SOFTWARE FOR ANALYZING DATA CONTAINED IN OUTPUT FILES CREATED BY THE SPATL AND MLTCRP ROUTINES OF THE ASSESSMENT SOFTWARE SYSTEM

INTRODUCTION

The output files from the Accuracy Assessment routines SPATL and MLTCRP contain information about individual Procedure 1 processings of Large Area Crop Inventory Experiment (LACIE) blind sites. To analyze this data and aggregate the results over many blind sites, a program was developed to sort the data, and was used as a basis for other programs to investigate analyst dot labeling accuracy, clustering purity, and classification accuracy. This memorandum describes the operation of this software.

BASIC PROGRAM FOR SORTING OUTPUT FILES – ANALYZE

Program ANALYZE uses the header information in the output files from MLTCRP or SPATL to sort the data on the basis of state, segment number, processing date, number of acquisitions, and dot type. (A description of the contents of these output files is contained in refs. 1 and 2.) ANALYZE requires two data files as inputs: DATSEL.DAT, which contains the selection criteria for the run, and INPUT.DAT, which contains the name of the output files to be used and the range of output file version numbers to be accessed. The input file INPUT.DAT can contain any additional information necessary for the processing of the data. The file must contain a minimum of two lines. The first line is the name of the output files to be accessed in the form DB0:[110,6] MCRP. The device and user identification code (UIC) are optional if they are the same as the device and UIC in which the task resides. The second line contains the starting and ending version numbers in an octal format (04,1X,04). Any additional information may follow this second line.

Input file DATSEL.DAT contains two lines for each selection criterion. The first line is the general selection criterion, and the second line is the specific selection basis. A sample data set using each of the criteria follows.

```
SEGMENT
 5 1005,1007,1923,1215,1515
STATE
 4 CO,ND,SD,MT
NUMBER OF ACQ.
 3
DATE
 7200,7300
DOTS
 3  1,2,3
(blank line)
```

The blank line indicates the end of a data set. More than one set of selection criteria can be included in the data set, each separated by a blank line. A line containing "END" must follow the blank line after the last set of selection criteria. If no selection is to be made for a particular criterion, it is not included in the data set. The limits on the selection criteria are: (1) the number of segments cannot exceed 10; (2) the number of states cannot exceed 5; and (3) the number of dot types cannot exceed 4.

Program ANALYZE produces a line printer listing indicating the file name accessed, the range of version numbers used, the basis for selection, and the number of files selected by the program.

Appendix A is a compiled listing of program ANALYZE. Three subroutines are required: DATSEL, which is used to input the selection criteria; SELECT, which determines if the individual files meet the selection criteria; and SELIST, which produces the line printer listing of the information concerning the selection process.

There are six blocks in the main program where code can be written to perform individual analyses using the output files selected by the program. The inserts, labeled 0 through 5, are used as follows.

0 — Comments concerning the analysis to be performed

1 — Array specifications and DATA statements necessary for the analysis

2 — Input of additional data about the processing from input file INPUT.DAT

3 — Initialization of aggregation arrays before the files are accessed

4 — Computations based on a file which has met the selection criteria

5 — Outputting the final results of the computations (This section is located after all files have been checked.)

The programs described in the following paragraphs are all based on ANALYZE.

PROGRAM TO DETERMINE ANALYST DOT LABELING ACCURACY — DOTANL

The program DOTANL uses the data contained in the fourth record of the SPATL output files to determine the analyst dot-labeling accuracy. The program creates a two-dimensional array; one dimension corresponds to the ground truth crop code and the other dimension corresponds to the analyst label. This array is loaded with a count of the mutual occurrences of a ground truth crop code and an analyst label for all of the analyst-labeled dots in a file. DOTANL produces a line printer output with the number of dots which were labeled in each of the analyst categories for each ground truth crop code. The total number of dots in each crop code and the total number of dots with each label are shown. The program can also produce a percentage of correct classification for each crop code.

Input file DATSEL.DAT is set up for the particular criteria required. Input file INPUT.DAT has the name of the SPATL files on the first line, and the version numbers to be accessed on the second line. Following the second line is a set of lines indicating the proper analyst label for each crop code. This information is loaded in the form of beginning crop code, ending crop code, and the correct analyst label, using FORTRAN format (3I5). If a particular crop code is not included, the percent correct column is left blank. When all of the crop codes have been used, a blank line is entered to indicate an end of data. If the percent correct option is not desired, a blank line should follow the line containing the range of version numbers.

Appendix B is a sample output line printer listing obtained from DOTANL.

PROGRAM TO ANALYZE CLUSTER PURITY — CLUANL

The program CLUANL uses the data contained in the fourth and sixth records of the MLTCRP output files to analyze the cluster purity for individual segments and to determine overall cluster purity. The program calculates two measures of cluster purity based on a two-category ground truth division of the pixels. The first measure is the average proportion, which is calculated by the following formula:

$$\text{Average proportion} = \frac{1}{N}\left(\sum_i N_i P_i\right)$$

where

N is the total number of subpixels in clusters other than the DO/DU cluster

N_i is the number of subpixels in the i*th* cluster

P_i is the proportion of the majority constituent in the cluster

The second measure of cluster purity is the average variance, which is calculated by:

$$\text{Average variance} = \frac{1}{N}\left(\sum_i N_i P_i (P_i - 1)\right)$$

Variables are defined above.

CLUANL also calculates histograms of the clusters based on small-grains proportions and of cluster small-grains proportions weighted by pixels. The program analyzes cluster labeling accuracy based on three labels for the type 1 dot closest to the mean of the cluster: analyst label, the classifier label, and the ground truth label. The program determines the number labeled as small grains, and those labeled as nonsmall grains for clusters with a majority of small grains and for clusters with a majority of nonsmall grains. Appendix C shows a typical listing for CLUANL. The program also has the capability of printing out the following information about the individual clusters:

a. Cluster number

b. Number of subpixels in cluster

c. Number of ground truth crop codes in cluster

d. Analyst label and location of dot used to label cluster

e. Classifier label for dot used to label cluster

f. Ground truth label for dot used to label cluster

g. Ground truth label and proportion for largest crop code in cluster

h. Same information for second largest crop code

i. Same information for third largest crop code

j. Same information for fourth largest crop code

k. Proportion of cluster not in the four largest crop codes

l. Proportion of either small grains or nonsmall grains, whichever is larger

m. Majority class (small grains or nonsmall grains) for cluster.

This printout is currently suppressed, but can be obtained by the removal of two comment characters (C) in print statements.

In order to use Program CLUANL, the DATSEL.DAT input file is set up for the particular criteria required, with type 1 dots. Input file INPUT.DAT has the name of the MLTCRP files on the first line, and the version numbers to be accessed on the second line. Following the second line of the data set is the information needed to sort the pixels into small grains or nonsmall grains. The information is loaded in the form of beginning crop code, ending crop code, and small-grains category. The small-grains category is a four-digit number, of which the first digit is the small-grains class, and the remaining three digits are the percentage of small grains in the crop code. This explicit percentage is used for strip fallow crop codes.

Program CLUANL can be used to investigate cluster purity for any crop by changing the input data set.

PROGRAM FOR ANALYZING CLASSIFICATION ACCURACY — CLSANL

Program CLSANL uses the data from records 4, 5, and 6 of the MLTCRP output files to determine the small-grains proportions at different stages in the Procedure 1 processing. The program makes three passes through the output files for type 1, 2, and 3 dots. Therefore, DATSEL.DAT must be the following:

```
DOTS
 1 1
DOTS
 1 2
DOTS
 1 3
END
```

Input file INPUT.DAT is the same as CLUANL.

Program CLSANL calculates the following proportions:

a. Ground truth proportion — Determined from the data in record 5 using the transformation in input data set INPUT.DAT.

b. Uncorrected machine proportion — Calculated from record 5. No threshold pixels are considered in determining the proportion.

c. Bias corrected machine proportion — The uncorrected machine proportion is bias corrected using the analyst labels for the type 2 or type 3 dots. (The type 3 dots are type 2 dots which were changed by the analyst after the classification results were available.) If type 3 dots are not present, type 2 dots are used for the bias correction.

d. Type 2 dots proportion using classifier labels — Uses the labeled type 2 dots as a random sample of the segment and calculates a proportion based on the classifier label for each dot.

e. Type 2 dots proportion using ground truth labels — Uses the labeled type 2 dots as a random sample of the segment and calculates a proportion based on the ground truth label for each dot.

f. Type 2 dots proportion using analyst labels – Uses the labeled type 2 dots as a random sample of the segment and calculates a proportion based on the analyst label for each dot.

g. Cluster proportion using analyst labels – The pixels in each cluster are sorted on the basis of the analyst label for the type dot used to label the cluster, and a proportion determined on this basis.

h. Cluster proportion using ground truth labels – The pixels in each cluster are sorted on the basis of the ground truth label for the type 1 dot used to label the cluster, and a proportion determined on this basis.

i. Machine proportion bias corrected using the ground truth labels for the type 2 data – The bias correction is made by comparing the classifier labels with the ground truth labels for the type 2 dots.

Appendix D is the line printer listing obtained from CLSANL. Data contained in this listing is also written to a disk file called CLSANL.DAT, which is used for automatic plotting of the classification accuracy calculated by the program. Both the line printer listing and the output file have the information ordered by state and segment number.
