ON THE DESIGN OF OPTIMAL INPUT SIGNALS IN SYSTEM IDENTIFICATION*

by

A.A. Lopez-Toledo
Michael Athans**

ABSTRACT

The problem of designing optimal inputs in the identification of linear systems with unknown random parameters is considered using a Bayesian approach. The information matrix, which is positive definite for the class of systems analyzed, gives a measure of performance for the system inputs. The computation of the optimal closed-loop input mappings is shown to be a nontrivial exercise in adaptive control. Deterministic optimal inputs are shown to be easily computable. Numerical examples are given. A Kalman filter is used to estimate the parameters. A necessary condition for the Kalman filter not to diverge when applying linear feedback, is also given.

** Room 35–308, M.I.T., Cambridge, Massachusetts 02139.
INTRODUCTION

The problem of designing deterministic system inputs to enhance the performance of some identification algorithms has received some attention in the literature. The formulations are based on the Fisher Information Matrix and on least squares identification. Continuous-time systems have been discussed by Levadi [1], Nahi et al [2,3] and Mehra [4]. Deterministic systems observed through additive Gaussian noise are considered in those works. Discrete-time single-input single-output systems are considered by Gagliardi [5], Aoki and Staley [6], Goodwin et al [7] and more recently by Mehra [8] whose frequency-domain approach allows multi-output systems.

The more general results have been obtained for formulations that lead to a linear model [1],[8], where linear least-squares techniques can be applied. The Fisher Information approach usually yields equations that depend on the unknown parameters [2,3,4,6,7] and thus some suboptimal scheme has to be used.

In this paper, we shall be concerned with a particular class of linear systems, namely those whose unknown random parameters appear linearly in the system description. Using a Bayesian approach, we will attempt to design optimal closed-loop inputs via the Information Matrix criterion. In Section II we indicate that this is a difficult problem in adaptive control. Section III gives the solution to the problem for deterministic inputs and some examples are given in Section IV. Finally, Section V gives an asymptotic result for identification of closed-loop systems.
II. OPTIMAL CLOSED-LOOP INPUT MAPPINGS

In this section we will derive conditions that the optimal feedback input mappings, maximizing the sensitivity of the system output with respect to the parameters, must satisfy. This sensitivity criterion is also shown to be equivalent to maximizing the trace of the Information Matrix (which is positive definite for the class of systems considered).

Consider the discrete-time linear system

\[
y(k) = \sum_{i=1}^{n} A_i(k-i)y(k-i) + \sum_{i=1}^{m} B_i(k-i)u(k-i) + \theta(k)
\]

where \(y(k) \in \mathbb{R}^{r}\) and \(u(k) \in \mathbb{R}^{s}\) are the observed system output and input, respectively, \(\theta(k) \in \mathbb{R}^{r}\) is a white Gaussian noise with known statistics (\(\delta_{kj}\) is Kronecker's delta) \(E\{\theta(k)\} = 0; E\{\theta(k)\theta^T(j)\} = \Theta(k)\delta_{kj}; \Theta(k) > 0\)

all \(k\), and where \(A_i(k) \in \mathbb{R}^{rxr}\) and \(B_i(k) \in \mathbb{R}^{rxs}\) are partially known random matrices.

It is assumed that the initial conditions \(y(0),...,y(-n+1)\) and \(u(-1) = ... = u(-m+1) = 0\) are known.

By an appropriate rearrangement of Eq. (2.1) as noisy observations on the unknown parameters, one can apply the results of Kalman filtering theory. Assume that all elements of the \(A_i(k)\) and \(B_i(k)\) matrices are unknown random parameters varying according to a Gauss-Markov process of the following form. Let \(a_i^j(k)\) and \(b_i^j(k)\) be the \(j\)-th row of \(A_i(k)\)

\[1\] Although this system has a very particular structure, it can be used in a large class of realistic problems. See e.g. [11], [12], [13].
and $B_i(k)$ respectively, the vector $y(k) \in \mathbb{R}^{r+m}$ of unknown parameters at the $k$-step is formed by placing the rows of $A_i(k-i)$ one after another in consecutive order $j = 1, \ldots, r$ and for $i = 1, \ldots, n$, followed by the rows of $B_i(k-i)$ in the same ordering fashion, i.e.

$$y(k) = [a_1(k-1) \ldots a_1(k-n) \ldots a_n(k-n) b_1(k-1) \ldots b_m(k-m)]^T$$

then $y(k)$ is assumed to vary according to

$$y(k+1) = F(k)y(k) + \xi(k)$$  \hspace{1cm} (2.2)

where $F(k)$ is known and $y(0)$ and $\xi(k)$ are mutually independent (also independent of $\Theta(j)$) Gaussian variables with known statistics,

$$E\{y(0)\} = \overline{y}, \quad E\{(y-\overline{y})(y-\overline{y})^T\} = \Sigma_y$$

$$E\{\xi(k)\} = 0, \quad E\{\xi(k)\xi^T(j)\} = \Xi(k)\delta_{kj}$$

With the above definitions, Eq. (2.1) can be rewritten as the linear model

$$y(k) = C^T(k)y(k) + \Theta(k) = h(k) + \Theta(k)$$  \hspace{1cm} (2.3)

where $C(k) \in \mathbb{R}^{(r^2+m)s \times r}$ is given by

$$C^T(k) = \begin{bmatrix}
Y^T(k-1) & 0 & \ldots & 0 & Y^T(k-n) & \ldots & 0 & Y^T(k-1) \\
0 & Y^T(k-2) & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots \\
0 & 0 & \ldots & Y^T(k-1) & 0 & \ldots & \ldots & \ldots & 0 & \ldots & Y^T(k-n) & 0 & \ldots \\
0 & 0 & \ldots & Y^T(k-m) & 0 & \ldots & \ldots & \ldots & 0 & \ldots & \ldots & \ldots & \ldots \\
& & & & & & \ddots & & & & & & \\
0 & 0 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots
\end{bmatrix}$$
The following lemma is merely a statement of the Kalman filter and will be used in the proof of Theorem 2.1 below. Its proof requires a modification of Kalman's original proof to take into account that $C(k)$ is random. A formal proof can be obtained paralleling Striebel's [9] derivation of the conditional distribution for a class of systems.

**Lemma 2.1**

Let $Y_k = \{y(1), \ldots, y(k)\}$ be the observed outputs of system (2.1) and assume that the inputs are of the feedback type (nonanticipative) $u(k) = u(k,Y_k)$. Then the a posteriori density $p(y(k)|Y_k)$ is Gaussian with mean and covariance given respectively by

$$\hat{y}(k) = \hat{F}(k-1)\hat{y}(k-1) + \sum(k|k)C(k)\bar{G}^{-1}(k)(y(k)-C(k)\hat{y}(k-1))$$

(2.4)

and

$$\sum(k|k) = (\sum^{-1}(k|k-1) + C(k)\bar{G}^{-1}(k)C^T(k))^{-1}$$

(2.5)

where $\sum(0|0) = \sum_i > 0$, $\hat{y}(0) = \bar{y}$.

If some of the parameters are known, one can write

$y(k) = \bar{z}(k) + C^T(k)\psi(k) + \bar{b}(k)$, where $\psi(k)$ is the vector of unknown parameters. Once again Striebel's procedure can be applied to derive $p(\psi(k)|y_k)$. The result is to substitute $y(k)$ by $y(k)-\bar{z}(k)$ and $C(k)$ by $C(k)$ in the above equations.

Equations (2.4) and (2.5) provide a recursive estimator for the unknown parameters, which is known to be unbiased ($E[\hat{y}(k)] = E[y(k)]$) and minimizes quadratic estimation errors. Moreover, if the parameters
are mutually independent or are simple unknown constants, Eqs. (2.4) and (2.5) can be broken down to yield $r$ Kalman filters of smaller dimension [10].

We now introduce some more definitions in order to state the main theorem of this section. Let $Q \in \mathbb{R}^{N \times N}$ be the diagonal matrix.

$$Q = \text{Diag}[(q_1 + \ldots + q_n)I^s, (q_2 + \ldots + q_{n+1})I^s, \ldots, (q_{N-m} + \ldots + q_{n-1})I^s, (q_{N-m+1} + \ldots + q_N)I^s, \ldots, (q_{N-n+1} + q_N)I^s, q_nI^s]$$
where $q_k = \text{tr} Q^{-1}(k)$ and $I^s$ is the $s \times s$ identity matrix. Similarly, let $P \in \mathbb{R}^{(N-1) \times (N-1) \times r}$ be the diagonal matrix $P = \text{Diag}[(q_2 + \ldots + q_{n+1})I^s, \ldots, (q_{N-n+1} + q_N)I^s, q_nI^s]$ and define the submatrices $Q_i \in \mathbb{R}^{s \times s}$ and $P_i \in \mathbb{R}^{r \times r}$ in correspondence with $Q$ and $P$ as follows

$$Q = \text{Diag}[Q_0, \ldots, Q_{N-1}]$$
$$P = \text{Diag}[P_1, \ldots, P_{N-1}], \quad P_0 = 0$$

**Theorem 2.1**

Let $y(k+1) = y(k) = \gamma$ with $y(0)$ a Gaussian variable with mean $\bar{y}$ and covariance $\Sigma_y > 0$ and let $M_N$ be the Information Matrix

$$M_N = \int \int (\nabla_y \log p(y_N, \gamma))^T (\nabla_y \log p(y_N, \gamma)) d\gamma d\gamma$$

(2.6)

where $\nabla_y$ denotes gradient and $y_N = [y^T(1) \ldots y^T(N)]^T$.

Then, for system (2.1) we have that

$$M_N > 0 \quad (M_N > \Sigma_y^{-1}) \quad (2.7)$$
The following problems are equivalent (maximization is with respect to input mappings \(u(k,Y_k)\))

(a) \(\text{Max } \text{tr } M_N^{-1}\)  

(b) Max of the sensitivity index

\[
E \left\{ \sum_{k=0}^{N-1} \sum_{i=1}^{r} p_i(k) \left( \frac{\partial h_i(k)}{\partial \gamma} \right)^T \left( \frac{\partial h_i(k)}{\partial \gamma} \right) \right\}
\]

where \(p_i(k) = [\Theta^{-1}(k)]_{ii}\) is the \(i\)-th diagonal element of \(\Theta^{-1}(k)\) and \(h_i\) is the \(i\)-th element of \(h\) (Eq. 2.3).

(c) \(\text{Max } E \left\{ \sum_{k=0}^{N-1} (\gamma^T(k)p \gamma(k) + u^T(k)Q_u u(k)) \right\}\)

Proof. See Appendix A.

Remarks.

It is known that \(M_N\) is related to the error covariance matrix \(\Sigma_N\) of any unbiased estimator of \(\gamma\) by the Cramer-Rao inequality

\[
\Sigma_N - M_N^{-1} \succeq 0
\]

Eq. (2.7) indicates that \(M_N\) has only nonzero eigenvalues and since \(1/\text{tr } M_N^{-1}\) and \(\text{tr } M_N^{-1}\) go to zero at the rate \(\theta(1/\lambda \min)\) as \(\lambda \min \rightarrow \infty\) [6], where \(\lambda \min\) is the minimum eigenvalue of \(M_N\), Eqs. (2.8) and (2.11) give a relationship of the optimal inputs with mean square estimation errors. Eqs. (2.9) and (2.3) show that the inputs should maximize the sensitivity of the system output with respect to the parameters, where \(p_i(k)\) has the
interpretation that if the noise is "high", the output contains "little information" about the parameters. Eq. (2.10) is derived from either (2.8) or (2.9) and remains unchanged if one considers time-varying Markov parameters (Eq. (2.2)) with the index (2.9) changed to

$$E\left\{ \sum_{k=0}^{N-1} \sum_{i=1}^{r} p_i(k) \left( \frac{\partial h_i(k)}{\partial y(k)} \right)^T \left( \frac{\partial h_i(k)}{\partial y(k)} \right) \right\}$$

Eq. (2.10) implies that this type of inputs for identification is conflicting with any input aimed to regulate the system.

III. **OPTIMAL OPEN-LOOP INPUTS.**

It is not difficult to check that unfortunately, the maximization of Eq. (2.10), subject to an energy constraint, cannot be performed analytically. Some suboptimal schemes, developed in the theory of adaptive controllers may however be applicable. In this section, we give the solution to the problem for the case of deterministic inputs. We will consider only the case of constant random parameters, the extension to time-varying parameters with index (2.11) is completely straightforward.

Let us define $A \in \mathbb{R}^{(N-1)\times(N-1)}$ and $B \in \mathbb{R}^{(N-1)\times(N-1)\times}$ by

$$A = \begin{bmatrix} -I & \cdots & 0 \\ A_1 & -I & \cdots \\ \vdots & \vdots & \ddots \\ 0 & \cdots & A_{n} & -I \end{bmatrix}$$

$$B = \begin{bmatrix} B_1 & \cdots & 0 \\ B_2 & \cdots & \cdots \\ \vdots & \ddots & \cdots \\ 0 & \cdots & B_m & \cdots & B_2 & B_1 \end{bmatrix}$$

(3.1)
Let $h \in \mathbb{R}^{(N-1)r}$ be a vector depending on the initial conditions through
\[
    h = \left[ \left( \sum_{i=1}^{n} A_i y_{i-1} \right)^T \left( \sum_{i=2}^{n} A_i y_{i-2} \right)^T \ldots \left( A_n y_0 \right)^T \right]_0 \stackrel{r}{\text{zeros}} (3.2)
\]

Let $H \in \mathbb{R}^{Ns \times Ns}$ be the symmetric positive definite matrix
\[
    H = Q + E \left\{ \begin{bmatrix} B A^{-T} P A^{-1} B & 0 \\ 0 & 0 \end{bmatrix} \right\} (3.3)
\]
where $A^{-T} = (A^{-1})^T$ always exists since $\det A = 1$, and let $d \in \mathbb{R}^{Ns}$
\[
    d = E\left\{ [(B A^{-T} P A^{-1} B)^T 0 \ldots 0]_s \right\} \text{ zeros} (3.4)
\]

Then we can state the following theorem.

**Theorem 3.1**

Let $U_N = [u^T(0) \ldots u^T(N-1)]^T \in \mathbb{R}^{Ns}$ be the vector of the first $N$ system inputs. The optimal input sequence $u^*(0), \ldots, u^*(N-1)$ that solves part (ii) of Theorem 2.1, subject to the energy constraint
\[
    \sum_{i=0}^{N-1} u^T(i) u(i) \leq W, \text{ is given by the vector}
\]
\[
    U_N^* = \left[ -H + \lambda I \right]^{-1} d \quad \text{if } d \neq 0 (3.5)
\]
where $I$ is the $Ns \times Ns$ identity matrix and $\lambda$ is such that
\[
    (U_N^*)^T (U_N^*) = W (3.6)
\]

If $d = 0$, then $U_N^*$ is the eigenvector corresponding to the maximum eigenvalue of $H$, normalized according to Eq. (3.6).

**Proof** See Appendix B.
Remarks.

In Eq. (3.5) \( \lambda \) is a Lagrange multiplier. If the initial conditions are zero, or \( \mathbb{E}[B] = 0 \) and \( B \) is independent of \( A \) (element-wise) then \( \mathfrak{d} = 0 \). These conditions are however not necessary for \( \mathfrak{d} \) to be zero. From Eqs. (3.1) through (3.4) it follows that \( H \) and \( \mathfrak{d} \) depend on the noise statistics, on the initial conditions and on \( \mathbb{E}[\gamma_i^k], k = 1, \ldots, 2N-4 \), where \( \gamma_i \) is the \( i \)-th unknown parameter. The only difficulty in the computation of explicit expressions for \( H \) and \( \mathfrak{d} \) is that of notation. As an example, the single-input single-output (SISO) case is considered next.

IV. EXAMPLES

Example 1

The SISO system is described by the equation

\[
y(k) = \sum_{i=1}^{\mathfrak{n}} a_i y(k-i) + \sum_{i=1}^{\mathfrak{m}} b_i u(k-i) + \theta(k)
\]

(4.1)

Proposition

If \( \gamma = [a_{1; \ldots; n}, b_{1; \ldots; n}]^T \) is a vector of Gaussian mutually independent random variables, the expectations required in \( H \) and \( \mathfrak{d} \) can be obtained as follows
\[ E_{\mathbf{B}^{T} \mathbf{A}^{-1} \mathbf{P}^{-1} \mathbf{B}} = \sum_{i,j=1}^{m} E_{\{b_{i}\}}E_{\{b_{j}\}} \Omega_{ij} + \sum_{i=1}^{m} E_{\{b_{i}^{2}\}} \Omega_{ii} \]

\[ + \sum_{k=1}^{2N-4} \sum_{k_{i}+\ldots+k_{n}=k}^{+} E_{\{a_{k_{i}}\} \ldots E_{\{a_{k_{n}}\}}} \left[ \sum_{i,j=1}^{m} E_{\{b_{i}\}}E_{\{b_{j}\}} R_{ij} \right] \]

\[ + \sum_{i=1}^{m} E_{\{b_{i}^{2}\}} R_{iik} \]

\[ E_{\mathbf{B}^{T} \mathbf{A}^{-1} \mathbf{P}^{-1} \mathbf{B}} = \sum_{i=1}^{n} \sum_{j=1}^{m} \sum_{\ell=1}^{i} E_{\{a_{i}\}}E_{\{b_{j}\}} y_{\ell-i} f_{\ell j} \]

\[ + \sum_{k=1}^{2N-4} \sum_{k_{i}+\ldots+k_{n}=k+1}^{+} \sum_{i=1}^{i} E_{\{a_{k_{i}}\} \ldots a_{k_{n}}} \sum_{\ell=1}^{\ell_{i}} E_{\{b_{i}\}} y_{\ell-i} f_{\ell kj} \]

where \( k_{\alpha} \in I \) reads "for all \( k_{\alpha} \in \{0,1,\ldots\}, \alpha = 1,\ldots,n" \) and the matrices \( R_{ijk}, \Omega_{ij}, f_{\ell kj}, P_{\ell kj} \in \mathbb{R}^{(N-1)\times(N-1)} \) can be precomputed for fixed \( N \) (they depend only on the noise statistics \( \Theta(k), k = 2,\ldots,N, \) and if \( \Theta(k) = \Theta \) all \( k \), they can be replaced by constant matrices independent of \( \Theta \)).

If \( Y \) is a vector of jointly Gaussian variables, with mean \( \bar{Y} \) and covariance \( \Sigma_{Y} \), the transformation \( Y_{1} = \Gamma Y \) where \( \Gamma \) satisfies
\[ \Sigma_{Y_{1}} \Gamma^T = \text{Diagonal Matrix} \quad \text{and} \quad \Gamma \Gamma^T = I, \]
yields a set \( Y_{1} \) of mutually
independent Gaussian variables. The expressions for the expectations are then similar to those above.

**Proof** See Appendix C.

**Example 2** (Numerical example).

Consider the two-input one-output system

\[ y(k) = ay(k-1) + b_1u_1(k-1) + b_2u_2(k-1) + \theta(k) \]

where \( \theta(k) \) is white Gaussian \( N(0,1) \). The following two cases of random parameters are analyzed.

**Case (i)** \( a, b_1 \) and \( b_2 \) are jointly Gaussian with

\[
\begin{pmatrix}
    a \\
    b_1 \\
    b_2
\end{pmatrix}
\sim N\left( \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} .5 & 0 & 0 \\ 0 & .1 & .1 \\ 0 & .1 & 1 \end{pmatrix} \right)
\]  

(4.2)

The inputs, computed according to Section III are (N=10) shown in Fig. 4.1.

**Case (ii)** \( a, b_1 \) and \( b_2 \) are jointly Gaussian with

\[
\begin{pmatrix}
    a \\
    b_1 \\
    b_2
\end{pmatrix}
\sim N\left( \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} .1 & 0 & 0 \\ 0 & .1 & .1 \\ 0 & .1 & 1 \end{pmatrix} \right)
\]  

(4.3)

The optimal inputs for this case are shown in Fig. 4.2.

The inputs of Fig. 4.3 with the same energy \( W = 85.23 \) that those of Figs. 4.1 and 4.2 were used as comparison.

Mean square errors for 2500 Monte Carlo runs were computed, the results are shown in Table 4.1.
Table 4.1 Mean Square Errors for Different Inputs

</table>

From the figures we can see that $u_2^*$ contains most of the energy of the optimal inputs. This agrees with our intuition, since $b_2$, the parameter multiplying $u_2$, has the largest uncertainty. The results of the simulation (Table 4.1) indicate that the mean square estimation errors corresponding to the optimal inputs (indicated by *) are approximately only 50% of those corresponding to constant inputs.

The optimal input for system (4.2), Fig. 4.1, is of the impulse type. An interesting result follows by comparing the optimal inputs for system (4.3) with the impulse type input Fig. 4.1 (3th vs. last row in Table 4.1). The former gives a 10% reduction on mean-square estimation errors corresponding to the latter. Thus impulse type inputs are not always the best.

V. ASYMPTOTIC ANALYSIS

Most identification algorithms have been designed on the basis of an open-loop operation of the plant and erroneous results may be obtained if one uses such algorithms for closed-loop system identification [14][15]. Nevertheless, if one is careful about the type of feedback being used, then correct results are obtained.
Consider for instance the system [16]

\[ x(k) + ax(k-1) = bu(k-1) + \theta(k) \]
\[ u(k) = ax(k) \]  \hspace{1cm} (5.1)

It is well known that the Kalman filter on least squares estimate can be obtained minimizing

\[ J(a, b) = \sum_{k=1}^{N} (x(k+1) + ax(k) - bu(k))^2 + (a-a^-b-b^-)^{-1} \left( \begin{array}{c}
\alpha^- \\
\beta^-
\end{array} \right) \]  \hspace{1cm} (5.2)

where \( \alpha^-, \beta^- \) is the a priori information. As \( N \to \infty \) the a priori information becomes negligible. Thus Eq. (5.2) becomes

\[ J(a, b) = \sum_{k=1}^{N} (x(k+1) + ax(k) - bu(k))^2 \]
\[ = \sum_{k=1}^{N} (x(k+1) + (a+a\lambda)x(k) - (b+b\lambda)u(k))^2 \]
\[ = J(a + a\lambda, b + b\lambda) \]  \hspace{1cm} (5.3)

and the parameters are not identifiable. They become identifiable if the feedback loop is changed to \( u(k) = a_1x(k) + a_2x(k-1) \).

The following theorem gives a necessary condition for the Kalman filter (Eqs. (2.4), (2.5)) not to diverge when linear feedback is being used. Only the SISO case is considered. The extension to multi-input multi-output systems is conceptually straightforward.

\[ \text{Note that this cost function can also correspond to a maximum likelihood estimate.} \]
Theorem 5.1

Let the system be

\[ y(k) = \sum_{i=1}^{n} a_i y(k-i) + \sum_{i=1}^{m} b_i u(k-i) + \theta(k) \]  

(5.4)

where \( \theta(k) \) is white Gaussian \( N(0, \sigma^2) \). Let \( \gamma = [a_1 \ldots a_n \ b_1 \ldots b_m]^T \)

be a Gaussian random vector \( N(\bar{\gamma}, \Sigma) \), and assume that linear feedback

\[ u(k) = \sum_{i=0}^{\ell} \alpha_i y(k-i) \]  

(5.5)

is being used. Then, if \( \ell < n \) we have that the mean square errors satisfy

\[ \lim_{N \to \infty} E[(y - \hat{Y}(N))^T (y - \hat{Y}(N))] < \infty \]  

(5.6)

Proof. See Appendix D.

VI. CONCLUSION

The design of inputs for system identification has been considered using a Bayesian approach. The optimal identifying inputs are shown to be conflicting with a system regulator. Optimal deterministic inputs have been shown to be easily computable and digital simulation shows that they yield smaller mean square estimation errors than arbitrary inputs. The divergence of the Kalman filter-estimator for closed-loop systems has been analyzed.
APPENDIX A

From the definition of the Information Matrix given by Eq. (2.6),

\[ M_N = E\{(V_Y \log p(Y_N | Y))^T (V_Y \log p(Y_N | Y))\} \]  

(A.1)

Using Baye's rule we get

\[ M_N = E\{(V_Y \log p(Y | Y_N) + V_Y \log p(Y_N)) (V_Y \log p(Y | Y_N)) + V_Y \log p(Y_N)\} \]

i.e. \[ M_N = E\{(V_Y \log p(Y | Y_N))^T (V_Y \log p(Y | Y_N))\} \]

From the results of Lemma 2.1, the density \( p(Y|Y_N) \) for any set of admissible (nonanticipative) input mappings \( u(k,Y_k) \) is Gaussian with mean and covariance given by \( \hat{Y}(N) \) and \( \Sigma(N|N) \), thus

\[ V_Y \log p(Y | Y_N) = - (Y - \hat{Y}(N))^T \Sigma^{-1}(N|N) \]

and using the properties of conditional expectations, \( M_N \) can be written as

\[ M_N = E\{E_{Y_N} (\Sigma^{-1}(N|N) (Y - \hat{Y}(N)) (Y - \hat{Y}(N))^T \Sigma^{-1}(N|N)|Y)\} \]

or

\[ M_N = E\{\Sigma^{-1}(N|N)\} \]

(A.2)

Now, from Eq. (2.5) of the lemma

\[ \Sigma^{-1}(k|k) = \Sigma^{-1}(k-1|k-1) + C(k) \Sigma^{-1}(k) C^T(k) \]

then

\[ \Sigma^{-1}(N|N) = \Sigma^{-1} + \sum_{k=1}^{N} C(k) \Sigma^{-1}(k) C^T(k) \]  

(A.3)

Substitution of (A.3) into (A.2) proves part (i) of the Theorem.
Maximization of \( \text{tr} \mathbf{M}_N \) is, by (A.2) and (A.3) equivalent to maximization of

\[
J_1 = \text{tr} \mathbb{E} \left\{ \sum_{k=1}^{N} \mathbf{C}^T(k) \mathbf{C}(k) \mathbf{Q}^{-1}(k) \right\}
\]

Using the definitions of \( \mathbf{C}(k), \mathbf{h}(k) \) and \( p_i(k) \), it follows after some algebra that Eqs. (2.9) and (A.4) are equivalent. This proves parts (ii-a) and (ii-b) of the theorem.

We also have that

\[
\mathbf{C}^T(k) \mathbf{C}(k) = \left( \sum_{i=1}^{N} \mathbf{Y}(k-i) \mathbf{Y}(k-i)^T + \sum_{i=1}^{M} \mathbf{U}(k-i) \mathbf{U}(k-i)^T \right) \mathbf{I}
\]

where \( \mathbf{I} \) is the \( r \times r \) identity matrix. Thus, using the definition of \( q_k \) we get

\[
\text{tr}[\mathbf{C}^T(k) \mathbf{C}(k) \mathbf{Q}^{-1}(k)] = q_k \left( \sum_{i=1}^{N} \mathbf{Y}(k-i) \mathbf{Y}(k-i)^T + \sum_{i=1}^{M} \mathbf{U}(k-i) \mathbf{U}(k-i)^T \right)
\]

Adding \( N \) of these terms as indicated by (A.4) and using the definitions of \( \mathbf{P} \) and \( \mathbf{Q} \) we have

\[
J_1 = \mathbb{E}\{\mathbf{Y}_{N-1}^T \mathbf{Y}_{N-1} + \mathbf{U}_N^T \mathbf{Q} \mathbf{U}_N\}
\]

where \( \mathbf{Y}_{N-1} = [\mathbf{Y}^T(1) \ldots \mathbf{Y}^T(N-1)] \), \( \mathbf{U}_N = [\mathbf{U}^T(0) \ldots \mathbf{U}^T(N-1)] \).

Using the partitions of \( \mathbf{P} \) and \( \mathbf{Q} \), from (A.5) we get

\[
J = \mathbb{E}\left\{ \sum_{k=0}^{N-1} (\mathbf{Y}(k) \mathbf{P}_k \mathbf{Y}(k) + \mathbf{U}(k) \mathbf{Q}_k \mathbf{U}(k)) \right\}
\]

This completes the proof.
For deterministic inputs, (A.5) can be written as

\[ J_1 = \text{tr} \mathbf{P} \mathbb{E}\{\mathbf{E}\{\mathbf{Y}_{N-1}^{T}/\mathbf{Y}\}\} + \mathbf{U}_N^T \mathbf{Q} \mathbf{U}_N \]

or

\[ J_1 = \text{tr} \mathbf{P} \mathbb{E}\{\bar{\mathbf{Y}}_{N-1}^{T} + \Sigma_{\mathbf{y}}\} + \mathbf{U}_N^T \mathbf{Q} \mathbf{U}_N \]  

(B.1)

where

\[ \bar{\mathbf{Y}}_{N-1} = \mathbb{E}\{\mathbf{Y}_{N-1}/\mathbf{Y}\} \]

\[ \Sigma_{\mathbf{y}} = \mathbb{E}\{(\mathbf{Y}_{N-1} - \bar{\mathbf{Y}}_{N-1})(\mathbf{Y}_{N-1} - \bar{\mathbf{Y}}_{N-1})^T/\mathbf{Y}\} \]

It is easy to see that the first N-1 system outputs satisfy

\[ A \mathbf{Y}_{N-1} + B \mathbf{U}_{N-1} + \mathbf{I} \theta_{N-1} + h = 0 \]  

(B.2)

where \( A, B \) and \( h \) are defined in the theorem, \( \mathbf{I} \in \mathbb{R}^{(N-1)\times(N-1)} \) is the identity matrix and

\[ \theta_{N-1} = [\theta^T(1), \ldots, \theta^T(N-1)]^T \]

Since \( A^{-1} \) always exists, the vector

\[ \mathbf{Y}_{N-1} = - A^{-1}(B \mathbf{U}_{N-1} + \theta_{N-1} + h) \]

has a Gaussian conditional (on \( \mathbf{Y} \)) density, with

\[ \bar{\mathbf{Y}}_{N-1} = - A^{-1}(B \mathbf{U}_{N-1} + h) \]

\[ \Sigma_{\mathbf{y}} = A^{-1} \Theta A^{-T} \]

where \( \Theta = \text{Diag} (\Theta(1), \ldots, \Theta(N-1)) \).

Therefore, substituting into (B.1) and considering only terms that depend on \( \mathbf{U}_N \), we must maximize

-17-
Using $H$ and $d$ as defined in the Theorem we have

$$J_1' = U_{N-1}^T (B^T A^{-T} F A^{-1} B) U_{N-1} + 2U_{N-1}^T B (B^T A^{-T} F A^{-1} h) + U_N^T Q U_N$$

To maximize $J_1'$ subject to the energy constraint

$$U_N^T U_N = W$$

notice that since $J_1'$ is strictly convex, the optimum occurs when $U_N^T U_N = W$, the optimization is thus equivalent to

$$\text{Min} -U_N^T H U_N - 2U_N^T d + \lambda (U_N^T U_N - W)$$

where $\lambda$ is a Lagrange multiplier. The necessary condition gives

$$H U_N^* + d - \lambda U_N^* = 0 \quad (B.3)$$

If $d \neq 0$, $U_N^* = [-H + \lambda I]^{-1} d$, which proves the first part of the Theorem.

If $d = 0$, then (B.3) gives $H U_N^* = \lambda U_N^*$, i.e. $U_N^*$ is an eigenvector of $H$.

Since for all $x \in \mathbb{R}^n$

$$\lambda_{\min} (H)x^T x \leq (J_1')' = x^T H x \leq \lambda_{\max} (H)x^T x$$

the cost attains its maximum when $U_N^*$ is the eigenvector corresponding to the maximum eigenvalue of $H$. This completes the proof.
APPENDIX C

The inverse $A^{-1} \in \mathbb{R}^{(N-1)\times(N-1)}$ can be obtained via

$$A^{-1} = -(I + G + \ldots + G^{N-2})$$

where

$$G = \sum_{i=1}^{n} a_i I_i$$

where

$$I_k \in \mathbb{R}^{(N-1)\times(N-1)}$$

is the shift matrix with $i$-$j$th element

$$[I_k]_{ij} = \delta_{i-j,k}$$

Since $G^k = \sum_{i_1,\ldots,i_k=1}^{n} a_{i_1} \ldots a_{i_k} I_{i_1} \ldots I_{i_k}$

we have that

$$A^{-T} P A^{-1} = P + \sum_{i=1}^{n} a_i (P I_i + I_i^T P)$$

$$+ \sum_{i_1,i_2=1}^{n} a_{i_1} a_{i_2} (P I_{i_1} I_{i_2} + I_{i_1}^T P I_{i_2} + I_{i_2}^T P I_{i_1} + I_{i_1}^T I_{i_2} P)$$

$$+ \ldots$$

$$+ \sum_{i_1,\ldots,i_{2N-5}=1}^{n} a_{i_1} \ldots a_{i_{2N-5}} (I_{i_1}^T \ldots I_{i_{2N-5}}^T P I_{i_1} \ldots I_{i_{2N-5}})$$

$$+ I_{i_{N-2}}^T \ldots I_{i_{N-1}}^T P I_{i_{N-2}} \ldots I_{i_{2N-5}}$$

$$+ \sum_{i_1,\ldots,i_{2N-4}=1}^{n} a_{i_1} \ldots a_{i_{2N-4}} (I_{i_1}^T \ldots I_{i_{2N-4}}^T P I_{i_1} \ldots I_{i_{2N-4}})$$

$$+ I_{i_{N-2}}^T \ldots I_{i_{N-1}}^T P I_{i_{N-2}} \ldots I_{i_{2N-4}}$$

-19-
or

\[
A^{-T}PA^{-1} = P + \sum_{k=1}^{2N-4} \sum_{i_1, \ldots, i_k}^{n} a_{i_1} \cdots a_{i_k} N_k
\]

where \(N_k\) is defined by correspondence.

Expressing \(B\) as \(B = \sum_{i=1}^{m} b_i I_{i-1}\), we have that

\[
B^{-T}A^{-T}PA^{-1}B = \sum_{i, j=1}^{m} (b_i b_j Q_{ij} + \sum_{k=1}^{2N-4} \sum_{i_1, \ldots, i_k=1}^{n} a_{i_1} \cdots a_{i_k} b_i b_j R_{ijk})
\]

where

\[
Q_{ij} = I_{i-1} T \frac{I_j}{j-1}
\]

\[
R_{ijk} = I_{i-1} N_k \frac{I_j}{j-1}
\]

The vector \(h\) can also be written as

\[
h = \sum_{i=1}^{n} \sum_{k=1}^{i} a_i y_{i-k-1} \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}
\]

therefore

\[
B^{-T}A^{-T}PA^{-1}h = \sum_{i=1}^{m} \sum_{j=1}^{m} \sum_{k=1}^{i} a_i b_j y_{i-k-1}^{j-k}
\]

\[
+ \sum_{k=1}^{2N-4} \sum_{i_1, \ldots, i_k=1}^{n} \sum_{j=1}^{m} a_{i_1} a_{i_2} \cdots a_{i_k} b_i b_j y_{i-k-1}^{j-k} (C.2)
\]

where
The expected values of (C.1) and (C.2) will lead to the expressions stated in the Proposition. If the vector $\mathbf{Y}$ has correlated variables, it can be substituted in (C.1) and (C.2) by $\mathbf{Y} = \mathbf{I}^{T} \mathbf{Y}_1$, where $\mathbf{Y}_1$ has independent variables. The resulting expectations will therefore be similar, in terms of expected values of $\mathbf{Y}_1$. This completes the proof.
APPENDIX D

The conditional error covariance matrix Eq. (2.5) corresponding to the system (5.4) is

\[
\Sigma^{-1}(N/N) = \Sigma^{-1} + \frac{1}{\sigma^2} \sum_{k=1}^{N} c(k)c^T(k)
\]  

(D.1)

where \( c(k) = [y(k-1) \ldots y(k-n)u(k-1) \ldots u(k-m)]^T \). Equation (5.5) can also be written as

\[
\begin{bmatrix} U(N) \end{bmatrix} = \begin{bmatrix} F(N) \end{bmatrix} \begin{bmatrix} Y(N) \end{bmatrix} \]  

(D.2)

where \( U(N) = [u(0) \ldots u(N)]^T \), \( Y(N) = [y(0) \ldots y(N)]^T \) and

\[
\begin{bmatrix} F(N) \end{bmatrix} = \sum_{i=0}^{L} \alpha_i I_{i-1} \]  

(D.3)

where \( I_{i} \) is the \((N+1)\times(N+1)\) shift matrix defined in a previous appendix.

Let \( \langle X, Y \rangle \) denote the usual inner product in \( \mathbb{R}^{N+1} \). Thus using (D.2) in (D.1) we have that as \( N \to \infty \),

\[
\Sigma^{-1}(N/N) = \begin{bmatrix} 
\langle Y(N), Y(N) \rangle & \langle Y(N), I_{1} Y(N) \rangle & \ldots & \langle Y(N), I_{n-1} Y(N) \rangle & \langle Y(N), F(N) Y(N) \rangle \\
\vdots & \vdots & & \vdots & \vdots \\
\langle I_{n-1} Y(N), Y(N) \rangle & \langle F(N) Y(N), Y(N) \rangle & \vdots & \vdots \\
\langle I_{n-1} F(N) Y(N), Y(N) \rangle & \ldots & \ldots & \langle I_{m-1} F(N) Y(N), F(N) Y(N) \rangle
\end{bmatrix}
\]
To check positive definiteness one can use Silvester's rule. By the properties of determinants and Eq. (D.3) it follows that if \( \ell < n \) the matrix (D.4) is singular. This implies that as \( N \to \infty \), at least one eigenvalue of \( \Sigma(N/N) \) will go to infinity a.s. and \( \text{tr} = \Sigma(N/N) \) will not be integrable. Thus \( \lim_{N \to \infty} \mathbb{E}\{(\hat{\gamma} - \gamma(N))^T(\hat{\gamma} - \gamma(N))\} = \lim_{N \to \infty} \mathbb{E}\{\text{tr} \Sigma(N/N)\} + \infty \).
