in the sections discussing the subroutines.

THERMODYNAMIC DATA

Thermodynamic data are included with the program. Reference 1 lists data for 62 reactants and 421 reaction species (solid, liquid, and gas phases of a species are counted as separate species).

Assigned Enthalpies

For each species, heats of formation (and, when applicable, heats of transition) were combined with sensible heats to give assigned enthalpies H_T^o. By definition,

$$H_T^o \equiv H_{298.15}^o + \left(H_T^o - H_{298.15}^o\right) \quad (1)$$

We have arbitrarily assumed $H_{298.15}^o = \left(\Delta H_f^o\right)_{298.15}$. Equation (1) then becomes

$$H_T^o = \left(\Delta H_f^o\right)_{298.15} + \left(H_T^o - H_{298.15}^o\right) \quad (2)$$

In general, $H_T^o \neq \left(\Delta H_f^o\right)_T$ for $T \neq 298.15$ K. For reference elements, $\left(\Delta H_f^o\right)_{298.15} = H_{298.15}^o = 0$. For the species included with the program these reference elements are Al(s), Ar(g), B(s) (beta), Be(s), $Br_2(l)$, C(s) (graphite), Cl_2(g), Cs(s), F_2(g), Fe(s), H_2(g), He(g), K(s), Li(s), Mg(s), N_2(g), Na(s), Ne(g), O_2(g), P(s) (red, V), S(s) (rhombic), Si(s), and Xe(g).

Assigned enthalpies for reactants are given in table IV (in cal/mole as required for program input) together with some other reactant data. For cryogenic liquids, assigned enthalpies are given at their boiling points. These are usually obtained by subtracting the following quantities from the heat of formation of the gas phase at 298.15 K: sensible heat between 298.15 K and the boiling point, difference in enthalpy between ideal gas and real gas at the boiling point, and heat of vaporization at the boiling point.

Least Squares Coefficients

For each reaction species, the thermodynamic functions specific heat, enthalpy, and entropy as functions of temperature are given in the form of least squares coefficients as follows:

$$\frac{C_p^o}{R} = a_1 + a_2T + a_3T^2 + a_4T^3 + a_5T^4 \quad (3)$$

$$\frac{H_T^o}{RT} = a_1 + \frac{a_2}{2}T + \frac{a_3}{3}T^2 + \frac{a_4}{4}T^3 + \frac{a_5}{5}T^4 + \frac{a_6}{T} \quad (4)$$

$$\frac{S_T^o}{R} = a_1 \ln T + a_2T + \frac{a_3}{2}T^2 + \frac{a_4}{3}T^3 + \frac{a_5}{4}T^4 + a_7 \quad (5)$$

Reference 12 describes a program which calculates the thermodynamic functions and fits the functions to equations of the form given in equations (3) to (5).

TRANSPORT DATA

Transport and relaxation data are provided for 59 species, and additional transport data are provided for interactions between unlike species for another 58 interactions. Sources of these data are described in the section SOURCES OF TRANSPORT AND RELAXATION DATA and in tables VIII and IX. All data are in tabular form as a function of temperature. In contrast with the thermodynamic data, the temperature range of the transport data is not the same for all interactions. The temperature ranges for the transport data are also shown in table VIII.

The temperature intervals in the table are not constant, but generally increase with increasing temperature. This was done in order to accommodate interpolation within the table. Interpolation is done by four-point Lagrange, and the number of arguments allowed per table is 20. This number was arrived at as a compromise between two considerations. First, storage space is limited (IBM 7094); and in order to allow sufficient storage for a large number of interactions, the number of intervals in each table should not be excessive. However, the interval size must be small enough such that interpolation errors are less than the uncertainty of the data within the table. Consequently, the temperature intervals tend to be closest in the vicinity of 300 K because usually the transport data are most accurately known at room temperature.

SAMPLE PROBLEMS

Ten sample problems are given to illustrate some of the features of the program. Five are rocket performance problems, RKT = T (cases 51, 122, 679, 5612, and 6666); two are combustion problems (case 123 is for combustion at constant pressure, HP = T; and case 1565 is for combustion at constant volume, UV = T); case 52 is a detonation problem, DETN = T; case 1207 is a shock problem, SHOCK = T; case 950 is an assigned temperature and pressure problem, TP = T; and case 6666 illustrates freezing in a rocket at a location other than the chamber.

It would not be practical to illustrate every possible combination of options permitted by the program. However, the sample problems were selected to illustrate many of the possible combinations and, in particular, those variations which we believe would most often be used. Included in the combinations illustrated are the following:

(1) Specifying proportions of various reactants
   (a) O/F: cases 122, 123, and 1565
   (b) Equivalence ratios: cases 52 and 950
   (c) Percent fuel by weight: cases 5612 and 6666
   (d) Complete information on reactant cards: cases 51, 679, and 1207

(e) Relative weights of reactants: cases 51, 52, 122, 123, 950, 1565, 5612, and 6666

(f) Relative moles of reactants: cases 679 and 1207

(2) Specifying enthalpies

(a) On reactant cards: cases 51 (partly), 122, 123, 679, 950, 1565 (partly), 5612, and 6666

(b) Calculated by program: cases 51 (partly), 52, 1207, and 1565 (partly)

(3) Pressure units

(a) psia: cases 51, 122, 679, 5612, and 6666

(b) atm: cases 52, 123, and 950

(c) mm Hg: case 1207

(4) INSERT: cases 51 and 5612

(5) OMIT: cases 51 and 950

(6) Composition in floating-point format: case 1565

(7) Program considers ions: case 679

(8) Special derivatives due to two condensed phases of a species: cases 51 and 5612

(9) Special throat interpolation: case 5612

(10) Omit transport property calculations: case 679

(11) Punched-card output: case 123

(12) Freezing at supersonic station: case 6666

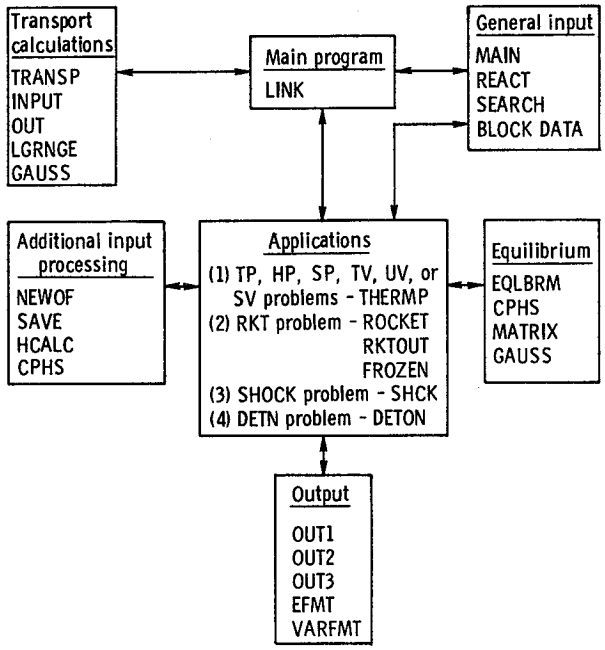
Some additional features of the program illustrated by the various cases are the following:

(1) Case 51: This case shows several condensed species being automatically inserted and removed by the program. Frozen expansion is stopped at point 3 inasmuch as the exit temperature is below the melting point of 2315 K.

(2) Case 122: This case shows that it is possible to assign a schedule of points which includes a mixture of pressure ratios, subsonic area ratios, and supersonic area ratios.

MODULAR FORM OF PROGRAM

In order to facilitate adding or deleting applications of the chemical equilibrium part of the program, the program was set up in 10 modules. These modules are concerned with overlay control, which is used on the IBM 7094 (main program), and with general input, additional input processing, four applications, equilibrium calculations, transport calculations, and output. The general flow of these modules and associated routines is given in the following schematic:



From this diagram, it is clear that, for example, the rocket application could be eliminated by omitting subroutines ROCKET, RKTOUT, and FROZEN and by omitting the statement which calls ROCKET in the main program.

LINK (MAIN PROGRAM)

LINK is the main program. Its sole function is to control the program flow between the thermodynamic and transport property calculations. The overlay structure used for the IBM 7094 is shown in figure 1. LINK and subroutine GAUSS are the only two routines in core storage at all times. (GAUSS solves a set of as many as 20 simultaneous linear equations.) Overlay is not required for machines which have sufficient storage for the entire program.

A flow chart of LINK is given in figure 2.

The number of storage locations used for each routine is shown in parentheses in figure 1. These numbers include allocations for block common, as they are introduced into storage in loading the program. That is, the number in parentheses includes a block common with the first routine in which it is used. Consequently, LINK and TRANSP have larger numbers than they would have if the common blocks had not been included.

When the program is doing thermodynamic property calculations, LINK 0 and LINK 1 are in core storage. This uses about 27 000 storage locations. When the program is doing transport property calculations, LINK 0 and LINK 2 are in core storage. This uses over 32 000 storage locations. These numbers include all the routines but not other storage needed by the computer system. This additional storage requirement will vary from

one computer installation to another. At NASA Lewis this amounts to 1548 storage locations for the system and an additional 5590 for the systems subroutines, for a total of 7138 additional storages.

DISCUSSION OF SUBROUTINES

This section describes the routines not included in reference 1 and also describes those in the CEC71 program which have been changed. Among the new routines are the subroutines needed for the transport property calculations and the main program (LINK), which links the thermodynamic calculations with the transport calculations. Subroutines which will not be discussed are those which are nearly the same as those in reference 1.

Some dimensions have been changed from the CEC71 program. In order to save storage, only 100 species and 10 elements are permitted, rather than 150 species and 15 elements, as are allowed in CEC71. Also, the number of temperatures T has been changed from 26 to 52. These dimension changes apply to any routine in which the variables appear. These changes affect the common blocks POINTS, SPECES, and MISC.

Two new common blocks, SAVED and CONTRL, have been added. SAVED is used to save information obtained from the thermodynamic calculations which is needed in the transport calculations. It is also used to save information obtained from the transport calculations which is needed later. This change also caused a slight reorganization of the variables in common blocks SPECES, MISC, and INDX. CONTRL contains additional logical variables TRNSPT, FROZN, PUNCH, and NODATA.

Flow charts are also included for aid in understanding of the program. The reader may find appendixes A and B helpful in relating symbols to the program variable names.

Subroutine MAIN

Subroutine MAIN is very similar to the main routine in the CEC71 program. A flow chart is given in figure 3. Perhaps the most noteworthy change is that it is now a subroutine. One other change is significant. That is, when thermodynamic data are being read in from cards, transport and relaxation data immediately follow the thermodynamic data. The format for the thermodynamic data is still the same as in reference 1. This change essentially involves only the insertion of 11 additional cards which are needed in order to read and write the transport and relaxation data on tape unit 4.

Subroutine SEARCH

SEARCH searches for data stored on logical tape unit 4. Thermodynamic data for all the species in the chemical system are located on tape unit 4 and saved in core storage. In addition, transport and relaxation data are also read from tape unit 4, and the data which are relevant to the chemical system are stored on logical tape unit 3 (disk storage).

Another search of the transport and relaxation data on tape unit 3 is made at the start of the transport property calculations in subroutine TRANSP. This second search is used in order to find the data involving interactions of only the important species and to save these data in core storage. This secondary search is discussed in the section Subroutine TRANSP.

Subroutine OUT1

Subroutine OUT1 is the output routine for the thermodynamic calculations. It is nearly the same as OUT1 in the CEC71 program. The only change is that punched-card output of the thermodynamic properties is now included. Only data of the standard thermodynamic properties which apply to all types of problems (rocket, shock, detonation, and assigned thermodynamic states) are punched. The additional properties, which apply only to the particular type of problem being run, are not punched.

Subroutines THERMP, ROCKET, SHCK, and DETON

These subroutines control the calculations for the same types of problems as in the CEC71 program: properties at assigned thermodynamic states, rocket combustion, normal shock waves, and Chapman-Jouguet detonations. The basic differences between the two programs are the modes of entry and return from these routines. Both standard and nonstandard entries and returns are used, in contrast with the CEC71 program, which uses only a standard entry and return. The modes of entry and return can be seen from figure 2 and the program listing (appendix C).

Another difference between the programs involves the DO loops on pressure, temperature, and O/F (P, T, OXF). The subroutines for the thermodynamic calculations and the subroutines for the transport calculations are in different core loads. So if the problem involves more than 13 points, the core load for the thermodynamic calculations has to be reloaded after each set of transport calculations is completed. However, in order to reenter the subroutines THERMP, ROCKET, SHCK, and DETON after each set of transport calculations, it would have been necessary to illegally enter inside the DO

loops. To avoid this problem, the DO loops have been eliminated and a simple, program-generated, indexing procedure on P, T, and OXF has been used.

Subroutine ROCKET has additional changes associated with the variable NFZ, the variable which specifies the freezing point for frozen flow. Since the CEC71 program permits only freezing at the chamber, the present program required some changes in order to allow freezing at the throat or at any supersonic station.

Subroutine TRANSP

Subroutine TRANSP is the main routine for the transport calculations. A flow diagram is given in figure 4. All calculations of the properties are done in this routine. The equations are given in the next section.

One other operation is carried out in this routine. Logical tape unit 3 is searched for the transport and relaxation data of the important interactions and saved in the variable TABLES. This search differs from the one in subroutine SEARCH. In SEARCH, data are saved for all interactions in the chemical system; whereas, in TRANSP, interactions involving a trace species are eliminated.

The remainder of the routine is the calculation of the properties. Calculation of the viscosity, monatomic thermal conductivity, reaction thermal conductivity, and reaction heat capacity all involve the solving of a set of simultaneous linear equations. The matrix elements for each are calculated in TRANSP, but the actual solution is obtained from subroutine GAUSS.

The solutions obtained from GAUSS are checked for accuracy for two of the properties, viscosity and reaction thermal conductivity. If the initial equations are not satisfied to a prescribed tolerance by using the solution obtained from GAUSS, an error message is printed out. (See the listing in appendix C of subroutine TRANSP for the specific information printed out in each error message.)

Subroutine INPUT

Subroutine INPUT sets up the transport and relaxation data needed for the transport property calculations done in TRANSP. It is called from TRANSP for each point. The various functions of this subroutine are outlined as follows:

(1) The EN array is searched for the most important gaseous species for the current point. These are identified and saved by storing the index of the species name in IND. A maximum of 20 species is allowed. All species of mole fractions less than 10^{-7} are omitted, as well as all condensed phases. However, all gaseous atomic elements are initially included, even if they are not among the 20 most important species, or even if

their mole fractions are less than 10^{-7}. This condition is imposed to satisfy a requirement imposed upon the A array, which is explained later in this section. If any elements have been omitted through use of an OMIT card, they are reinserted into the A array at this point. A message is printed out giving the name of the element reinserted into the A array: "NO ELEMENT WAS FOUND IN THE LIST OF SPECIES WITH THE NAME (name of species), OR ELSE THERE IS AN ERROR IN THE A(I,K) ARRAY."

(2) The mole fractions and molecular weights are now calculated for the new reduced composition obtained in step 1.

(3) Transport and relaxation data are initialized to zero. Then, data stored in TABLES are searched, interaction by interaction, for data pertinent to the current point. When such data are found, subroutine LGRNGE(TT) is called. LGRNGE(TT) interpolates for the temperature TT. If data are missing for a pure species, an empirical equation is used to estimate the data. If data are missing for an interaction between unlike species, data are estimated from combining rules, using the data of the pure species. The empirical equation and the combining rules are described in the next section. If data for a pure species are missing, an error message is printed out: "NO TRANSPORT DATA WERE FOUND FOR THE SPECIES (name of species)." If the logical variable NODATA is not specified in the INPT2 namelist, the program sets NODATA = .F. and the message is printed. If NODATA = .T. is set in namelist INPT2, the message is not printed. However, no message is ever printed when data are missing for an interaction between unlike species. In either case, the program continues.

The purpose of this error message is to warn the program user when transport data for a major species are missing. When the user is certain this is not the situation, he may wish to omit the message, in order to avoid getting the message every time the program fails to find data for a minor species.

(4) The final operation of INPUT is to read the stoichiometric coefficients from the A array into the STC array and reorder them so as to express them as a set of chemical reaction equations, suitable for use in equation (25). As was mentioned earlier, all the elements in the system are initially included. This is not a necessary requirement, but was done as a matter of convenience. By including all the elements among the 20 (or less) gaseous species in the system, it is possible to use the A array to express the system in terms of a sufficient set of independent chemical equations. The number of required independent equations is given by taking the total number of species and subtracting the number of chemical elements in the system. So by choosing the set of chemical equations as the chemical reactions of formation of each species, a set of equations can be easily written directly from the stoichiometric coefficients in the A array. For instance, in the A array corresponding to the column for CH_4, there is a 1 in the row for carbon, a 4 in the row for hydrogen, and a 0 in the rows for the remaining elements. By assigning a -1 to CH_4, the chemical equation $C + 4H - CH_4 = 0$ is formed.

This procedure is applied to each species in the system, and the result is the initial set of equations. This initial set of equations is then reduced in order to eliminate any species or element (in this case always an element) not found among the 20 most important species in the system. This reduction is accomplished by searching through the chemical equations for an element with a mole fraction less than 10^{-7}, solving the chemical equation for that element, and then substituting the result in any other equation in which the element appears. The new set of equations is one less in number than the original set. This procedure is repeated until all the elements of mole fractions less than 10^{-7} have been eliminated from the chemical equations. The stoichiometric coefficients of this final set of equations are stored in STC and are used in equation (25) for calculating the reaction contribution to the heat capacity and thermal conductivity.

Subroutine OUT

The output routine, appropriately called OUT, handles all the output of the transport property calculations. This includes table headings, units, calculated data, spacing, and punched-card output.

This routine was written with the capability of saving the transport data for as many as 52 points. These data are saved in STORE. Including the current set of 13 points, this means that as many as 65 points can be printed at one time. If the problem has more than 65 points, such as might occur for a TP problem, transport data will be printed out after every multiple of 65 points.

Subroutine LGRNGE(TT)

Subroutine LGRNGE(TT) is a four-point Lagrange interpolation routine. It is used to interpolate within the tables of transport and relaxation data at temperature TT.

TRANSPORT PROPERTY EQUATIONS

The rigorous theory for the transport properties of real, dilute, monatomic gases has been reviewed and studied in great detail by Chapman and Cowling (ref. 13) and Hirschfelder, Curtiss, and Bird (ref. 14). Both references 13 and 14 express the transport coefficients in terms of Sonine polynomial expansions. However, in actually solving the equations, they use different but equivalent methods. Another method originated by Maxwell and refined by Chapman is called the moment method. More recently, Grad (ref. 15) has made the expansion in the moment method more systematic, using Hermite

polynomials rather than Sonine polynomials; his method is frequently referred to as the "thirteen-moment method." An historical review of the early work in this field is given in reference 13.

The methods described in references 13 to 15 result in mathematical solutions with increasing orders of approximation to the transport coefficients. As the order of approximation increases, so does the arithmetic complexity. Fortunately, what is usually referred to as the first approximation is sufficiently accurate for nearly all practical applications. The most notable exception to this is when ionization becomes appreciable (refs. 10 and 11). This is particularly true for the thermal conductivity. The present program uses only the first approximations, and this suggests an upper limit to the range of applicability for the transport coefficient calculations. This limit is incipient ionization. When the degree of ionization is low, collisions between ionized species and neutral particles are infrequent, and collisions where both species are ionized are very infrequent. With a further increase in temperature (or decrease in pressure), ionization increases and interactions between charged particles become important. At this point the first approximation is no longer sufficient.

However, it should be reiterated that what we are referring to here are approximations to the solution of the general equation. There are other assumptions in the mathematical formulation which have been discussed in the section ASSUMPTIONS AND CAPABILITIES. These assumptions restrict the range of applicability of the general equation at high pressures and at low temperatures and pressures.

Viscosity

The viscosity of the gas mixture is calculated from the following equation (ref. 14, p. 489, eqs. (7.4-56) and (7.4-57), see also pp. 531 and 532):

$$\eta_{mixture} = \sum_{i=1}^{n} x_i \eta_i \tag{6}$$

where n is the number of species in the mixture, x_i is the mole fraction of species i, and η_i is found by solving the following set of simultaneous algebraic equations, which are linear in the unknown η_j:

$$\sum_{j=1}^{n} c_{ij} \eta_j = x_i \qquad i = 1, 2, \ldots, n \tag{7}$$

and the c_{ij} matrix coefficients are given by

$$c_{ii} = \frac{x_i^2}{\eta_{ii}} + \sum_{\substack{k=1 \\ k \neq i}}^{n} \frac{2x_i x_k}{\eta_{ik}} \frac{M_i M_k}{(M_i + M_k)^2} \left(\frac{5}{3A_{ik}^*} + \frac{M_k}{M_i} \right) \tag{7a}$$

$$c_{ij} = -\frac{2x_i x_j}{\eta_{ij}} \frac{M_i M_j}{(M_i + M_j)^2} \left(\frac{5}{3A_{ij}^*} - 1 \right) \qquad i \neq j \tag{7b}$$

where

$$\eta_{ij} = \frac{5}{16N_A} \frac{\sqrt{2\pi M_i M_j RT/(M_i + M_j)}}{\pi \bar{\Omega}_{ij}^{(2,2)}} \tag{7c}$$

and

$$A_{ij}^* = \frac{\bar{\Omega}_{ij}^{(2,2)}}{\bar{\Omega}_{ij}^{(1,1)}} \tag{7d}$$

where N_A is Avogadro's number, M_i is the molecular weight of species i, R is the gas constant, T is the temperature, and $\bar{\Omega}_{ij}^{(1,1)}$ and $\bar{\Omega}_{ij}^{(2,2)}$ are cross sections. The $\bar{\Omega}_{ij}^{(1,1)}$ are the diffusion cross sections. When j = i, the $\bar{\Omega}_{ij}^{(2,2)}$ are viscosity cross sections, and η_{ij} simplifies to the equation for the viscosity of a pure gas $\left(5\sqrt{\pi M_i RT}/16\pi N_A \bar{\Omega}_{ii}^{(2,2)}\right)$.

Thermal Conductivity

The thermal conductivity is usually expressed as

$$\lambda_{mixture} = \lambda_{trans} + \lambda_{int} + \lambda_{reaction} = \lambda_{frozen} + \lambda_{reaction} \tag{8}$$

An equation for the first term on the right side of equation (8) was derived by Muckenfuss and Curtiss (ref. 16) and may be written in the form

$$\lambda_{trans} = 4\sum_{i=1}^{n} x_i\lambda_i \tag{9}$$

where the λ_i are found by solving the following set of simultaneous linear equations, similar to those for the viscosity:

$$\sum_{j=1}^{n} b_{ij}\lambda_j = x_i \qquad i = 1, 2, \ldots, n \tag{10}$$

and the b_{ij} matrix coefficients are given by

$$b_{ii} = \frac{4x_i^2}{\lambda_{ii}} + \sum_{\substack{k=1 \\ k\neq i}}^{n} \frac{2x_i x_k \left(\frac{15}{2} M_i^2 + \frac{25}{4} M_k^2 - 3B_{ik}^* M_k^2 + 4A_{ik}^* M_i M_k\right)}{\left(M_i + M_k\right)^2 A_{ik}^* \lambda_{ik}} \tag{10a}$$

$$b_{ij} = -\frac{2x_i x_j M_i M_j}{\left(M_i + M_j\right)^2 A_{ij}^* \lambda_{ij}} \left(\frac{55}{4} - 3B_{ij}^* - 4A_{ij}^*\right) \qquad i \neq j \tag{10b}$$

where

$$\lambda_{ij} = \frac{75R}{64N_A} \frac{\sqrt{\pi(M_i + M_j)RT/2M_iM_j}}{\pi\bar{\Omega}_{ij}^{(2,2)}} = \frac{15}{4} R \left(\frac{M_i + M_j}{2M_iM_j}\right) \eta_{ij} \tag{10c}$$

and

$$B_{ij}^* = \frac{5\bar{\Omega}_{ij}^{(1,2)} - 4\bar{\Omega}_{ij}^{(1,3)}}{\bar{\Omega}_{ij}^{(1,1)}} \tag{10d}$$

The $\bar{\Omega}_{ij}^{(1,2)}$ and $\bar{\Omega}_{ij}^{(1,3)}$ are cross sections similar to the $\bar{\Omega}_{ij}^{(1,1)}$ and $\bar{\Omega}_{ij}^{(2,2)}$ but are not associated with any particular transport property.

The preceding result for λ_{trans} represents the total thermal conductivity of a mixture of inert monatomic gases, species without internal structure. For polyatomic gases, Monchick, Yun, and Mason (ref. 17) and Monchick, Pereira, and Mason (ref. 18)

have extended the theory to include internal energy. Two assumptions were needed in order to obtain workable equations. The first assumption was that "complex collisions" (collisions involving more than a single quantum jump) could be ignored, and the second was that there was no correlation between internal energy states and relative velocities. With these assumptions plus suitable definitions of internal diffusion coefficients and relaxation times, they obtained a working equation for the thermal conductivity. They then simplified the equation to include only first-order correction terms and rearranged it to correctly give the thermal conductivity of the pure gas automatically. They expressed λ_{int} as

$$\lambda_{int} = (\lambda_{int})_{HE} + \Delta\lambda \tag{11}$$

where $(\lambda_{int})_{HE}$ is the Hirschfelder-Eucken approximation for the internal contribution to the thermal conductivity (ref. 19) and $\Delta\lambda$ is a correction term containing the inelastic effects between unlike species and some of the inelastic effects between like species. The Hirschfelder-Eucken approximation is given by

$$(\lambda_{int})_{HE} = \sum_{i=1}^{n} \left(\frac{\lambda_{int,i}}{\sum_{j=1}^{n} \frac{D_{ii}}{D_{ij}} \frac{x_j}{x_i}} \right) \tag{12}$$

where the D_{ij} are binary diffusion coefficients, the D_{ii} are self-diffusion coefficients, and $\lambda_{int,i}$ is the internal energy contribution of species i to the thermal conductivity. The $\lambda_{int,i}$ are given by (ref. 18)

$$\frac{(\lambda_{int,i})M_i}{\eta_{ii}} = \left(\frac{\rho_i D_{int,i}}{\eta_{ii}} \right) C_{int,i} - \frac{\left(\frac{2C_{int,i}}{\pi Z_i} \right) \left(\frac{5}{2} - \frac{\rho_i D_{int,i}}{\eta_{ii}} \right)^2}{1 + \left(\frac{2}{\pi Z_i} \right) \left(\frac{5}{3} \frac{C_{int,i}}{R} + \frac{\rho_i D_{int,i}}{\eta_{ii}} \right)} \tag{13}$$

where ρ_i is the density, $C_{int,i}$ the internal heat capacity, Z_i the collision number, $D_{int,i}$ a quantity which is frequently referred to as the diffusion coefficient for internal energy, and the subscript i again refers to species i. For elastic collisions, $D_{int,i}$ is reasonably well approximated by the self-diffusion coefficient (ref. 20). However, for

some molecules, this approximation is no longer valid. For example, polar molecules may exchange internal energy even at large separations. In particular, for the case of the exchange of rotational energy when the exchange is energetically resonant, Mason and Monchick have derived expressions for $D_{int,i}$ which can be expressed as (ref. 20)

$$D_{int,i} = \frac{D_{ii}}{1 + \delta_i} \tag{14}$$

They give explicit expressions for the δ_i in terms of the molecular weight, dipole moment, and moments of inertia for linear molecules and various symmetric-top molecules.

From reference 14 (p. 540),

$$\frac{\rho_i D_{ii}}{\eta_{ii}} = \frac{6}{5} A_{ii}^* \tag{15}$$

Then from equations (14) and (15),

$$\frac{\rho_i D_{int,i}}{\eta_{ii}} = \frac{6}{5}\left(\frac{A_{ii}^*}{1 + \delta_i}\right) \tag{16}$$

where $\delta_i = 0$ for nonpolar molecules.

One additional modification of equation (13) should be mentioned. Only one collision number is indicated for each species in equation (13). However, there is a different collision number for each internal energy mode. If each internal energy mode is separable and a collision number identified with each mode, then one can write (ref. 18)

$$\frac{C_{int,i}}{Z_i} = \sum_k \frac{C_{int,ki}}{Z_{ki}} \tag{17}$$

where the subscript k runs over all internal energy modes and the subscript i refers to species i. However, in practice, the rotational energy modes are usually the only ones of importance, though the vibrational ones may become important at high temperatures.

If it is assumed that the species can be characterized by one rotational collision number and by one vibrational collision number and that $D_{int,i} = D_{ii}/(1 + \delta_i)$, then from equations (13), (15), and (17) and the relationship for an ideal gas, which is

$$C_{int,i} = C_{p,i} - \frac{5}{2}R \tag{18}$$

the following is obtained:

$$\frac{(\lambda_{int,i})M_i}{\eta_{ii}} = \frac{6}{5}A_{ii}^*\left(C_{p,i} - \frac{5}{2}R\right) - \frac{\left(\frac{C_{rot,i}}{Z_{rot,i}} + \frac{C_{vib,i}}{Z_{vib,i}}\right)\left(\frac{5}{2} - \frac{6}{5}A_{ii}^*\right)^2 R}{\frac{\pi R}{2} + \left(\frac{C_{rot,i}}{Z_{rot,i}} + \frac{C_{vib,i}}{Z_{vib,i}}\right)\left[\frac{5}{3} + \frac{6/5A_{ii}^*}{(c_p/R) - (5/2)}\right]} \tag{19}$$

Equation (19) is written for nonpolar gases. For polar molecules, A_{ii}^* is replaced by $A_{ii}^*/(1 + \delta_i)$. To transform the denominator of equation (12), the following relationship is used (ref. 14, p. 530):

$$D_{ij} = \frac{3}{5}\left(\frac{M_i + M_j}{M_i M_j}\right)\left(\frac{RT}{P}\right)A_{ij}^*\eta_{ij} \tag{20}$$

When this equation is substituted into equation (12), the result is

$$(\lambda_{int})_{HE} = \sum_{i=1}^{n} \frac{\lambda_{int,i}}{\sum_{j=1}^{n} \frac{A_{ii}^*}{A_{ij}^*}\left(\frac{2M_j}{M_i + M_j}\right)\frac{\eta_{ii}}{\eta_{ij}}\frac{x_j}{x_i}} \tag{21}$$

The denominator contains quantities which have been previously defined. The computer program uses equation (21) with $\lambda_{int,i}$ obtained from equation (19). Again, for polar molecules, A_{ii}^* is replaced by $A_{ii}^*/(1 + \delta_i)$. The program does not calculate the δ_i. It is assumed that the A_{ii}^* are provided in a form which is suitable for direct use in equations (19) and (21).

Monchick, Pereira, and Mason (ref. 18) have compared calculated results for some binary mixtures with experimental measurements in order to determine the effect of including relaxation effects. Equation (11) was used along with the internal thermal conductivity of a pure species $\lambda_{int,i}$ expressed in the form

$$\lambda_{int,i} = \lambda_{exp,i} - \lambda_{monatomic,i} = \lambda_{exp,i} - \frac{15}{4}\frac{R}{M}\eta_{ii} \tag{22}$$

At the temperatures of the experimental measurements, only rotational relaxation was important. In general, satisfactory agreement was obtained between experiment and the theory of binary mixtures. Their results showed that the calculations were relatively insensitive to the inelastic collision corrections, provided that as the mole fraction of one species reached zero the calculated results were forced to agree with the experimental value of the pure gas for the other species. They concluded that for most purposes it was satisfactory to neglect inelastic effects in the mixture between different species, but that inelastic effects must be included in the calculations of the pure species. In other words, to a good approximation, $\Delta\lambda$ can be ignored in equation (11). A further consideration is that relaxation information between unlike species is almost completely lacking (ref. 18). In view of the preceding considerations the present program assumes $\Delta\lambda = 0$, and thus equation (21) is the only term contributing to equation (11).

The third and final term in equation (8) represents the contribution from chemical reaction. For a mixture of nonreacting gases (frozen mixture), this term is zero. But when chemical reactions occur, there is a contribution to the thermal conductivity. A general expression has been derived (refs. 21 and 22) for the contribution to the conductivity when local chemical equilibrium exists in a mixture of reacting gases:

$$\lambda_{reaction} = R\sum_{i=1}^{\nu}\left(\frac{\Delta H_i}{RT}\right)\lambda_{r,i} \tag{23}$$

where ν is the total number of chemical reactions and ΔH_i is the heat of reaction expressed as

$$\Delta H_i = \sum_{k=1}^{n} a_{ik}H_k \qquad i = 1,2,\ldots,\nu \tag{24}$$

In equation (24) the a_{ik} are the stoichiometric coefficients written for the chemical reactions involving species A_k as follows

$$\sum_{k=1}^{n} a_{ik}A_k = 0 \qquad i = 1,2,\ldots,\nu \tag{25}$$

The $\lambda_{r,i}$ are found by solving a set of simultaneous linear equations

$$\sum_{j=1}^{\nu} g_{ij}\lambda_{r,j} = \frac{\Delta H_i}{RT} \qquad i = 1, 2, \ldots, \nu \tag{26}$$

where the g_{ij} are given by

$$g_{ij} = \sum_{k=1}^{n-1} \sum_{l=k+1}^{n} \left(\frac{RT}{PD_{kl}} x_k x_l\right)\left(\frac{a_{ik}}{x_k} - \frac{a_{il}}{x_l}\right)\left(\frac{a_{jk}}{x_k} - \frac{a_{jl}}{x_l}\right) \tag{26a}$$

Rearranging equation (20) gives

$$\frac{RT}{PD_{kl}} = \frac{5M_k M_l}{3A^*_{kl}\eta_{kl}(M_k + M_l)}$$

which is the form of RT/PD_{kl} used in the program to evaluate g_{ij} in equation (26a). The sum of equations (9), (21), and (23) gives the total thermal conductivity of the gas mixture.

Specific Heat

The specific heat given in the transport properties table is calculated from the equation of reference 23

$$c_{p,eq} = c_{p,frozen} + c_{p,reaction} \tag{27}$$

where

$$c_{p,frozen} = \frac{\sum_{i=1}^{n} x_i C_{p,i}}{\sum_{i=1}^{n} x_i M_i} = \frac{1}{M}\sum_{i=1}^{n} x_i C_{p,i} \tag{27a}$$

and $c_{p,\text{reaction}}$ is found from an equation very similar to that for calculating $\lambda_{\text{reaction}}$ (eq. (23))

$$c_{p,\text{reaction}} = \frac{R}{M} \sum_{i=1}^{\nu} \left(\frac{\Delta H_i}{RT} \right) X_i \tag{28}$$

The X_i are found by solving the following set of linear equations:

$$\sum_{j=1}^{\nu} d_{ij} X_i = \frac{\Delta H_i}{RT} \qquad i = 1, 2, \ldots, \nu \tag{29}$$

where the d_{ij} are given by

$$d_{ij} = \sum_{k=1}^{n-1} \sum_{l=k+1}^{n} x_k x_l \left(\frac{a_{ik}}{x_k} - \frac{a_{il}}{x_l} \right) \left(\frac{a_{jk}}{x_k} - \frac{a_{jl}}{x_l} \right)$$

Equation (28) is different from, but equivalent to, that given in reference 1. It is also very similar to the equation (from refs. 21 and 22) for calculating $\lambda_{\text{reaction}}$ (eq. (23)). The only difference from equation (23) is that the (RT/PD_{kl}) term is missing in the d_{ij} coefficients. Consequently, it provides a means for checking for errors in the transport calculations, especially $\lambda_{\text{reaction}}$.

Agreement between the specific heat in the thermodynamic calculations and the specific heat in the transport calculations indicates that the transport calculations proceeded satisfactorily. However, as mentioned earlier in the section DESCRIPTION OF PROGRAM OUTPUT, differences do frequently occur for perfectly valid reasons. First, if condensed phases appear in the composition there will be some differences, because the specific heat listed in the results of the thermodynamic calculations includes condensed and gas phases, whereas the specific heat listed in the results of the transport calculations includes only the gas phase. The other reason is that sometimes not all the species appearing in the results of the thermodynamic calculations will be used in the transport calculations. This occurs because, as explained previously, only 20 gaseous species are included in the transport calculations and, among these, all the elements in the chemical system are initially included. The reason for including the elements was discussed in the section describing subroutine INPUT.

Remaining Properties

The equations for the remaining properties are summarized as follows: The frozen and equilibrium Prandtl numbers are

$$Pr_{frozen} = \frac{(c_{p,frozen})(\eta_{mixture})}{\lambda_{frozen}} \tag{30}$$

$$Pr_{eq} = \frac{(c_{p,eq})(\eta_{mixture})}{\lambda_{mixture}} \tag{31}$$

For the generalized Lewis number, as defined by Brokaw (ref. 24)

$$Le = \frac{(\lambda_{reaction})(c_{p,frozen})}{(\lambda_{frozen})(c_{p,reaction})} \tag{32}$$

A few other thermodynamic properties for the gas phase (molecular weight, enthalpy, and density) are included in the punched-card output but not in the printed output:

$$M = \sum_{i=1}^{n} x_i M_i \tag{33}$$

$$H = \sum_{i=1}^{n} x_i H_i \tag{34}$$

$$\rho = \frac{PM}{RT} \tag{35}$$

Estimation Techniques

The final subject concerns the equations used to estimate the transport cross-section data when these data are missing from the TRANSPORT data library (physical tape 4). When this occurs, empirical rules are used. For interactions involving molecules of different species, the rules suggested from the analogy to a rigid sphere (ref. 25) are

$$\bar{\Omega}_{ij}^{(2,2)} = \frac{1}{4}\left[\bar{\Omega}_{ii}^{(2,2)} + 2\sqrt{\bar{\Omega}_{ii}^{(2,2)}\bar{\Omega}_{jj}^{(2,2)}} + \bar{\Omega}_{jj}^{(2,2)}\right] \tag{36}$$

$$A_{ij}^{*} = \frac{1}{2}\left(A_{ii}^{*} + A_{jj}^{*}\right) \tag{37}$$

$$B_{ij}^{*} = \frac{1}{2}\left(B_{ii}^{*} + B_{jj}^{*}\right) \tag{38}$$

For molecules composed of hard rigid spheres the preceding equations are exact ($A_{ij}^{*} = B_{ij}^{*} = 1$).

For interactions involving molecules of the same species, an empirical relation was derived from the experimental and theoretical transport data of the pure species. This relation should not be considered as a means for providing missing data, but rather as a means for estimating cross sections of the correct order of magnitude, in order that the calculations will proceed smoothly. Problems might occur, such as division by zero, if the assigned storage locations for cross sections were allowed to remain empty. Only species for which information on transport data were available over a large temperature range were used in the analysis. These included species such as He, Ne, Ar, Kr, Xe, N, O, N_2, O_2, H_2, CO_2, and H_2O. The empirical relationship is

$$\bar{\Omega}_{ii}^{(2,2)} = \ln\left(320\,\frac{M_i^4}{T^{1.4}}\right) \tag{39}$$

where $\bar{\Omega}_{ii}^{(2,2)}$ is given in the units of square angstroms. The largest errors in equation (39) occurred for species of very low molecular weight. For very high temperatures or low molecular weights, $\bar{\Omega}_{ii}^{(2,2)}$ can become negative. In order to avoid this, $\bar{\Omega}_{ii}^{(2,2)} = 1$ was arbitrarily assigned as the smallest allowable value. For all conditions where $\bar{\Omega}_{ii}^{(2,2)}$ calculated by equation (39) is less than unity, it is set equal to unity.

The A_{ii}^{*} and B_{ii}^{*} generally show only a very slight temperature dependence and usually are close to unity. Consequently, both were set equal to 1 for all temperatures. This is also consistent with equations (37) and (38) in that this approximation is exact for molecules composed of hard rigid spheres.

Also, for each species, relaxation data are needed (Z_i), and these data are often lacking. If relaxation data for the species are not found in the tape library, the program uses the Hirschfelder-Eucken approximation (ref. 19), which is equivalent to letting $Z_{rot} = Z_{vib} = \infty$ in equation (19). There is no scheme for estimating collision numbers included in the program.

SOURCES OF TRANSPORT AND RELAXATION DATA

Sources of the transport cross-section data included with the program are given in table VIII. The data are in the nature of a preliminary set of input. In order to provide data for the large number of interactions needed in a general program, data included with the program were generally obtained directly from the literature. For the most part, the data were not examined critically, and so are not necessarily the most recent or most accurate data. There is one important exception, however. This is the input for the inert gases. A considerable amount of high-temperature experimental viscosity and thermal conductivity data have become available for the inert gases in recent years. These data, as well as the earlier data, have been used to obtain the cross-section data included with the set of input. Molecular beam scattering data were used at the higher temperatures.

One method given in table VIII which should be commented upon is method 9, which applies to the CO interactions. From consideration of the electron configurations and molecular weights of N_2 and CO, it would be anticipated that the transport cross sections for interactions involving N_2 should be about the same as those for the corresponding interactions involving CO. In order to test this supposition, the viscosity data of N_2 were compared with the viscosity data of CO (refs. 26 and 27); and the binary diffusion data for N_2-X were compared with the binary diffusion data for CO-X (ref. 28), where X is some third species. Good agreement was obtained. This suggested the possibility that if data for an interaction involving CO were unavailable, data for the corresponding interaction involving N_2 could be used. The reverse would also be true. However, since data for the N_2 interactions are considerably more extensive than those for the CO interactions, this approximation usually amounts to a method for estimating data for interactions involving CO from the corresponding interactions involving N_2.

Although the list of interactions in table VIII is not complete, it is fairly comprehensive. An effort was made to include data for all the important species and for many of the interactions between unlike species. There are two exceptions, however. First, no data have been included for ionized species; and second, data for only a few organic molecules have been included.

Relaxation data included with the program are given in table IX. Only rotational collision numbers are included. The Hirschfelder-Eucken approximation is used for vibrational relaxation ($Z_{vib} \equiv \infty$). Most of the collision numbers given for nonpolar or slightly polar molecules were obtained by fitting the experimental thermal conductivity data to equation (22), with $\lambda_{internal}$ given by equation (19), and letting $Z_{vib} = \infty$. All Z_{rot} were assumed to be independent of temperature. (The numbers given in table IX represent average values over the entire temperature range.) There were two reasons for doing this. One reason is that calculated values of Z_{rot} are usually quite sensitive to changes in the values of the viscosity and thermal conductivity used in the calculations.

Furthermore, since the uncertainty in the thermal conductivity is sometimes rather large, it often leads to very large uncertainties in the calculated collision number. The other reason is that at higher temperatures the absence of experimental thermal conductivity data means that Z_{rot} would have to be determined by some alternate technique. A reasonable procedure would be to extrapolate Z_{rot} to higher temperatures by means of some theoretical expression for the temperature dependence. However, investigators who have studied the temperature dependence from theoretical considerations have obtained significantly different results (refs. 29 to 31). Therefore, it seemed unwise to include temperature-dependent collision numbers without even being sure of the temperature dependence of Z_{rot}. Consequently, Z_{rot} was assumed to be a constant, and the numbers listed in table IX apply to all temperatures.

In some cases the experimental thermal conductivity data indicated a Z_{rot} less than unity. However, this seems inconsistent with the general physical notion of a collision number, and so for these cases Z_{rot} was set equal to 1.

For large collision numbers the calculated thermal conductivity is insensitive to variations in the collision number. A large range of Z_{rot} will adequately fit the experimental data. It becomes difficult, if not impossible, to determine a rotational collision number by just fitting thermal conductivity data. For a Z_{rot} of about 20 or more, there is very little difference between the thermal conductivity calculated by using Z_{rot} and that calculated from the Hirschfelder-Eucken approximation ($Z_{rot} = \infty$). Consequently, when the experimental thermal conductivity data indicated rather large collision numbers, the Hirschfelder-Eucken approximation was assumed.

For some species, viscosity data were available but thermal conductivity data were not. For these species the rotational collision numbers were estimated from the expression derived by Sather and Dahler (ref. 32) for a rough sphere surrounded by an attractive square-well potential. Their results for the rotational relaxation time τ may be expressed as

$$\tau^{-1} = \frac{16}{3}\left(\frac{\rho}{m_a}\right)\sigma^2\left(\frac{\pi kT}{m_a}\right)^{1/2}\left[\frac{4I/m_a\sigma^2}{\left(1 + 4I/m_a\sigma^2\right)^2}\right]g(\sigma) \tag{40}$$

Considering only the low-density limit of the radial distribution function $g(\sigma)$ (ref. 14, p. 321)

$$g(\sigma) \cong \exp\left(\frac{\epsilon}{kT}\right) \tag{41}$$

and defining a collision number Z_{rot} as (ref. 18)

$$Z_{rot} = \left(\frac{4}{\pi}\right)\left(\frac{P\tau}{\eta}\right) \tag{42}$$

we can substitute into equation (40) to obtain a value for Z_{rot}. If we further assume that the viscosity η can be calculated from the equation for viscosity of rigid-sphere molecules (ref. 14)

$$\eta = \frac{5}{16}\frac{\left(\pi m_a kT\right)^{1/2}}{\pi\sigma^2} \tag{43}$$

and use the ideal-gas law, the rotational collision number is given by

$$Z_{rot}^{-1} = \frac{5\pi}{12}\left[\frac{4I/m_a\sigma^2}{\left(1 + 4I/m_a\sigma^2\right)^2}\right]\exp\left(\frac{\epsilon}{kT}\right) \tag{44}$$

Equation (44) can be used to calculate a collision number directly or to calculate a ratio of the collision numbers of two species. The advantage of calculating a ratio is that it enables one to make use of a species for which the rotational collision number is known. This was the procedure used in obtaining the collision numbers shown in table IX. Molecules treated in this way are indicated, along with the species of "known" Z_{rot} used to make the estimate. In this report, the collision numbers obtained by fitting thermal conductivity data are considered to be the known Z_{rot}.

The equation is temperature dependent. However, since temperature dependences are not given for the species of "known" Z_{rot}, they are not given for the calculated ones either. The temperature actually used in each calculation was an average temperature. This average temperature was found by taking the average of the temperature range used in determining the Z_{rot} of the reference species ("known" Z_{rot}).

Collision numbers for the polar gases were taken from Zeleznik and Svehla (ref. 29). These are theoretical values of Z_{rot} based on a classical calculation of rotational relaxation times. The calculated values of Z_{rot} do have a temperature dependence. These are shown in table IX.

CONCLUDING REMARKS

The program described in this report is complete as it is presented herein. However, changes may occur from time to time as the authors become aware of improved techniques for doing the calculations. Though these changes may not be published, an outside organization requesting the program automatically receives the latest version.

Improved calculational results may also be obtained with the addition of new thermodynamic and transport data or with the updating of data already included in the program. This can be done by the program user if he has data to be added or changed, or he can send for the authors' updated version of the data.

APPENDIX A

SYMBOLS

A_e/A_t	ratio of nozzle exit area to throat area, dimensionless
A_k	chemical formula of species k, dimensionless
A_{ij}^*	$\bar{\Omega}_{ij}^{(2,2)}/\bar{\Omega}_{ij}^{(1,1)}$, dimensionless
a	sonic velocity, m/sec
a_{ik}	stoichiometric coefficient for species k in reaction i, dimensionless
B_{ij}^*	$\left[5\bar{\Omega}_{ij}^{(1,2)} - 4\bar{\Omega}_{ij}^{(1,3)}\right]/\bar{\Omega}_{ij}^{(1,1)}$, dimensionless
b_{ij}	matrix coefficient in eq. (10), (m)(sec)(K)/J
C_F	coefficient of thrust, dimensionless
C_p	heat capacity at constant pressure, J/(kg-mole)(K)
c_{ij}	matrix coefficient in eq. (7), (m)(sec)/kg
c_p	specific heat at constant pressure, J/(kg)(K)
c^*	characteristic velocity, m/sec
D_{ij}	binary diffusion coefficient, m^2/sec
d_{ij}	matrix coefficient in eq. (29), dimensionless
F/A	fuel-to-air weight (or mass) ratio or fuel-to-oxidant weight (or mass) ratio, dimensionless
% F	percent of total fuel in total reactant by weight (or mass), dimensionless
g_{ij}	matrix coefficient in eq. (26), (m)(sec)/kg-mole
$g(\sigma)$	radial distribution function evaluated at σ, dimensionless
H	enthalpy, J/kg-mole
H_0^o	standard-state enthalpy at 0 K, J/kg-mole
ΔH	heat of reaction, J/kg-mole
$\left(\Delta H_f^o\right)_T$	heat of formation at temperature T, J/kg-mole
h	enthalpy, J/kg
I	moment of inertia, (kg)(m^2)
I_{sp}	specific impulse with exit and ambient pressure equal, (N)(sec)/(kg)
I_{vac}	vacuum specific impulse, (N)(sec)/(kg)

k	Boltzmann's constant per molecule, 1.380622×10^{-23} J/K
Le	Lewis number (defined by eq. (32)), dimensionless
M	molecular weight, kg/kg-mole
m_a	molecular mass, kg
N_A	Avogadro's number, 6.022169×10^{26} molecules/kg-mole
n	number of gaseous species included in transport calculations, dimensionless
O/F	oxidant-to-fuel weight (or mass) ratio, dimensionless
P	pressure, N/m^2
P_c/P	ratio of combustion pressure to exit pressure, dimensionless
Pr	Prandtl number ($c_p\eta/\lambda$), dimensionless
R	gas constant, 8314.3 J/(kg-mole)(K) or 1.987165 cal/(g-mole)(K)
r	equivalence ratio, dimensionless
S	entropy, J/(kg-mole)(K)
S_0^o	standard-state entropy at 0 K, J/(kg-mole)(K)
s	entropy, J/(kg)(K)
T	temperature, K
U	internal energy, J/kg-mole
u_1	velocity of unshocked gas relative to incident shock front, m/sec
u_2	velocity of incident-shocked gas relative to incident shock front, m/sec
V	volume, m^3
v_2	actual velocity of incident-shocked gases in fixed coordinates, m/sec
X_i	unknown in eq. (28), dimensionless
x_i	mole fraction of species i, dimensionless
Z_i	collision number of species i, dimensionless
γ	isentropic exponent $(\partial \ln P/\partial \ln \rho)_S$, dimensionless
δ	correction term in eq. (14) for resonant exchange of rotational energy, dimensionless
ϵ	depth of potential energy well, J
η	viscosity, kg/(m)(sec)
η_i	unknown in eq. (6), kg/(m)(sec)

η_{ii}	viscosity of species i, kg/(m)(sec)
η_{ij}	defined quantity (see eq. (7c)), kg/(m)(sec)
λ	thermal conductivity, J/(m)(sec)(K)
λ_j	unknown in eq. (9), J/(m)(sec)(K)
λ_{ij}	defined quantity (see eq. (10c)), J/(m)(sec)(K)
$\lambda_{r,i}$	unknown in eq. (23), kg-mole/(m)(sec)
$\Delta\lambda$	correction term involving relaxation effects, J/(m)(sec)(K)
ν	number of chemical reactions, dimensionless
$\pi\bar{\Omega}(l,s)$	collision cross section (equivalent to $\pi\sigma^2\Omega^{(2,2)*}$ of ref. 14), m^2
ρ	density, kg/m^3
σ	molecular diameter in eq. (40), m
τ	rotational relaxation time, sec

Subscripts:

MAXNM	1	DATA STATEMENT	INPUT	Maximum number of species allowed
MAXNP	1	SAVED	TRANSP INPUT OUT	Index used in controlling transport output
MONCON	1	EQUIVALENCE STATEMENT	TRANSP	Translational thermal conductivity of mixture, λ_{trans}, real variable

FORTRAN symbol	Dimension	Common label	Transport subroutines used	Description and comments
N	1	TRANS	TRANSP INPUT OUT	Index of current point
ND	1	DATA STATEMENT	SEARCH TRANSP INPUT	Indicates end of transport data
NFZ	1	PERF	INPUT OUT	Index of freezing point
NLM	1	INDX	INPUT	Number of elements in the system
NM	1	SAVED	TRANSP INPUT	Number of species in transport calculations, n
NODATA	1	CONTRL	INPUT	If NODATA = T, message is printed out whenever cross section data are not found in the library - applies only to data for a pure species, logical variable
NPT	1	INDX	TRANSP	Number of points in current set
NR	1	TRANS	TRANSP INPUT	Number of chemical reactions, ν
NS	1	INDX	SEARCH TRANSP INPUT	Number of species in the thermodynamic calculations
NSP	1	----------	INPUT	Special index used to change A array to add an element which has been omitted through use of an OMIT card
NTAB	100	TRANS	TRANSP INPUT	Code to specify type of data used in transport calculations: = 0 if relaxation data = 1 if transport cross sections
NTB	1	----------	SEARCH TRANSP INPUT	
NTP	1	----------	SEARCH TRANSP INPUT LGRNGE	Number of entries in table of transport or relaxation data (data stored in TABLES)
NTT	100	TRANS	TRANSP INPUT	
OF	1	MISC	OUT	Oxidant-to-fuel weight ratio
OMEGA	20,20	TRANS	TRANSP INPUT	Viscosity cross section, $\bar{\Omega}^{(2,2)}$
PI	1	DATA STATEMENT	TRANSP	π, 3.14159265
PP	1	MISC	TRANSP OUT	Pressure of current point
PPP	13	POINTS	TRANSP OUT	Pressure schedule for output
PREQ	1	EQUIVALENCE STATEMENT	TRANSP	Equilibrium Prandtl number of mixture, Pr_{eq}
PRFROZ	1	EQUIVALENCE STATEMENT	TRANSP	Frozen Prandtl number of mixture, Pr_{frozen}
PUNCH	1	CONTRL	OUT	If PUNCH = T output is included on punched cards, logical variable
R	1	MISC	TRANSP OUT	Universal gas constant, 1.987165 cal/(g-mole)(K) or 8.31430 J/(kg-mole)(K)

FORTRAN symbol	Dimension	Common label	Transport subroutines used	Description and comments
REACON	1	EQUIVALENCE STATEMENT	TRANSP	Reaction thermal conductivity of mixture, $\lambda_{reaction}$
RELXTN	20	TRANS	TRANSP	Temporary storage used in calculating $\lambda_{internal}$
ROTM	20	TRANS	TRANSP INPUT	Number of rotational degrees of freedom
ROTN	1	----------	SEARCH TRANSP	
ROTNM	80	TRANS	TRANSP INPUT	
RPVT	1	DATA STATEMENT	TRANSP	Universal gas constant, 82.0562 $(cm^3)(atm)/(g\text{-}mole)/(K)$
SPECE	2,3	DIMENSION STATEMENT	SEARCH	Alphameric identification of current interaction, integer variable
		TRANS	TRANSP	
SPECIE	100,2,3	TRANS	TRANSP INPUT	Alphameric identification of interaction which is put in core storage with TABLES, integer variable
STC	17,20	TRANS	TRANSP INPUT	Table of stoichiometric coefficients, a_{ik}
STCF	17,20	TRANS	INPUT	Intermediate storage of stoichiometric coefficients
STCOEF	20	TRANS	INPUT	Result of dividing stoichiometric coefficients of each species (in the reaction to be eliminated) by COEFF
STORE	52,16	SAVED	OUT	Temporary storage of transport calculations, while thermodynamic calculations are continued
SUB	100,3	SPECES	SEARCH TRANSP INPUT	Alphameric name of species included in thermodynamic calculations, integer variable
TABLES	100,20,3	TRANS	TRANSP INPUT	Tables of cross sections and relaxation data
TABLS	20,3	DIMENSION STATEMENT	SEARCH	
TEM	100,20	TRANS	TRANSP INPUT	Temperature schedule for TABLES
TEMPR	20	DIMENSION STATEMENT	SEARCH	Temperature schedule for TABLS
TESTEN	1	----------	INPUT	Smallest EN allowed in transport calculations
TRNSPT	1	CONTRL	LINK	If TRNSPT = F transport calculations are omitted, logical variable
TT	1	MISC	TRANSP INPUT OUT LGRNGE	Temperature of current point
TTT	13	POINTS	TRANSP	Temperature schedule for output
VISC	1	EQUIVALENCE STATEMENT	TRANSP	Viscosity of mixture, $\eta_{mixture}$
WM	13	POINTS	INPUT	Molecular weight of the mixture in thermodynamic calculations
WMOL	20	SAVED	TRANSP INPUT	Molecular weight of pure species, M_i
WTMOL	1	EQUIVALENCE STATEMENT	TRANSP	Molecular weight of the mixture in transport calculations, M

FORTRAN symbol	Dimension	Common label	Transport subroutines used	Description and comments
X	20	DOUBLE	TRANSP GAUSS	Answer region for matrix solution, double precision
XS	20	SAVED	TRANSP INPUT	Mole fraction of species used in transport calculations
XSKL	20,20	DIMENSION STATEMENT	TRANSP	$(XS(k) \cdot XS(l))^{-1}$
Y	20,3	INTERP	INPUT LGRNGE	Table in subroutine LGRNGE interpolation
Z	20	INTERP	INPUT LGRNGE	Argument in subroutine LGRNGE interpolation
ZROT	20	TRANS	TRANSP INPUT	Rotational collision number, Z_{rot}
ZVIB	20	TRANS	TRANSP INPUT	Vibrational collision number, Z_{vib}

TABLE I. - FORMAT OF THERMODYNAMIC AND TRANSPORT DATA

(a) THERMO (thermodynamic) data

Card order	Content	Format	Card column
1	THERMO	3A4	1 to 6
2	Temperature ranges for two sets of coefficients: lowest T, common T, and highest T	3F10.3	1 to 30
3	Species name	3A4	1 to 12
	Date	2A3	19 to 24
	Atomic symbols and formula	4(A2, F3.0)	25 to 44
	Phase of species (S, L, or G for solid, liquid, or gas, respectively)	A1	45
	Temperature range	2F10.3	46 to 65
	Integer 1	I15	80
4	Coefficients a_i(i = 1 to 5) in equations (3) to (5) (for upper temperature interval)	5(E15.8)	1 to 75
	Integer 2	I5	80
5	Coefficients in equations (3) to (5) (a_6 and a_7 for upper temperature interval and a_1, a_2, and a_3 for lower)	5(E15.8)	1 to 75
	Integer 3	I5	80
6	Coefficients in equations (3) to (5) (a_4, a_5, a_6, and a_7 for lower temperature interval)	4(E15.8)	1 to 60
	Integer 4	I20	80
(a)	Repeat cards numbered 1 to 4 in card column 80 for each species		
Final card	END (indicates end of thermodynamic data)	3A4	1 to 3

[a]Gaseous species and condensed species with only one condensed phase can be in any order. However, the sets for two or more condensed phases of the same species must be adjacent. If there are more than two condensed phases of a species, their sets must be either in increasing or decreasing order according to their temperature intervals.

TABLE I. - Concluded. FORMAT OF THERMODYNAMIC AND TRANSPORT DATA

(b) TRANSPORT data

Card type	Content[a]	Format	Card column
1	Identification of interaction: chemical formula of species 1, chemical formula of species 2, number of temperatures in table (NTP), code to indicate type of data (1 for transport and 2 for relaxation), and number of rotational degrees of freedom	2(3A4, 6X), 2I5, F24.1	1 to 70
[b]2	Tables of data: either transport data (temperature, viscosity cross section, A^*, and B^*) or relaxation data (temperature, rotational collision number, vibrational collision number, and dimensionless vibrational heat capacity (C_{vib}/R))	4F10.4	1 to 40
3	End card to indicate end of transport data; LAST written in card columns 1 to 4	A4	1 to 4

[a]Identification of interaction is done by giving chemical formula of particular species involved, whether they are the same or different. They may be specified in either order, inasmuch as the program assumes interaction A-B to be same as B-A. The number of rotational degrees of freedom is meaningful only for data of a pure species (interaction of the type A-A). The temperature schedule is arbitrary, provided the number of temperatures is not more than the maximum of 20. In addition, the data should be ordered in either an increasing or decreasing function of temperature, in order that interpolation within the table be meaningful. As a matter of input convenience, the Hirschfelder-Eucken approximation is denoted by setting the collision number equal to 0.0. If the vibrational heat capacity is not specified ($C_{vib}/R = 0$), the program will calculate a value assuming that the electronic heat capacity is zero and that the rotational heat capacity is classical. For polar molecules A^* should be corrected for resonant exchange of internal energy. See the main-text section TRANSPORT PROPERTY EQUATIONS for an explanation.

[b]There are NTP cards of type 2. They are followed by a card of either type 1 or type 3.

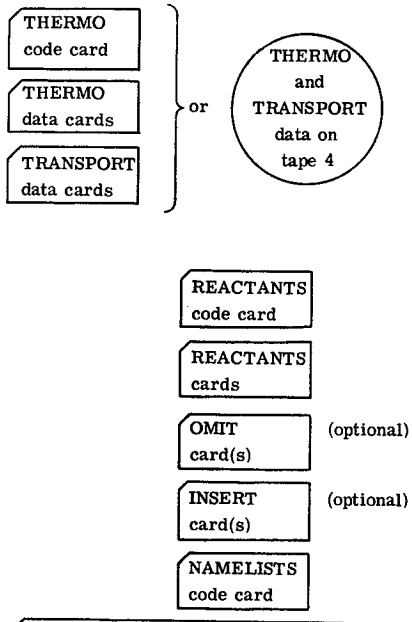

TABLE II. - PROGRAM INPUT

Problem	Namelist	Variables	
		Required	Optional
Assigned temperature and pressure (TP)	INPT2	TP = .TRUE. T(1 to 52); P(1 to 26)	NSQM, PSIA, or MMHG
Assigned enthalpy and pressure (HP)	INPT2	HP = .TRUE. P(1 to 26)	NSQM, PSIA, or MMHG
Assigned entropy and pressure (SP)	INPT2	SP = .TRUE. S0(1); P(1 to 26)	NSQM, PSIA, or MMHG
Assigned temperature and volume or density (TV)	INPT2	TV = .TRUE. T(1 to 52); V(1 to 26) or RHO(1 to 26)	
Assigned internal energy and volume or density (UV)	INPT2	UV = .TRUE. V(1 to 26) or RHO(1 to 26)	
Assigned entropy and volume or density (SV)	INPT2	SV = .TRUE. V(1 to 26) or RHO(1 to 26); S0(1)	
Detonation (DETN)	INPT2	DETN = .TRUE. P(1 to 26) (initial gas)	T(1 to 52)(initial gas); NSQM, PSIA, or MMHG
Shock (SHOCK)	INPT2	SHOCK = .TRUE. P(1 to 13) (initial T(1 to 13) gas)	NSQM, PSIA, or MMHG
	SHKINP	U1(1 to 13) or MACH1 (1 to 13)	INCDEQ = .FALSE. or INCDFZ = .FALSE.
Rocket (RKT)	INPT2	RKT = .TRUE. P(1 to 26) (chamber pressures)	T(1 to 52) (chamber); NSQM, PSIA, or MMHG
	RKTINP		EQL = .FALSE. or FROZ = .FALSE. NFZ PCP(1 to 22) SUPAR(1 to 13) SUBAR(1 to 13)

TABLE III. - REACTANTS CARDS

Card order	Content	Format	Card column
First	REACTANTS	3A4	1 to 9
Any	One card for each reactant species (maximum, 15). Each card contains		
	(1) Atomic symbols and formula numbers (maximum, five sets)[a]	5(A2,F7.5)	1 to 45
	(2) Relative weight[b] or number of moles	F7.5	46 to 52
	(3) Blank if (2) is relative weight, or M if (2) is number of moles	A1	53
	(4) Enthalpy or internal energy[a], cal/mole	F9.5	54 to 62
	(5) State: S, L, or G for solid, liquid, or gas, respectively	A1	63
	(6) Temperature associated with enthalpy in (4)	F8.5	64 to 71
	(7) F if fuel, or O if oxidant	A1	72
	(8) Density in g/cm^3 (optional)	F8.5	73 to 80
Last	Blank		

[a]Program will calculate the enthalpy or internal energy (4) for species in the THERMO data at the temperature (6) if zeros are punched in card columns 37 and 38.

[b]Relative weight of fuel in total fuels or oxidant in total oxidants. All reactants must be given either all in relative weights or all in number of moles. This number must never be zero.

TABLE IV. - LIST OF REACTANTS CARDS FOR SOME OXIDANTS AND FUELS

Chemical	Chemical formula (card columns 1 to 45)	Percent (cc 46-52)	Assigned enthalpy, cal/mole (cc 54-62)	(a)	Temperature, K (cc 64-71)	(b)	Density, g/cm^3 (cc 73-80)
Acetonitrile	C 2. H 3. N 1.	100.	12800.	L	298.15	F	.7857

[a]Phase: S, solid; L, liquid; G, gas.

[b]Fuel, F; oxidant, O.

[e]Inhibited red fuming nitric acid based on following weight percents: $HNO_3(\ell)$= 83.5, $N_2O_4(\ell)$= 14, $H_2O(\ell)$= 2, HF(g) = 0.5.

[f]Typical jet fuel having following properties: H/C weight ratio = 0.161, heat of combustion = 18 600 Btu/lb.

[g]Typical jet fuel having following properties: H/C weight ratio = 0.163, heat of combustion = 18 640 Btu/lb.

TABLE V. - VARIABLES IN INPT2 NAMELIST

Variable	Dimension	Type	Common label	Value before read	Definition and comments
KASE	1	I	INDX	0	Optional assigned number associated with case
P	26	R	POINTS	0	Assigned pressures: chamber pressures for rocket problems; values in atm unless PSIA, NSQM, or MMHG = T (see below)
NSQM	1	L	----------	FALSE	Values in P array in N/m^2 [b]
PSIA	1	L	----------	FALSE	Values in P array in psia units[b]
MMHG	1	L	----------	FALSE	Values in P array in mm Hg units[b]
V	26	R	POINTS	0	Volume, cm^3/g
RHO	26	R	POINTS[a](P)	0	Density, g/cm^3
T	26	R	POINTS	0	Assigned temperature, K
MIX	15	R	MISC[a](OXF)	0	Values of equivalence ratios if ERATIO = T; oxidant-to-fuel weight ratio if OF = T; percent fuel by weight if FPCT = T; and fuel-to-air weight ratio if FA = T
ERATIO	1	L	MISC	FALSE	Equivalence ratios given in MIX[b]
OF	1	L	MISC	FALSE	Oxidant-to-fuel weight ratios given in MIX[b]
FPCT	1	L	MISC	FALSE	Percent fuel by weight given in MIX[b]
FA	1	L	----------	FALSE	Fuel-to-air weight ratios given in MIX[b]
TRACE	1	R	MISC	0 (5. E-9 for SHOCK problem)	Option to print mole fractions ≥ TRACE in special E-format
IONS	1	L	INDX	FALSE	Consider ionic species[b]
IDEBUG	1	I	INDX	0	Print intermediate output for all points indexed ≥ integer value
TP	1	L	INDX	FALSE	Assigned temperature and pressure problem[b]
HP	1	L	INDX	FALSE	Assigned enthalpy and pressure problem[b]
SP	1	L	INDX	FALSE	Assigned entropy (S0) and pressure problem[b]
S0	1	R	MISC	0	Assigned entropy, cal/(g)(K)
TV	1	L	INDX	FALSE	Assigned temperature and volume (or density) problem[b]
UV	1	L	INDX	FALSE	Assigned internal energy and volume (or density) problem[b]
SV	1	L	INDX	FALSE	Assigned entropy (S0) and volume (or density) problem[b]
RKT	1	L	----------	FALSE	Rocket problem[b]
DETN	1	L	----------	FALSE	Detonation problem[b]
SHOCK	1	L	INDX	FALSE	Shock problem[b]
TRNSPT	1	L	CONTRL	TRUE	Transport properties included with the calculations[b]
PUNCH	1	L	CONTRL	FALSE	Punched cards of calculations included with output[b]
NODATA	1	L	CONTRL	FALSE	Message concerning missing transport data not printed[b]
FROZN	1	L	CONTRL	FALSE	Frozen transport properties calculated for the current point[b]

[a]Equivalenced to variable given in parentheses.

[b]If variable is set to be TRUE.

TABLE VI. - VARIABLES IN RKTINP NAMELIST[a]

Variable	Dimension	Type	Common label	Value before read	Definition and comments
EQL	1	L	PERF	TRUE	Calculate rocket performance assuming equilibrium composition during expansion[b]
FROZ	1	L	PERF	TRUE	Calculate rocket performance assuming frozen composition during expansion[b]
NFZ	1	I	PERF	1	Freezing point; must be ≤13
PCP	26	R	PERF	0	Ratio of chamber pressure to exit pressure; list should not include values for the chamber and throat; storage allows for 22 values
SUBAR	13	R	PERF	0	Subsonic area ratios
SUPAR	13	R	PERF	0	Supersonic area ratios

[a]Required for rocket problems only.
[b]Set variable to be FALSE if these calculations are not desired.

TABLE VII. - VARIABLES IN SHKINP NAMELIST[a]

Variable	Dimension	Type	Value before read	Definition and comments
INCDEQ	1	L	TRUE	Calculate incident shock parameters assuming equilibrium compositions[b]
INCDFZ	1	L	TRUE	Calculate incident shock parameters assuming frozen compositions[b]
REFLEQ	1	L	FALSE	Calculate reflected shock parameters assuming equilibrium composition[c]
REFLFZ	1	L	FALSE	Calculate reflected shock parameters assuming composition frozen at incident composition[c]
U1	13	R	0	Shock velocity in m/sec (not required if values of Mach1 are listed)
MACH1	13	R	0	Ratio of shock velocity to the velocity of sound in the unshocked gas (not required if values of U1 are listed)

[a]Required for shock problems only.
[b]Set variable to be FALSE if these calculations are not desired.
[c]If variable is set to be TRUE.

[a]Methods used to obtain transport data:

1. Lennard-Jones (12-6) potential. Parameters were taken from reference 33.
2. Stockmayer (12-6-3) potential. Parameters were obtained from reference 29. Equations for resonant correction were obtained from reference 20.
3. Same as previous method, except that parameters were obtained from reference 34.
4. Reference 35. Data were extended to lower temperatures in some cases by using the potential energy parameters of reference 35.
5. Reference 36. Data were extended to lower temperatures for H_2-H_2 by using the potential energy parameters of reference 36.
6. Reference 37.
7. Reference 25. Data were extended to lower temperatures in some cases by using the potential energy parameters of reference 25.
8. Lennard-Jones (12-6) potential. Parameters were obtained from reference 38.
9. Cross-section data for interactions of the type CO-X were assumed to be the same as those for interactions of the type N_2-X.
10. Data were obtained directly from the available transport property measurements. The cross sections were selected in order to adequately reproduce both the viscosity and thermal conductivity data. At higher temperatures the cross-section data were smoothed into the results obtained from molecular beam scattering measurements (ref. 39).
11. Reference 40. Data were extended to lower temperatures in some cases by using the potential energy parameters of reference 40.
12. Exponential-6 potential. Parameters were taken from reference 28.
13. Lennard-Jones (12-6) potential. Parameters were taken from reference 41.
14. Lennard-Jones (12-6) potential. Parameters were taken from reference 42.
15. Lennard-Jones (12-6) potential. Parameters were taken from reference 43.
16. Exponential-6 potential. Parameters were taken from reference 28. Experimental diffusion data (ref. 44) and molecular beam scattering measurements (ref. 45) were used.
17. Exponential-6 potential. Parameters were taken from reference 46.
18. Reference 47.
19. Reference 48.
20. Reference 49.
21. Reference 50. Method 10 was used at higher temperatures.
22. Reference 51.

TABLE IX. - ROTATIONAL COLLISION NUMBERS

Molecule	Z_{rot}[a]	Source[b]
Ar	----------	Atom with no rotational energy modes
BCl_3	1	Obtained by fitting thermal conductivity data
BF_3	1	↓
Br_2	2	
CCl_4	1	
CF_4	1	
$CHCl_3$	908 to 26 581	Reference 29[b]
CH_3Cl	20 to 406	Reference 29[b]
CH_3OH	19 to 401	Reference 29[b]
CH_4	8	Obtained by fitting thermal conductivity data
CO	2	↓
COS	HE	
CO_2	3	
CS_2	HE	
C_2H_2	1	
C_2H_4	3	
C_2H_6	HE	
C_2N_2	2	Equation (44) using $Z_{rot}(N_2)$ as a reference
C_6H_6	HE	Obtained by fitting thermal conductivity data
Cs	----------	Atom with no rotational energy modes
Cl_2	1	Obtained by fitting thermal conductivity data
DCl	46 to 1084	Reference 29[b]
DF	4.3 to 22	Reference 29[b]
D_2O	13 to 37	Reference 29[b]
F_2	3	Obtained by fitting thermal conductivity data
H	----------	Atom with no rotational energy modes
HBr	485 to 6099	Reference 29[b]
HCN	2.8 to 10.5	↓
HCl	61 to 1349	
HF	5.7 to 27	
HI	HE	Equation (44) using $Z_{rot}(I_2)$ as a reference

[a]HE refers to Hirschfelder-Eucken approximation.

[b]Calculations of theoretical collision numbers were extended to cover the temperature range shown in table VIII.

TABLE IX. - Concluded. ROTATIONAL COLLISION NUMBERS

Molecule	Z_{rot} [a]	Source [b]
H_2	12	Obtained by fitting thermal conductivity data
H_2O	15 to 40	Reference 29[b]
H_2S	168 to 3393	Reference 29[b]
He	----------	Atom with no rotational energy modes
I_2	1	Obtained by fitting thermal conductivity data
K	----------	Atom with no rotational energy modes
Kr	----------	↓
Li	----------	↓
N	----------	↓
ND_3	12 to 193	Reference 29[b]
NH_3	16 to 235	Reference 29[b]
NO	2	Obtained by fitting thermal conductivity data
NO_2	3	↓
N_2	8	↓
N_2O	3	↓
N_2O_4	1	Equation (44) using $Z_{rot}(NO_2)$ as a reference
Na	--------	Atom with no rotational energy modes
Ne	--------	Atom with no rotational energy modes
O	--------	Atom with no rotational energy modes
OH	8	Estimated
O_2	8	Obtained by fitting thermal conductivity data
Rb	--------	Atom with no rotational energy modes
SF_6	1	Obtained by fitting thermal conductivity data
SO_2	28 to 657	Reference 29[b]
SiF_4	1	Obtained by fitting thermal conductivity data
SiH_4	9	Equation (44) using $Z_{rot}(CH_4)$ as a reference
UF_6	2	Equation (44) using $Z_{rot}(SF_6)$ as a reference
Xe	--------	Atom with no rotational energy modes

[a]HE refers to Hirschfelder-Eucken approximation.

[b]Calculations of theoretical collision numbers were extended to cover the temperature range shown in table VIII.

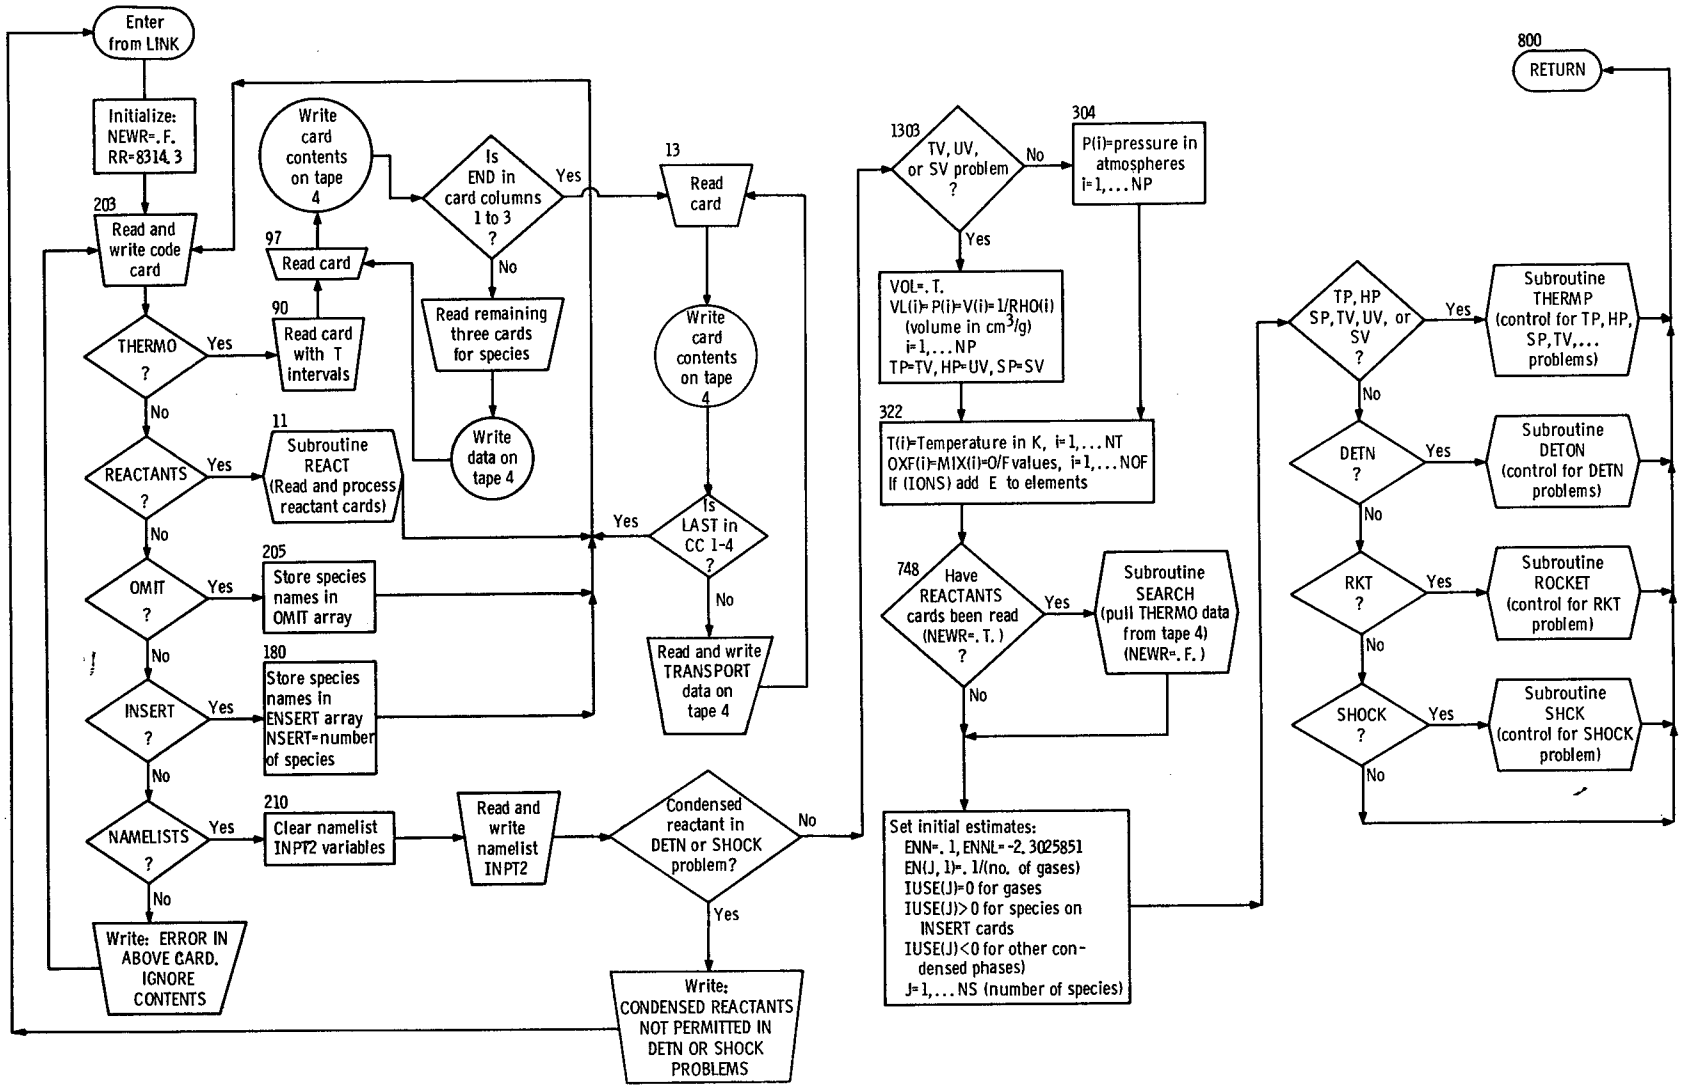

Figure 3. - Subroutine MAIN.

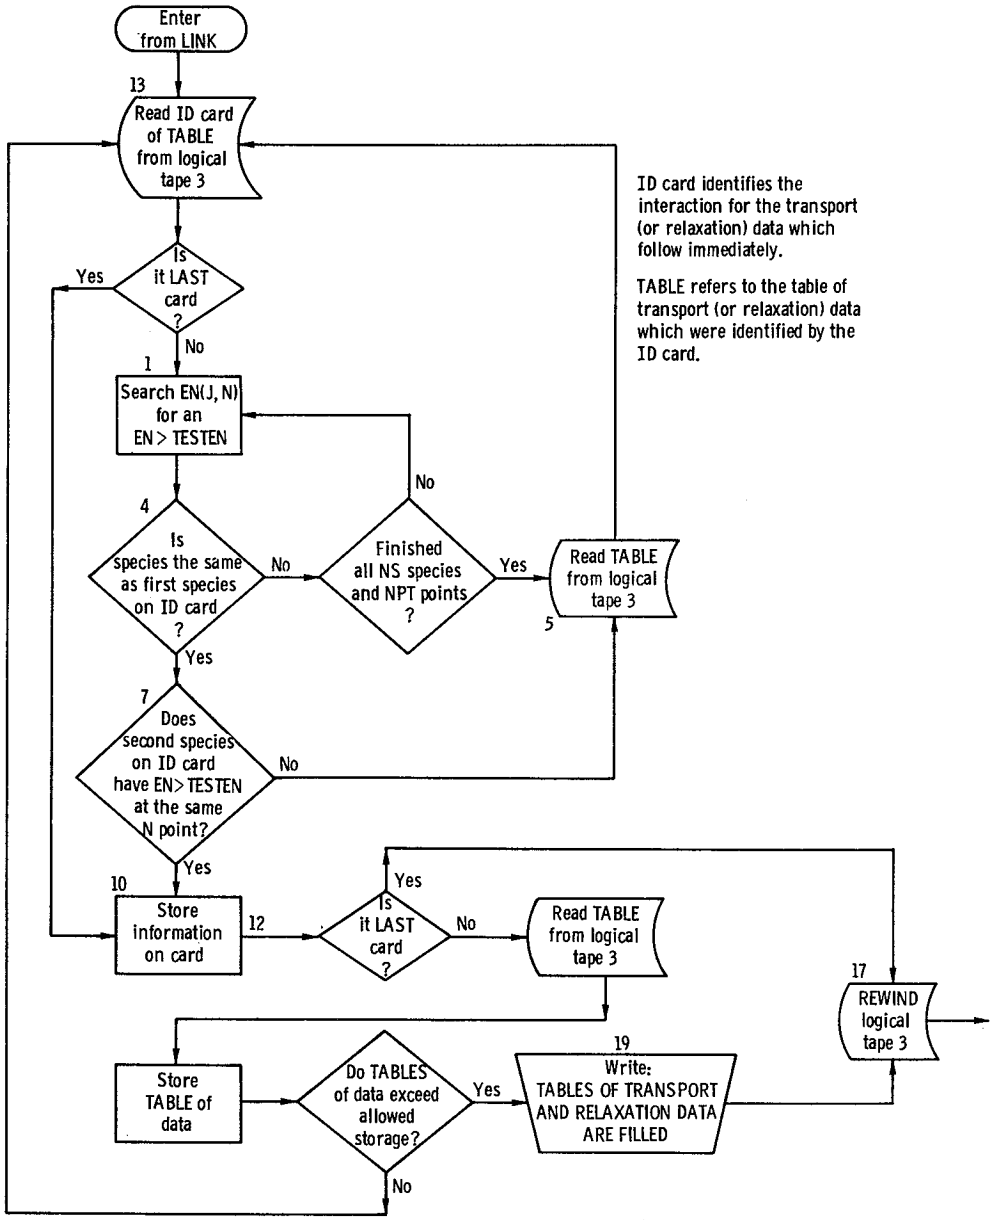

Enter from LINK
13
Read ID card of TABLE from logical tape 3
Is it LAST card ?
Yes
No
1
Search EN(J, N) for an EN > TESTEN
4
Is species the same as first species on ID card ?
No
Finished all NS species and NPT points ?
No
Yes
Read TABLE from logical tape 3
5
Yes
7
Does second species on ID card have EN > TESTEN at the same N point?
No
Yes
10
Store information on card
12
Is it LAST card ?
Yes
No
Read TABLE from logical tape 3
17
REWIND logical tape 3
Store TABLE of data
Do TABLES of data exceed allowed storage?
Yes
19
Write: TABLES OF TRANSPORT AND RELAXATION DATA ARE FILLED
No
ID card identifies the interaction for the transport (or relaxation) data which follow immediately.
TABLE refers to the table of transport (or relaxation) data which were identified by the ID card.
