15. Supplementary Notes			
16. Abstract Attenuation and cross-polarization isolation at 11.7 GHz, measured at Austin, Texas by receiving the circularly polarized emissions from the CTS satellite are presented. The data are a 12 month summary for Feb 78 to Jan 79. For .016% of the time the attenuation was greater than 10 dB, the isolation was less than 21 dB and the rainrate exceeded 55 mm/hr. Ice depolarization has been observed frequently.

I. INTRODUCTION

The nominally right hand circularly polarized 11.7 GHz beacon transmitter on the CTS satellite has been monitored at The University of Texas at Austin for the periods of its operation. The data presented in this report cover the attenuation and isolation measurements made with a dually polarized receiver and rain rate measurements made with a single tipping bucket rain gauge during the period of February 1978 to January 1979. Reports to be issued later will cover the other two experiments going on in connection with the one presented here. They are (1) the adjustable receiver polarization experiment and (2) COMSTAR attenuation and diversity measurements at 19, 28 and 13 GHz. In addition, at the conclusion of the CTS experiment a summary report covering all the data collected will be issued. The data collected before February 1978 have been summarized in two previous reports. The first of these also contains a detailed description of the receiver.

II. RECEIVER DESCRIPTION

The pertinent characteristics of the receiver and data collection system are given in Table I.

Vogel, W. J. and Straiton, A. W., 1977, "CTS Attenuation and Cross-Polarization Measurements at 11.7 GHz," Final Report under Contract NAS5-22576 for 12 June 1976 - 30 August 1976.

Vogel, W. J., 1978, "CTS Attenuation and Cross-polarization Measurements at 11.7 GHz," Final Report under Contract NAS5-22576 for 18 October 1976 - 31 January 1978.

TABLE I
DUAL POLARIZATION RECEIVER CHARACTERISTICS

Antenna:	3m parabola, prime focus feed, $f/D = .375$ program pointing to $.02^\circ$, elevation $\approx 50^\circ$
Feed:	turnstile polarizer
Polarization:	RHC, LHC (nominally), matched by adjusting for minimum power in cross-polar channel during clear-air propagation
Isolation:	better than 45 dB with optimum pointing
Fade margin:	30 dB for co-polarized channel 45 dB for cross-polarized channel
Calibration:	Precision attenuated 11.7 GHz signal injected into front end
Output:	logarithmic amplitudes, recorded on stripchart, digitized at 5 samples per minute

III. METEOROLOGICAL DATA

The total precipitation for each month and the number of thunderstorms, as reported by the Weather Service are given in Table II.

Dec 78	72	1
Jan 79	54	1
TOTAL	819	36

Integrating over the rain rate distribution measured at the receiver site from 5 mm/hr to 150 mm/hr gives a total of 480 mm. This means that about 40% of the rain fell at rates below 5 mm/hr. Comparing the total rain and number of thunderstorms to their long term average of 846 mm and 41 thunderstorms, it can be concluded that this reporting period had close to average weather.

IV. 12 MONTH SUMMARY OF THE ATTENUATION AND CROSS-POLARIZATION ISOLATION MEASUREMENTS

The percentage of time the attenuation exceeded specific values is

shown in Figure 1. For example 10 dB were exceeded for 1.6×10^{-2} percent of the time. From Figure 2 it can be seen that for the same percentage the isolation was less than 21 dB. The isolation is defined as the power ratio between the co-polarized and cross-polarized channel, or when expressed in dB:

$$\text{CPI(dB)} = \text{Co-polarized signal level (dB)} - \\ \text{cross-polarized signal level (dB)}$$

where the signal levels are measured with respect to some arbitrary reference. In this case this reference was the clear air level of the co-polarized signal. As shown in Figure 3 for 1.6×10^{-2} percent of time the rain rate exceeded 55 mm/hr.

The distribution curves define statical relationships between the measured parameters which can be used for modelling. For example, from the equal probability pairs of attenuation A and cross-polarization isolation CPI one can derive that the two are statistically related as

$$\text{CPI} = 33.4 - 13.1 \log A.$$

This equation represents the least squared error fit to the points indicated in Figure 5.

The density function of the quantities A in the range 0 to 30 dB and CPI in the range 10 to 40 dB was calculated from the data. From this the curves given in Figure 4 were derived. They show the 10% expectation, median and 90% expectation of exceeded isolation for each attenuation. For instance the three points at 5 dB mean that for

RAIN RATE DISTRIBUTION
AUSTIN, TEXAS

7

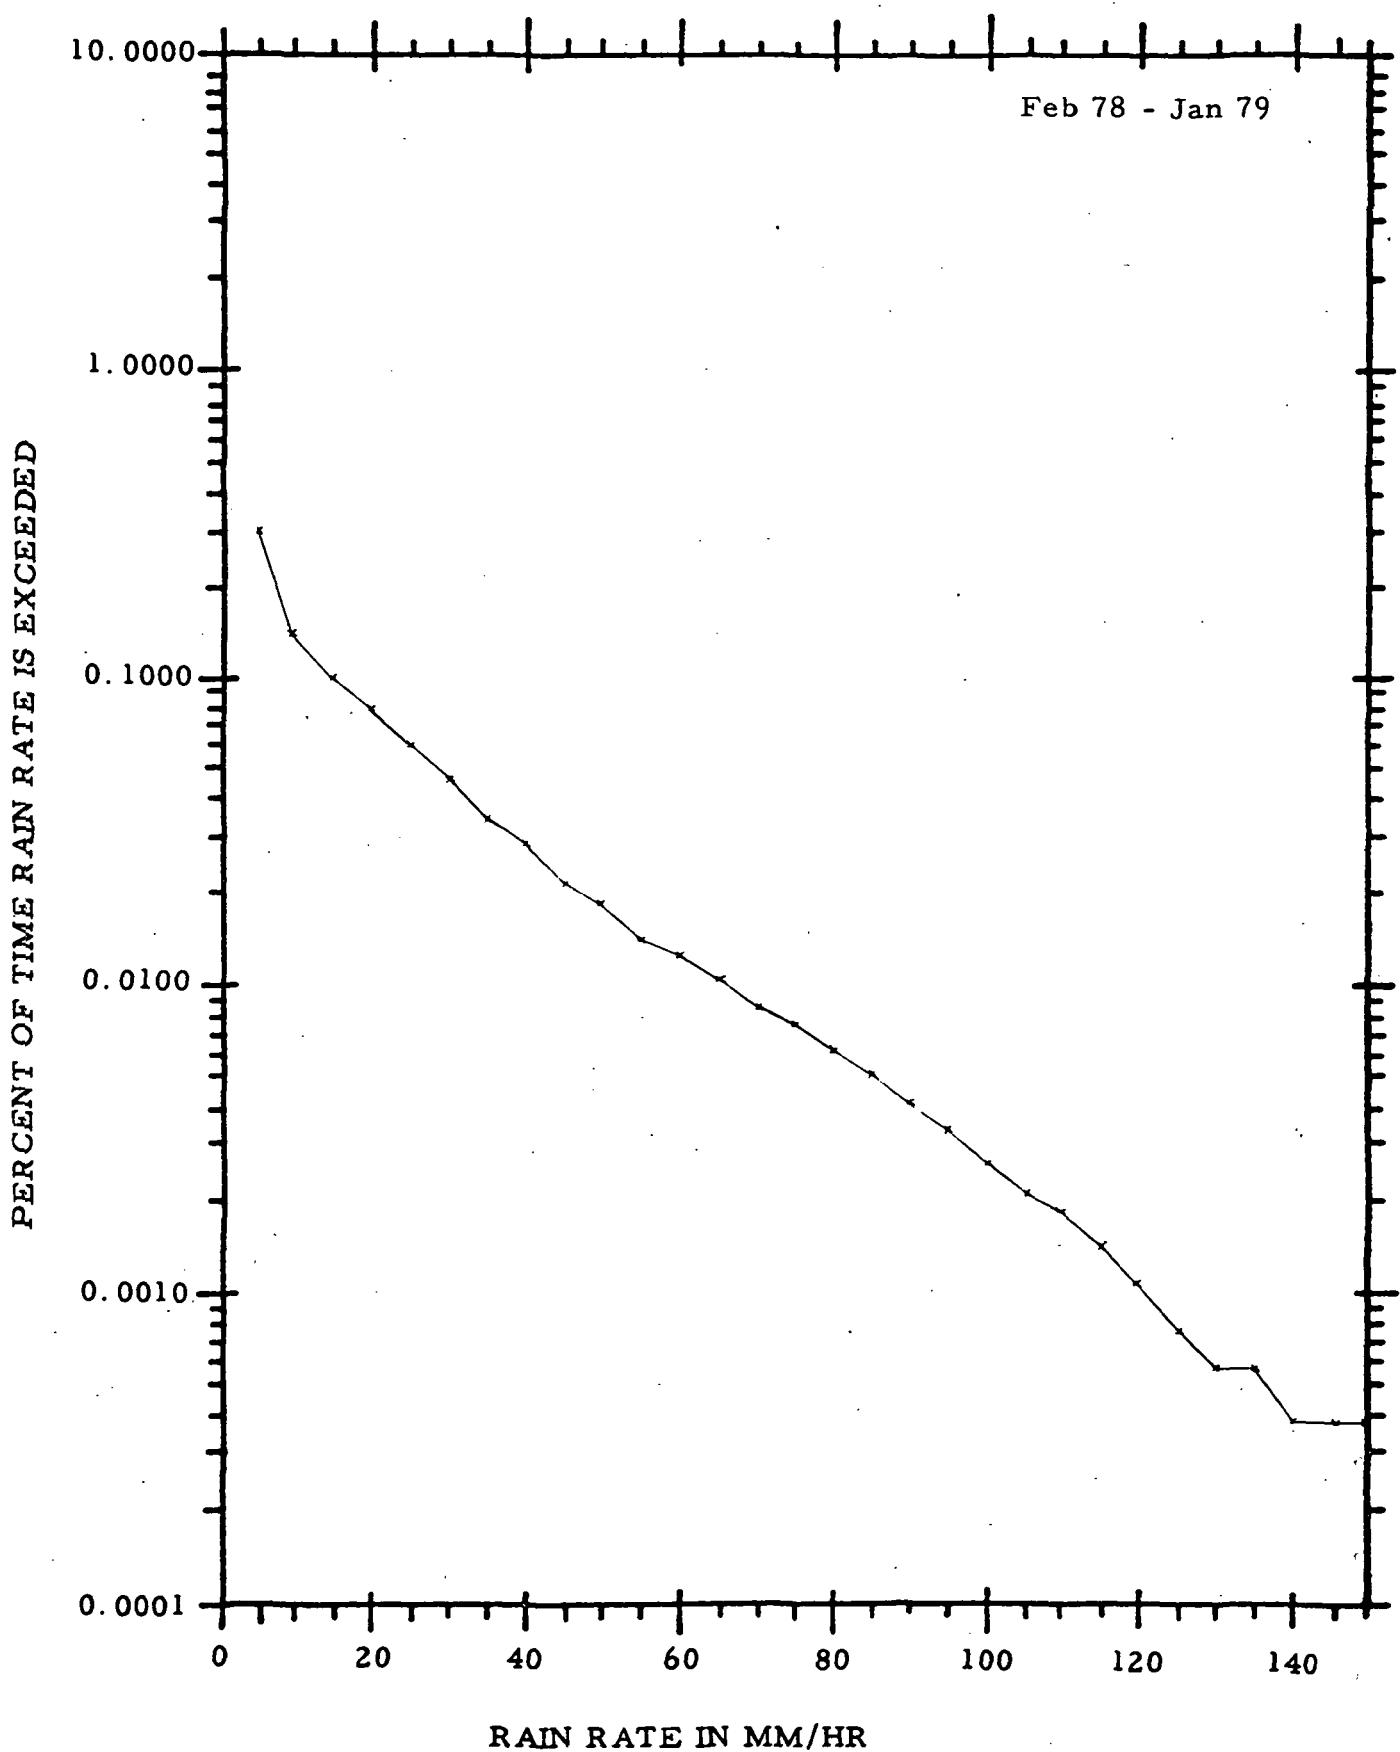

Fig. 3 12 Month Rain Rate Exceedence Plot

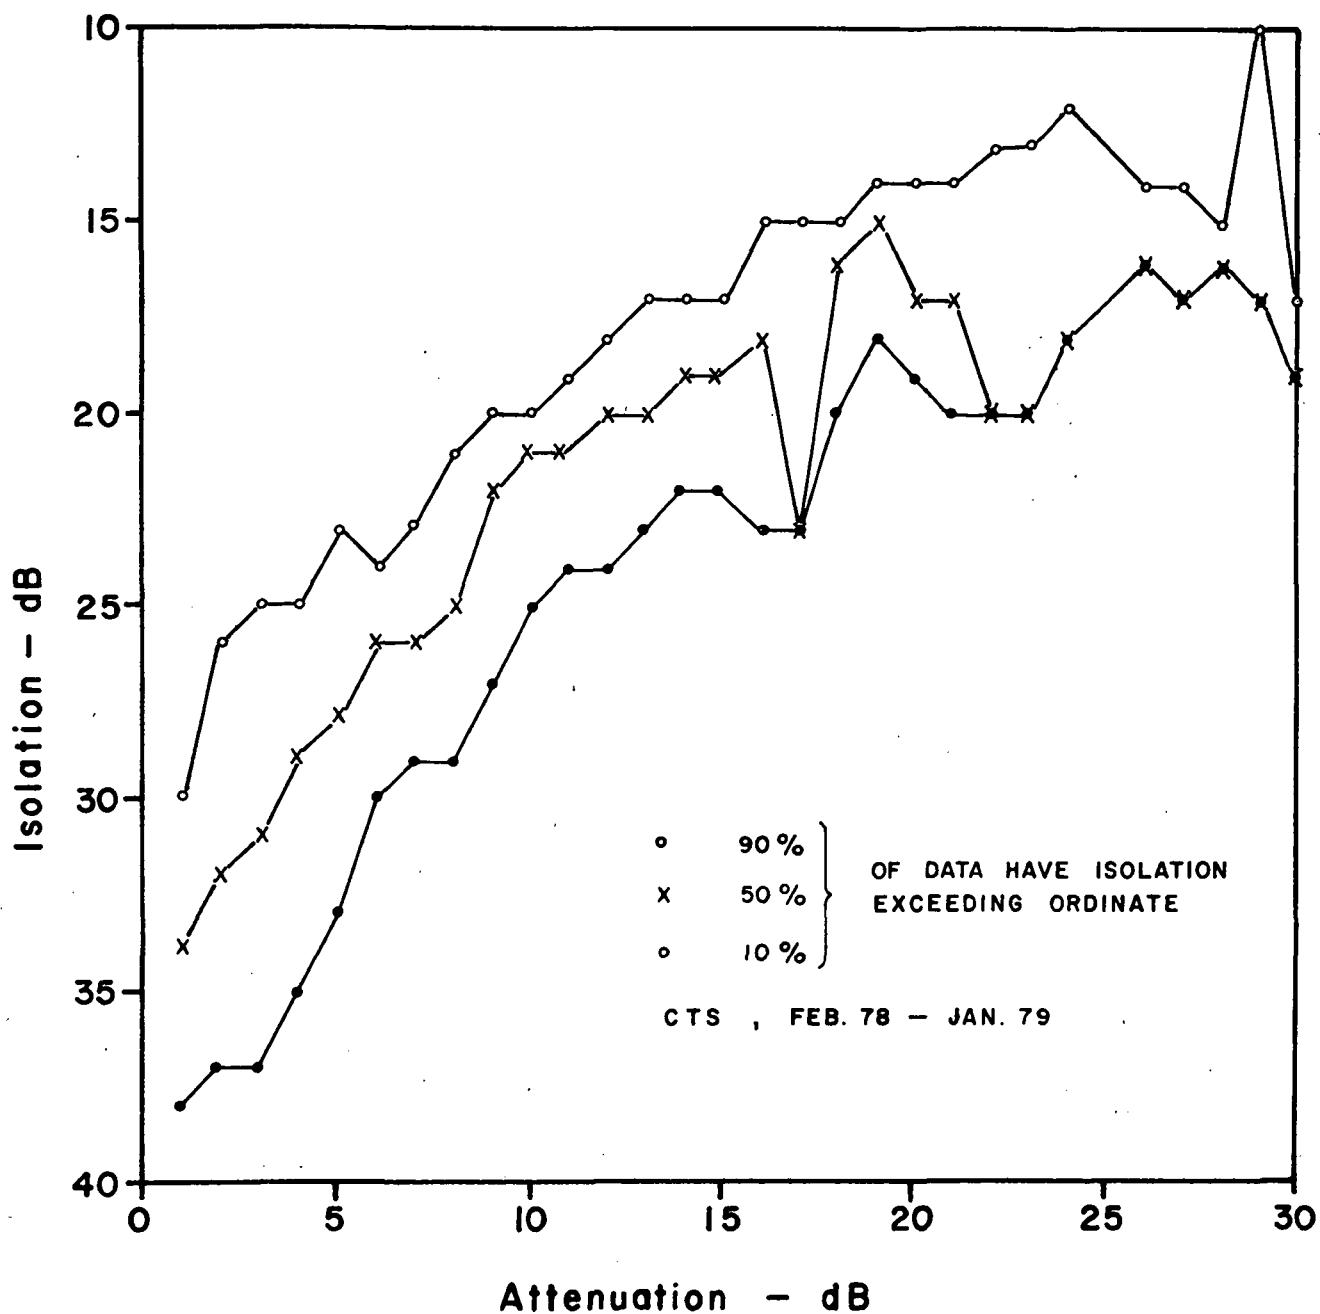

Fig. 4 12 Month Isolation vs. Attenuation

$$4 < A \leq 5 \text{ dB}$$

90% of the data collected had CPI better than 23 dB, 50% of the data (the median value) had isolation better than 28 dB and for 10% of the data the isolation was better than 33 dB. These curves given some indication of the consistency of the relationship between the two parameters. It should be noted that the curves are better defined in the lower attenuation range where they are based on more samples.

The logarithmic fit to these three curves was determined to be:

$$10\%: \quad \text{CPI} = 42.9 - 17.5 \log A \quad (r^2 = .94)$$

$$50\%: \quad \text{CPI} = 35.8 - 13.4 \log A \quad (r^2 = .89)$$

$$90\%: \quad \text{CPI} = 31.5 - 12.6 \log A \quad (r^2 = .90)$$

The value of r^2 is a measure of the quality of the fit. If $r^2 = 1$ all points lie exactly on the line and if $r^2 = 0$ the points were randomly distributed. (For the equal probability fit r^2 was .99). The curves defined by the above equations have been added to Figure 5. It is apparent that the equal probability curve predicts less isolation than the median data curve, a fact related to the particular shape of the density curve.

To estimate the contribution of ice depolarization to the isolation statistics, Figure 6 shows the percentage of ice depolarization in the total depolarization events. The points were calculated by

$$\begin{aligned} \text{Percent} = & (\text{Time the isolation was less than the abscissa} \\ & \underline{\text{and the attenuation less or equal 1 dB}})/(\text{Time} \\ & \text{the isolation was less than the abscissa}) \times 100. \end{aligned}$$

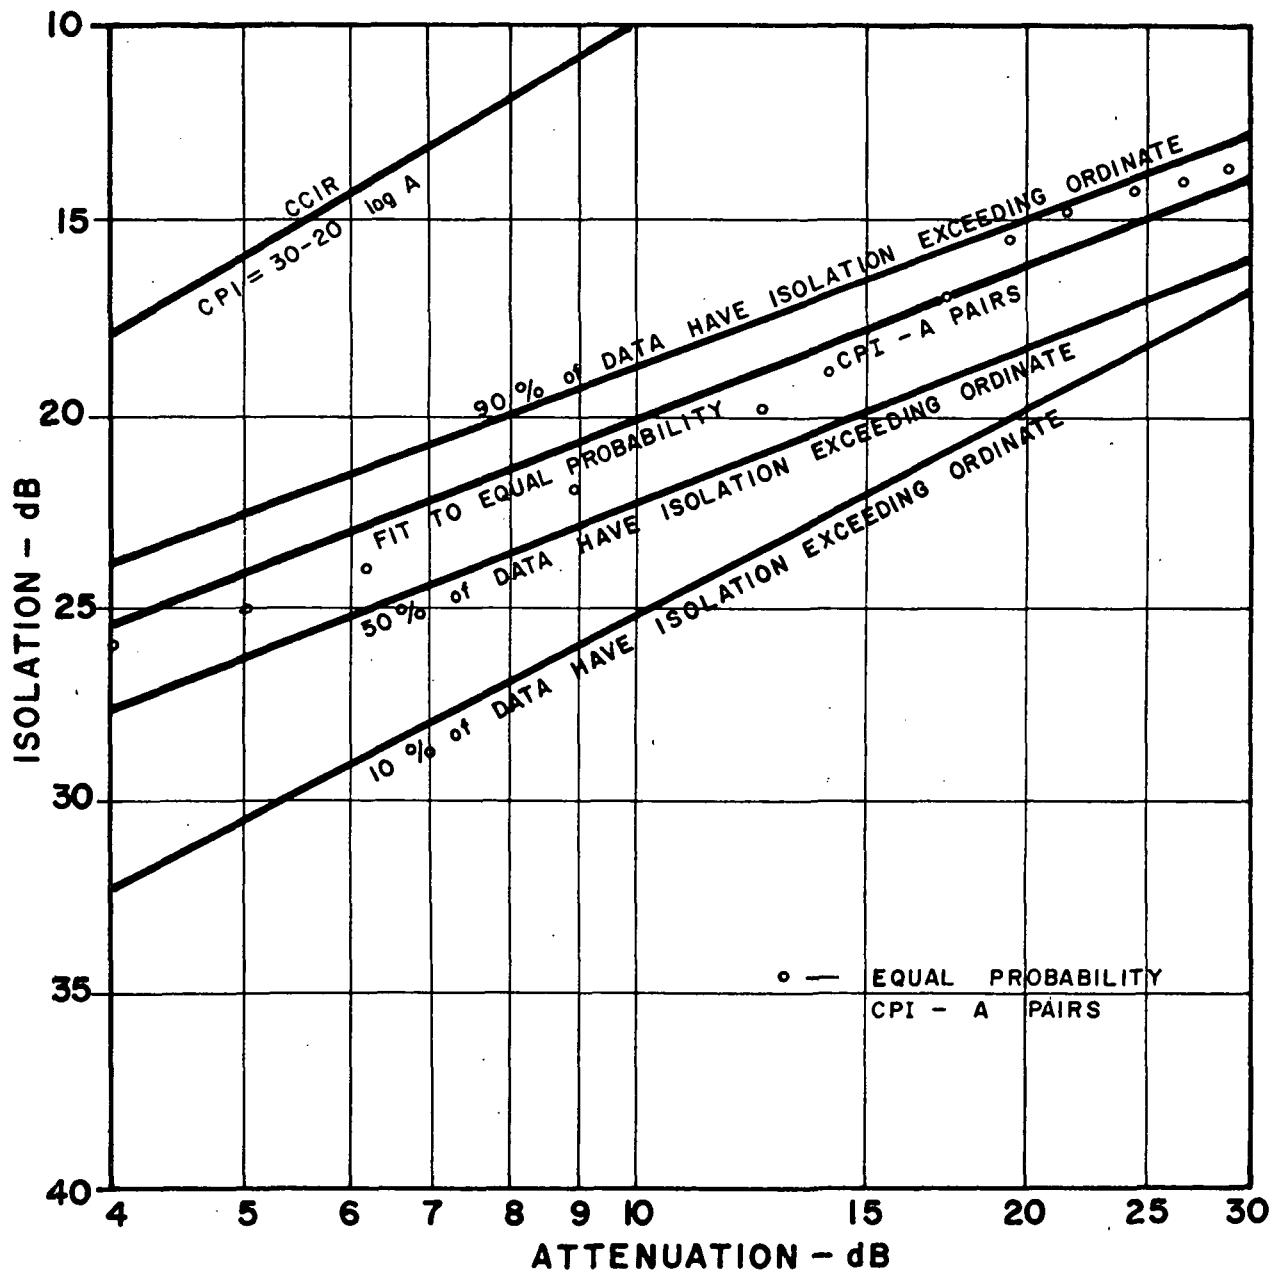

Fig. 5 Logarithmic Fits to Isolation vs. Attenuation

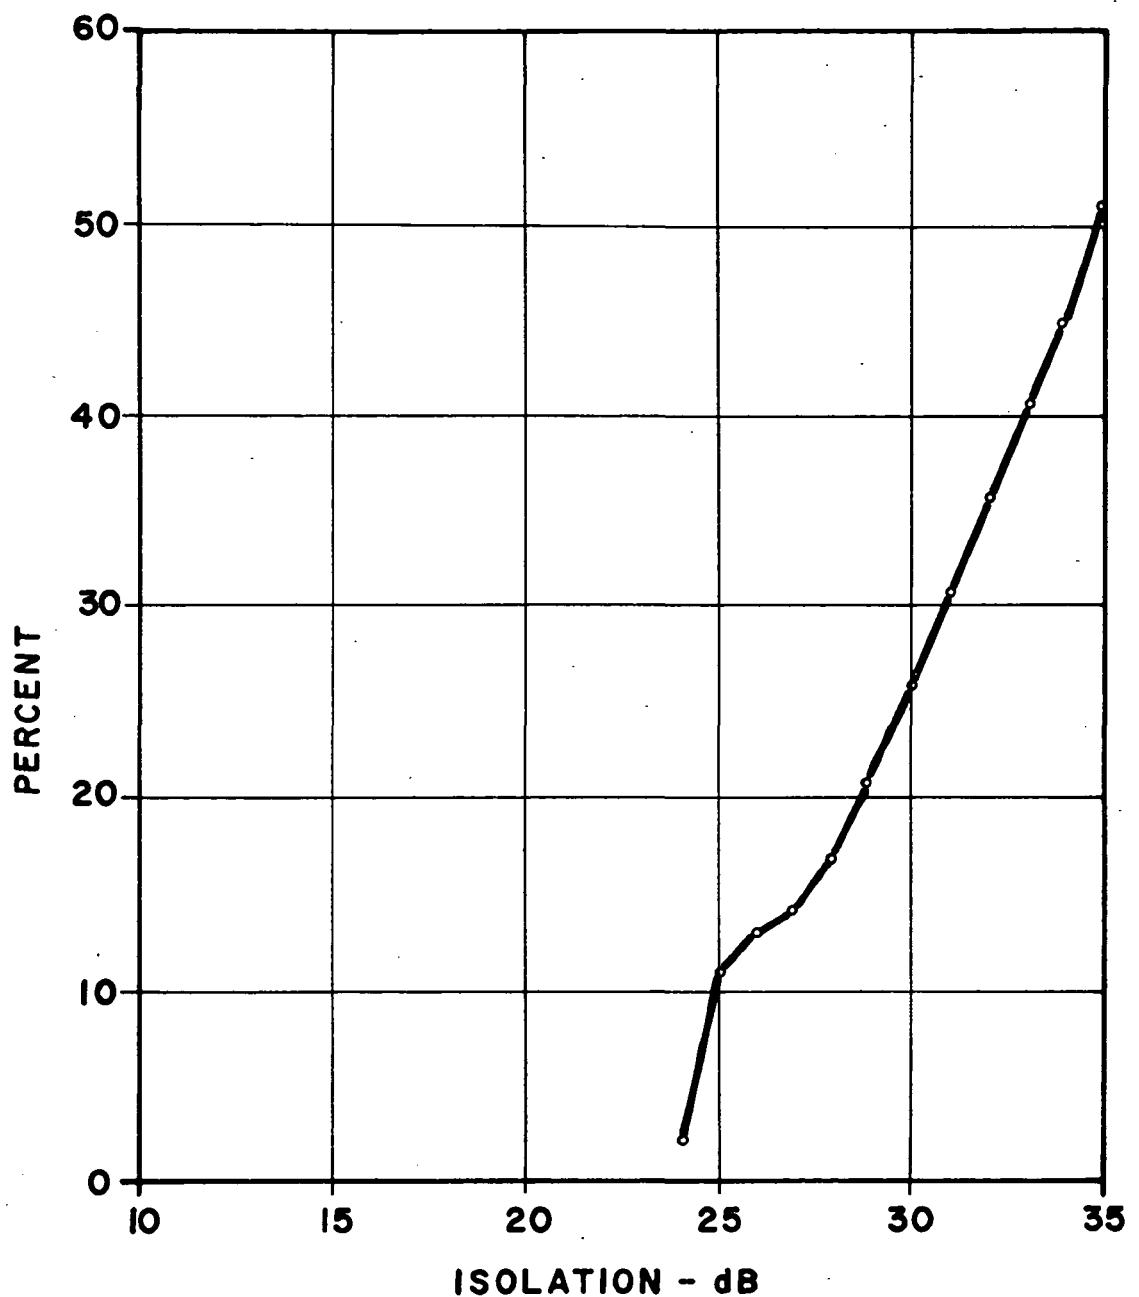

Fig. 6 The Contribution of Ice Depolarization to all
Depolarization Events

The interpretation of this curve is that caution has to be exercised when using the logarithmic fits to the CPI - A relationship in conjunction with attenuation statistics to predict depolarization at low attenuations. The derived isolation statistics will need correction as per Figure 6 to account for the contribution of ice depolarization. The excess depolarization will decrease with increasing attenuation. Also part of the data summary are Tables 3 - 8.

Table 3 gives the distribution data in minutes. These were used to draw the exceedence plots Figures 1 - 3.

Tables 4, 5 and 6 gives distribution data resolved into time of day of the occurrence of fades, depolarization and rain rate. While the density of the data events is not uniform over the 24 one-hour intervals, it is hard to make a general statement as to whether events are more serious at certain times than at others. The times are Universal Time (GMT), which is 6 hours advanced from Central Standard Time. Maybe it will be possible, when all the data collected will be analyzed in this fashion, to discern if the probability of data events is evenly distributed over all 24 hours of a day. Table 7 orders the data events by their duration. It gives the number of events for each threshold level and their duration. The data show that the events with higher attenuation, lower isolation or higher rain rate tend to be fewer and shorter. The lower number of events when the rain rate exceeded 5 mm/hr for short durations is due to the fact that the rain

rate is calculated from the interval between accumulating .254 mm of precipitation. Therefore short durations of low rainfall rate are not resolved.

The data in Table 8 were used to plot Figure 4. They give the spread of isolation values for the measured attenuations.

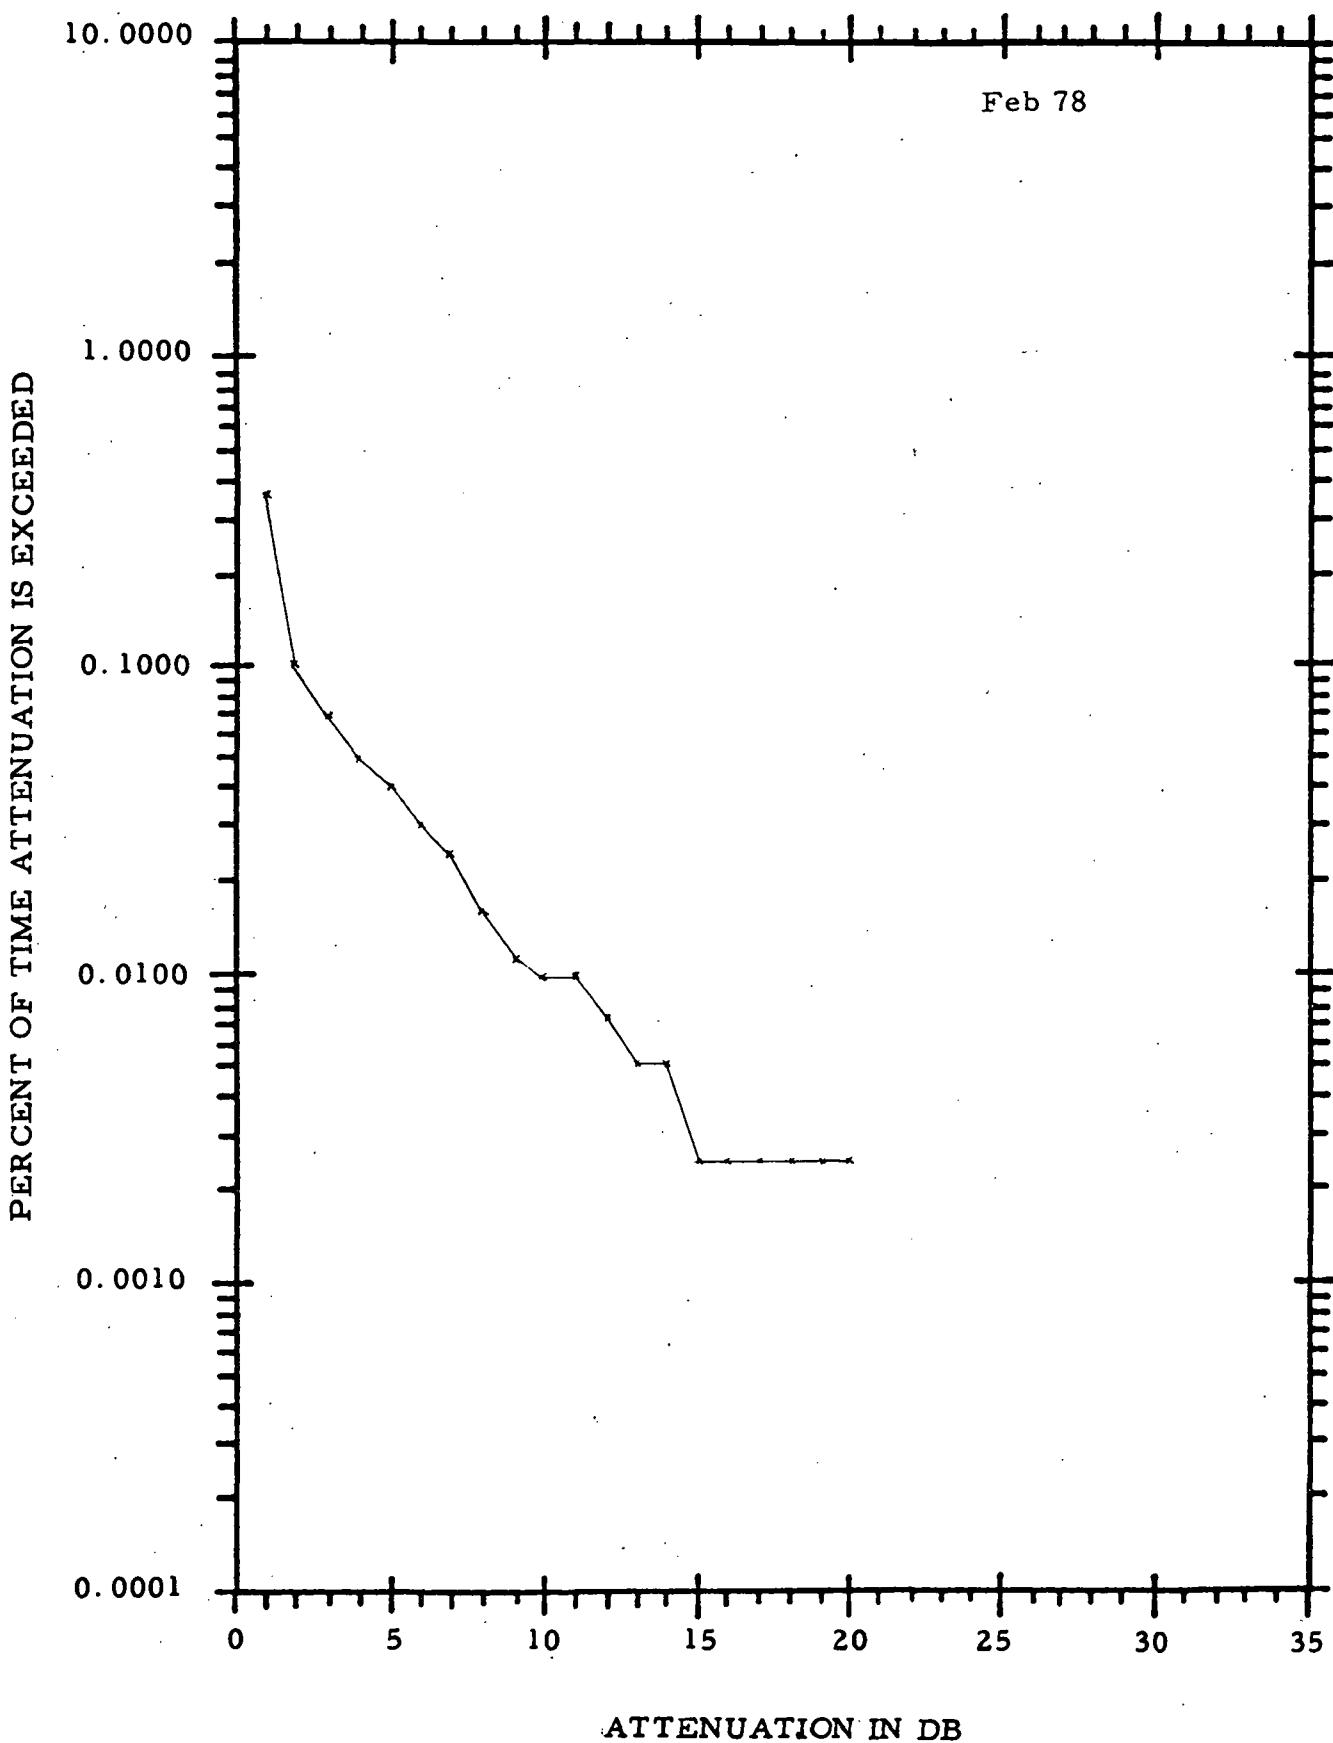

The data for each month of this reporting period are presented in the Appendix. Given are the distribution plots for attenuation, isolation and rain rate and the same set of numerical tables as has been included for the yearly summary, i. e. distribution tables, time of day tables, the duration data and the isolation vs. attenuation table.

V. CONCLUSION

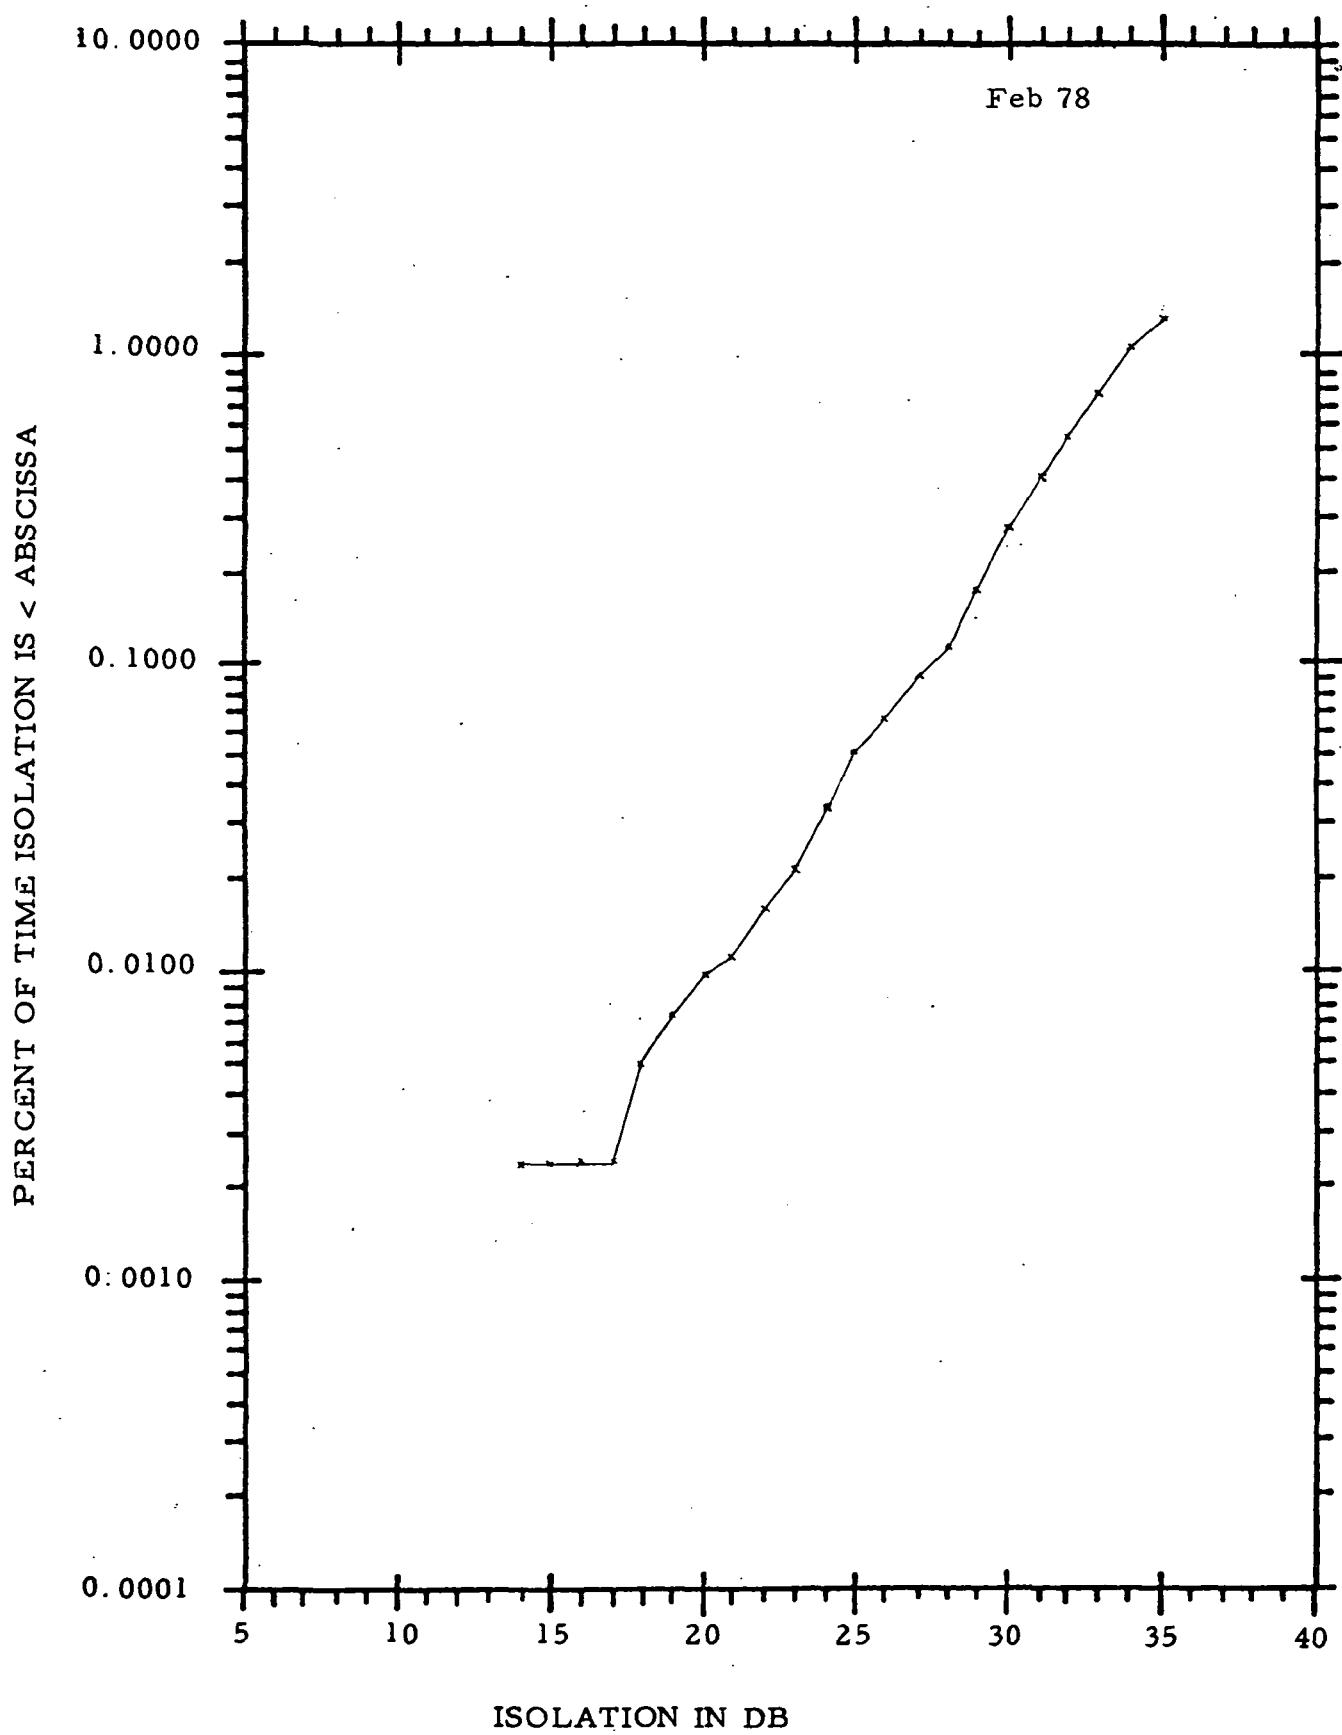

Attenuation and cross-polarization isolation data have been presented for a 12 month period. During this time the weather was close to the long term mean. Fades exceeded 10 dB for about .02 percent of time. With the same probability isolation was reduced below 21 dB. The data events were not evenly distributed over the time of day, however it is hard to identify a distinct pattern from the 12 months data.
