| 16. Abstract For the 1980 requirements of the Early Warning Project, crop calendars for wheat and barley are required for the U.S., the U.S.S.R., and Canada. In this report, new crop calendars are produced for U.S. regions where several years of periodic growth stage observations are available on a CRD basis. Preexisting crop calendars from the LACIE are also collected as are U.S. crop calendars currently being created for the Foreign Commodities Production Forecast project. For the U.S.S.R. and Canada, no new crop calendars are created because no new data are available. Instead, LACIE crop calendars are compared against simulated normal daily temperatures and against the Robertson wheat and Williams barley phenology models run on the simulated normal temperatures. Severe inconsistencies are noted and discussed. For the U.S.S.R., spring and fall planting dates can probably be estimated accurately from satellite or meteorological data. For the starter model problem, the Feyerherm spring wheat model is recommended for spring-planted small grains, and the results of an analysis are presented. For fall-planted small grains, use of normal planting dates supplemented by spectral observation of an early stage is recommended. The importance of non-meteorological factors as they pertain to meteorological factors in determining fall planting is discussed. Crop calendar data available at the Johnson Space Center for the U.S., U.S.S.R., Canada, and other countries are inventoried. | | | | | |

1. INTRODUCTION

The Agriculture and Resources Inventory Surveys Through Aerospace Remote Sensing (AgRISTARS) is a 6-year program of research, development, evaluation, and application of aerospace remote sensing for agricultural resources beginning in fiscal year (FY) 1980. The AgRISTARS program is a cooperative effort of the National Aeronautics and Space Administration (NASA), the U.S. Agency for International Development (AID), and the U.S. Departments of Agriculture, Commerce, and the Interior (USDA, USDC, and USDI).

The goal of the program is to determine the usefulness, cost, and extent to which aerospace remote sensing data can be integrated into existing or future USDA systems to improve the objectivity, reliability, timeliness, and adequacy of information required to carry out USDA missions. The overall approach is comprised of a balanced program of remote sensing research, development, and testing which addresses domestic resource management as well as commodity production information needs.

The technical program is structured into eight major projects as follows:

1. Early Warning/Crop Condition Assessment (EW/CCA)
2. Foreign Commodity Production Forecasting (FCPF)
3. Yield Model Development (YMD)
4. Supporting Research (SR)
5. Soil Moisture (SM)
6. Domestic Crops and Land Cover (DCLC)
7. Renewable Resources Inventory (RRI)
8. Conservation and Pollution (C/P)

The majority of these projects will make direct use of information on crop phenology. Specific areas of these projects to which phenological information is pertinent include classification, acreage and yield estimation, and detection of episodal events.

For identification in satellite imagery of factors affecting crop production over large areas, it is necessary to have information about the expected course of crop development (and hence spectral appearance) in any area. The simplest approach is to gather information about crop development in previous years. For the Large Area Crop Inventory Experiment (LACIE), such information was collected primarily in the U.S., but also in Canada, the U.S.S.R., China, India, and other countries. The information was used to produce historical or normal crop calendars in several formats. In this study, we used additional U.S. data to generate new U.S. crop calendars, we evaluated LACIE crop calendars for the U.S.S.R and Canada, and we prepared an inventory of crop development data available at the Johnson Space Center.

2. U.S. CROP CALENDARS

For nine states in the U.S., we have 5 or more years of periodic observations of crop development on a Crop Reporting District (CRD) level. The crops and CRD's covered by these data are shown in table 1. Additionally, in Louisiana, Mississippi, Arkansas, Ohio, Kentucky, Michigan, and Wisconsin, we have 50-percent dates for some stages of major crops for 4 to 5 years.

During the LACIE, crop calendars were prepared for many of the wheat-growing states, based on limited data or data of uncertain quality. Table 2 lists all the states for which various types of crop development data or crop calendars are available at the Johnson Space Center.

The periodic observations of crop development were processed to calculate 10-, 50-, and 90-percent stage dates by fitting to a linear transformation of the logistic curve as follows:

$$\text{Logistic curve: } P = \frac{100}{1 + be^{-at}}$$

$$\text{Linear transformation: } \ln\left(\frac{100}{P} - 1\right) = \ln b - at$$

where

- P = percent at stage
- t = Julian date of stage observation
- a,b = arbitrary coefficients to be fitted
- e = base of natural logarithm
- ln = function of the natural logarithm

After fitting, the curve was reverse substituted with 10, 50, and 90 percent in order to obtain the appropriate stage dates. The 10-, 50-, and 90-percent dates for stages of each crop are to be found by state, crop, and CRD in reference 10. Each curve was then plotted against the Julian date at 10-day intervals to obtain plots of crop development (ref. 10).

TABLE 1. - CRD'S WITH PERIODIC CROP CALENDAR DATA BY STATE AND CROP

| Crop | CRD number by State | | | | | | | | | |
|---------------|---------------------|--------------|-----------------|-------------------|-------------------|---------------------|----------------------|----------------------|------------------------------------|--|
| | Colorado (8) | Iowa (19) | Kansas (20) | Minnesota (27) | Montana (30) | Nebraska (31) | North Dakota (38) | South Dakota (46) | Texas (48) | |

For the states with 4 or 5 years of 50-percent dates for stages of various crops, mean 50-percent dates and standard deviations are in reference 10 as well as the crop calendar plots produced for the LACIE. The glossy color photographs of bar graphs are not included in this report because of difficulty of reproduction. We believe that the new crop calendars based on periodic observations over known periods are generally more accurate than the LACIE crop calendars and should be preferred for regions where they are available.

Recently, statewide crop calendars have been produced for many crops for 10 states in the U.S. These crop calendars include documentation of data sources and an evaluation of the reliability of the crop calendars. Eventually, almost all of the continental U.S. will be covered by these crop calendars. Currently available crop calendars are in reference 10.

3. U.S.S.R. AND CANADA CROP CALENDARS

For the LACIE, normal crop calendars were prepared for numerous regions of the U.S.S.R. and Canada based on limited historical phenology data or data of uncertain quality. To check the quality of the U.S.S.R. normal crop calendars, we decided to run the Robertson (1968) spring and winter wheat and Williams (1974) spring barley phenology models on simulated long term average daily maximum and minimum temperatures. The daily temperatures were estimated from 20-year mean monthly temperatures for economic regions using a second order harmonic. A constant difference of 20° C between daily maximum and minimum temperatures was assumed to get simulated daily values of maximum and minimum temperatures. A better simulation could probably be done by varying the difference between maximum and minimum temperatures by season and by location, but data were not available to do this. The Robertson and Williams models were run using 30 or 60 consecutive planting dates around the planting dates specified in the LACIE crop calendars. Russian crop calendars, phenology model outputs, and simulated daily temperatures are in reference 11. U.S.S.R. crop calendars, latitudes, planting periods, and availability of long term mean monthly temperatures are summarized in table 3. For several economic regions where temperatures were not available, LACIE crop calendars could not be compared to the phenology models.

For Canada, long term mean monthly maximum and minimum temperatures were available for portions of the provinces of Alberta, Saskatchewan, and Manitoba. The Robertson and Williams spring wheat and barley models were run for those regions on simulated daily temperatures. The LACIE crop calendars, simulated daily temperatures, and phenology model outputs are in reference 12. Crop calendars, planting dates, and latitudes are summarized in table 4.

In the Robertson and Williams phenology models, jointing is defined as the beginning of stem elongation. The LACIE crop calendars are probably reporting jointing when the first internode of the stem has elongated sufficiently to raise the first node above the ground, about a week later than the model definition.

TABLE 3.- SUMMARY OF LACIE U.S.S.R. CROP CALENDAR

TABLE 4.- SUMMARY OF LACIE CANADA CROP CALENDARS

| Province and region | Latitude | Planting period | |
|------------------------|----------|-----------------|---------|
| | | SW | SB |
| Alberta | | | |
| South (area 1) | 51° | 90-155 | -- |
| Central (area 2) | 56° | 115-163 | -- |
| North (area 3) | 57° | 124-163 | -- |
| Lethbridge (S.) | 49.7° | 95-140 | 105-152 |
| Edmonton (C.) | 53.5° | 98-145 | 110-162 |
| Beaver Lodge (N.) | 55.2° | 98-145 | 122-170 |
| Lacombe (S.) | 52.5° | 100-145 | 115-163 |
| Saskatchewan | | | |
| Southeast (area 1) | 49.7° | 90-155 | -- |
| Regina-Wyeth (area 2) | 50.0° | 90-155 | -- |
| South central (area 3) | 49.8° | 90-155 | -- |
| Southwest (area 4) | 49.8° | 90-155 | -- |
| East central (area 5) | 51.2° | 105-163 | -- |
| Central (area 6) | 51.5° | 105-163 | -- |
| West central (area 7) | 51.6° | 105-163 | -- |
| Northeast (area 8) | 52.7° | 118-158 | -- |
| Northwest (area 9) | 53° | 118-158 | -- |
| Indian Head (SE.) | 50.6° | 100-145 | 105-150 |
| Scott (WC.) | 52.4° | 90-145 | 110-155 |
| Saskatoon (C.) | 52.2° | 100-145 | 110-158 |
| Melfort (NE.) | 52.85° | 95-142 | 120-165 |
| Swift Current (SC.) | 50.4° | 102-149 | 105-150 |
| Regina (RW) | 50.47° | 90-136 | 105-149 |
| Manitoba | | | |
| Southeast | 50° | 90-155 | -- |
| South central | 49.7° | 90-155 | -- |
| Southwest | 49.8° | 90-155 | -- |
| North | 50.5° | 118-158 | -- |
| Brandon (SW.) | 49.85° | 100-145 | 110-155 |
| Morden (SC.) | 49.2° | 90-140 | 110-155 |
| Winnipeg (SE.) | 49.8° | 90-140 | 110-155 |

The concept of running a phenology model on normal weather data was tested by running the Robertson spring wheat model on South Dakota daily temperatures simulated from long term monthly average temperatures. The model stage dates were generally within 5 to 10 days of the historical average stage dates for heading and ripe as shown in table 5. Phenological response to weather and planting date variability over several years will not necessarily average in the same way that weather variability averages, and the Robertson and Williams models are not proven to be accurate for the U.S.S.R., so we cannot assume that the phenology model stage dates are generally better than the LACIE crop calendar stage dates.

This technique of running a phenology model on long term average daily weather variables can be used to evaluate crop calendars in areas where historical phenology data are inadequate or to generate new crop calendars where none are available.

In the following sections, the LACIE crop calendars are evaluated as to earliness or lateness for planting, heading, and ripe dates in the U.S.S.R. and for planting, jointing, heading, and ripe dates in Canada. Comments are based on the simulated daily temperatures, on the output of the phenology models, and on general characteristics of wheat and barley. Where possible, some specific correction is indicated. Because the available temperature data are the means of very large areas, they may differ greatly from temperatures at any particular point in a region.

3.1 GENERAL COMMENTS: U.S.S.R.

In the U.S.S.R., winter small grains are planted by calendar date within about a 2-week period specific to each area, provided fields are not too wet to work.¹ Spring small grains are planted after about 3 days of 40° F or greater mean temperatures, again provided the fields are dry enough to work. In the New Lands, spring planting is done by date in the middle of May so that

¹ Pat Ashburn, personal communication, 1980.

TABLE 5.- NORMAL AND ROBERTSON PHENOLOGY MODEL ESTIMATES FOR 10-, 50-, AND 90-PERCENT DATES FOR SOUTH DAKOTA CRD'S^a

| CRD | Percent | Planting | Heading | | | Ripe | | |
|-----|---------|----------|-----------|--------|-------------|-----------|--------|-------------|
| | | | Robertson | Normal | Error (R-N) | Robertson | Normal | Error (R-N) |
| 1 | 10 | 105 | 168 | 172 | -4 | 199 | 198 | 1 |
| | 50 | 117 | 172 | 178 | -6 | 202 | 212 | -10 |
| | 90 | 128 | 178 | 184 | -6 | 207 | 226 | -19 |
| 2 | 10 | 99 | 166 | 170 | -4 | 194 | 197 | -3 |
| | 50 | 111 | 168 | 176 | -8 | 196 | 202 | -6 |
| | 90 | 123 | 173 | 183 | -10 | 200 | 206 | -6 |
| 3 | 10 | 99 | 168 | 170 | -2 | 196 | 198 | -2 |
| | 50 | 108 | 169 | 176 | -7 | 197 | 202 | -5 |
| | 90 | 118 | 172 | 181 | -9 | 199 | 207 | -8 |
| 4 | 10 | 92 | 166 | 168 | -2 | 197 | 195 | 2 |
| | 50 | 109 | 169 | 174 | -5 | 200 | 203 | -3 |
| | 90 | 125 | 176 | 179 | -3 | 206 | 211 | -5 |
| 5 | 10 | 101 | 164 | 166 | -2 | 192 | 194 | -2 |
| | 50 | 111 | 167 | 172 | -5 | 194 | 200 | -6 |
| | 90 | 122 | 171 | 177 | -6 | 198 | 207 | -9 |
| 6 | 10 | 103 | 165 | 167 | -2 | 193 | 197 | -4 |
| | 50 | 110 | 167 | 172 | -5 | 195 | 204 | -9 |
| | 90 | 117 | 170 | 178 | -8 | 197 | 212 | -15 |
| 7 | 10 | 96 | 165 | 169 | -4 | 196 | 199 | -3 |
| | 50 | 109 | 169 | 175 | -6 | 200 | 204 | -4 |
| | 90 | 123 | 175 | 182 | -7 | 206 | 208 | -2 |
| 8 | 10 | 95 | 161 | 163 | -2 | 190 | 196 | -6 |
| | 50 | 106 | 164 | 171 | -7 | 192 | 200 | -8 |
| | 90 | 118 | 169 | 179 | -10 | 196 | 205 | -9 |
| 9 | 10 | 100 | 162 | 166 | -4 | 189 | 192 | -3 |
| | 50 | 107 | 164 | 171 | -7 | 191 | 196 | -5 |
| | 90 | 114 | 166 | 177 | -11 | 193 | 200 | -7 |

^aNormal 10-, 50-, and 90-percent dates for planting, heading, and ripe stages for South Dakota spring wheat and Robertson phenology estimates for heading and ripe dates run on daily maximum and minimum temperatures simulated from long term mean monthly temperatures with $T \text{ mean} = T \text{ max} - 10^\circ \text{ F}$
 $= T \text{ min} + 10^\circ \text{ F}$

flowering occurs after the hottest part of the season. Once planting begins, CRD-sized areas are planted in about 3 to 5 days.¹ Therefore, tracking the movement of planting activities across the U.S.S.R. by satellite may allow accurate estimates of planting dates. Where satellite data are unavailable, a meteorological starter model may give acceptable results.

Jointing should occur 20 to 30 days before heading, but in most of the crop calendars, jointing is listed only 10 to 20 days before heading. This is clearly in error.

Generally, late plantings at a given site should mature in fewer days than early plantings, because of the effects of long days and high temperatures. The only exceptions would be when ripening occurs after late August and is further delayed by cooling conditions in the fall. This means that stages of later plantings should generally be slightly closer together than stages of earlier plantings. The forms of the Robertson model used in this study do not always reflect this principle because of unrealistic response curves in the models for day length, T_{max} , and T_{min} .

Spring planting should not occur before mean air temperature is about 45° F (soil temperature about 42° F). This will, of course, occur earlier or later than the normal date in a given year. Some of the regions for which normal temperatures are available are quite large. The Far East Region covers 16° of latitude, the East Siberia region covers 8° of latitude, and several regions cover more than 5° of latitude. Differences in temperature and even more differences in day length across such regions could account for some differences in plant growth stages and planting dates. Except for areas far north or south of the center of an economic region, it is probably reasonable to expect earliest plantings in any year not more than 3 weeks before mean temperature reaches 40° F and to expect the mean beginning of planting not before the mean temperature reaches 45° F.

¹ Pat Ashburn, personal communication, 1980.

3.1.1 BALTICS: ECONOMIC REGION 0100

Estonia, Latvia, Lithuania, and Kaliningrad - The period between jointing and heading is 10 days too short in all cases. Otherwise, crop calendars look reasonable. The crop calendars probably should be corrected by moving the planting dates 5 days earlier and the harvest dates 5 days later.

3.1.2 WEST UKRAINE: ECONOMIC REGION 0300

L'vov and Volyn - The period between jointing and heading is about 10 days too short in all cases. The periods of entering jointing and heading are longer than implied by the short planting periods. The placement of the stages looks reasonable. The best correction probably would be to shorten the periods of entering jointing and heading and make the mean of the entering jointing period 10 days earlier than it is.

3.1.3 NORTH CENTRAL UKRAINE: ECONOMIC REGION 0400

Same comments as for West Ukraine.

3.1.4 NORTHEAST UKRAINE: ECONOMIC REGION 0500

Same comments as for West Ukraine. Also, the model indicates jointing may be 10 days early for winter wheat, but this is not certain.

3.1.5 EAST UKRAINE: ECONOMIC REGION 0600

Dnepropetrovsk - Jointing is probably 10 days too late for spring barley. The jointing to heading period is about 10 days too short in all cases. Fall planting may be 10 to 20 days early.

3.1.6 MOLDAVIA: ECONOMIC REGION 0800

Same comments as for West Ukraine. Also, for the spring-planted grains, the planting to jointing period is too long relative to the whole growing period. The crop calendars probably should be corrected by making jointing 5 to 10 days earlier.

3.1.7 KRASNODAR: ECONOMIC REGION 0900

The jointing to heading period is 5 to 10 days too short. Otherwise, the stages look reasonable. The crop calendars probably should be corrected by making jointing 5 to 10 days earlier.

3.1.8 NORTHEAST CAUCASUS: ECONOMIC REGION 1000

Stavropol', Rostov, Dagestan, Kabardino-Balkar, Checheno-Ingush, and Kalmyk - Planting of winter wheat in Dagestan, Checheno-Ingush, and Kalmyk is about 30 days too late. Spring grains are planted 30 days too early in Stavropol and 10 days too early in Rostov. The jointing to heading period is 5 to 15 days too short in all cases. For spring barley, the model is underestimating the rate of development during the last stages for late plantings. The crop calendars should be corrected by shortening the planting periods to 30 days starting in late March and mid-September. Make jointing 5 to 15 days earlier.

3.1.9 WEST BLACK SOIL: ECONOMIC REGION 1100

Belgorod, Kursk, and Orel - The 70-day entering jointing period following a 10-day planting period in Orel is incorrect. Probably winter wheat jointing should start in early or middle May in all three areas. Planting of spring grains is 10 to 15 days too early in Belgorod and Kursk. The jointing to heading period is 5 to 15 days too short in all cases. For Orel winter wheat, set jointing on May 1 to May 25. Make jointing 5 to 10 days earlier elsewhere. Shorten the planting period to 30 days or less in all cases.

3.1.10 EAST BLACK SOIL: ECONOMIC REGION 1200

Lipetsk, Tambov, and Voronezh - Planting of spring grains is 10 to 20 days early in Voronezh and lasts 20 to 30 days too long. For winter wheat, jointing, heading, and ripe periods may be 10 to 20 days early in Lipetsk and Tambov. The jointing to heading period is 10 to 20 days too short in all cases except for winter wheat at Voronezh. Correct the calendar by setting planting in April and September. Make jointing to harvest of winter wheat 10 to 20 days later in Lipetsk and Tambov. Make the heading to harvest period about 10 days later in all cases except for winter wheat in Voronezh.

3.1.11 CENTRAL: ECONOMIC REGION 1300

Bryansk, Vladimir, Ivanovo, Kalinin, Kaluga, Moscow, Ryazan, Smolensk, and Yaroslavl - There are 3 crop calendars here: Bryansk and Smolensk are identical; Vladimir, Ivanovo, Kaluga, Moscow, Ryazan, and Yaroslavl are identical; and Kalinin is a third pattern. The same comments apply as for West Ukraine. Otherwise, everything looks reasonable.

3.1.12 VOLGA-VYATSK: ECONOMIC REGION 1400

Gor'kiy, Mari, Mordva, and Chuvash - There is no spring barley for these regions in the LACIE crop calendars. Winter wheat jointing is starting 20 days early in Mari and Mordva. The jointing to heading period is 5 to 20 days too short in all cases. Sixty-day entering jointing periods in Mari and Mordva do not follow from the 20-day planting periods. Otherwise, the stages look reasonable. Correct the calendar by shortening the entering jointing period to 20 days. Delay heading to harvest periods sufficiently to give a 20 to 30 day jointing to heading period.

3.1.13 UPPER VOLGA: ECONOMIC REGION 1500

Tatar and Ul'yanovsk - Spring small grains planting in Ul'yanovsk is 20 days too early. The jointing to heading period is 5 to 15 days too short in all cases, except for winter wheat in Tatar where jointing is 15 to 25 days too early. Correct the calendar by starting spring planting in late April and winter wheat jointing in early May. Delay heading to harvest stages sufficiently to give a 20 to 30 day jointing to heading period.

3.1.14 MIDDLE VOLGA: ECONOMIC REGION 1600

Kuybyshev, Penza, and Saratov - Planting of spring small grains is 10 days too early in Kuybyshev and 20 days too early in Penza. For fall planted grains, jointing in the spring is 10 to 20 days too early in all cases. The jointing to heading period is 5 to 15 days too short in all cases. Correct the crop calendar by starting spring planting in early April and winter wheat jointing in late April. Delay heading to harvest stages 5 to 15 days in all cases.

3.1.15 LOWER VOLGA: ECONOMIC REGION 1700

Astrakhan' and Volgograd - Winter wheat planting in Astrakhan' should be 30 days earlier in the fall, and spring stages should be 20 days later. In Astrakhan', all stages of spring grains should be 10 to 20 days later. The jointing to heading period is 10 to 15 days too short in all cases so stages after jointing should be an additional 10 to 15 days later.

3.1.16 NORTH WEST URALS: ECONOMIC REGION 1800

Udmurt - For winter wheat, jointing begins 15 to 20 days too late in the spring. The jointing to heading period is 5 to 25 days too short in all cases. Some long periods for entering stages do not agree with relatively short planting periods.

3.1.17 SOUTHERN URALS: ECONOMIC REGION 1900

Bashkir and Orenburg - Planting is 10 to 20 days too early and lasts 40 days too long for spring wheat. The jointing to heading period is 5 to 20 days too short in all cases.

3.1.18 NORTH EAST URALS: ECONOMIC REGION 2000

Chelyabinsk, Kurgan, Sverdlovsk, and Tyumen' - Spring grains are planted 20 to 30 days too early in Sverdlovsk and Tyumen'. In Chelyabinsk, the spring barley model does not allow ripening after day 236 which is probably an error in the model. In some cases, the jointing to heading period is up to 20 days too short. Correct the crop calendar by starting spring planting in late April and by making the entering jointing period last about 20 days starting in early June in Sverdlovsk and Tyumen'.

3.1.19 KUSTANAY: ECONOMIC REGION 2200

Planting for spring wheat should take 20 to 30 days starting in late April. The spring barley model does not allow ripening after day 239, which is probably an error in the model. The jointing to heading period is up to 20 days too short so stages after jointing should be 10 to 20 days later.

3.1.20 WEST SIBERIA: ECONOMIC REGION 2600

Kemerovo and Omsk - Except for a too short jointing to heading period, everything looks reasonable.

3.1.21 ALTAY KRAY: ECONOMIC REGION 2700

Everything looks reasonable.

3.1.22 TRANSCAUCASUS: ECONOMIC REGION 2800

Azerbaijan, Armenia, and Georgia - Winter wheat planting may be 20 days late in Azerbaijan, or it may be correct. The jointing to heading period is 10 to 15 days too short in all cases.

3.1.23 SOUTH KAZAKHSTAN: ECONOMIC REGION 2900

South Kazakhstan, Kzyl-Orda, Chimkent, Dzambul, Dzhezkazgan, Alma-Ata, Taldy-Kurgan, and Vostochno - Since this region covers about 10° of latitude, as well as 20° of longitude, the single set of normal temperatures that is available, probably does not represent all parts of the region equally well. In the southernmost area of Chimkent, fall planting appears to be 20 to 30 days early, and in the northern area of Dzhezkazgan, spring planting appears to be 20 to 30 days late. The jointing to heading period is up to 20 days too short in some cases.

3.1.24 CENTRAL ASIA: ECONOMIC REGION 3000

Uzbek, Kirgiz, and Turkmen - Fall planting seems to be 20 to 30 days too late in Uzbek and in Turkmen. Otherwise, except for the short period between jointing and heading in some cases, everything looks reasonable.

3.1.25 EAST SIBERIA: ECONOMIC REGION 3100

Krasnoyarsk, Irkutsk, Chita, Buryat, and Tuva - Spring planting in Buryat appears to start 30 to 40 days too early. The jointing to heading period is 10 to 20 days too short, in some cases.

3.1.26 FAR EAST: ECONOMIC REGION 3200

Far East and Amur - The barley model does not run for the given planting dates except for day 110 at 60° N. The spring wheat data look reasonable except for the duration of the entering jointing period.

3.2 GENERAL COMMENTS: CANADA

For Canada during LACIE, crop calendars were prepared for spring wheat for several large areas of each of the prairie provinces of Alberta, Saskatchewan, and Manitoba. Additionally, crop calendars were prepared for spring wheat, spring barley, spring oats, and winter rye for several sites in each of these provinces. The set of crop calendars which only cover spring wheat shows an unrealistically long period between jointing and heading (about 60 days); and sometimes, the set shows a shift from a relatively short planting period and short stage entry periods through jointing to long stage entry periods after jointing.

As in the U.S.S.R., periods between stages should get shorter for later plantings until middle to late August when cooling temperatures will delay development.

Beginning of planting for spring barley is shown as occurring 10 to 25 days later than for spring wheat in almost all cases. However, the beginning of planting for spring wheat is frequently shown as the end of March, when night temperatures are usually well below 20° F and day temperatures are only occasionally above freezing. Based on normal temperatures, early planting probably does not begin until late April or May when low temperatures approach 30° F.

Harvest is shown as continuing into late October when low temperatures are well below 20° F. Since ripening is shown as ending 20 to 30 days earlier, that seems a bit late.

3.2.1 ALBERTA

3.2.1.1 South (Spring Wheat)

Planting is started 20 to 30 days too early and the jointing to heading period is 30 to 35 days too long, so delay early stages and advance later stages.

3.2.1.2 Lethbridge (Spring Wheat and Barley)

For spring wheat, planting is started 15 to 20 days too early, and the time between late jointing and late heading is 10 to 15 days too short. For spring barley, the heading to soft dough period may be a little too long.

3.2.1.3 Lacombe (Spring Wheat and Barley)

For spring wheat, planting begins 20 days too early and the jointing to heading period is up to 15 days too short.

3.2.1.4 Central (Spring Wheat)

Planting may be started 5 to 10 days too early and the planting to jointing period is 10 to 15 days too short. The jointing to heading period ranges from 20 days too short (early planting) to 30 days too long (late planting). The heading to soft dough period is probably 10 to 20 days too long.

3.2.1.5 Edmonton (Spring Wheat and Barley)

For spring wheat, planting begins 20 to 30 days too early and the jointing to heading period for late planting is 10 days too short.

3.2.1.6 North (Spring Wheat)

Planting may begin 5 to 10 days early. The jointing to heading period is 20 days too long for late plantings. Late ripening in early October is probably 10 to 15 days too late.

3.2.1.7 Beaver Lodge (Spring Wheat and Barley)

For spring wheat, planting begins 20 to 30 days too early. The jointing to heading period is 5 to 10 days too short.

3.2.2 SASKATCHEWAN

3.2.2.1 Southeast (Spring Wheat)

Planting is started 30 days too early. The jointing to heading period is 40 to 45 days too long, and the soft dough to ripe period may be a few days too short. Early stages should be made later and later stages should be advanced.

3.2.2.2 Indian Head (Spring Wheat and Barley)

For spring wheat, the jointing to heading period is 5 to 10 days too short.

3.2.2.3 Regina-Wyeth (Spring Wheat)

Planting is started 30 days too early and the jointing to heading period is 30 to 35 days too long. Correct the crop calendar by making planting later.

3.2.2.4 Regina (Spring Wheat and Barley)

Planting for spring wheat is probably started about 30 days too early and, for barley, about 10 days too early.

3.2.2.5 South Central (Spring Wheat)

Planting is started 20 to 25 days too early and the jointing to heading period is about 10 days too short.

3.2.2.6 Swift Current (Spring Wheat and Barley)

Planting is started 15 to 20 days too early and the jointing to heading period is 5 to 10 days too short for both crops.

3.2.2.7 Southwest (Spring Wheat)

Planting is started about 30 days too early and the jointing to heading period is 30 to 35 days too long. Correct the crop calendar by delaying planting.

3.2.2.8 East Central (Spring Wheat)

Planting is started 20 to 30 days too early and the jointing to heading period is 10 to 20 days too long.

3.2.2.9 Central (Spring Wheat)

Planting is started 20 to 30 days too early. Correct the crop calendar by delaying planting.

3.2.2.10 Saskatoon (Spring Wheat and Barley)

Planting is started 20 days too early and the jointing to heading period is 5 to 10 days too short for spring wheat.

3.2.2.11 West Central (Spring Wheat)

Planting is started 20 days too early, the jointing to heading period is 10 to 25 days too long, and the heading to soft dough period may be 10 days too long. Correct the crop calendar by delaying planting.

3.2.2.12 Scott (Spring Wheat and Barley)

For spring wheat, planting is started 30 days too early, and for spring barley, the jointing and heading period is 5 days too short.

3.2.2.13 Northeast (Spring Wheat)

Planting is started possibly 10 days too early. The jointing to heading period ranges from 10 days too short to 30 days too long. The short planting period does not agree with the long stage entry periods after jointing.

3.2.2.14 Melfort (Spring Wheat and Barley)

Planting is started 20 days too early, and the jointing to heading period is 5 days too short for spring wheat. For spring barley, the jointing to heading period is 10 days too short.

3.2.2.15 Northwest (Spring Wheat)

Planting may be started 10 days too early, and the jointing to heading period ranges from 10 days too short to 30 days too long.

3.2.3 MANITOBA

3.2.3.1 Southeast (Spring Wheat)

Planting is started 30 days too early, and the jointing to heading period is 30 to 40 days too long. Correct the crop calendar by delaying planting.

3.2.3.2 Winnipeg (Spring Wheat and Barley)

For spring wheat, planting is started 20 to 30 days too early, and the jointing to heading period is 5 to 10 days too short.

3.2.3.3 South Central (Spring Wheat)

Planting is started 30 days too early, and the jointing to heading period is 30 to 40 days too long. Correct the crop calendar by delaying planting.

3.2.3.4 Morden (Spring Wheat and Barley)

For spring wheat, planting is started 30 days too early, and the jointing to heading period is a few days too short.

3.2.3.5 Southwest (Spring Wheat)

Planting is started 30 days too early, and the jointing to heading period is 30 to 40 days too long. Correct the crop calendar by delaying planting.

3.2.3.6 Brandon (Spring Wheat and Barley)

For spring wheat, planting is started about 20 days too early, and the jointing to heading period is 10 days too short.

3.2.3.7 North (Spring Wheat)

The jointing to heading period ranges from 10 days too short to 30 days too long. The long stage entry periods after jointing do not agree with the relatively short planting period and should be shortened.

4. STARTER MODELS

One of the major factors affecting plant development is the planting date (reference 6). Planting occurs in a relatively long period (20 to 60 days) in a region in any given year. Some years, the planting period may be earlier or later than the average (normal) planting period due to weather conditions or other factors. A meteorologically based starter model may attempt to predict the mean planting date or the shift in the planting period in a given year due to meteorological factors.

4.1 SPRING GRAINS

For spring planted grains, several approaches have been developed (refs. 1, 9, and 13) and evaluated (ref. 13). The Feyerherm model was found to be the best existing model (table 6).

Development of the Feyerherm spring wheat starter model was based on the concept that a cool, wet late spring could delay planting while a warm, dry condition permits early planting. The weather variations among seasons and regions were defined as a warming/planting (W/P) day. W/P is assigned a 0 to 1 value for each calendar day beginning January 19. (This date was arbitrarily chosen and coincides roughly with the coldest time of the year in the northern hemisphere.) Accumulated W/P days were then related to the percentage of wheat planted. When the accumulated W/P value reached 35.5 degree-days, it was assumed that 50 percent of the crop had been planted. The general form of the model was as follows:

$$WP = 0, \text{ if } TA \leq 32$$

$$WP = \alpha(TA - 32)(PRE), \text{ if } 32 < TA \leq 32 + \frac{1}{\alpha}$$

$$WP = 1, \text{ if } TA > 32 + \frac{1}{\alpha}$$

where

$$TA = \frac{T_{\max} + T_{\min}}{2}$$

T_{\max} = maximum daily air temperature (°F)

T_{\min} = minimum daily air temperature (°F)

TABLE 6.- RESULTS OF STARTER MODEL EVALUATION

| N | Segment | Year | Normal | | Feverherm | | Stuff-Phinney | |
|-----|---------|-------|--------|-------------------|-----------|-------------------|---------------|-------------------|
| | | | RMSE | Bias ^a | RMSE | Bias ^a | RMSE | Bias ^a |
| 45 | 1987 | 1975 | 5.993 | 2.489 | 5.651 | 1.489 | 15.339 | 14.178 |
| 8 | 1965 | 1975 | 8.254 | 0.125 | 8.329 | 1.125 | 16.359 | 14.125 |
| 5 | 1967 | 1976 | 5.495 | 5.000 | 14.184 | 14.000 | 16.162 | 16.000 |
| 2 | 1970 | 1976 | 15.652 | 14.000 | 6.964 | -2.500 | 30.806 | 30.000 |
| 8 | 1965 | 1976 | 4.213 | -1.250 | 18.688 | -18.250 | 12.420 | 11.750 |
| 12 | 1987 | 1976 | 34.000 | 33.600 | 18.300 | 17.600 | 46.900 | 46.600 |
| 31 | 1966 | 1976 | 21.579 | 19.710 | 10.477 | 5.710 | 32.904 | 31.710 |
| 9 | 1687 | 1976 | 23.840 | 19.889 | 15.868 | 8.889 | 37.283 | 34.889 |
| 10 | 1687 | 1977 | 9.654 | -5.000 | 12.215 | -9.000 | 11.500 | 8.000 |
| 11 | 1987 | 1977 | 31.700 | 31.182 | 16.217 | 15.182 | 37.616 | 37.182 |
| 141 | Total | 75-77 | 18.518 | 11.647 | 11.90 | 3.831 | 27.486 | 23.619 |

^aError is defined as the estimated planting date minus the observed planting date. A positive bias indicates the model prediction was late, while a negative bias indicates the model prediction was early.

α = the threshold value

PRE = a value between 0 and 1 as a function of the previous 3 days of precipitation.

For spring wheat, Feyerherm assigned $\alpha = 0.1$ and PRE = 1 since precipitation had an effect that was statistically insignificant.

4.2 WINTER GRAINS

Estimating the rate of planting of small grains in the fall is an extremely complex problem. Several factors combine to allow a long period for possible planting in any year and considerable flexibility as to when to plant in that period. For very early plantings, excessive vegetation before winter may reduce winter hardiness; however, excessive vegetation may be cut for silage or simply grazed off a few weeks before the beginning of dormancy, and the crop will winter harden. For extremely late plantings, insufficient crown and root development may lead to increased winter kill, if the winter cold is severe while the crop has little snow cover.

Within the rather long period (60 to 90 days) of safe planting, factors effecting a farmer's decision about when to plant are convenience, grazing plans, and soil moisture. Convenience may be affected by activities associated with another crop (summer crop or forage), off-farm employment, and seasonal availability of labor (before or after corn, soybean, or other major harvests). Excessive soil moisture makes it impossible to work in the fields. During dry conditions the farmer may wait for rain. However, since seeds will sit in dry ground for a substantial period, a farmer may plant in dry ground and hope for rain before the seeds are eaten or winter cold sets in. Thus, weather factors have very limited importance in determining the planting date.

A number of researchers have considered the problem of meteorologically-based starter models for winter wheat (refs. 2, 3, 8, and 9) but have been thwarted by the relative unimportance of meteorological constraints for determining planting date. The recommended approach is to use the normal planting dates until the crop is visible in spectral imagery, either in the fall or in early spring.

5. INVENTORY

Crop development data for the U.S. are shown in tables 1 and 2. Data available for the U.S.S.R. and Canada are shown in tables 3 and 4. Other sources of crop planting and development data for non-U.S. areas are listed below.

6. SUMMARY

For the 1980 requirements of the Early Warning Project, crop calendars for wheat and barley are required for the U.S., the U.S.S.R., and Canada. In this report, new crop calendars are produced for U.S. regions where several years of periodic growth stage observations are available on a CRD basis. Preexisting crop calendars from the LACIE are also collected as are U.S. crop calendars currently being created for the Foreign Commodities Production Forecast task.

For the U.S.S.R. and Canada, no new crop calendars are created because no new data are available. Instead, LACIE crop calendars are compared against simulated normal daily temperatures and against the Robertson wheat and Williams barley phenology models run on the simulated normal temperatures. Severe inconsistencies are noted and discussed. For the U.S.S.R., spring and fall planting dates can probably be estimated accurately from satellite or meteorological data.

For the starter model problem, the Feyerherm spring wheat model is recommended for spring-planted small grains and results of an analysis are presented. For fall-planted small grains, use of normal planting dates supplemented by spectral observation of an early stage is recommended. The relative importance of non-meteorological factors relative to meteorological factors in determining fall planting is discussed. Crop calendar data available at the Johnson Space Center for the U.S., U.S.S.R., Canada, and other countries are inventoried.
