SUMMARY

Tests were made in the Ames 40- by 80-Foot Wind Tunnel to determine the forward speed effects on wing-mounted thrust augmentors. The large-scale model was that used in previous investigations and was powered by the compressor output of J-85 driven vane compressors. The flap settings used were 15° and 30° with 0°, 15° and 30° aileron settings. The maximum duct pressure, and wind-tunnel dynamic pressure were 66 cmHg (26 in Hg) and 1190 N/m² (25 lb/ft²), respectively. All tests were made at zero sideslip. Test results are presented without analysis.

INTRODUCTION

Augmentor-wing research for use on STOL aircraft configurations has resulted in a series of large-scale static and wind-tunnel tests on a swept wing configuration. Overviews of this research have been published in references 1 and 2. Test results for the slotted primary nozzle are published in references 3 and 4 for the configuration to be referred to as 2 SW. Static gross augmentation was 1.27 at a pressure ratio of 1.7 for this slotted configuration.

To improve the augmentation ratio and to document thrust augmentation at airspeed, a series of static and wind-tunnel tests were made. As with previous tests this program was undertaken in cooperation with the Defense Research Board of Canada and De Havilland Aircraft of Canada, Limited. The tests included in the program were performed and reported in the following sequences.

<u>Type of test and location</u>	<u>Configuration</u>	<u>Report</u>
Static test, complete model, at Ames	4 SW cruciform nozzles	DHC DIR 74-1 ^a
Static test semispan (cold air) at De Havilland	4 SW lobed nozzles	DHC-DIR 76 ^a
Wind-tunnel test, Ames 40 by 80 test 460	4 SW	DHC 77-2 ^a
Wind-tunnel test Ames 40 by 80 test 487	5 SW - nozzles same as 4 SW - nozzle fairing added (see fig. 3(f))	Present report and reference 5

^aDe Havilland reports

The results from the 4 SW tests may be obtained on request from either Ames or De Havilland and the data for the last tests are presented herein and in reference 5. The basic force and moment data are documented without analysis in this report. Flap and aileron deflections were limited to 15° and 30° in order to minimize profile drag due to flap deflection. For some tests, the shroud was removed with and without the augmentor vent sealed in order to simulate basic jet flap performance. In addition, tests were made with leading-edge slat deflection reduced and with slat removed in order to evaluate effects of possible flow separation on the slat lower surface.

SYMBOLS

b	wing span, m (ft)
c	chord, m (ft)
$\bar{c}$	mean aerodynamic chord, m (ft)
c _s	wing leading-edge slat chord, m (ft)
C _d	discharge coefficient (ratio of measured to calculated flow through the nozzle)
C _D	drag coefficient, $\frac{\text{drag}}{qS}$
C _{Dm}	total momentum drag coefficient, $\frac{\text{momentum drag}}{qS}$

C_{JA}	isentropic augmentor jet force coefficient, $\frac{\text{isentropic force}}{qS}$
C_{JI}	total isentropic thrust coefficient, $C_{JA} + C_{\mu_a}$
C_L	lift coefficient, $\frac{\text{lift}}{qS}$
C_{LAERO}	C_L used for wall corrections (see "Data Reduction")
C_m	pitching-moment coefficient, $\frac{\text{pitching moment}}{qSc}$
C_T	augmentor turbocompressor jet-pipe thrust coefficient, $\frac{\text{thrust}}{qS}$
C_v	thrust (velocity) coefficient (ratio of measured thrust to thrust using measured flow and isentropically expanded jet velocity)
C_{μ_a}	isentropic aileron boundary-layer control (BLC) coefficient, $\frac{\text{isentropic BLC force}}{qS}$
h	lobe height of primary nozzle, inside dimension see figure 3(g), cm (in.)
ℓ_z	distance from face of primary nozzle to flap pivot, see figure 3(b), m (ft)
p	primary nozzle lobe spacing, see figure 3(g), cm (in.)
P_a	ambient pressure, N/m ² (in Hg)
P_T	wing duct total pressure, N/m ² (in Hg)
P_{TN}	total pressure at exit of calibrating nozzle, N/m ² (in Hg)
q	free-stream dynamic pressure, N/m ² (lb/ft ²)
S	wing area, sq m (sq ft)
t	airfoil thickness, or primary nozzle lobe width inside dimension (fig. 3(g)) m (ft), cm (in.)
x	chordwise station, m (ft)
y	airfoil ordinate or distance out from the model plane of symmetry, m (ft)
z	distance from primary nozzle center and tangent to flap upper surface, see figure 3(b), cm (in.)
Z	distance between moment center and line of action of tailpipe thrust, m (ft)

α	model angle of attack, deg
δ_a	aileron deflection, positive with trailing edge down, deg
δ_f	augmentor flap deflection measured with respect to centerline of the diffuser, (see fig. 3(a), deg)
δ_{JP}	deflection of augmentor turbocompressor jet pipes relative to fuselage datum plane, deg
δ_s	slat deflection, (see fig. 2(c)), deg
η	wing station, (distance from model plane of symmetry), $2y/b$
ϕ_G	ratio of measured augmentor thrust to measured primary nozzle thrust
ϕ_N	ratio of measured augmentor or primary nozzle thrust to isentropic nozzle thrust

Subscripts:

a	aileron
A	augmentor
f	flap
JP	jet pipe
l	isentropic
L	left
R	right
s	slat
u	uncorrected for wall effects
uu	uncorrected for either wall effects or jet-pipe thrust

MODEL AND APPARATUS

Basic Model

The model is shown installed in the wind tunnel in figures 1(a) and (b). The basic geometric details of the model are summarized in figure 2 and the model reference dimensions and airfoil coordinates are listed in tables 1 and 2. Except for slight modifications to the aileron and L.E. slat, the basic

configuration is similar to that for which test results are reported in references 1, 3 and 4. All tests were made without horizontal tail, under-slung engine pods, and fuselage boundary-layer control (BLC).

As with the previous investigations using the model, the air for the augmentor and aileron BLC systems was supplied by a pump consisting of two turbocompressors, or modified viper engines driven by a J-85 turbojet engine. The turbines of the vipers were driven by the J-85 hot gas which was then ejected at the rear of the fuselage through two tailpipes. A diagram of this pumping system is presented in figure 2(e) of reference 4.

The geometry of the aileron and aileron BLC is presented in figure 5 of reference 4, also see figure 2(b) of this report. The system was fed through an extension of the augmentor primary air duct without a valve and therefore, always functioned when the augmentor was operating. Airflow to the aileron was 5% of the total turbocompressor airflow.

Augmentor Flap

The geometry of the flap cross section is shown in figure 3(a). The flap and shroud configuration was the same as that of reference 4 except for the following: (1) the augmentor assembly was reinstalled using the bracket configuration shown in figure 3(b) to facilitate the optimization of augmentor position; (2) the shroud BLC slot inlet lip was rounded and a flexible sealer plate was installed over the intake door hinge as shown in figure 3(c), (note that the intake door was set at its optimum position for each flap angle); and (3) the nozzle configuration had been changed from the slot nozzle of the previous investigation to a lobed configuration. The nozzles, installed, are shown without and with a fiberglass fairing in figures 3(d) and 3(e). Geometric details of the nozzle installation are presented in figures 3(f), 3(g), and 3(h). The configuration shown resulted from the static test program completed by the De Havilland Aircraft of Canada, Limited, using a short-span augmentor, and the static performance improvement measured for the complete model are close to that predicted from results of those tests.

TESTS

A run index of the model configuration and test conditions is presented in table 3. To measure the augmentor thrust at zero airspeed, the tests were made with the model at zero attitude with the overhead doors of the test section open. The tests were completed as quickly as possible in order to minimize entrainment of the flow through the test section. The test procedure for the wind on testing consisted primarily of varying angle-of-attack at a given combination of power and airspeed. All tests were made at zero sideslip and at flap and aileron settings which were symmetrical except for run 1. All flap, aileron and leading-edge slat settings were set within $\pm 1/2^\circ$ of the values listed and the duct pressures listed are within ± 1 in Hg of the

measured values. The value of C_J listed for each polar in the numerical average of values at all angles of attack.

DATA REDUCTION

For all force and moment data, the effects of compressor residual jet thrust, and the intake momentum drag of the fuselage mounted J-85 and viper compressors have been subtracted from the measured values. The corrections made for thrust and momentum drag are as follows:

$$C_{L_u} = C_{L_{uu}} - C_T \sin (\alpha - \delta_{JP})$$

$$C_{D_u} = C_{D_{uu}} - C_{D_m} + C_T \cos (\alpha - \delta_{JP})$$

$$C_{m_u} = C_{m_{uu}} - C_T \frac{Z}{\bar{c}}$$

The forces and moments are referred to the stability axes. The moment center used for data computation was located longitudinally at $0.25\bar{c}$ and vertically $0.20\bar{c}$ below the wing chord plane.

Initial values of C_{J_I} were computed on the basis of the measured mass flow and total pressure in the wing duct feeding the primary nozzles. To verify the duct calibration, and because the analysis of the previous calibration indicated the measured flow rates to be suspect, the wing ducts were disconnected from the compressor and replaced with the calibrating nozzles shown in figures 4(a) and (b). The calibration run was designated run 70 as indicated in table 3. A detailed analysis of the use of this run is presented in reference 5 but a summary of the results is presented in figure 4(c). The symbol C_d was derived from values of $C_v C_d$ using data from calibrations of the nozzles. Also shown are values of C_d (indicated for the calibrating nozzles using flow rates derived from the viper metering pressures. These were clearly in error and all flow quantities derived for the earlier test runs were corrected downward as indicated.

Wind-tunnel boundary corrections were based upon the lift coefficient evaluated as follows:

$$C_{L_{AERO}} = C_{L_u} - C_{J_A} \sin (\delta_f + \alpha_u) - C_{\mu_a} \sin (\delta_a + \alpha_u)$$

Then the following boundary corrections were made:

$$\alpha = \alpha_u + 0.458 C_{L_{AERO}}$$

$$C_D = C_{D_u} + 0.00799 C_{L_{AERO}}^2$$

DATA PRESENTATION

Results of wind off tests are presented in figures 5 and 6. The results of test runs 1 and 69 with the shroud and flap removed were somewhat different, the latter showing higher efficiency. No definite reason for this has been determined, but it is the opinion of the authors that the latter results are more valid since they were obtained after repeated calibration of the data acquisition system and are closer to the unpublished results obtained by the De Havilland Aircraft of Canada. These results are also shown in figure 5 for reference. Both net (ϕ_N) and gross (ϕ_G) augmentation ratios with the complete augmentor installed are also presented in figure 5. Gross augmentation values with the shroud off are presented in figure 6 and are based on the primary nozzle thrust values measured in run 69.

Results of tests at airspeed are presented in figures 7 through 23. Table 4 is an index to the figures. The effect of power on the performance for several augmentor and leading-edge slat configurations are presented in figures 7 through 16. Figure 17 shows the effect of possible metric-nonmetric mechanical interference in the support system which was suspected for some of the later tests. As shown, any effect proved small. Results of additional attempts to repeat test conditions are presented in figure 18. The remaining figures show effects of changing wing-augmentor configurations.
