INTRODUCTION.

In recent years a considerable amount of work has been done on noise reduction in machines in general. In particular, attention of many workers in the field has been focussed on the noise reduction in jet engines, which radiate a high level of noise. In this context a study of sound propagation in cylindrical ducts assumes an understandable importance.

Propagation of sound in circular cylindrical ducts has been investigated extensively in connection with a jet engine compressor. It is important here to mention the work done by Tyler and Sofrin²⁶ which forms a basis for much work done in the field. They have shown that at very low shaft speeds a very high frequency noise is generated due to the interaction of the rotor blades and stator-vanes. Low frequency noise tends to attenuate exponentially in a duct; whereas high frequency noise propagates along the duct giving rise to spinning modes. These result in an annoying noise radiated from the open face of the duct.

From the noise control viewpoint, departures from circular symmetry of the cross-section of the duct evoke considerable interest. Elliptic duct intakes have been used in aircraft design, e.g. Boeing 727. Equations governing sound propagation in a duct of elliptic cross-section are quite well known.^{2,18} Using elliptic cylindrical coordinates the wave equation separates into Mathieu equation and modified Mathieu equation. This has

been discussed in the works of many authors, e.g. Chu (6), Jeffreys (13), Daymond (7) in connection with electromagnetic wave guides and oscillations in a lake with elliptic boundaries. However all work has been concentrated on the lowest order principal frequencies. These eigen frequencies decrease rapidly in the case of even solutions of the modified Mathieu equation for increasing eccentricity of the cross-section and increase in the case of odd solutions. It is, therefore, of interest to investigate the behaviour of these waves for higher order modes.

The pressure gradient normal to the duct wall vanishes under the boundary conditions that there are no reflections of the pressure fluctuations at the open end of the duct and that the duct is hard walled. This means the derivative, normal to the duct wall, of the pressure function is zero. The pressure function is a combination of Mathieu function and modified Mathieu function. Due to the continuity of pressure function in any particular cross-section of the duct, the solution are periodic. For a particular eccentricity, the eigen frequencies for various modes are obtained as the lowest parametric zeros of the derivatives of the modified Mathieu functions.

In a duct of circular section, the eigen frequencies are obtained directly as parametric zeros of the derivatives of the Bessel functions. But, in a duct of elliptic section, the eigen frequencies for the relevant eccentricities cannot be obtained in a straight forward manner. To obtain the eigen frequencies, a family of

ellipses of same area, say π , are considered. For chosen positive increasing values of the parameter, the zeros of the derivative of the modified Mathieu function are found. From these the corresponding eccentricities and the eigen frequencies are computed. Then the eigen frequencies for the particular eccentricities are obtained by interpolation of the values already known.

For higher order modes, high values of the parameter have to be considered. Further the function has to be evaluated for these high values of the parameter. It is essential, therefore to check the validity and the rapidity of convergence of the various series expansions of the modified Mathieu function. The separation constant, which appears due to the separation of the wave equation, known as the characteristic value is tabulated in Blanch and Rhodes (5) for large values of the parameter. With the help of a computer program the coefficients for the series expansions for modified Mathieu functions are generated from these characteristic values. The zeros are then found and the eigen frequencies obtained as mentioned in the previous paragraph.

The eigen frequencies for ellipses of eccentricities .1 (0.1) .9 and 0.95 have been obtained for the integral orders 1-15 of the function, both even and odd. The eigen frequencies for even functions have been tabulated in Tables C and those for odd functions in Tables D.

1. PROPAGATION OF WAVES IN CIRCULAR DUCTS.

1.1 The study of noise in a jet engine compressor may be broadly classified into three main divisions: ²⁶

(1) generation of noise due to the movement of the rotor blades

(2) the propagation of the noise through a cylindrical duct enclosing the rotor blades

and (3) the radiation of the noise into free space from the open face of the duct.

The work described herein is mainly concerned with the propagation of noise through elliptic ducts. Propagation in circular ducts has been described extensively in the literature. A brief review of the propagation in circular ducts (which lends itself more easily for analysis) will help in a better understanding of the more general case of propagation through elliptic ducts.

1.2 The noise in a compressor engine is generated mainly due to two causes.

(1) When the rotor blades move with given angular velocity, pressure fluctuations are caused at a blade passage frequency. These pressure fluctuations rotate with rotor angular velocity giving rise to harmonically related frequencies.

(2) Due to the interaction of rotor blades and stator vanes high frequency noise is generated when

(a) the wakes of upstream stator are cut by the rotor blades

(b) the rotor blade wakes are cut by the downstream stators

and (c) the rotating periodic pressure field is interrupted by reflecting objects nearby.

These give rise to very high frequency noise even at low rotor speeds. The sound field so generated is allowed to pass through a duct of rigid walls enclosing the rotor.

1.3 The sound pressure fields obey the well-known wave equation 20,21

$$\frac{\partial^2 p}{\partial x^2} + \frac{\partial^2 p}{\partial y^2} + \frac{\partial^2 p}{\partial z^2} - \frac{1}{c^2} \frac{\partial^2 p}{\partial t^2} = 0 \quad (1.1)$$

x, y, z being the cartesian coordinates and c is the free space velocity of sound.

If (r, θ, z) denote cylindrical polar coordinates

$$\begin{aligned} x &= r \cos \theta \\ y &= r \sin \theta \\ z &= z \\ t &= t \end{aligned}$$

the wave equation (1.1) takes the form

$$\frac{\partial^2 p}{\partial r^2} + \frac{1}{r} \frac{\partial p}{\partial r} + \frac{1}{r^2} \frac{\partial^2 p}{\partial \theta^2} + \frac{\partial^2 p}{\partial z^2} - \frac{1}{c^2} \frac{\partial^2 p}{\partial t^2} = 0 \quad (1.2)$$

By the separation of variables (so that the normal modes are obtained) the solution is of the form

$$p = p_r(r) p_\theta(\theta) p_z(z) p_t(t)$$

Substituting in equation (1.2) and dividing by p , gives

$$\frac{1}{p_r} \frac{d^2 p_r}{dr^2} + \frac{1}{r p_r} \frac{dp_r}{dr} + \frac{1}{r^2 p_\theta} \frac{d^2 p_\theta}{d\theta^2} + \frac{1}{p_z} \frac{d^2 p_z}{dz^2} - \frac{1}{c^2 p_t} \frac{d^2 p_t}{dt^2} = 0 \quad (1.3)$$

The z and t terms can then each be equated to constants, say, $-k_z^2$ and $-\frac{\omega^2}{c^2}$ respectively, and

$$\text{so } \frac{d^2 p_z}{dz^2} = -k_z^2 p_z \quad \text{and} \quad \frac{d^2 p_t}{dt^2} = -\omega^2 p_t$$

Equation (1.3) then reduces to

$$\frac{1}{p_r} \frac{d^2 p_r}{dr^2} + \frac{1}{r p_r} \frac{dp_r}{dr} + \frac{1}{r^2 p_\theta} \frac{d^2 p_\theta}{d\theta^2} + \left(-k_z^2 + \frac{\omega^2}{c^2}\right) = 0$$

$$\text{If } \frac{1}{p_\theta} \frac{d^2 p_\theta}{d\theta^2} = -m^2 \quad (\text{where } m \text{ is a positive integer}) \quad (1.4)$$

the above equation reduces to

$$\frac{d^2 p_r}{dr^2} + \frac{1}{r} \frac{dp_r}{dr} + \left(-k_z^2 + \frac{\omega^2}{c^2} - \frac{m^2}{r^2}\right) p_r = 0 \quad (1.5)$$

The equations in θ , z and t are all of the same form and their solutions are all given by imaginary exponentials.

$$\text{If } k^2 = \frac{\omega^2}{c^2} - k_z^2 \quad (1.6)$$

the equation (1.5) for p_r takes the form of Bessel's equation and the solution is given by ^{18,26}

$$p_r = A_m J_m(kr) + B_m Y_m(kr)$$

where J_m and Y_m are Bessel's functions of the first and second kind respectively. A_m , B_m are weight constants for an arbitrary pressure distribution.

But since $Y_m \rightarrow \infty$ as $r \rightarrow \infty$ and since the pressure function is finite everywhere within the duct including the duct axis, Y_m is not included in the solution.

1.4 For a hard-walled duct, the normal pressure gradient at the duct walls is zero. The equation of the duct wall is given by $r=R$ (a constant).

$$\text{Hence } \left. \frac{\partial p}{\partial r} \right|_{r=R} = 0$$

which is the same as

$$\left. \frac{d}{dr} [J_m(kr)] \right|_{r=R} = 0$$

i.e. $J'_m(kR) = 0$.

For a given value of m and R , there is an infinity $k_{m\mu}$ ($\mu=0,1,2,\dots$) of values of k which satisfies this equation, each $k_{m\mu}$ increasing in magnitude with μ . For a given μ , the pressure function has μ pressure nodes in the radial direction.

So the pressure distribution function can be written as

$$p = J_m(k_{m\mu}r) \begin{Bmatrix} \sin m\theta \\ \cos m\theta \end{Bmatrix} e^{i(k_z z + \omega t)}$$

(At any fixed position, ω represents the circular frequency of the pressure fluctuations).

In the above equation

$$k_z^2 = \frac{\omega^2}{c^2} - k_{m\mu}^2$$

1.5 Thus for any given value of $k_{m\mu}$ only values of ω which are greater than $ck_{m\mu}$ give rise to real values of k_z . Hence the 'g' mode of the pressure function gives rise to a sinusoidal pressure distribution along the axis of the duct, causing the wave to propagate in this direction. Values of $\omega < ck_{m\mu}$, give imaginary values of k_z ; the pressure function becomes a negative exponential in z which results in an exponential attenuation of the pressure wave along the duct axis. This is known as the 'cut-off' phenomenon.

The values of $k_{m\mu}$ give the cut-off frequencies for the various modes m of the pressure distribution. It is interesting to note that, as μ increases in value, $k_{m\mu}$ also increase. k_{m0} gives the lowest cut-off frequency for a particular mode 'm' of the pressure function. These values may be found in any tables relating to Bessel functions - see for example Olver 22.

The decay rates for frequencies below cut-off and their significance in a practical situation has been demonstrated by several workers. 3,25,26

2.

DERIVATION OF THE WAVE EQUATION IN ELLIPTIC COORDINATE SYSTEM AND BOUNDARY CONDITIONS.

2.1 To study the behaviour of waves in an elliptic duct it becomes essential that a proper system of co-ordinates is chosen, the most convenient and relevant being the elliptic coordinate system.

If (x, y, z) are the cartesian coordinates and (ξ, η, z) the elliptic cylindrical coordinates, the following relation holds between them:

$$\begin{aligned}x &= h \cosh \xi \cos \eta \\y &= h \sinh \xi \sin \eta \\z &= z\end{aligned}$$

and when the wave equation (1.1) is considered, the time variable is kept unchanged.

In any z -constant plane, the η -constant curves are hyperbolae; the ξ -constant curves are ellipses with major axis $2h \cosh \xi$ and minor axis $2h \sinh \xi$. The foci are at $(+h, 0)$ and $(-h, 0)$. (Fig. 2)

With this transformation the wave equation takes the form

$$\frac{2}{h^2(\cosh 2\xi - \cos 2\eta)} \left\{ \frac{\partial^2 p}{\partial \xi^2} + \frac{\partial^2 p}{\partial \eta^2} \right\} + \frac{\partial^2 p}{\partial z^2} - \frac{1}{c^2} \frac{\partial^2 p}{\partial t^2} = 0 \quad (2.1)$$

To obtain a separable solution, as before, can be written as

$$p = p_\xi(\xi) p_\eta(\eta) p_z(z) p_t(t)$$

so that equation (2.1) reduces to, on substitution of the value of p and division by p ,

$$\frac{2}{h^2 (\cosh 2\xi - \cos 2\eta)} \left\{ \frac{1}{p_\xi} \frac{d^2 p_\xi}{d\xi^2} + \frac{1}{p_\eta} \frac{d^2 p_\eta}{d\eta^2} \right\} + \frac{1}{p_z} \frac{d^2 p_z}{dz^2} - \frac{1}{c^2 p_t} \frac{d^2 p_t}{dt^2} = 0$$

Equating z and t terms to constants $-k_z^2$ and $-\frac{\omega^2}{c^2}$ respectively,

$$\frac{d^2 p_z}{dz^2} = -k_z^2 p_z \quad \text{and} \quad \frac{d^2 p_t}{dt^2} = -\frac{\omega^2}{c^2} p_t$$

and

$$\frac{1}{p_\xi} \frac{d^2 p_\xi}{d\xi^2} + \frac{1}{p_\eta} \frac{d^2 p_\eta}{d\eta^2} + \left(\frac{\omega^2}{c^2} - k_z^2 \right) \frac{h^2}{2} (\cosh 2\xi - \cos 2\eta) = 0$$

$$\text{Let } \frac{1}{p_\xi} \frac{d^2 p_\xi}{d\xi^2} + \left(\frac{\omega^2}{c^2} - k_z^2 \right) \frac{h^2}{2} \cosh 2\xi = a$$

$$\text{and } \frac{1}{p_\eta} \frac{d^2 p_\eta}{d\eta^2} - \frac{h^2}{2} \left(\frac{\omega^2}{c^2} - k_z^2 \right) \cos 2\eta = -a$$

where 'a' is a separation constant, known as the characteristic number.

The above equations can now be written out separately as follows:

$$\frac{d^2 p_\eta}{d\eta^2} + \left[a - \frac{h^2}{2} \left(\frac{\omega^2}{c^2} - k_z^2 \right) \cos 2\eta \right] p_\eta = 0 \quad (2.2)$$

$$\frac{d^2 p_\xi}{d\xi^2} - \left[a - \frac{h^2}{2} \left(\frac{\omega^2}{c^2} - k_z^2 \right) \cosh 2\xi \right] p_\xi = 0 \quad (2.3)$$

$$\text{If } q = \frac{h^2}{4} \left(\frac{\omega^2}{c^2} - k_z^2 \right). \quad (2.4)$$

the equations (2.2) and (2.3) reduce to the form

$$\frac{d^2 p_\eta}{d\eta^2} + (a - 2q \cos 2\eta) p_\eta = 0 \quad (2.5)$$

$$\frac{d^2 p_\xi}{d\xi^2} - (a - 2q \cosh 2\xi) p_\xi = 0 \quad (2.6)$$

which are the canonical forms of Mathieu's equation and the modified Mathieu equation. ^{2,19}

It can be seen here that if $\eta = i\xi$ equation (2.5) transforms to equation (2.6) and conversely if $\xi = i\eta$, equation (2.6) transforms to equation (2.5).

The separation constant 'a' here is such that as $q \rightarrow 0$, $a \rightarrow m^2$, where m is a positive integer.

2.2 The solutions of equation (2.5) are the even and odd Mathieu functions, ce_m and se_m of order m , when $a \rightarrow m^2$ as $q \rightarrow 0$. These functions ce_m, se_m are functions of both η and q and are such that as $q \rightarrow 0$, $ce_m \rightarrow \cos m\eta$ and $se_m \rightarrow \sin m\eta$. The even 'cosine-elliptic' functions correspond to the cosine functions in the circular case and the odd 'sine-elliptic' functions correspond to the sine functions. In a circular duct the periodic sinusoidal waves of order m around its periphery can be of either sinusoidal or cosinusoidal form depending on their values at any particular vectorial axis. In an elliptic duct, these wave forms are dependent on the axis of symmetry. For the same value of a and q , ce_m and se_m form a fundamental system of solution for the Mathieu equation (2.5). The solution, therefore, can be written as

$$p_\eta = A_c ce_m(\eta, q) + A_s se_m(\eta, q)$$

which gives us the pressure distribution in the circumferential mode. The ce_m and se_m are periodic with period π or 2π depending on m being even or odd.

The solutions of the modified Mathieu equation (2.6) are the modified Mathieu functions, also called radial Mathieu Functions as they represent the radial pressure distribution in the duct. It can be shown that as $q \rightarrow 0$, the equation (2.6) reduces to the Bessel's equation (1.5).¹⁹ The radial Mathieu functions ce_m and se_m of the first kind are the even 'cosh-elliptic' and odd 'sinh-elliptic' functions respectively and they are periodic with period πi or $2\pi i$. As a matter of fact

$$ce_m(\xi, q) = ce_m(i\eta, q)$$

$$se_m(\xi, q) = -i se_m(i\eta, q)$$

There exist radial Mathieu functions of the second, third and fourth kind, but these functions do not satisfy (as shall be shown) the necessary boundary conditions and hence are not included in the pressure distribution function.

2.3 The boundary conditions to be satisfied by the pressure function p in a reference plane $y=0$ are as follows:

(a) Since p is single-valued, it is periodic in η with a maximum period of 2π .

(b) $p(\xi, \eta)$ is continuous in the duct and in particular, it is continuous across the interfocal line,

$$\text{i.e. } p(0, \eta) = p(0, -\eta)$$

(c) On crossing the interfocal line, there is continuity of the pressure gradient, so that

$$\frac{\partial p}{\partial \xi}(0, \eta) = -\frac{\partial p}{\partial \xi}(0, -\eta)$$

and (d) the component of the pressure gradient normal to the wall of the duct (it being hard walled) is zero at the walls. On this boundary $\xi = \xi_0$.

Hence

$$\left. \frac{\partial p}{\partial \xi} \right|_{\xi = \xi_0} = 0$$

The functions ce_m and se_m are periodic in η (and with period π or 2π , so long as m is a positive integer). Hence they satisfy condition (a).

If $ce_m(\xi, \eta)$ is a solution of equation (2.6), $ce_m(0, \eta)$ is a constant. $ce_m(\eta) = ce_m(-\eta)$, as ce_m are even functions.

so $ce_m(\xi)ce_m(\eta)$ satisfies condition (b).

Since $se_m(0, \eta)$, $se_m(0)se_m(\eta) = se_m(0)se_m(-\eta)$. Hence $se_m(\xi)se_m(\eta)$ satisfies condition (b)

Consider now $ce_m(\xi)se_m(\eta)$. Since $se_m(\eta) = -se_m(-\eta)$, se_m being odd, $ce_m(0)se_m(\eta) \neq ce_m(0) \times se_m(-\eta)$. So $ce_m(\xi)se_m(\eta)$ does not satisfy condition (b). On the same lines it can be proved that $se_m(\xi)ce_m(\eta)$ does not satisfy condition (b).

It can be proved that the combinations $Ce_m(\xi) \times Ce_m(\eta)$ and $Se_m(\xi) \times Se_m(\eta)$ satisfy the conditions (a), (b) and (c) and are in fact the only possible combinations of Mathieu and modified Mathieu functions satisfying the boundary conditions (a), (b) and (c). The solutions of the second, third and fourth kinds fail to satisfy the condition (c) and hence are not included in the pressure function.

Hence the only acceptable solutions of the wave equation for the pressure field are given by

$$p = \begin{Bmatrix} C_m Ce_m(\xi, q) Ce_m(\eta, q) \\ S_m Se_m(\xi, q) Se_m(\eta, q) \end{Bmatrix} e^{2k_z z} \cos(\omega t + \alpha)$$

which satisfy the conditions (a), (b) and (c).

Now the condition (d) requires that when $\xi = \xi_0$ (i.e. on the boundary of the elliptic duct) $\frac{\partial p}{\partial \xi} = 0$ which is

$$\left. \frac{d}{d\xi} Ce_m(\xi, q) \right|_{\xi=\xi_0} = 0 \quad \text{or} \quad \left. \frac{d}{d\xi} Se_m(\xi, q) \right|_{\xi=\xi_0} = 0 \quad (2.7, 2.8)$$

corresponding to each value of m , these equations, for a given value ξ_0 of ξ , give an infinity of positive values of q , which satisfy the above equations. The first equation gives a set of values $q_{m\mu}$ ($\mu = 0, 1, 2, \dots$) which satisfy it. The second equation gives a set of values $\bar{q}_{m\mu}$ (say) which satisfy it. These are known as the parametric zeros of the functions. For each value of μ , both

$q_{m\mu}$ and $\bar{q}_{m\mu}$ give the nodal (zero pressure) ellipses in the reference plane. Since Ce_m and Se_m form a fundamental system of solution for equation (2.6), it is to be noted that none of the $q_{m\mu}$ and $\bar{q}_{m\mu}$ are the same for the same value of m and μ and a given characteristic value α .¹¹

3. PREVIOUS WORK ON ELLIPTIC WAVE PROPAGATION.

3.1 From equation (2.4),

$$q = \frac{h^2}{4} \left(\frac{\omega^2}{c^2} - k_z^2 \right)$$

the important relationship

$$k_z = \left(\frac{\omega^2}{c^2} - \frac{4q}{h^2} \right)^{1/2} \quad (3.1)$$

is obtained. $4q/h^2$ here corresponds to the ' k ' mentioned in the circular case. As $q \rightarrow 0$, equation (2.6) reduces to equation (1.4) as mentioned earlier. Indeed, this corresponds to $h \rightarrow \infty$ with the ellipses becoming circles.

If ω/c is such that $\omega/c < 2\sqrt{q_{m\mu}}/h$, where $q_{m\mu}$ is a parametric zero obtained from equation (2.7), the value of k_z from (3.1) becomes imaginary; the pressure function becomes a negative exponential resulting in an exponential decay of waves along the axial direction of the duct.

If $\omega/c \geq 2\sqrt{q_{m\mu}}/h$, real values of k_z are obtained and this mode is propagated along the duct without attenuation.

For a particular m , q_{m0} gives the parametric zero such that $\omega/c \geq 2\sqrt{q_{m0}}/h$, which gives the cut-off frequency for the particular mode m . The higher order radial modes associated with $q_{m\mu}$ are of less significance and will not be considered further.

Though the theory of propagation and attenuation

of waves with elliptic boundary conditions have been considered by many authors ^{6,7,10,13}, actual determination of the 'non-dimensionalised' cut-off frequencies, though only for the lowest order modes, 0 and 1, have been found only by Chu and by Daymond. In what follows work done by Jeffreys, Chu and Daymond is described as a basis for further development.

3.2 ¹³ In an elliptical lake of uniform depth d , let ζ represent the vertical displacement from its equilibrium position of the water surface. Let the lake be stationary in space and let ζ be an imaginary exponential function of the time variable t . If ζ is so small that its second and higher powers could be neglected, it can be proved that ζ satisfies the reduced wave equation

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} + \frac{\omega^2}{c^2} \zeta = 0 \quad (3.2)$$

$c^2 = g d$, c being the free wave velocity in an unrestricted expanse of water of uniform depth d and g being the acceleration due to gravity. x, y coordinates are chosen with axes along the major and minor axes respectively of the elliptic boundary, origin being at its centre (Fig. 2).

Transforming to elliptic coordinates (see chapter II) the equation (3.2) reduces to

$$\frac{\partial^2 \zeta}{\partial \xi^2} + \frac{\partial^2 \zeta}{\partial \eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) \zeta = 0, \quad 2k = \frac{\omega h}{c} \quad (3.3)$$

The form of ζ is then given by

$$\psi(\xi, \eta, t) = \frac{C_m C e_m(\xi, q) c e_m(\eta, q)}{S_m S e_m(\xi, q) s e_m(\eta, q)} \int_0^e e^{i(\omega_m t + \epsilon_m)} \quad (3.4)$$

ω_m is the angular frequency of vibration of the m th mode and ϵ_m is the relative phase angle.

The velocity normal to an elemental arcual length ds of an ellipse, that is, in the direction dn , is given by

$$u_n = \frac{ig}{\omega} \frac{\partial \psi}{\partial n} = \frac{ig}{\omega l_1} \frac{\partial \psi}{\partial \xi} \quad \text{where } dn = l_1 d\xi, \quad l_1 = \frac{h}{\sqrt{2}} (\cosh 2\xi - \cos 2\eta)^{1/2}$$

On the boundary $\xi = \xi_0$, the normal velocity is zero and hence

$$\left[\frac{\partial \psi}{\partial \xi} \right]_{\xi = \xi_0} = 0$$

which reduces to $C e'_m(\xi_0, q) = 0$ and $S e'_m(\xi_0, q) = 0$ from equation (3.4).

The values $q_{m\mu}$ and $\bar{q}_{m\mu}$ satisfying the above respective equations have now to be found.

Consider the lowest modes $m=1, \mu=1$ when ψ is proportional to $C e_1(\xi, q_{11}) c e_1(\eta, q_{11})$. Let us consider an ellipse of given eccentricity.

Suppose the boundary of the elliptic lake has eccentricity $e = 0.8$. Then $\cosh \xi_0 = 1/e = 1.25$, $\exp(\xi_0) = 2$, $\exp(-\xi_0) = 0.5$ and $\xi_0 = .6931$

From the expansions of $C e_1(\xi_0, q)$ (see Chapter IV)

* Though the function is normalised differently.

Therefore

$$Ce_1(\xi_0, q) \simeq -\alpha^3 \left(\frac{1}{18} \cosh 7\xi_0 - \frac{4}{9} \cosh 5\xi_0 + \frac{1}{3} \cosh 3\xi_0 \right) + \alpha^2 \left(\frac{1}{3} \cosh 5\xi_0 - \cosh 3\xi_0 \right) - \alpha \cosh 3\xi_0 + \cosh \xi_0$$

where $\alpha = \frac{1}{8} q$

Therefore

$$Ce_1'(\xi_0, q) \simeq -\alpha^3 \left(\frac{7}{18} \sinh 7\xi_0 - \frac{20}{9} \sinh 5\xi_0 + \sinh 3\xi_0 \right) - \alpha^2 \left(\frac{5}{3} \sinh 5\xi_0 - 3 \sinh 3\xi_0 \right) - 3\alpha \sinh 3\xi_0 + \sinh \xi_0$$

Since $Ce_1'(\xi_0, q) = 0$, substituting in terms of $\exp(\xi_0)$ and $\exp(-\xi_0)$ for $\sinh \xi_0$, an equation in α is obtained. The smallest positive root of this equation gives $\alpha \simeq 0.07$, i.e. $q \simeq 0.56$, and since $4q = \omega^2 h^2 / c^2$ and $h = ae$

$$\omega_1^2 = \frac{4q_{11} c^2}{a^2 e^2}$$

Therefore $\omega_1 \simeq 1.87 c / a$, which gives the pulsatace of the water waves mainly parallel to the direction of the major axis. From Bessel function tables, the lowest root for a circular lake is given by $\omega_1 a / c \simeq 1.84$ or $\omega_1 = 1.84 c / a$

Thus we see that the pulsatace of this mode for a lake of eccentricity $e = 0.8$ is only slightly different from the same for a circular lake.

Let $\xi \propto Se_1(\xi, \bar{q}_{11}) se_1(\eta, \bar{q}_{11})$, in which case the oscillations are across the major axis.

$$Se_1'(\xi_0, \bar{q}) \simeq \bar{\alpha}^3 \left(\frac{7}{18} \cosh 7\xi_0 + \frac{20}{9} \cosh 5\xi_0 + \cosh 3\xi_0 \right) + \bar{\alpha}^2 \left(\frac{5}{3} \cosh 5\xi_0 + 3 \cosh 3\xi_0 \right) - 3\bar{\alpha} (\cosh 3\xi_0) + \cosh \xi_0$$

where $\bar{\alpha} = \frac{1}{8} \bar{q}$

Considering an elliptic boundary of eccentricity $e = 0.8$ the equation $Se_1'(\xi_0, \bar{q}) = 0$ reduces to a cubic in $\bar{\alpha}$, whose smallest positive root $\bar{\alpha} \simeq .175$, so that $\bar{q}_{11} \simeq 1.4$.

Hence, since $\bar{\omega}_1^2 = \frac{4\bar{q}_{11}^2 c^2}{a^2 e^2}$, $\bar{\omega}_1 = 2.96 \frac{c}{a} = 1.78 \frac{c}{b}$. Comparing $\bar{\omega}_1$, and ω_1 ,

$$\frac{\bar{\omega}_1}{\omega_1} = \frac{2.96}{1.87} = 1.58$$

which shows that the pulsance across the major axis is about 40 per cent more than that parallel to the major axis.

When the eccentricity of the lake boundary tends to unity, the lake is a long narrow ellipse. Now, since $\cosh \xi_0 = 1/e$, ξ_0 has values very near zero and $\sinh \xi_0 \simeq \xi_0$.

If $\xi \simeq Ce_1(\xi, q_{11}) ce_1(\eta, q_{11})$, the equation $Ce_1'(\xi_0, q) = 0$ reduces to $5.39\alpha^3 - 0.667\alpha^2 - 9\alpha + 1 = 0$, where $\alpha = 1/8 q$.

The smallest positive root of this equation is

$\alpha \simeq 0.111$, so $q_{11} = 0.888$.

Hence as $e \rightarrow 1$, we get $\omega_1 = 1.886 c/a$ which shows that the effect of elongating an ellipse on the frequency for the lowest mode is quite negligible.

3.3 In the paper by Chu ⁶, electro-magnetic waves in a perfectly conducting elliptic metal pipe have been discussed. The values of the critical cut-off wavelengths have been calculated for the electrical field E waves and the magnetic field H-waves.

For an electro-magnetic wave, the Maxwell's equations have to be solved, assuming a boundary condition that the tangential component of the electrical field in air must vanish. It is further assumed that the metal pipe has perfect conductivity. With the help of these equations, the wave equations for E_z and H_z components of the electric and magnetic field respectively are obtained. As the wave is propagating in an elliptic guide, both E_z and H_z satisfy the Mathieu equation (2.5) and the modified Mathieu equation (2.6).

Hence their forms are given by

$$\left. \begin{array}{l} E_z \\ H_z \end{array} \right\} = \left. \begin{array}{l} c_m Ce_m(\xi, q) ce_m(\eta, q) \\ s_m Se_m(\xi, q) se_m(\eta, q) \end{array} \right\} e^{i(\omega t - k_z z)} \quad (3.5)$$

(3.6)

m th order of the functions being considered.

If the longitudinal component of the electric field is zero then $E_z = 0$ and the propagating wave is called

an H-wave. So the components of the field in this case are given by

$$H_z = \text{as in equation (3.6)}$$

$$H_\xi = \frac{\beta}{\mu\omega} E_\eta \quad (\mu \text{ being the permeability of the medium})$$

$$H_\eta = \frac{\beta}{\mu\omega} E_\xi$$

$$E_z = 0$$

$$E_\xi = \frac{\mu\omega}{k_1^2 h (\cosh 2\xi - \cos 2\eta)^{1/2}} \left\{ \begin{array}{l} C_m C_{e_m}(\xi, \eta) c e'_m(\eta, \eta) \\ S_m S_{e_m}(\xi, \eta) s e'_m(\eta, \eta) \end{array} \right\}_x e^{i(\omega t - k_3 z)}$$

$$(k_1 h = 2\sqrt{q})$$

$$E_\eta = \frac{\mu\omega}{k_1^2 h (\cosh 2\xi - \cos 2\eta)^{1/2}} \left\{ \begin{array}{l} C_m C_{e'_m}(\xi, \eta) c e_m(\eta, \eta) \\ S_m S_{e'_m}(\xi, \eta) s e_m(\eta, \eta) \end{array} \right\}_x e^{i(\omega t - k_3 z)}$$

Since the tangential component of the electric field E_η must vanish on the boundary $\xi = \xi_0$,

$$C_{e'_m}(\xi_0, \eta) = 0$$

$$S_{e'_m}(\xi_0, \eta) = 0$$

These equations determine values q_{m0} , $\bar{q}_{m0}$ of q which give the critical cut-off frequencies of the m th order wave. It is particularly interesting to note that the sound waves in a duct behave very similarly to these H-waves.

If the longitudinal component of the magnetic field vanishes while both the transverse and the longitudinal components of the electric field exist, this wave is called an E-wave. In this case $H_z = 0$, and E_z is given by equation (3.5). These waves satisfy the boundary conditions $C e_m(\xi_0, \eta) = 0$ and $S e_m(\xi_0, \eta) = 0$.

The wavelengths λ_{m0} for cut-off condition are given by the relation $k_{m0} = 2\pi/\lambda_{m0}$, where $k_{m0} = 2\pi \sqrt{q_{m0}}/h$ or $2\sqrt{q_{m0}}/h$ depending on whether even or odd function is considered.

Fig. 3 represents the ratios λ_0/p as functions of the eccentricity e of the ellipses; λ_0 are cut-off wavelengths for orders 0 and 1, p is the periphery of the pipe given by

$$p = h \cosh \xi_0 \int_0^{2\pi} \left\{ 1 - (\cos \eta / \cosh \xi_0)^2 \right\}^{1/2} d\eta$$

3.4 The above gave an idea of the behaviour of the waves when a circular pipe was deformed into an elliptic one. The values of the cut-off frequencies were found not independent of the periphery of the ellipse. In what follows⁷, the ellipse is so deformed that the area of the cross-section remains constant, while the eccentricity changes. Let this constant area be π , which is also the area of a circle of unit radius.

An important property¹⁴ connected with the reduced wave equation

$$\frac{\partial^2 p}{\partial x^2} + \frac{\partial^2 p}{\partial y^2} + k^2 p = 0 \quad (3.7)$$

for a region R is given below. The cut-off frequencies

for ellipses of different sizes but same eccentricity can be scaled from this property.

If the equation (3.7) is valid under the boundary condition $\partial p / \partial n = 0$, on the boundary of R , then there is an infinity of values of k , k_i ($i = 0, 1, 2, \dots$) such that

$$0 = k_0 < k_1 \leq k_2 \leq \dots$$

which satisfy the equation (3.7). These k_i are known as the eigen values of equation (3.7).

If A is the area of the region R , $\bar{A}$ is the area of another region $\bar{R}$ which is similar to R and if $\bar{k}_i$ are the values of k satisfying equation (3.7) for the region $\bar{R}$, then

$$\frac{\bar{k}_i^2}{\bar{R}_i^2} = \frac{A}{\bar{A}} \quad (3.8)$$

Hence, the eigen values $\bar{k}_i$ corresponding to any other elliptical boundary with the same eccentricity e can be found with the help of equation (3.8), once the eigen values corresponding to an ellipse, with area π and eccentricity e , have been found.

Consider an ellipse of eccentricity e and area π . The reduced wave equation (3.7) when transformed to elliptic coordinates gives

$$\frac{d^2 p_\eta}{d\eta^2} + (a - 2q \cos 2\eta) p_\eta = 0$$

$$\frac{d^2 p_\xi}{d\xi^2} - (a - 2q \cosh 2\xi) p_\xi = 0$$

where

$$p = p_{\xi}(\xi) / p_{\eta}(\eta) \text{ and } k^2 = 4q/h^2$$

Since the area of the ellipse is π , $h^2 = e^2(1-e^2)^{-1/2}$

$$\text{Let } \delta = 4q = k^2 h^2 = k^2 e^2 (1-e^2)^{-1/2} \quad (3.9)$$

If $\xi = \xi_0$ on the boundary, then $\cosh \xi_0 = 1/e$

If $u = \sqrt{q} \exp(\xi_0)$ and $v = \sqrt{q} \exp(-\xi_0)$

$$\omega_0 = u+v = 2\sqrt{q} \cosh \xi_0 = \sqrt{\delta} \cosh \xi_0$$

$$\text{Hence } \omega_0^2 = \delta \cosh^2 \xi_0 = \delta / e^2 \quad (3.10)$$

and since $\delta = k^2 e^2 (1-e^2)^{-1/2}$ (from (3.9))

$$\omega_0^2 = k^2 (1-e^2)^{-1/2} \quad (3.11)$$

The boundary conditions reduce to

$$C e'_m(\xi_0, q) = 0 \text{ and } S'_{2m+1}(\xi_0, q) = 0, m = 0, 1, 2, \dots$$

Determining the parametric zeros by direct evaluation is not possible in practice. The method used to obtain the values of $k (= 2\sqrt{q}/h)$ is given in detail in Chapter V. In Daymond's work⁷ the principal frequencies have been found. It shall be discussed how the cut-off frequencies have been found for higher orders. The values calculated for the lowest order agree with those found in Daymond.

4. MATHIEU FUNCTIONS AND EXPANSIONS IN SERIES.

4.1

$$\frac{d^2 z}{d\eta^2} + (a - 2q \cos 2\eta) z = 0 \quad (4.1)$$

$$\frac{d^2 z}{d\xi^2} - (a - 2q \cosh 2\xi) z = 0 \quad (4.2)$$

are Mathieu equation and modified Mathieu equation respectively.

The solutions of equation (4.1) can be classified into four categories as follows:

(i) $ce_{2n}(\eta, q)$, even functions with period π

(ii) $ce_{2n+1}(\eta, q)$, even functions with period 2π

(iii) $se_{2n+2}(\eta, q)$, odd functions with period π

(iv) $se_{2n+1}(\eta, q)$, odd functions with period 2π

(Only periodic functions occur in the pressure function and hence they are considered here).

Functions ce_{2n} , ce_{2n+1} , se_{2n+2} , se_{2n+1} respectively correspond to the above functions and are solutions of equation (4.2). These functions have imaginary periods.

The functions ce_m and se_m can be expanded in Fourier series

$$ce_{2n}(\eta, q) = \sum_{h=0}^{\infty} A_{2h}^{(2n)} \cos 2\eta h \quad (a_{2n}) \quad (4.3) \quad (i)$$

$$ce_{2n+1}(\eta, q) = \sum_{h=0}^{\infty} A_{2h+1}^{(2n+1)} \cos(2h+1)\eta \quad (a_{2n+1}) \quad (4.3) \quad (ii)$$

$$se_{2n+2}(\eta, q) = \sum_{h=0}^{\infty} B_{2h+2}^{(2n+2)} \sin(2h+2)\eta \quad (b_{2n+2}) \quad (4.3) \quad (iii)$$

$$se_{2n+1}(\eta, q) = \sum_{h=0}^{\infty} B_{2h+1}^{(2n+1)} \sin(2h+1)\eta \quad (b_{2n+1}) \quad (4.3) \quad (iv)$$

where the coefficients A, B are functions of q , and so are the characteristic numbers a, b. The functions in (4.3) are normalised such that

$$\frac{1}{\pi} \int_0^{2\pi} ce_m^2(\eta, q) d\eta = \frac{1}{\pi} \int_0^{2\pi} se_m^2(\eta, q) d\eta = 1 \quad (4.4)$$

for all q . From (4.3) and the orthogonal property of the circular functions, (4.4) gives

$$\begin{aligned} 2 \left[A_0^{(2n)} \right]^2 + \sum_{h=1}^{\infty} \left[A_{2h}^{(2n)} \right]^2 &= 1 = \sum_{h=0}^{\infty} \left[A_{2h+1}^{(2n+1)} \right]^2 \\ &= \sum_{h=0}^{\infty} \left[B_{2h+2}^{(2n+2)} \right]^2 = \sum_{h=0}^{\infty} \left[B_{2h+1}^{(2n+1)} \right]^2 \end{aligned} \quad (4.5)$$

The constant term in the expansion of $ce_0(\eta, q)$ is $2^{-1/2}$, for if $q=0$, the equation (4.4) would become

$$\frac{1}{\pi} \int_0^{2\pi} d\eta = 2$$

If $\xi = i\eta$, then the solutions of (4.2) can be written as

$$ce_{2n}(\xi, q) = ce_{2n}(i\eta, q) = \sum_{h=0}^{\infty} A_{2h}^{(2n)} \cosh 2h\xi \quad (a_{2n}) \quad (i)$$

$$Ce_{2n+1}(\xi, q) = ce_{2n+1}(i\eta, q) = \sum_{h=0}^{\infty} A_{2h+1}^{(2n+1)} \cosh(2h+1)\xi \quad (a)_{2n+1} \text{ (ii)}$$

$$Se_{2n+2}(\xi, q) = se_{2n+2}(i\eta, q) = \sum_{h=0}^{\infty} B_{2h+2}^{(2n+2)} \sinh(2h+2)\xi \quad (b)_{2n+2} \text{ (iii)}$$

$$Se_{2n+1}(\xi, q) = se_{2n+1}(i\eta, q) = \sum_{h=0}^{\infty} B_{2h+1}^{(2n+1)} \sinh(2h+1)\xi \quad (b)_{2n+1} \text{ (iv)} \quad (4.6)$$

The A, B, a and b being the same as in (4.3) for the same

q .

4.2 At this point, another method of normalisation of the solutions of equation (4.1) is given. ²² (This has been used by most American authors). The solutions in this case are Se_n, So_n (not to be confused with Se_n , solutions of (4.2)) normalised by the conditions

$$Se_n(s, 0) = 0 \quad \text{and} \quad \frac{d}{d\eta} [So_n(s, \eta)] = 1$$

where $s = 4q$, q is the same as in equation (4.1).

The expansions of Se_n and So_n are given respectively by

$$Se_{2n+p}(s, \eta) = \sum_{h=0}^{\infty} De_{2h+p}^{(2n+p)} \cos(2h+p)\eta \quad (be)_{2n+p}$$

and

$$So_{2n+p}(s, \eta) = \sum_{h=0}^{\infty} Do_{2h+p}^{(2n+p)} \sin(2h+p)\eta \quad (bo)_{2n+p}$$

where $p = 0$ or 1 according as the function under consideration is of period π or 2π and $b_e = a_n + 2q$, $b_o = b_n + 2q$,

a_n, b_n being the even and odd characteristic numbers in (4.3) respectively.

The normalisation condition gives

$$\sum_{n=0}^{\infty} D e_{2n+p} = 1, \quad \sum_{n=0}^{\infty} (2n+p) D o_{2n+p} = 1.$$

The relationship between the coefficients here and the coefficients in (4.3) is given by

$$D e_{2n+p}^{(m)} = A_{2n+p}^{(m)} / A$$

and

$$D o_{2n+p}^{(m)} = B_{2n+p}^{(m)} / B$$

where

$$\frac{1}{A^2} = \left[2 (D e_0^{(m)})^2 + (D e_2^{(m)})^2 + \dots \right] \partial \left[(D e_1^{(m)})^2 + (D e_3^{(m)})^2 + \dots \right]$$

and

$$\frac{1}{B^2} = \sum_{n=0}^{\infty} (D o_{2n+p}^{(m)})^2$$

4.3 On substituting the value of $C e_{2n}$ from (4.3) in the Mathieu equation (4.1) and equating to zero the coefficients of $\cos 2n\eta$, the following recurrence relation is obtained¹⁹

$$\begin{aligned} a A_0 - q A_2 &= 0 \\ -2q A_0 + (a-4) A_2 - q A_4 &= 0 \\ -q A_{2n-2} + (a-4n^2) A_{2n} - q A_{2n+2} &= 0 \end{aligned} \quad (4.7)$$

Let A_{2n} decrease to zero as n becomes very large

compared to the order of the function.

If $v_{2n} = A_{2n+2} / A_{2n}$, the third of the equations (4.7) gives

$$-\frac{q}{v_{2n-2}} + (a - 4n^2) - qv_{2n} = 0 \quad \left(\text{As } \frac{A_{2n-2}}{A_{2n}} = \frac{1}{v_{2n-2}} \right)$$

Therefore

$$(a - 4n^2)v_{2n-2} - qv_{2n}v_{2n-2} - q = 0$$

Hence

$$v_{2n} + \frac{1}{v_{2n-2}} = \frac{a - 4n^2}{q}$$

If $(n+1)$ is written for n ,

$$v_{2n+2} + \frac{1}{v_{2n}} = \frac{a - 4(n+1)^2}{q}$$

$$\text{So, when } n \rightarrow \infty, \quad v_{2n+2} + \frac{1}{v_{2n}} \rightarrow -\infty$$

Thus v_{2n} cannot have a unique finite limit other than zero.

Hence

$$v_{2n} \rightarrow 0 \quad \text{or} \quad |v_{2n}| \rightarrow \infty \quad \text{as } n \rightarrow \infty$$

As the coefficients A_{2n} are so found that $A_{2n} \rightarrow 0$ as $n \rightarrow \infty$,

v_{2n} too must approach zero. Hence one of the solutions of the third of the equations (4.7) tends to zero when

$n \rightarrow \infty$ while the other tends to ∞ . But we cannot have

a solution tending to ∞ . Hence when n is very large

$$v_{2n+2} v_{2n} \leq 1 \quad \text{and} \quad a \leq 4(n+1)^2. \quad \text{With } a, q \text{ finite}$$

$$|v_{2n}| \sim \frac{q}{4(n+1)^2} \rightarrow 0 \text{ as } n \rightarrow \infty$$

So for a real η as $|\cos 2n\eta| \leq 1$, $ce_{2n}(\eta, q)$ is absolutely convergent. Since for any η in a given closed interval, it is possible to find an M independent of η such that

$$\left| \frac{A_{2n} \cos 2n\eta}{A_{2n-2} \cos (2n-2)\eta} \right| \sim \frac{q}{4(n+1)^2} < M$$

the series is uniformly convergent. Thus the expansion (4.3) for ce_{2n} represents a continuous function for all real η .

When η is not real (i.e. when $\eta = i\xi$)

$$\left| \frac{u_{n+1}}{u_n} \right| = \left| \frac{A_{2(n+1)}}{A_{2n}} \frac{\cosh 2(n+1)\xi}{\cosh 2n\xi} \right| = |v_{2n}| \left| \frac{\cosh 2(n+1)\xi}{\cosh 2n\xi} \right|$$

$$\sim \frac{q}{4(n+1)^2} e^{2|\xi|} \rightarrow 0 \text{ as } n \rightarrow \infty$$

so long as $|\xi|$ remains finite, i.e. ξ is finite.

From the above, it follows that the fourier-series expansion for ce_{2n} is absolutely and uniformly convergent for

any finite ξ . On the same lines of proof as above, taking the relevant difference equations, it can be proved that the series expansions (4.6) for Ce_{2n+1} , Se_{2n+2} , Se_{2n+1} are all absolutely and uniformly convergent. Since the expansions are uniformly convergent for a given q and for any finite ξ , the series can be differentiated term by term and the series expansions so obtained for the derivations are absolutely and uniformly convergent for any finite ξ .

4.4 It will now be shown that the solutions of equation (4.2) can be expressed as a rapidly converging Bessel function series. 9, 19

If $\xi = 2k \cosh k \xi$, where $k^2 = q > 0$, then the equation (4.2) becomes

$$(\xi^2 - 4k^2) \frac{d^2 z}{d\xi^2} + \xi \frac{dz}{d\xi} + \{\xi^2 - (a+2q)\} z = 0 \quad (4.8)$$

Suppose

$$z = \sum_{m=0}^{\infty} (-1)^m C_{2m} J_{2m}(\xi) \quad (4.9)$$

is a solution of the above equation (4.8). Substituting the value of z from (4.9) into (4.8), we obtain

$$\sum_{m=0}^{\infty} (-1)^m C_{2m} \left[(\xi^2 - 4k^2) J_{2m}'' + \xi J_{2m}' + (\xi^2 - p^2) J_{2m} \right] = 0 \quad (4.10)$$

where

$$p^2 = a + 2q = a + 2k^2$$

Since J_{2m} are solutions of Bessel's equation,

$$\xi^2 \frac{d^2 z}{d\xi^2} + \xi \frac{dz}{d\xi} - (4m^2 - \xi^2) z = 0,$$

$$\xi^2 J_{2m}'' + \xi J_{2m}' + \xi^2 J_{2m} = 4m^2 J_{2m} \quad (4.11)$$

Also

$$4 J_{2m}'' = J_{2m-2} - 2 J_{2m} + J_{2m+2} \quad (4.12)$$

from the recurrence relationship between Bessel function and its derivative.

So, from (4.11), (4.12), the equation (4.10) becomes

$$\sum_{m=0}^{\infty} (-1)^m c_{2m} \left[(4m^2 - \beta^2) J_{2m} - k^2 (J_{2m-2} - 2J_{2m} + J_{2m+2}) \right] = 0 \quad (4.13)$$

$$\text{or } \sum_{m=0}^{\infty} (-1)^m c_{2m} \left[(4m^2 - \alpha) J_{2m} - k^2 (J_{2m-2} + J_{2m+2}) \right] = 0 \quad (4.14)$$

Equating the coefficients of J_{2m} to zero ($m = 0, 1, 2, \dots$)

$$\left. \begin{aligned} \alpha c_0 - k^2 c_2 &= 0 \\ (\alpha - 4) c_2 - k^2 (c_4 + 2c_0) &= 0 \\ (\alpha - 4m^2) c_{2m} - k^2 (c_{2m+2} + c_{2m-2}) &= 0, \quad m \geq 2 \end{aligned} \right\} \quad (4.15)$$

Comparing equations (4.15) and equations (4.7), they are found to be the same, with A_m in (4.7) replaced by c_m .

Hence c_{2m} are proportional to A_{2m} .

$$c_{2n}(\xi, q) = \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cosh 2m \xi$$

C_{2m} are proportional to A_{2m} and it can be noticed that $\cosh 2m\xi$ and $J_{2m}(\cosh 2m\xi)$ are both periodic with period πi

Hence $\sum_{m=0}^{\infty} (-1)^m A_{2m} J_{2m}(2k \cosh \xi)$ are solutions of the equation (4.2)

If $\xi = \frac{\pi i}{2}$, $J_{2m}(0) = 0$ for all m , except $J_0(0)$ which is $= 1$

and

$$C_{e_{2n}}\left(\frac{\pi i}{2}, q\right) = C_{e_{2n}}\left(\frac{\pi}{2}, q\right) / A_0^{(2n)}$$

$$C_{e_{2n}}(\xi, q) = \frac{C_{e_{2n}}\left(\frac{\pi}{2}, q\right)}{A_0^{(2n)}} \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_{2m}(2k \cosh \xi) \quad (4.16)$$

Following arguments similar to above, we obtain the series solutions for $C_{e_{2n+1}}$, $S_{e_{2n+2}}$, $S_{e_{2n+1}}$ as follows:

$$C_{e_{2n+1}}(\xi, q) = \frac{C'_{e_{2n+1}}\left(\frac{\pi}{2}, q\right)}{k A_1^{(2n+1)}} \sum_{m=0}^{\infty} (-1)^m A_{2m+1}^{(2n+1)} J_{2m+1}(2k \cosh \xi) \quad (4.17)$$

$$S_{e_{2n+2}}(\xi, q) = - \frac{S'_{e_{2n+2}}\left(\frac{\pi}{2}, q\right)}{k^2 B_2^{(2n+2)}} \tanh \xi \times \sum_{m=0}^{\infty} (-1)^m (2m+2) B_{2m+2}^{(2n+2)} J_{2m+2}(2k \cosh \xi) \quad (4.18)$$

$$\text{and } S_{e_{2n+1}}(\xi, q) = \frac{S'_{e_{2n+1}}\left(\frac{\pi}{2}, q\right)}{k B_1^{(2n+1)}} \tanh \xi \times \sum_{m=0}^{\infty} (-1)^m (2m+1) B_{2m+1}^{(2n+1)} J_{2m+1}(2k \cosh \xi) \quad (4.19)$$

4.5 Here a new set of functions are introduced, which are respectively proportional to functions (4.16) - (4.19), but are normalised differently.

$$J_{e_{2n+p}}(\xi, \eta) = \sqrt{\frac{\pi}{2}} (-1)^n \sum_{m=0}^{\infty} (-1)^m D_{e_{2m+p}} J_{2m+p}(2k \cosh \xi), \quad (4.20)$$

$p = 0 \text{ or } 1.$

$$J_{o_{2n+p}}(\xi, \eta) = \sqrt{\frac{\pi}{2}} (-1)^n \tanh \xi \sum_{m=0}^{\infty} (-1)^m (2m+p) \times \\ D_{o_{2m+p}} J_{2m+p}(2k \cosh \xi) \quad (4.21)$$

As in Article 4.4, it can be proved, by direct substitution in equation (4.2), that expansion (4.20) and (4.21) are solutions of the equation (4.2) and again as these are periodic functions with period π^2 or $2\pi^2$ corresponding to the functions with the same period, it follows that $J_{e_{2n}}$ are proportional to $C_{e_{2n}}$, $J_{o_{2n+1}}$ to $S_{e_{2n+1}}$

$J_{e_{2n+1}}$ to $C_{e_{2n+1}}$ and $J_{o_{2n+2}}$ to $S_{o_{2n+2}}$.

The J_e and J_o have been used in the computations in this work, as they are more convenient than the C_e and S_e .

The convergence of the above series is discussed at the end of this chapter.

4.6 Consider the reduced wave equation

$$\frac{\partial^2 G}{\partial x^2} + \frac{\partial^2 G}{\partial y^2} + k^2 G = 0 \quad (4.22)$$

From Chapter II, it is known that this equation takes the

form

$$\frac{\partial^2 G}{\partial \chi^2} + \frac{\partial^2 G}{\partial \mathcal{Y}^2} + 2\eta (\cosh 2\chi - \cos 2\mathcal{Y}) G = 0 \quad (4.23)$$

where $k, h = 2/q$, when the cartesian coordinates (x, y) are transformed to elliptic coordinates (χ, ξ) .

If in the above, $\chi = 2\xi$, so that $x = h \cos \xi \cos \zeta$,

$y = 2h \sin \xi \sin \zeta$ (these are the modified elliptic coordinates) equation (4.23) takes the form

$$\frac{\partial^2 G}{\partial \xi^2} - \frac{\partial^2 G}{\partial \zeta^2} + 2q (\cos 2\xi - \cos 2\zeta) G = 0 \quad (4.24)$$

It shall now be proved that any solution of the above equation (4.24) forms a nucleus for an integral equation involving a solution of the Mathieu's equation.^{2,19} The main aim of this theorem is to obtain a series expansion for the modified Mathieu function in a product of Bessel functions.

4.7 If (i) $\phi(\xi)$ is a function satisfying the Mathieu's equation for a particular value of a and q ,

(ii) $G(\xi, \zeta)$ is an analytic function of ξ, ζ

(ξ belongs to a region X in the complex ξ -plane, ζ belongs to a region Z in the complex ζ -plane) satisfying equation (4.24)

and (iii) (a) the values of the expression $\left[G(\xi, \zeta) \times \frac{d}{d\zeta} \phi(\zeta) - \frac{\partial G(\xi, \zeta)}{\partial \zeta} \phi(\zeta) \right]$ at the ends of a path C of integration, lying wholly within the Z -region of the ζ -plane, are the same

and also (b) $\int_C G(\xi, \zeta) \phi(\zeta) d\zeta$ exists for all ξ in X ,

and the integral converges uniformly in ξ for all ξ in X , if it is singular;

then

$$x(\xi) = \int_c G(\xi, \varsigma) \phi(\varsigma) d\varsigma$$

satisfies the Mathieu's equation for all ξ in X for the same a and q for which $\phi(\xi)$ satisfies Mathieu's equation.

Now the proof.

Because of the hypothesis (iii) (b), the integral $\int_c G(\xi, \varsigma) \phi(\varsigma) d\varsigma$ can be differentiated under the integral sign.

$$\text{Hence } \frac{d^2 x}{d\xi^2} = \int_c \frac{\partial^2 G}{\partial \xi^2}(\xi, \varsigma) \phi(\varsigma) d\varsigma$$

$$\text{Therefore } \frac{d^2 x}{d\xi^2} + (a - 2q \cos 2\xi)x = \int_c \left\{ \frac{\partial^2 G}{\partial \xi^2} + (a - 2q \cos 2\xi)G \right\} \phi(\varsigma) d\varsigma,$$

$$= \int_c \left\{ \frac{\partial^2 G}{\partial \xi^2} + (a - 2q \cos 2\varsigma)G \right\} \phi(\varsigma) d\varsigma \quad (4.25)$$

(from hypothesis (ii))

Integrating $\int_c \frac{\partial^2 G}{\partial \xi^2} \phi(\varsigma) d\varsigma$ by parts, we obtain

$$\begin{aligned} \int_c \frac{\partial^2 G}{\partial \xi^2} \phi(\varsigma) d\varsigma &= \left[\frac{\partial G}{\partial \xi} \phi(\varsigma) \right]_c - \int_c \frac{\partial G}{\partial \xi} \phi'(\varsigma) d\varsigma \\ &= \left[\frac{\partial G}{\partial \xi} \phi(\varsigma) \right]_c - \left[G \phi'(\varsigma) \right]_c + \int_c G \phi''(\varsigma) d\varsigma \\ &= \left[\phi(\varsigma) \frac{\partial G}{\partial \xi} - G \frac{d\phi}{d\varsigma} \right]_c + \int_c G \phi''(\varsigma) d\varsigma \\ &= \int_c \frac{d^2 \phi}{d\varsigma^2} G d\varsigma \end{aligned} \quad (4.26)$$

(due to hypothesis (iii) (a))

$$\text{so } \frac{d^2 x}{d\xi^2} + (a - 2q \cos 2\xi)x = \int_c \left[\frac{d^2 \phi}{d\varsigma^2} + (a - 2q \cos 2\varsigma)\phi \right] G d\varsigma$$

(from (4.25) and (4.26))

By hypothesis (i), ϕ satisfies Mathieu's equation hence the integral on the right vanishes and

$$\frac{d^2 x}{d\xi^2} + (a - 2q \cos 2\xi)x = 0$$

which shows that x satisfies the Mathieu's equation.

From above it follows that:

If $\phi(\xi)$ is a basically periodic solution of Mathieu's equation; $G(\xi, \xi')$ is symmetric in ξ, ξ' , with the same period as $\phi(\xi)$, and the integration is over any finite period of $\phi(\xi)$, then $\phi(\xi)$ satisfies the integral equation

$$\phi(\xi) = \lambda \int_c G(\xi, \xi') \phi(\xi') d\xi' \quad (4.27)$$

where the integral is not improper.

As the integrand is basically periodic in ξ , the integral itself is basically periodic in ξ . By the theorem above, it satisfies the same Mathieu equation as $\phi(\xi)$. Since there is only one basically periodic solution of this equation, the integral itself is a multiple of $\phi(\xi)$. Hence the equation (4.27). It may happen that the integral itself is zero, in which case λ can be taken to be infinite and the result holds.

4.8 Thus we know that any basically periodic solution of equation (4.24) in modified elliptic coordinates can be the nucleus of the integral equation (4.27).

Consider a solution of the reduced wave equation (4.22) in cylindrical polar coordinates.

Now $x = \rho \cos \theta$ and $y = \rho \sin \theta$,

which reduces the equation (4.22) to two second order linear equations

$$\frac{d^2 R}{d\rho^2} + \frac{1}{\rho} \frac{dR}{d\rho} + \left(k_1^2 - \frac{\nu^2}{\rho^2}\right) R = 0$$

$$\text{and } \frac{d^2 T}{d\theta^2} + \nu^2 T = 0 \quad (\nu \text{ a positive integer})$$

(see Chapter I)

where $G = R(\rho) T(\theta)$

Hence the solution of equation (4.22) can be given as

$$\begin{matrix} J_\nu(k_1 \rho) \\ Y_\nu(k_1 \rho) \end{matrix} \begin{cases} \cos(\nu \theta) \\ \sin(\nu \theta) \end{cases}$$

Since $x = h \cos \xi \cos \zeta$, $y = i h \sin \xi \sin \zeta$

$$\rho = h \left[\frac{1}{2} (\cos 2\xi + \cos 2\zeta) \right]^{1/2} \quad (4.28)$$

and since $k_1 h = 2/q$,

$$k_1 \rho = \left[2q (\cos 2\xi + \cos 2\zeta) \right]^{1/2}$$

The expressions for $\cos \theta$ and $\sin \theta$ are given as follows:

$$\cos \theta = \frac{\cos \xi \cos \zeta}{\left[\frac{1}{2} (\cos 2\xi + \cos 2\zeta) \right]^{1/2}} \quad \left(= \frac{x}{\rho} \right)$$

$$\sin \theta = \frac{i \sin \xi \sin \zeta}{\left[\frac{1}{2} (\cos 2\xi + \cos 2\zeta) \right]^{1/2}} \quad \left(= \frac{y}{\rho} \right)$$

DeMoivre's theorem gives $\cos \nu \theta + i \sin \nu \theta = (\cos \theta + i \sin \theta)^\nu$

Hence equating the real and imaginary parts and substituting the values of $\cos \theta$ and $\sin \theta$, the expressions for $\cos \nu \theta$ and $\sin \nu \theta$ are obtained.

Consider the expression

$$\int_0^\pi J_{2\nu}(k, \rho) \cos 2\nu \theta c e_{2\nu}(\xi, \eta) d\xi$$

Obviously $c e_{2\nu}(\xi, \eta)$ satisfies condition (i) Article 4.7. $J_{2\nu}(k, \rho)$ is symmetric in ξ and η (since ρ is symmetric in ξ and η) and since $\cos \nu \theta = \cos \left\{ \nu \cos^{-1} \left(\frac{\sqrt{2} \cos \xi \cos \eta}{(\cos 2\xi + \cos 2\eta)^{1/2}} \right) \right\}$, so is $\cos \nu \theta$ and for that matter, so is $\sin \nu \theta$.

Hence $J_{2\nu}(k, \rho) \cos 2\nu \theta$ satisfies condition (ii)

Article 4.7.

Since ρ, θ are periodic in ξ with period $\pi/2$, so is $J_{2\nu}(k, \rho) \cos 2\nu \theta$.

Hence condition (iii) (a) of article 4.7 is satisfied and so is condition (iii) (b), due to the nature of the function $J_{2\nu}(k, \rho) \cos 2\nu \theta$. As a result of Article 4.7,

$c e_{2\nu}$, therefore satisfies the integral equation

$$c e_{2\nu}(\xi, \eta) = \lambda \int_0^\pi J_{2\nu}(k, \rho) \cos 2\nu \theta c e_{2\nu}(\xi, \eta) d\xi \quad (4.29)$$

4.9 In the equation (4.29) let $\nu = 0$.

Then that equation can be written as

$$c e_{2n}(\xi, \eta) = \lambda \int_0^\pi J_0 \left[\left\{ 2\eta (\cos 2\xi + \cos 2\eta) \right\}^{1/2} \right] c e_{2n}(\xi, \eta) d\xi \quad (4.30)$$

Consider the addition formula for Bessel function of the

first kind and order zero.

$$J_0[(x^2+y^2+2xy\cos\theta)^{1/2}] = J_0(x)J_0(y) + 2\sum_{n=1}^{\infty} (-1)^n J_n(x)J_n(y)\cos n\theta \quad (4.31)$$

Let $x = ke^{i\xi}$, $y = ke^{-i\xi}$, then

$$\begin{aligned} J_0[(x^2+y^2+2xy\cos\theta)^{1/2}] &= J_0[(k^2e^{2i\xi} + k^2e^{-2i\xi} + 2k^2\cos\theta)^{1/2}] \\ &= J_0[\{2k^2(\cos 2\xi + \cos\theta)\}^{1/2}] \end{aligned}$$

If $\theta = 2\xi$ and $k^2 = q$

$$J_0[(x^2+y^2+2xy\cos\theta)^{1/2}] = J_0[\{2q(\cos 2\xi + \cos 2\xi)\}^{1/2}]$$

Therefore applying formula (4.31),

$$\begin{aligned} J_0[\{2q(\cos 2\xi + \cos 2\xi)\}^{1/2}] &= J_0(k^2e^{i\xi})J_0(k^2e^{-i\xi}) + 2\sum_{n=1}^{\infty} (-1)^n J_n(k^2e^{i\xi})J_n(k^2e^{-i\xi})\cos 2n\xi \\ &= J_0(k^2e^{i\xi})J_0(k^2e^{-i\xi}) + 2\sum_{n=1}^{\infty} (-1)^n J_n^2(k^2e^{i\xi})\cos 2n\xi \end{aligned}$$

If $\xi = 0$,

$$J_0(2k\cos\xi) = J_0^2(k) + 2\sum_{n=1}^{\infty} (-1)^n J_n^2(k)\cos 2n\xi$$

Therefore, from the integral equation (4.29)

$$\begin{aligned} ce_{2n}(0, \gamma) &= \lambda_{2n} \int_0^\pi [J_0^2(k) + 2\sum_{n=1}^{\infty} (-1)^n J_n^2(k)\cos 2n\xi] \times \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\xi d\xi \end{aligned}$$

Orthogonality of the circular functions gives

$$\int_0^\pi \cos 2n\xi \cos 2m\xi d\xi = \begin{cases} 0, & n \neq m \\ \pi/2, & n = m \end{cases} \quad (4.32)$$

and

$$\int_0^{\pi} \cos 2m\xi d\xi = 0 \quad (4.33)$$

Hence

$$\int_0^{\pi} \left[J_0^2(k) + 2 \sum_{n=1}^{\infty} (-1)^n J_n^2(k) \cos 2n\xi \right] \cos 2m\xi d\xi = (-1)^m \pi J_m^2(k)$$

Therefore

$$ce_{2n}(0, q) = \lambda_{2n} \pi \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_m^2(k)$$

$$\text{and so } \lambda_{2n} = \frac{ce_{2n}(0, q)}{\pi \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_m^2(k)} \text{ where } q=k^2 \quad (4.34)$$

A simpler expression for λ_{2n} can be obtained as follows:

If in the expansion (4.16) for ce_{2n} , we write 2ξ for ξ , it becomes

$$ce_{2n}(\xi, q) = \frac{ce_{2n}(\frac{\pi}{2}, q)}{A_0^{(2n)}} \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_{2m}(2k \cos \xi)$$

$$ce_{2n}(\xi, q) = \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\xi$$

Therefore

$$\sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\xi = \frac{ce_{2n}(\frac{\pi}{2}, q)}{A_0^{(2n)}} \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_{2m}(2k \cos \xi)$$

As the series on both sides of the above equation are uniformly convergent (see articles 4.3, 4.12), term by term integration is permissible. Integrating both sides with respect to ξ from 0 to π , we get

$$\int_0^{\pi} \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\xi d\xi = \frac{ce_{2n}(\frac{\pi}{2}, q)}{A_0^{(2n)}} \int_0^{\pi} \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_{2m}(2k \cos \xi) d\xi$$

or

$$\pi A_0^{(2n)} = \frac{ce_{2n}(\frac{\pi}{2}, q)}{A_0^{(2n)}} \pi \sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_m^2(k)$$

Therefore

$$\sum_{m=0}^{\infty} (-1)^m A_{2m}^{(2n)} J_m^2(k) = \frac{[A_0^{(2n)}]^2}{ce_{2n}(\frac{\pi}{2}, q)}$$

Hence

$$\lambda_{2n} = \frac{ce_{2n}(0, q) ce_{2n}(\frac{\pi}{2}, q)}{\pi [A_0^{(2n)}]^2} \quad (4.35)$$

Hence, from equation (4.30),

$$ce_{2n}(\xi, q) = \frac{ce_{2n}(0, q) ce_{2n}(\frac{\pi}{2}, q)}{\pi [A_0^{(2n)}]^2} \times \int_0^{\pi} J_0 \left[k \left\{ 2(\cos 2\xi + \cos 2\eta) \right\}^{1/2} \right] ce_{2n}(\eta, q) d\eta$$

Since $ce_{2n}(\eta, q) = \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\eta$

and

$$J_0 \left[k \left\{ 2(\cos 2\xi + \cos 2\eta) \right\}^{1/2} \right] = J_0(ke^{i\xi}) J_0(ke^{-i\xi}) + 2 \sum_{n=1}^{\infty} (-1)^n J_n(ke^{i\xi}) J_n(ke^{-i\xi}) \cos 2n\eta$$

$$\begin{aligned} ce_{2n}(\xi, q) &= \frac{ce_{2n}(0, q) ce_{2n}(\frac{\pi}{2}, q)}{\pi [A_0^{(2n)}]^2} \times \int_0^{\pi} \left[J_0(ke^{i\xi}) J_0(ke^{-i\xi}) \right. \\ &\quad \left. + 2 \sum_{n=1}^{\infty} (-1)^n J_n(ke^{-i\xi}) J_n(ke^{i\xi}) \cos 2n\eta \right] \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\eta d\eta \\ &= \lambda_{2n} \int_0^{\pi} J_0(ke^{i\xi}) J_0(ke^{-i\xi}) \sum_{m=0}^{\infty} A_{2m}^{(2n)} \cos 2m\eta d\eta \\ &\quad + 2\lambda_{2n} \int_0^{\pi} \sum_{n=1}^{\infty} \sum_{m=0}^{\infty} (-1)^n J_n(ke^{i\xi}) J_n(ke^{-i\xi}) A_{2m}^{(2n)} \cos 2n\eta \cos 2m\eta d\eta \end{aligned}$$

In the above equation, the first term gives

$$\lambda_{2n} J_0(ke^{i\xi}) J_0(ke^{-i\xi}) \pi A_0^{(2n)}, \text{ from equation (4.33)}$$

and the second term gives

$$\lambda_{2n} \pi \sum_{h=1}^{\infty} (-1)^h J_{2h}(ke^{i\xi}) J_{2h}(ke^{-i\xi}) A_{2h}^{(2n)}$$

Hence

$$ce_{2n}(\xi, q) = \lambda_{2n} \pi \sum_{h=0}^{\infty} (-1)^h A_{2h}^{(2n)} J_{2h}(ke^{i\xi}) J_{2h}(ke^{-i\xi}) \quad (4.36)$$

If in equation (4.36) we write $i\xi$ for ξ , the equation becomes

$$ce_{2n}(\xi, q) = \pi \lambda_{2n} \sum_{h=0}^{\infty} (-1)^h A_{2h}^{(2n)} J_{2h}(ke^{\xi}) J_{2h}(ke^{-\xi}) \quad (4.37)$$

where λ_{2n} has the value given by equations (4.34) or (4.35).

This is the expansion for $ce_{2n}(\xi, q)$ in Bessel function product series.

4.10 Obtaining a series of the form (4.37) for the other functions ce_{2n+1} , se_{2n+2} , se_{2n+1} is not as straight forward as above.

We obtain, for ce_{2n+1} , (say), a series of the form
constant $\times \cosh \xi \sum_{h=0}^{\infty} \bar{A}_{2h+1}^{(2n+1)} J_{2h+1}(ke^{i\xi}) J_{2h+1}(ke^{-i\xi})$

where $\bar{A}_{2h+1}^{(2n+1)}$ are not the same as $A_{2h+1}^{(2n+1)}$. This can be obtained using the method described in articles 4.7, 4.8 and 4.9.

We can also have expansions with the same coefficients, but in this case the expansion functions are more complicated. In what follows, a series expansion for $ce_{2n+1}(\xi, q)$ is obtained.

As in articles 4.7 and 4.8, it can be proved that

$$ce_{2n+1}(\xi, \eta) = \phi_{2n+1} \int_0^{2\pi} J_{2\nu+1}(k_1 \rho) \cos(2\nu+1)\theta \sum_{s=0}^{\infty} A_{2s+1}^{(2n+1)} \cos(2s+1)\eta d\eta$$

If we write 2ξ for ξ

$$ce_{2n+1}(\xi, \eta) = \phi_{2n+1} \int_0^{2\pi} J_{2\nu+1}(k_1 \rho) \cos(2\nu+1)\theta \sum_{s=0}^{\infty} A_{2s+1}^{(2n+1)} \cos(2s+1)\eta d\eta$$

where

$$k_1 \rho = k [2(\cos 2\eta + \cosh 2\xi)]^{1/2} = k(e^{2\xi} + e^{-2\xi} + 2\cos 2\eta)^{1/2}$$

For any cylinder function Z,

$$\frac{Z_\nu(\omega)}{\omega^\nu} = 2^\nu \Gamma(\nu) \sum_{m=0}^{\infty} \frac{(-1)^m (m+\nu) J_{m+\nu}(v_1) Z_{m+\nu}(v_2)}{v_1^\nu v_2^\nu} C_m^\nu(\cos 2\eta) \quad (4.38)$$

where $\omega^2 = v_1^2 + v_2^2 + 2v_1 v_2 \cos 2\eta$, $|v_1| < |v_2|$ and

C_m^ν are the Gegenbauer's polynomials, (coefficients of x^m in the expansion of $(1 - 2x \cos 2\eta + x^2)^\nu$ in the ascending powers of x), so that

$$C_m^\nu(\cos 2\eta) = \sum_{s=0}^{\leq m/2} \frac{(-1)^s 2^{m-2s} \Gamma(m+\nu-s) \cos^{m-2s} 2\eta}{(m-2s)! s! \Gamma(\nu)}$$

In particular if $\nu = 1$,

$$C_m^1(\cos 2\eta) = \sum_{s=0}^{\leq m/2} \frac{(-1)^s 2^{m-2s} \Gamma(m+1-s) \cos^{m-2s} 2\eta}{(m-2s)! s!}$$

From the above we obtain

$$\cos \eta C_m^1(\cos 2\eta) = \frac{\sin(2m+2)\eta}{2\sin \eta} = \sum_{p=0}^m \cos(2p+1)\eta$$

$$\begin{aligned} \text{(As } \sum_{p=0}^m 2\sin \eta \cos(2p+1)\eta &= \sin 2\eta + (\sin 4\eta - \sin 2\eta) + \dots \\ &\quad + [\sin(2m+2)\eta - \sin 2m\eta] \\ &= \sin(2m+2)\eta) \end{aligned}$$

$$\cos \theta = \frac{x}{\rho} = \frac{h}{\rho} \cosh \xi \cos \eta = \frac{2k \cosh \xi \cos \eta}{k_1 \rho}$$

If in equation (4.38) $Z_\nu = J_\nu$, $v_1 = k e^{-\xi}$, $v_2 = k e^{\xi}$ and $\nu = 1$

$$\begin{aligned} J_1(k_1 \rho) \cos \theta &= \frac{J_1(k_1 \rho)}{k_1 \rho} \cdot 2k \cosh \xi \cos \eta \\ &= 2k \cosh \xi \cdot 2 \sum_{m=0}^{\infty} \frac{(-1)^m (m+1) J_{m+1}(v_1) J_{m+1}(v_2)}{v_1 v_2} \times \\ &\quad C_m^1(\cos 2\eta) \cos \eta \\ &= \frac{4}{k} \cosh \xi \sum_{m=0}^{\infty} (-1)^m (m+1) \omega_{m+1} \sum_{p=0}^m \cos(2p+1)\eta \\ &\quad \text{(as } v_1 v_2 = k^2) \end{aligned}$$

where $\omega_{m+1} = J_{m+1}(v_1) J_{m+1}(v_2)$

Hence

$$\begin{aligned} C_{e_{2n+1}}(\xi, \eta) &= \phi_{2n+1} \frac{4}{k} \cosh \xi \sum_{m=0}^{\infty} (-1)^m (m+1) \omega_{m+1} \times \\ &\quad \int_0^{2\pi} \sum_{p=0}^m \cos(2p+1)\eta \sum_{s=0}^{\infty} A_{2s+1}^{(2n+1)} \cos(2s+1)\eta d\eta \end{aligned}$$

As

$$\int_0^{2\pi} \cos(2p+1)\eta \cos(2s+1)\eta d\eta = \begin{cases} 0, & p \neq s \\ \pi, & p = s \end{cases}$$

Now

$$\begin{aligned} (m+1) \int_0^{2\pi} \sum_{p=0}^m \cos(2p+1)\eta \sum_{s=0}^{\infty} A_{2s+1}^{(2n+1)} \cos(2s+1)\eta d\eta \\ = \pi (m+1) (A_1 + A_3 + A_5 + \dots + A_{2m+1}) \end{aligned}$$

$$= \pi \bar{A}_{2m+1}^{(2n+1)} \quad (\text{say})$$

Then

$$C e_{2n+1}(\xi, \eta) = \phi_{2n+1} \frac{4\pi \cosh \xi}{k} \sum_{m=0}^{\infty} (-1)^m A_{2m+1}^{(2n+1)} J_{m+1}(k e^{\xi}) J_{m+1}(k e^{-\xi})$$

$$\text{where } A_{2m+1}^{(2n+1)} = (m+1) \left(A_1^{(2n+1)} + A_3^{(2n+1)} + A_5^{(2n+1)} + \dots + A_{2m+1}^{(2n+1)} \right).$$

To obtain the series with $A_{2\lambda+1}^{(2n+1)}$ as coefficients,¹⁹

$$\text{consider } W_{\lambda} = J_{\lambda}(v_1) J_{\lambda+1}(v_2) + J_{\lambda+1}(v_1) J_{\lambda}(v_2)$$

Using the recurrence relation

$$J_n(x) = \frac{2(n+1)}{x} J_{n+1}(x) - J_{n+2}(x),$$

$$\begin{aligned} W_{\lambda} &= J_{\lambda+1}(v_2) \left[\frac{2(\lambda+1)}{v_1} J_{\lambda+1}(v_1) - J_{\lambda+2}(v_1) \right] \\ &\quad + J_{\lambda+1}(v_1) \left[\frac{2(\lambda+1)}{v_2} J_{\lambda+1}(v_2) - J_{\lambda+2}(v_2) \right] \\ &= 2(\lambda+1) J_{\lambda+1}(v_1) J_{\lambda+1}(v_2) \left[\frac{1}{v_1} + \frac{1}{v_2} \right] \\ &\quad - \left[J_{\lambda+1}(v_2) J_{\lambda+2}(v_1) + J_{\lambda+1}(v_1) J_{\lambda+2}(v_2) \right] \\ &= \frac{4(\lambda+1) \cosh \xi}{k} \omega_{\lambda+1} - W_{\lambda+1} \end{aligned}$$

Using this recurrence relation,

$$W_{\lambda} = \frac{4}{k} \cosh \xi \left[(\lambda+1) \omega_{\lambda+1} - (\lambda+2) \omega_{\lambda+2} + (\lambda+3) \omega_{\lambda+3} - \dots \right]$$

$$\text{so } \sum_{m=0}^{\infty} (-1)^m A_{2m+1}^{(2n+1)} W_m$$

$$\begin{aligned} &= \frac{4}{k} \cosh \xi \left[A_1^{(2n+1)} (\omega_1 - 2\omega_2 + 3\omega_3 - \dots) - A_3^{(2n+1)} (2\omega_2 - 3\omega_3 + 4\omega_4 - \dots) \right. \\ &\quad \left. + A_5^{(2n+1)} (3\omega_3 - 4\omega_4 + \dots) - \dots \right] \end{aligned}$$

$$= \frac{4}{k} \cosh \xi \sum_{m=0}^{\infty} (-1)^m (m+1) \left(A_1^{(2n+1)} + A_3^{(2n+1)} + \dots + A_{2m+1}^{(2n+1)} \right) \omega_{m+1}$$

$$= \frac{4}{k} \cosh \xi \sum_{m=0}^{\infty} (-1)^m A_{2m+1}^{(2n+1)} J_{m+1}(k e^{\xi}) J_{m+1}(k e^{-\xi})$$

Hence

$$ce_{2n+1}(\xi, q) = \pi \phi_{2n+1} \sum_{m=0}^{\infty} (-1)^m A_{2m+1}^{(2n+1)} W_m$$

where

$$W_m = J_m(ke^{-\xi}) J_{m+1}(ke^{\xi}) + J_m(ke^{\xi}) J_{m+1}(ke^{-\xi})$$

The value of ϕ_{2n+1} can be found as in Article (4.9),

$$\phi_{2n+1} \text{ corresponds to } \lambda_{2n}, \phi_{2n+1} = - \frac{ce_{2n+1}(0, q) ce'_{2n+1}(\frac{\pi}{2}, q)}{\pi k [A_1^{(2n+1)}]^2}$$

On the same lines as these, the expansions for Se_{2n+1} and Se_{2n+2} are obtained and are given as follows:

$$Se_{2n+1}(\xi, q) = \frac{se'_{2n+1}(0, q) se_{2n+1}(\frac{\pi}{2}, q)}{k [B_1^{(2n+1)}]^2} \sum_{m=0}^{\infty} (-1)^m B_{2m+1}^{(2n+1)} W_m$$

where

$$W_m = J_m(v_1) J_{m+1}(v_2) - J_{m+1}(v_1) J_m(v_2)$$

and

$$Se_{2n+2}(\xi, q) = - \frac{se'_{2n+2}(0, q) se'_{2n+2}(\frac{\pi}{2}, q)}{k^2 [B_2^{(2n+2)}]^2} \sum_{m=0}^{\infty} (-1)^m B_{2m+2}^{(2n+2)} W_m$$

where

$$W_m = J_m(v_1) J_{m+2}(v_2) - J_{m+2}(v_1) J_m(v_2)$$

These expansions of the modified Mathieu functions can also be obtained by another method - see Dougall 8, McLachlan 19.

4.11 As in Article 4.5, functions $Je_{2n}, Je_{2n+1},$

Jo_{2n+2}, Jo_{2n+1} can now be written down as

$$Je_{2n}(s, \xi) = \sqrt{\frac{\pi}{2}} \frac{(-1)^n}{De_0} \sum_{h=0}^{\infty} (-1)^h De_{2n} J_h(u) J_h(v)$$

$$Je_{2n+1}(s, \xi) = \frac{(-1)^n}{De_1} \sqrt{\frac{\pi}{2}} \sum_{h=0}^{\infty} (-1)^h De_{2n+1} \times$$

(4.39)

$$\left[J_{h+1}(u) J_h(v) + J_h(u) J_{h+1}(v) \right]$$

$$J_{0_{2n+2}}(\delta, \xi) = \frac{(-1)^n}{D_{02}} \sqrt{\frac{\pi}{2}} \sum_{h=0}^{\infty} (-1)^h D_{0_{2h+2}} \times \\ \left[J_{h+2}(u) J_h(v) - J_{h+2}(v) J_h(u) \right]$$

$$J_{0_{2n+1}}(\delta, \xi) = \frac{(-1)^n}{D_{01}} \sqrt{\frac{\pi}{2}} \sum_{h=0}^{\infty} (-1)^h D_{0_{2h+1}} \times \\ \left[J_{h+1}(u) J_h(v) - J_h(u) J_{h+1}(v) \right]$$

$$\text{where } u = \frac{\sqrt{\delta}}{2} e^{\xi} \quad \text{and} \quad v = \frac{\sqrt{\delta}}{2} e^{-\xi}$$

Though for computational work these expansions are not convenient, they are helpful in as much as they provide an independent means of evaluating the functions.

In the next article it will be proved that these expansions converge much faster than expansions in Article 4.5.

4.12 Let u_n denote the n th term in the expansion of $J_{e_{2n+p}}$, equation (4.20)

Then

$$u_n = \sqrt{\frac{\pi}{2}} (-1)^{n+n} D_{e_{2n+p}} J_{2n+p}(2k \cosh \xi)$$

and

$$u_{n+1} = \sqrt{\frac{\pi}{2}} (-1)^{n+n+1} D_{e_{2n+p+2}} J_{2n+2+p}(2k \cosh \xi)$$

When $2n$ is very large in comparison with the argument $2k \cosh \xi$ of the Bessel function,

$$J_{2n+p}(2k \cosh \xi) \text{ is (asymptotically) } = \frac{1}{(2n+p)!} (k \cosh \xi)^{2n+p} \quad 18$$

$$\text{Hence } \frac{u_{n+1}}{u_n} = - \frac{D_{e_{2n+p+2}}}{D_{e_{2n+p}}} \frac{(k \cosh \xi)^2}{(2n+p+2)(2n+p+1)}$$

$$\text{But } \left| \frac{D_{e_{2n+p+2}}}{D_{e_{2n+p}}} \right| \rightarrow \frac{|k|^2}{4(n+1)^2} \quad \text{as } n \rightarrow \infty$$

$$\text{Hence } \left| \frac{u_{n+1}}{u_n} \right| \rightarrow \frac{|k|^4 |\cosh^2 \xi|}{4(n+1)^2 \cdot 4(n+1)^2} \quad \text{whether } p \text{ is } 0 \text{ or } 1. \quad (4.40)$$

As $n \rightarrow \infty$, the above expression tends to zero, and so by the ratio test the series is absolutely convergent.

As $\frac{|k^4| |\cosh^2 \xi|}{16(n+1)^4} \rightarrow 0$ faster than $\frac{|k^2| e^{2|\xi|}}{4(n+1)^2}$ (see Article 4.3)

expansions (4.20), (4.21) converge faster than expansions (4.6).

Now, in any finite closed region of the ξ -plane, for a given q , it is possible to find an 'M', independent of ξ such that $|k^4| |\cosh^2 \xi| \leq 16M(n+1)^4$ as $n \rightarrow \infty$

Hence by 'M' test the series are uniformly convergent and term by term integration or differentiation with respect to ξ is permissible in any finite region of the ξ -plane.

Differentiating Te_{2n} with respect to ξ ,

$$\frac{d}{d\xi} Te_{2n}(\xi, q) = 2k \sinh \xi (-1)^n \frac{\pi}{\sqrt{2}} \sum_{m=0}^{\infty} (-1)^m 2^m De_{2m} J'_{2m}(2k \cosh \xi)$$

$$\text{Hence } \left| \frac{u_{n+1}}{u_n} \right| = \left| \frac{De_{2n+2}}{De_{2n}} \cdot \frac{(2n+2)}{2n} \cdot k^2 \cosh^2 \xi \frac{(2n)!}{(2n+2)!} \right|$$

(when $2n$ is very large compared to $2k \cosh \xi$)

$$\sim \frac{|k^4| |\cosh^2 \xi|}{16(n+1)^4} \left(1 + \frac{1}{n}\right) \rightarrow 0 \text{ as } n \rightarrow \infty. \quad (4.41)$$

Hence the above series is absolutely convergent and as above it can also be proved that it is uniformly convergent.

In a similar manner, it can be proved that the other modified Mathieu functions Te_{2n+1} , To_{2n+1} and To_{2n+2} and their derivatives are absolutely and uniformly convergent.

As the functions Ce_m , Se_m differ from the above functions Je_m , Y_0m only by factors, which are independent of ξ , it can be proved that they and their derivatives are also uniformly and absolutely convergent.

Consider now the expansions given in a series of products of Bessel functions.

If W_n denotes the coefficient of A_{2n+p} or B_{2n+p} in the appropriate expansion,

$$\left| \frac{W_{n+1}}{W_n} \right| \simeq \frac{q}{4(n+1)^2}$$

Consider, for example $W_n = J_n(v_1)J_{n+2}(v_2) - J_{n+2}(v_1)J_n(v_2)$,
 $v_1 = ke^{-\xi}$, $v_2 = ke^{\xi}$ and $q = k^2$

If n is very large compared to v_1 or v_2

$$J_n(v_1) \simeq \frac{1}{n!} \left(\frac{k}{2} e^{-\xi} \right)^n, \quad J_{n+2}(v_2) \simeq \frac{1}{(n+2)!} \left(\frac{k}{2} e^{\xi} \right)^{n+2}$$

$$\text{Hence } |W_n| \simeq \frac{1}{n!} \frac{1}{(n+2)!} \frac{k^{2n+2}}{2^{2n}} |e^{2\xi} - e^{-2\xi}|$$

$$\text{So } \left| \frac{W_{n+1}}{W_n} \right| \simeq \frac{k^2}{4(n+1)^2}$$

$$\text{Therefore } \left| \frac{u_{n+1}}{u_n} \right| \simeq \left| \frac{A_{2n+2}}{A_{2n}} \right| \frac{k^2}{4(n+1)^2}$$

$$\simeq \frac{k^4}{16(n+1)^4} \rightarrow 0 \text{ as } n \rightarrow \infty \quad (4.42)$$

Comparing (4.40) and (4.42), it can be seen that the series (4.39) converge more rapidly than (4.20), (4.21).

The uniform convergence of the series and hence the absolute and uniform convergence of the derivatives is easily proved and it can also be proved that the derivatives of the series (4.39) converge faster than the derivatives of the series (4.20), (4.21).

5. METHOD OF FINDING THE HIGHER ORDER
CUT-OFF FREQUENCIES.

5.1 The three sets of expansions for the modified Mathieu functions (and hence their derivatives) obtained in Chapter IV, are uniformly and absolutely convergent for a given q and for any given order of the function, so long as ξ remains finite. For the evaluation of the functions any of these expansions can be used. The expansions (4.6) converge but slowly and even though expansions (4.39) converge extremely rapidly, they are not so convenient for computation purposes. Hence the expansions (4.20), (4.21) are the most appropriate ones for any computational work. The expansions (4.39) are independently obtained. Hence they are most useful when the accuracy of the results which have been obtained earlier by using expansions (4.20), (4.21) is to be checked.

5.2 As mentioned in Chapter III, the calculation of the cut-off frequencies are obtained by finding the parametric zeros of

$$Ce'_m(\xi_0, q) = 0 \quad \text{and} \quad Se'_{m+1}(\xi_0, q) = 0; \quad m = 0, 1, 2, \dots$$

where ξ_0 is such that if e is the eccentricity of the elliptic boundary, $\cosh \xi_0 = 1/e$.

In the expansions of $Ce_m(\xi, q)$ and $Se_{m+1}(\xi, q)$ the coefficients themselves are functions of q and hence the functions can be evaluated for each ξ , only for a given q . So even if ξ_0 is known it is not practicable to find the parametric zeros directly. So we adopt the following method.

For a given order m , for each value of s , the value $\omega_0 = \sqrt{s \cosh \xi_0}$, which makes the function Ce_m or Se_{m+1} zero is calculated.

From equation (3.10) which gives

$$e = \frac{\sqrt{s}}{\omega_0}$$

the eccentricity e of the ellipse is calculated. Once e is known, from equation (3.11), $k = \omega_0 (1 - e^2)^{1/4}$ the eigen values k (i.e. the cut-off frequencies) are found. But the e obtained here are not the required values, the values to be found being for ellipses of eccentricities $e = .1 (.1) .9$ and $e = .95$. Hence by linear iterated interpolation the values of k corresponding to the required e 's are obtained. Tables A (1-15) and Tables B (1-15) give the e and k obtained for the various values of s . Tables C and D give the values of k for the $e = .1 (.1) .9$ and $e = .95$ for even and odd radial functions respectively of orders 1-15. These cut-off frequencies have been calculated for ellipses each of area π , so that while the eccentricity varies, the area has been kept constant. When the cut-off frequency in an elliptic duct of a particular eccentricity e of cross section, but not of area π , is required, equation (3.8) can be used to obtain the result.

5.3 From Chapter IV, Article 4.5, it is known that $Ce'_m(\xi, \eta)$ are proportional to $Je'_m(\xi, \delta)$ and $Se'_{m+1}(\xi, \eta)$ are proportional to $Jo'_{m+1}(\xi, \delta)$, where $\delta = 4\eta$; the constant of proportionality is a function of η . These are called 'joining factors' and are tabulated in 'Tables Relating to Mathieu Functions'.²² The value of ξ which

be considered to a fixed number of term depending ofcourse on the order of the function, the value of s and the needed accuracy of the result.

The coefficients De and Do, correct to nine significant figures, for given values of s (at certain intervals) up to 100 have been tabulated²² for functions of up to order 15.

5.31 A computer program subroutine^{*} (in Fortran IV) calculates the values (up to a required accuracy) of Bessel functions, up to a few orders less than 200 for the same argument.^{1,15}

Let $J_n(x) = 0$ for a 'n' very large compared to the argument and let $J_{n-1}(x) = 10^{-70}$

With the help of the recurrence relation

$$J_{n-1}(x) + J_{n+1}(x) = \frac{2n}{x} J_n(x)$$

that is $J_{n-1}(x) = \left(\frac{2n}{x}\right) J_n(x) - J_{n+1}(x)$

the values of Bessel functions with decreasing n are successively evaluated for the same argument x.

Then the factor A, such that

$$\frac{1}{A} = J_0(x) + 2J_2(x) + 2J_4(x) + \dots$$

is obtained and each value of $J_n(x)$ obtained earlier is multiplied by A to give the required values of the Bessel functions of all orders up to a few orders less than n.

This method avoids the accumulation of rounding errors which occur when $n > x$ and the recurrence relation is used with ascending n.

5.32 It now becomes possible to compute the values of

$$J_e'{}_m \quad (\text{or } J_o'{}_m) \quad \text{for a given s and a given } \sqrt{s} \cosh \xi (= \omega).$$

^{*} used with the kind permission of Dr. M.V. Lowson.

makes ce'_m vanish for a given value of q hence would not differ from that, which makes Je'_m zero for the same q . Hence without any loss of generality the functions $Je'_m(\xi, s)$ and $Jo'_{m+1}(\xi, s)$ can be considered. Now $Je_{2n+p}(\xi, s) = (-1)^n \sqrt{\frac{\pi}{2}} \sum_{h=0}^{\infty} (-1)^h De_{2n+p} J_{2n+p}(\sqrt{s} \cosh \xi)$ $p = 0$ or 1 according as a function of period πi or $2\pi i$ is being considered.

Due to uniform convergence (Article 4.12), we can differentiate Je_{2n+p} , Jo_{2n+p} with respect to ξ , term by term.

Hence $Je'_{2n+p}(\xi, s) = (-1)^n \sqrt{\frac{\pi s}{2}} \sinh \xi \sum_{h=0}^{\infty} (-1)^h De_{2n+p} J'_{2n+p}(\sqrt{s} \cosh \xi)$ which can be written as ²⁹

$$Je'_{2n+p}(\xi, s) = (-1)^n \sqrt{\frac{\pi s}{2}} \sinh \xi \sum_{h=0}^{\infty} (-1)^h De_{2n+p} \times \left[J_{2n+p-1}(\sqrt{s} \cosh \xi) - J_{2n+p+1}(\sqrt{s} \cosh \xi) \right] \quad (5.1)$$

(from a recurrence relation for Bessel functions).

Similarly

$$\begin{aligned} Jo'_{2n+p}(\xi, s) &= \frac{d}{d\xi} \left[(-1)^n \sqrt{\frac{\pi}{2}} \tanh \xi \sum_{h=0}^{\infty} (-1)^h (2n+p) Do_{2n+p} J_{2n+p}(\sqrt{s} \cosh \xi) \right] \\ &= (-1)^n \sqrt{\frac{\pi s}{2}} \tanh \xi \sinh \xi \sum_{h=0}^{\infty} (-1)^h (2n+p) Do_{2n+p} J'_{2n+p}(\sqrt{s} \cosh \xi) \\ &\quad + (-1)^n \sqrt{\frac{\pi}{2}} \frac{1}{\cosh^2 \xi} \sum_{h=0}^{\infty} (-1)^h (2n+p) Do_{2n+p} J_{2n+p}(\sqrt{s} \cosh \xi) \\ &= \frac{Jo_{2n+p}}{\sinh \xi \cosh \xi} + (-1)^n \sqrt{\frac{\pi s}{2}} \tanh \xi \sinh \xi \times \\ &\quad \sum_{h=0}^{\infty} (2n+p) Do_{2n+p} \left[J_{2n+p-1}(\sqrt{s} \cosh \xi) - J_{2n+p+1}(\sqrt{s} \cosh \xi) \right] \quad (5.2) \end{aligned}$$

It is of importance to note here that though in principle the series is infinite, due to the rapid decrease of the coefficients to zero, for a given s , the series need only

A program evaluates the values of $Je'_m (Jo'_m)$ for values of w starting with $\sqrt{s}$ (which means $\omega = \sqrt{s} \cosh \xi = \sqrt{s}$, or $\cosh \xi = 1$ or $\xi = 0$) (we know the value of Je'_m for $\xi = 0$ is zero). The values of w increase by increments of 0.5 or 0.1 depending on the value of s and the order of the function. When the function changes sign from positive to negative, by chord iterative inverse interpolation¹⁷ the value ω_0 of ω which makes the function $Je'_m (Jo'_m)$ vanish is obtained.

Suppose $Je'(1)$ for a value $w(1)$ of w is positive and $Je'(k)$ is negative for $w(k)$. Then a better approximation to the zero of the function is obtained by the intersection of the line through $(\omega(1), Je'(1))$ and $(\omega(k), Je'(k))$ with the X-axis (where the ω is along the X-axis and Je' along the Y-axis).

The equation of the line is given by

$$Je' - Je'(k) = \frac{Je'(1) - Je'(k)}{\omega(1) - \omega(k)} [\omega - \omega(k)]$$

$$\begin{aligned} \text{So that } \omega(k+1) &= \omega(k) - Je'(k) \frac{\omega(1) - \omega(k)}{Je'(1) - Je'(k)} \\ &= \frac{\omega(k) Je'(1) - \omega(1) Je'(k)}{Je'(1) - Je'(k)} \end{aligned}$$

gives a nearer value to the zero. We can find $Je'(k+1)$ for this $\omega(k+1)$ and apply the above formula again replacing k by $k+1$. This process can be continued until the required accuracy is obtained. The program provides for 18 such iterations and the result obtained is accurate to 8 significant figures. If even after 18 iterations the accuracy required is not obtained, it shows that ω has been incremented excessively. Hence a smaller increment to ω is to be given.

With this value of ω_0 , e and k are found in a straight-forward manner from equations (3.10) and (3.11). Since the values of ω_0 are correct to eight significant figures and the values of $\sqrt{\lambda}$ are correct to eleven significant figures (due to computer limitations) the values of e are correct to eight significant figures at least and the values of k have an accuracy of seven significant figures. All this has been said on the assumption that the values of the function $J_{e'_m}(J_{o'_m})$ are correct to eight significant figures.

With the help of expansions (4.39), the values of function $J_{e'_m}(J_{o'_m})$ were calculated and from these the values of ω_0 , e and k were obtained as mentioned above. It was found that accuracy of eight significant figures has been maintained for ω_0 so that e and k are respectively accurate as mentioned above.

5.4 The values of e , obtained in the previous article, are at irregular intervals. They are, however, in an ascending order of magnitude. To obtain the values of k for $e = .1$ (.1) .9 and $e = .95$, the method of linear iterated interpolation is applied.²⁴

Let x_i be the values of a variable and let values $f(x_i)$ of a function f be known for these x_i . Let x be an interior point (between the smallest and the largest of x_i) and we are to find the value of the function for this x . We calculate, successively, the functions $f_2(x_i, x_{i+1})$, $f_3(x_i, x_{i+1}, x_{i+2})$, ...

$$\text{where } f_2(x_i, x_{i+1}) = \frac{(x_i - x)f(x_{i+1}) - (x_{i+1} - x)f(x_i)}{(x_i - x) - (x_{i+1} - x)}$$

$$f_3(x_i, x_{i+1}, x_{i+2}) = \frac{(x_i - x)f(x_{i+1}, x_{i+2}) - (x_{i+2} - x)f(x_i, x_{i+1})}{(x_i - x) - (x_{i+2} - x)}$$

etc., until we obtain the final convergent. For example, if $i=7$, we have to obtain $f_7(x_1, x_2, x_3, x_4, x_5, x_6, x_7)$. The final convergent gives the value of $f(x)$ at x . If the $x_i - x$ are so arranged that $|x_i - x|$ are in an ascending order, the convergence is rapid and a more accurate result is obtained.

The program from which the values of k for particular values of e are obtained, incorporates the above and the results so obtained are given in Tables C and D. These values are accurate to six significant figures.

The values of k corresponding to $e = 0$, (which is a circle) were obtained from Olver.²³

5.5 The method described above was followed and the values of the cut-off frequencies for ellipses of the required eccentricities were obtained.¹⁶ However, there were two main hurdles to be overcome.

(1) For higher values of e , but smaller orders of the function, the above program did not converge so fast so that the results obtained were not sufficiently accurate.

(2) For large orders of the function, the cut-off frequencies could not be found, as values of coefficients for Δ larger than 100 were needed in this case and these are not tabulated in National Bureau of Standards.²²

In the first case, the values k decreased more rapidly as e increased. Hence it was necessary that more values of k be calculated nearer the required eccentricities.

Hence for larger values of s , smaller increments in s were to be considered. The characteristic values b_{e_n} , b_{o_n} ($a_n = b_{e_n} - s/2$ and $b_n = b_{o_n} - s/2$) * are tabulated at smaller intervals of s in National Bureau of Standards.²² If the coefficients D_e (D_o) could be generated from these characteristic values, then the functions could be evaluated by the method described above and then the values of ω_0 , e , and k computed.

In the second case, the characteristic values for s larger than 100 have been tabulated in Blanch and Rhodes 5. Here the tabulation has been done for values of t and the characteristic numbers $B_{e_n}(t)$ and $B_{o_n}(t)$ are given, where

$$t = 1/\sqrt{s}$$

$$B_{e_n}(t) = b_{e_n}(s) - \nu_1 \sqrt{s}, \quad \text{where } \nu_1 = 2n+1$$

and

$$B_{o_n}(t) = b_{o_n}(s) - \nu_2 \sqrt{s}, \quad \text{where } \nu_2 = 2n-1$$

The range of t is $0 \leq t \leq 1$ so that s ranges from ∞ to 100. The characteristic values a_n and b_n for a given s can be obtained from $a_n = b_{e_n}(s) - s/2$ and $b_n = b_{o_n}(s) - s/2$, which are obtained from B_{e_n} and B_{o_n} . Once again, when the characteristic values are known, the problem just reduces to one of generating the coefficients D_{e_m} (D_{o_m}).

5.6 The method of obtaining the characteristic values a (or b) for the Mathieu's equation for a given value of $q (=4s)$ and then generating the coefficients from these values is given in Ince,¹² Goldstein,⁹ McLachlan.¹⁹ A detailed method by which the coefficients of expansion can

* See expansions 4.6

be found, once the characteristic values are known is given in Blanch 4, and it has been found most useful, when the coefficients have to be found for low order functions with not too high q and for high order functions with large q . The method is discussed in detail below.

Substituting the expansions (4.3) in the Mathieu's equation (4.1) and equating the coefficients of $\cos m\eta$ (or $\sin m\eta$) to zero, the following relations are obtained:

$$A_2 = \nu_0 A_0, \nu_2 A_2 - 2A_0 = A_4; A_3 = A_1(\nu_1 - 1) \quad (5.3)$$

$$B_0 = 0, B_4 = \nu_2 B_2; B_3 = B_1(\nu_1 + 1) \quad (5.4)$$

$$\left. \begin{array}{l} \text{and} \\ A_{m-2} + A_{m+2} = \nu_m A_m \\ \text{or} \\ B_{m-2} + B_{m+2} = \nu_m B_m \end{array} \right\} m \geq 4 \quad (5.5)$$

$$\text{where } \nu_m = \frac{a - m^2}{q} \quad \text{or} \quad \frac{b - m^2}{q} \quad (5.6)$$

a (or b) being the characteristic value of the function.

$$\text{If } G_m = \frac{A_m}{A_{m-2}} \quad \text{or} \quad \frac{B_m}{B_{m-2}}, \quad \text{and} \quad H_m = \frac{1}{G_m}$$

then the above equations reduce to

$$G_2 = \nu_0, G_4 = \nu_2 - \frac{2}{G_2} = \nu_2 - 2H_2 = \frac{1}{\nu_1 - G_6}, \quad \text{for } ce_{2n} \quad (5.7)$$

$$G_3 = \nu_1 - 1 = \frac{1}{\nu_3 - G_5} \quad \text{for } ce_{2n+1} \quad (5.8)$$

$$H_2 = 0, \quad G_4 = v_2 = \frac{1}{v_4 - G_6} \quad \text{for } \Delta e_{2n+1} \quad (5.9)$$

$$G_3 = v_{1+1} = \frac{1}{v_3 - G_5} \quad \text{for } \Delta e_{2n+2} \quad (5.10)$$

$$\text{And in general } G_m = \frac{1}{v_m - G_{m+2}}, \quad m \geq 3 \quad (5.11)$$

$$\text{and } G_m = v_{m-2} - \frac{1}{G_{m-2}} = v_{m-2} - H_{m-2}, \quad m \geq 5 \quad (5.12)$$

Since the series (4.3) are absolutely convergent for given values of q , there is a number M for each series such that

$$|G_m| < 1, \quad \text{for } m \geq M$$

Let m_1 be one such value. Then v_{m_1} has a very large numerical value.

Since

$$|G_{m_1}| = |v_{m_1-2} - H_{m_1-2}| < 1$$

the magnitude of H_{m_1-2} must be of the same order as that of v_{m_1-2} and also it must have the same sign as v_{m_1-2} . This means there will be a loss of considerable number of significant figures when H_{m_1-2} is subtracted from v_{m_1-2} . No doubt, the values of the coefficients do decrease rapidly in this region; however, the loss of accuracy of the result, if this formula were used is more and hence it is not possible to generate all the G_m from this formula. Once the $G_2, G_4, \dots$ (or $G_1, G_3, \dots$) have been evaluated, the coefficients $AD_0, AD_2, \dots$ (or $AD_1, AD_3, \dots$), can be found, A being an arbitrary

constant. (Without any loss of generality, we use D_m to represent coefficient A_m or B_m , since for a characteristic value 'a' or 'b' gives rise to only one periodic solution, when q is not zero and no confusion arises as to the type of coefficients considered.)

Of the four type of solutions considered, only the first (even function with period π) is a bit complicated. The rest can be obtained without much difficulty. So we shall consider even functions of period π .

Initially the coefficients D_m are all positive and they increase up to a largest coefficient, say, D_ν and then they start decreasing so that

$$D_{\nu+n} < D_{\nu+n-2}, \quad n \geq 2$$

This means

$$G_{\nu+n} < 1, \quad \text{if } n > 0$$

and

$$G_{\nu-n} > 1, \quad \text{if } n > 0$$

Since the coefficients decrease to zero, let us suppose that the series is terminated after a certain number of terms for the required accuracy. From the order of the function and the value of q , it is possible to determine this number without much difficulty. Let D_w be the last term of the series.

We first compute the values of $\nu_0, \nu_2, \dots, \nu_w$ from equation (5.6) to the required number of significant figures, which is the number of significant figures needed in the largest coefficient D_m .

After this, the quantities $G_2, H_2, G_4, H_4, \dots$, G_{2j}, H_{2j} are evaluated, where each G_m is computed from equations (5.7) or (5.12) and the H_m are obtained as reciprocals of G_m . The computation continues until the G_m are numerically greater than unity, G_{2j} being the last of these. The computation in this direction is now stopped after H_{2j} has been found. This is known as the 'forward' process.

Since D_w is the last term of the series, it will be very near zero, and we can write

$$G_w \simeq \frac{1}{v_w} \quad \text{(Actually } G_w = \frac{1}{v_w - G_{w+2}}, \text{ but since } v_w \text{ is very large and } G_{w+2} \text{ negligible, we get the result)}$$

From G_w , the values of $H_{w-2}, H_{w-4}, \dots, H_{2j}$ are obtained from equation (5.12), as that equation gives

$$H_{m-2} = v_m - G_m$$

The G_m are now obtained as the reciprocals of H_m . $G_{w-2} = 1/H_{w-2}$ and so on. In these calculations the number of significant figures obtained increases in accuracy at each step until a maximum accuracy is reached. The last value obtained in this process is H_{2j} . This is known as the 'backward' process.

The value of H_{2j} obtained here is compared with the value of H_{2j} obtained earlier. If the agreement is satisfactory (if, for example, we desire to have the largest coefficient to nine significant figures, the two values of H_{2j} should agree to that extent), The coeffi-

coefficients can now be determined.

The coefficients so determined can then be normalised in the manner required.

We now write $D_\nu = 1$.

The remaining coefficients D_m are obtained by the relationships

$$D_{\nu+2} = G_{\nu+2}, \quad D_{\nu+4} = D_{\nu+2} G_{\nu+4}, \quad \dots, \quad D_\omega = D_{\omega-2} G_\omega$$

$$D_{\nu-2} = H_\nu, \quad D_{\nu-4} = D_{\nu-2} H_{\nu-2}, \quad \dots, \quad D_0 = D_2 H_2, \quad \nu \geq 2$$

If $\nu = 0$, $D_0 = 1$, $D_2 = G_2$, and so on.

To obtain the coefficients De_{2m} ,

$$\text{Let } A = \sum_{n=0}^{\omega} D_{2n} = 1$$

$$\text{Then each } De_{2n} = D_{2n} / A$$

Methods have to be found to increase the accuracy, when the values of H_ν , found by the two processes do not agree to the required number of significant figures.

The error in the ratios G_m is due to

(1) rounding off errors in the various calculations, which could be avoided by taking sufficient number of significant figures

and (2) error in the value of the characteristic value a .

Suppose $a = \bar{a} + \lambda$, where a is the real value, $\bar{a}$ is the assumed value and λ is the error.

Let the ratios G_m and H_m evaluated from the 'forward process' be denoted by $G_{m,i}$ and $H_{m,i}$ respectively and their errors from the actual value be $\epsilon_{m,i}$ and $\eta_{m,i}$ respectively.

Hence

$$\epsilon_{m,1} = G_m - G_{m,1} \text{ and } \eta_{m,1} = H_m - H_{m,1}$$

Since

$$G_2 = \frac{a}{q}, \quad \epsilon_{2,1} = \frac{\lambda}{q}$$

Again since

$$H_2 = 1 / (G_{2,1} + \epsilon_{2,1}),$$

$\eta_{2,1} \simeq \epsilon_{2,1} H_{2,1}^2 \simeq -\frac{\lambda}{q} H_2^2$ neglecting powers of λ/q greater than 1 and replacing $H_{2,1}$ by H_2 .

From the methods used to obtain the ratios G_m and H_m in the forward process, we obtain

$$\begin{aligned} \epsilon_{2,1} &= \frac{\lambda}{q}, & \eta_{2,1} &= -\frac{\lambda}{q} H_2^2 \\ \epsilon_{4,1} &= \frac{\lambda}{q} (1 + 2H_2^2), & \eta_{4,1} &= -\frac{\lambda}{q} (H_4^2 + 2H_4^2 H_2^2) \end{aligned}$$

$$\epsilon_{m,1} = \frac{\lambda}{q} (1 + H_{m-2}^2 + H_{m-2}^2 H_{m-4}^2 + \dots + 2H_{m-2}^2 H_{m-4}^2 \dots H_2^2), \quad m \geq 6$$

$$\eta_{m,1} = -\frac{\lambda}{q} H_m^2 \epsilon_{m,1}$$

$$\text{If } R_{m,1} = H_m^2 + H_m^2 H_{m-2}^2 + \dots + 2H_m^2 H_{m-2}^2 \dots H_2^2 \quad m \geq 4$$

$$R_{2,1} = H_2^2, \quad R_{0,1} = 0.$$

it at once follows that

$$\left. \begin{aligned} \epsilon_{m,1} &= \frac{\lambda}{q} (1 + R_{m-2,1}) & m \geq 6 \\ \epsilon_{4,1} &= \frac{\lambda}{q} (1 + 2R_{2,1}) \\ \epsilon_{2,1} &= \frac{\lambda}{q} \\ \eta_{m,1} &= -\frac{\lambda}{q} R_{m,1} \end{aligned} \right\} \quad (5.13)$$

Let $H_{m,2}$ and $G_{m,2}$ denote the values of H_m , G_m evaluated from the 'backward process' and let $\eta_{m,2}$, $\epsilon_{m,2}$ denote the respective errors from the real values H_m and G_m so that $\eta_{m,2} = H_m - H_{m,2}$ and $\epsilon_{m,2} = G_m - G_{m,2}$. If G_w is the last ratio evaluated $G_w \simeq 1/v_w$

$$\text{Hence } \epsilon_{w,2} = -\frac{\lambda}{q} G_w^2$$

With the help of the method used in generating the ratios G_m and H_m in the 'backward process' we obtain

$$\eta_{w-2,2} = \frac{\lambda}{q} (1 + G_w^2), \quad \epsilon_{w-2,2} = -\frac{\lambda}{q} (G_{w-2}^2 + G_{w-2}^2 G_w^2)$$

$$\eta_{m,2} = \frac{\lambda}{q} (1 + G_{m+2}^2 + G_{m+2}^2 G_{m+4}^2 + \dots + G_{m+2}^2 G_{m+4}^2 \dots G_w^2), \quad (5.14)$$

$$\eta_{2,2} = \frac{\lambda}{q} \cdot \frac{1}{2} (1 + G_4^2 + G_4^2 G_6^2 + \dots + G_4^2 G_6^2 \dots G_w^2) \quad m \geq 4$$

$$\epsilon_{m,2} = -G_m^2 \eta_{m,2}$$

If

$$R_{m,2} = 1 + G_{m+2}^2 + G_{m+2}^2 G_{m+4}^2 + \dots + G_{m+2}^2 G_{m+4}^2 \dots G_w^2 \quad m \geq 4$$

$$R_{2,2} = \frac{1}{2} (1 + G_4^2 + G_4^2 G_6^2 + \dots + G_4^2 G_6^2 \dots G_w^2)$$

$$R_{0,2} = 2 + G_2^2 + G_2^2 G_4^2 + \dots + G_2^2 G_4^2 G_6^2 \dots G_w^2$$

it follows that

$$\eta_{m,2} = \frac{\lambda}{q} R_{m,2}, \quad m \geq 2 \quad (5.15)$$

$$\epsilon_{m,2} = -\frac{\lambda}{q} (R_{m-2,2} - 1), \quad m \geq 6 \quad (5.16)$$

$$\epsilon_{4,2} = -\frac{\lambda}{q} (2 R_{2,2} - 1)$$

If H_{ν} is the real value,

$$H_{\nu} = H_{\nu,1} - \frac{\lambda}{q} R_{\nu,1} \quad (\text{from equation (5.13)})$$

$$H_{\nu} = H_{\nu,2} + \frac{\lambda}{q} R_{\nu,2} \quad (\text{from equation (5.15)})$$

$$\text{Hence } \frac{\lambda}{q} = (H_{\nu,1} - H_{\nu,2}) / (R_{\nu,1} + R_{\nu,2})$$

$$\text{and } H_{\nu} = (R_{\nu,2} H_{\nu,1} + R_{\nu,1} H_{\nu,2}) / (R_{\nu,1} + R_{\nu,2})$$

Since the ratios G_m and H_m are so obtained that $G_m > 1$ for $m \leq \nu$, and $G_m < 1$ for $m > \nu$, from the expressions for $R_{\nu,1}$ and $R_{\nu,2}$ it is obvious that $R_{\nu,1}$ is generally < 1 and $R_{\nu,2} > 1$ when $\nu > 2$. Hence, generally $H_{\nu,1}$ will be nearer H_{ν} than $H_{\nu,2}$.

With this corrected value of H_{ν} , we now proceed to correct a few of the ratios G_m , H_m , m having values near ν . (As the coefficients rapidly reduce in magnitude when m is much greater than ν , only a few of the ratios H_m , G_m , m near ν , need correction).

$$\text{Evaluate } H_m = H_{m,1} - \frac{\lambda}{q} R_{m,1} \quad (m < \nu)$$

(as H_m generates the value G_m , only H_m need be corrected)

and

$$G_m = G_{m,2} - \frac{\lambda}{q} (R_{m+2,2} - 1) \quad (m > \nu)$$

(as G_m generates H_m , only G_m , for a few values of m need be corrected)

After these corrections, it can be checked whether the H_{ν} obtained above agrees with $H_{\nu,1}$ to the required number of significant figures (which, has been found to be

true).

The coefficients D_m are computed and the values of D_m can be checked by the formula

$$v_{m-2} D_{m-2} = D_{m-4} + D_m \quad m \geq 5$$

$$v_2 D_2 = D_4 + 2 D_0$$

which gives the accuracy of the values found. Now the

D_m could be normalised to obtain the coefficients $D_{e,m}$.

The above method could be applied to all the four periodic functions with the appropriate initial relations given by equations (5.7) to (5.10).

Once the coefficients are found the required values are obtained by a method described earlier in this chapter.

CONCLUSION.

The cut-off frequencies for high order circumferential modes have been calculated for various eccentricities of the elliptic duct section.

The cut-off frequencies for even functions decrease with increasing eccentricity as was expected. For odd functions, though for the lowest two orders the eigen frequencies increase with eccentricity, it is of interest to note that the third order eigen frequencies are oscillatory as the eccentricity increases. For higher order odd functions, the eigen frequencies decrease in as much as, for high orders, they assume the same values as those for even functions. As a matter of fact, we find that deforming a circular pipe into an elliptic one of sufficiently large eccentricity produces only a small reduction in the cut-off frequency, provided the area of the pipe section is kept invariable.

ACKNOWLEDGEMENTS.

Herein I wish to express my grateful thanks to my supervisor Dr. M. V. Lowson for his guidance and encouragement throughout this work.

My thanks are due to Miss. Vivian Johnson who typed this work and also to Mrs. Brenda Moore who helped with the Figures.

This work was jointly supported by contracts from National Aeronautics and Space Administration and National Gas Turbine Establishment.

APPENDIX I.

SOME PROPERTIES OF BESSEL FUNCTIONS.

Bessel functions $J_n(x)$ of the first kind are solutions of the Bessel's equation

$$\frac{d^2 y}{dx^2} + \frac{1}{x} \frac{dy}{dx} + \left(1 - \frac{n^2}{x^2}\right) y = 0$$

where n is a positive integer.

A few of the important properties of these functions are listed below. These properties have been used frequently in the text.

$$(1) J_{-n}(x) = (-1)^n J_n(x)$$

$$(2) J_n(-x) = (-1)^n J_n(x)$$

$$(3) J_n'(x) = n J_n(x)/x - J_{n+1}(x)$$

$$(4) J_n'(x) = -n J_n(x)/x - J_{n-1}(x)$$

$$(5) 2 J_n'(x) = J_{n-1}(x) - J_{n+1}(x)$$

$$(6) 2n J_n(x)/x = J_{n+1}(x) + J_{n-1}(x)$$

The formulae (3) - (6) are recurrence relationships.

(7) Addition formulae:

If $R = (x^2 + y^2 - 2xy \cos a)^{1/2}$ then

$$(i) J_0(R) = J_0(x) J_0(y) + 2 \sum_{h=1}^{\infty} J_h(x) J_h(y) \cos h a$$

$$\text{and } (ii) R^{-n} J_n(R) = (xy/2)^{-n} \prod_{h=0}^{n-1} \sum_{h=0}^{\infty} (h+n) J_{h+n}(x) J_{h+n}(y) C_h^n(\cos a),$$

where C_h^n represents Gegenbauer polynomial and $|x| < |y| e^{+ia}$

APPENDIX II. Computer Program Flow-chart.

APPENDIX III. About the Computer Programs.

A In programs EJ and OJ, the eccentricities of the ellipses and the corresponding eigen values for given values of the parameter s were obtained. Programs EJ were for even radial Mathieu functions and Programs OJ were for odd radial Mathieu functions.

The input variables were

- (i) S = parameter s
- (ii) BE = the characteristic number 'be' or 'bo' according as the function is even or odd

The variables used in the programs were

- (i) DE = the coefficients De or Do of expansions, which are computed in the program for each particular s and the corresponding characteristic number.
- (ii) $X = w = \sqrt{\lambda} \cosh \xi$
- (iii) $ZI = \xi$
- (iv) $CEDASH$ or $SEDASH$ = the value of Je' or Jo' for the X .

The values obtained were

- (i) $W = W_0$ = the value $\sqrt{\lambda} \cosh \xi_0$ of w which makes the function zero.
- (ii) E = the eccentricity of the ellipse
- (iii) $EIGEN\ VALUE$ = the cut-off frequency corresponding to the eccentricity.

B In program LCM, the cut-off frequencies in elliptic ducts of eccentricities $e = .1$ (.1) .9 and $e = .95$ were obtained.

The input variables were

- (i) X = the eccentricities obtained from Program EJ
or OJ
- (ii) Y = the eigen values corresponding to the above
eccentricities, also obtained from the Program
EJ or OJ

The variables used in the program were

- (i) XL = seven values of X, nearest to the eccentricity
for which the eigen value is to be evaluated.
- (ii) YL = seven values of Y, corresponding to the seven
values of X above.

Subroutine INTER evaluates the successive convergents for
linear iterated interpolation.

The values obtained were

FUN = the successive convergents and hence also the
final convergent for this interpolation.

APPENDIX IV COMPUTER PROGRAM LISTING.

ORGANISATION OF COMPRESSOR NOISE STUDY.

Figure 1

Figure 2: COORDINATE SYSTEM FOR ELLIPTIC DUCT.

CRITICAL WAVE-LENGTHS OF WAVES IN ELLIPTICAL PIPES.

Here the H-curves are the critical magnetic wavelengths and E-curves are the critical electrical wavelengths.

Thus ${}_oH_1$ and ${}_eH_1$ are respectively odd and even curves of order one. ${}_eH_0$ is an even curve of order zero.
