Abstract

This report describes the high speed Dynamic Data Acquisition System (DDAS) which provides the capability for the simultaneous measurement of velocity, density, and total temperature fluctuations. The system of hardware and software is described in context of the wind tunnel environment.

The DDAS replaces both a recording mechanism and a separate data processing system. The data acquisition and data reduction process has been combined within DDAS. DDAS receives input from hot wires and anemometers, amplifies and filters the signals with computer controlled modules, and converts the analog signals to digital with real-time simultaneous digitization followed by digital recording on disk or tape. Automatic acquisition (either from a computer link to an existing wind tunnel acquisition system, or from data acquisition facilities within DDAS) collects necessary calibration and environment data. The generation of hot wire sensitivities is done in DDAS, as is the application of sensitivities to the hot wire data to generate turbulence quantities. The presentation of the raw and processed data, in terms of root mean square values of velocity, density and temperature, and the processing of the spectral data is accomplished on demand in near-real-time with DDAS.

This paper describes the interface to DDAS and the internal mechanisms of DDAS. A summary of operations relevant to the use of the DDAS is also provided.
Symbols

$A_1-A_8$ Constants in equation (1)

$E$ mean voltage across wire

e' instantaneous voltage across wire (less the mean)

$G_w$ instrumentation amplifier scalar

$S_u$ velocity sensitivity $\frac{\partial \log e}{\partial \log u} \rho, T_0, T_w$

$S_\rho$ density sensitivity $\frac{\partial \log e}{\partial \log \rho} u, T_0, T_w$

$S_{T_0}$ temperature sensitivity $\frac{\partial \log e}{\partial \log T_0} u, \rho, T_w$

$T_0$ mean total temperature

$T_w$ mean temperature of heated wire

$u$ mean velocity

$\rho$ mean density

1. INTRODUCTION

Recent advancements have been made in hot wire anemometry techniques which allow a three wire probe to separate three components of the perturbations in the flow field. Velocity, density and total temperature fluctuations can be determined as a function of three parallel hot wires, since at subsonic and transonic speeds it is generally conceded that the voltage measured across a heated wire mounted normal to the flow and operated with a constant temperature anemometer is a function of velocity, density and total temperature. Under these conditions, a single equation is obtained
for the fluctuating voltage across a single wire which is a function of the three variables - velocity, density, and total temperature. Quantitative measurements for the three fluctuations in the flow variables have used probes with three wires mounted normal to the flow and operated at three different "overheats".

The development of a dedicated hardware and software system to support hot wire anemometry at NASA Langley Research Center in the Fluid Dynamics Branch of the Transonic Aeronautics Division was precipitated by the necessity to process simultaneous hot wire data from three wire probes more rapidly than previously possible.

Prior to the development of the DDAS, all data was acquired on FM tape, and all processing was done in an off-line batch mode. This method delayed recognition of faulty or incomplete data, and test results were often delayed several months.

During a flow diagnostics test in the 8 Foot Transonic Pressure Tunnel (8'TPT) at NASA Langley Research Center in January of 1988 the DDAS was connected in parallel to the existing test instrumentation systems to provide an initial test bed for the new system. See Figure 1. The DDAS was not designated as a primary data acquisition or reduction system, but it soon became apparent that the data logging capabilities would be especially helpful in collecting the hot wire calibration data in an easily manageable format. The hot wire calibration data and the generation of hot wire sensitivities were processed only by the DDAS and the calibration data and sensitivities were used both by DDAS and by other data processing facilities. As a test of the digitization and recording capability, dynamic data was routinely digitized in parallel with the FM tape recordings. As soon as adequate calibration data was collected, the DDAS processed some of the data, and provided velocity, density, and total
temperature turbulence measurements. These results compared favorably with subsequent off-line batch data processing.

A second test was supported to compare hot wire techniques and laser velocimetry techniques in the Basic Aerodynamic Research Facility (B.A.R.F.).

The DDAS provides the processes necessary to:
1) acquire the hot wire calibration data
2) acquire the dynamic hot wire data
3) generate hot wire coefficients and sensitivities
4) compute velocity, density, and total temperature fluctuations
5) compute other statistical relationships
6) provide spectral analysis
7) manage data
8) produce reports and plots

2. SYSTEM DESCRIPTION

DDAS is a system of hardware and software based on systems purchased from Data Laboratories, Ltd., Precision Filters, Inc., and Hewlett Packard Corporation. Modifications and enhancements to the software and hardware have converted a waveform recorder into a hot wire anemometry acquisition and processing system specifically tailored to the three wire technique that yields separate velocity, density and total temperature components of turbulence.

2.1. HARDWARE
The system (fig. 1) is divided into an analog front end, and a computer-based processing and display section. The analog front end consists of a filter/amplifier subsystem, a high speed digitizer, and a low speed digitizer (or a data link to another acquisition computer). All are fully computer controlled. The processing and display subsystem controls the analog subsystems, and receives the digitized data, processes the data, displays the data, and stores the data in a permanent file.

2.1.1. Amplifier and Filter Subsystem

The analog signals from the hot wire anemometers are first routed to the Precision Filters, Inc. precision amplifier and filter subsystem. This subsystem is currently configured for four channels, providing support for only one three wire probe. Each channel successively passes the anemometer signal through a pre amplifier, high pass filter, low pass filter, and a post amplifier. The full bandwidth capability of each channel is 0.1Hz to 200KHz, but the high pass and low pass filters usually provide a narrower bandwidth (1Hz to 5KHz). The high pass filter acts as the anti-aliasing filter for the high speed digitizer.

2.1.2. High Speed Digitizer Subsystem

A high speed digitizer, called a Multitrap modular waveform recorder by Data Laboratories, Ltd., is configured to digitize up to 14 channels of fluctuating hot wire data (three channels are required for each 3-wire probe) at rates of up to one million (1M) samples per second (6 channels at up to 1M samples/sec, and 8 channels at up to 256 thousand (256K) samples/second. This data is stored temporarily in the Multitrap buffer memories (up to 256,000 samples per channel), and then transferred to the
HP 9000/330 computer at about 100,000 samples per second - one channel memory at a time - via a dedicated 16 bit parallel bus (GPIO).

2.1.3. **Low speed digitizer**

This subsystem is not currently implemented, and an existing wind tunnel data acquisition system provided DDAS the functions of a low speed digitizer subsystem. However, the optional low speed digitizer subsystem would consist of a multiplexor and digitizer selected for collection of mean values, not fluctuating values. This subsystem would be used to collect calibration data and tunnel parameter data, which would be logged for further processing of the calibration and fluctuating data.

2.1.4. **Computer link to tunnel computer**

The General Purpose Interface Bus (GPIB), an IEEE488 standard bus, is used to receive static data from the existing tunnel data acquisition system computer. The tunnel computer transmits a packet of data relevant to the tunnel conditions and hot wire calibration data. This link was selected because of its availability in both the tunnel computer and in the DDAS computer. It provides an 82,000 byte per second transfer rate, which is more than adequate to receive as many as four complete ASCII data packets per second. The tunnel computer actually sent only one packet per second.

Use of the existing tunnel data acquisition system to collect the tunnel conditions and the additional mean values related to the hot wire calibration data eliminates the need for a parallel hardware system (the low speed digitizer), and the need to develop instrument calibration software and hardware. It does, however, provide additional work for the tunnel computer personnel to configure their acquisition setup to handle
the additional channels, and to provide the GPIB software to generate the
data packets for the DDAS.

The link is configured with the DDAS end as not system controller, and as
device 01. This was accomplished by setting switches on the HP 98624A HP-
IB Interface Card inserted into the computer specifically for the link.
The select code was set to 8; interrupts are not relevant, since they are
not used. The wind tunnel computer providing the data packet is
configured as system controller, and outputs ASCII data packets at a rate
set by the wind tunnel computer.

The packet is read into a DDAS packet buffer with one program statement in
the subroutine Get_packet in module MODUSR2: ENTER Pkt_sc;Pkt$(*)
, where
Pkt_sc is equal to 8, and the Pkt$ array was sized for 47 each 80
character strings.

The packet format is shown in Table 1.

2.1.5. Computer Peripherals

2.1.5.1. Disk storage

75Mb of non removable disk storage is available for programs and data. In
addition, a 1.2Mb removable disk drive is available for program
development and hot wire calibration data.

2.1.5.1.1. 55Mb hard disk

The computer then transfers the data to a 55Mb hard disc at about the same
100,000 samples per second - one channel at a time.
2.1.5.1.2. 20Mb hard disk

Programs and support software is stored on the 20Mb hard disk.

2.1.5.2. Tape storage

Once the data disc is full, the data is copied to a 67Mb tape cartridge for permanent storage.

2.1.5.3. Display

A color CRT is the system console and data display.

2.1.5.4. Plotter

An 8 pen autoload flatbed plotter is available for plot generation, and is used to display dynamic data and hot wire calibration data.

2.1.5.5. Printer

A dot matrix printer is available for data display. It can produce screen dumps, but is used primarily to generate a record of the hot wire calibration data, and, as data processing is accomplished, the results of the processing are printed.

2.2. SOFTWARE

2.2.1. Software environment
All DDAS programs operate under a BASIC operating system, in an interpretive BASIC language. Several compiled subroutines are a part of the ACQUIRE software system to enhance computational speed in some parts of the software.

2.2.2. **Baseline software**

The ACQUIRE software system, provided by Data Laboratories, Ltd. is the basis for the Dynamic Data Acquisition System (DDAS) used for the acquisition of hot wire anemometry data.

Since the ACQUIRE package is an off-the-shelf product, no attempt to describe its full capability will be made.

ACQUIRE has been slightly modified in only one area - the addition of a sequence number to a dynamic data disk file was inhibited if it was not necessary to discriminate between two files with the same name. See Section 2.2.6.2.1.2. for further discussion on the requirement for the modification.

2.2.3. **Hot wire application software**

Major additions were made to ACQUIRE in the form of two sub-programs: MODUSR1 and MODUSR2. These user written modules are configured according to guidelines provided by ACQUIRE, so that they will be automatically included in ACQUIRE. Appendix A contains the full program listings of these two modules.

The functions implemented in both MODUSR1 and MODUSR2 are listed in Appendix B.
2.2.4. **Configuration files**

Configuration files used by ACQUIRE for the 8'TPT test include acquisition setup parameters, hardware configuration parameters, and default display parameters. They are set, saved and stored by a variety of ACQUIRE functions.

2.2.5. **Sequence program files**

The sequence program functions of ACQUIRE provide a mechanism for specifying a series of functions to be accomplished. Both the initialization and acquisition sequence program files used to tailor the DDAS for support of the 8'TPT test are listed in Appendix C.

Although the configuration files and sequence files are not the easiest to configure, the result is a system that is literally a "turnkey" system. Turn on the hardware, allow the hardware and software to be configured, and press a button to simultaneously acquire calibration and dynamic data.

2.2.6. **Hot wire data acquisition**

The ACQUIRE software system was augmented to support the specific requirements of hot wire anemometry systems currently in use at NASA Langley Research Center in the Fluid Dynamics Branch of the Transonic Aeronautics Division. Software design and implementation followed both form and style of the supplied ACQUIRE software, maintaining the appearance of a seamless environment within ACQUIRE. This feature resulted in a software system for an instrument that has evolved from a waveform recorder to a hot wire anemometry system designed to acquire and process both mean hot wire calibration data and fluctuating hot wire data.
The end result has been an easily used flow diagnostics instrument that minimizes the researchers workload.

With hot wires, there are most often two concurrent tasks: calibration of the wires, and acquisition of the dynamic, or fluctuating data. This system is designed to calibrate and process three wire probe data. The current implementation supports two three wire probes, and acquires, processes, and stores them separately.

Once the instrument is configured, each data point is acquired with the push of a single button -- one button recording. Data processing does require a few more button sequences, but only because the researcher provides more direction in the data reduction process.

For the 8'TPT flow diagnostics test in January of 1988, the hot wires had not been previously calibrated, so concurrent calibration data and dynamic data acquisition was necessary.

2.2.6.1. Calibration

Calibration of three wire probes require a complete data system to acquire mean (static) conditions of both the operational environment and of the mean hot wire values.

It is assumed that the hot wires are sensitive to velocity, density, and total temperature. To determine what the sensitivity is to each variable, the mean voltage output of each hot wire must be measured at each combination of velocity, density, and temperature. The tunnel run schedule was configured to assure that adequate data points are taken to provide a realistic profile of sensitivities.
The run schedule was also selected to expose the hot wire probe to the highest dynamic pressures first, so that if a wire is going to break, then the least amount of tunnel time will be lost.

Each of the three parallel hot wires on a probe are operated at different overheats, to encourage a wide separation of sensitivity between each hot wire.

The calibration data consists of mean values, which do not require the high sampling rates normally invoked to digitize the dynamic data, so the calibration data is not acquired through the high speed digitizers. An existing wind tunnel data acquisition system collected the data, and then transferred it through a GPIB link to the DDAS computer. Several data packets of data are averaged and then stored in a formatted record on disk.

2.2.6.1.1. Observation files

This calibration data is stored in a file called an observation file. Other related mean data is also stored in the observation file:
- tunnel conditions,
- test identification parameters,
- auxillary data (such as RMS microphone readings, and amplifier gain settings), and
- simple calculated data (such as density, velocity, static temperature, the logs of a variety of data, and the products of the logs of a variety of data).
The observation "file" is really several files. The first is a file containing the data received from a packet sent from the MODCOMP via the HP-IB link. (Actually, several packets are averaged, and the average is stores as an observation in the first observation file.) The second and third files each contain data related only to a specific three wire probe. These files also contain tunnel condition and test identification data as well, but only the tunnel computer data and simple, computed values related to a specific probe is contained in these files.

The internal format of the observation files was carefully selected to conform to the format specifications of an existing statistics package. The Basic Data Statistics package from HP has historically been the statistics package used to reduce the hot wire calibration data, so the file format was made compatible with that package.

2.2.6.2. Dynamic data

The acquisition of the dynamic hot wire data is entirely accomplished by the off-the-shelf ACQUIRE software. ACQUIRE has all the mechanisms necessary to configure the actual data acquisition hardware and the capability to manage the data once it has been digitized and buffered by the high speed digitizer hardware, which includes the transfer from the buffer to computer memory, and the transfer of the data to disk. These functional modules are "strung together" in a sequence program mechanism, which is also an inherent part of ACQUIRE.

2.2.6.2.1. Fluctuating data
Fluctuating data is either digitized data from the hot wire anemometers, or it is calculated data from the process of computing velocity, density, and temperature fluctuations, which is discussed later. In either case, the result is a time varying array of samples of data.

2.2.6.2.1.1. Fluctuating data volume

The sheer volume of fluctuating data is worth note: since each channel can handle 256K samples (512K bytes) at a time, and there are 3 channels per probe, and the same amount of results exist, 256K X 2 X 3 X 2 = 31457K bytes per observation. For 117 observations (8' Transonic Pressure Tunnel Test 934), 368M bytes of data storage becomes necessary.

2.2.6.2.1.2. Fluctuating data disk file naming convention

DDAS collects and generates multiple channels of fluctuating data files for each test condition or observation. These files are related to a specific record in an observation file, which contains non-fluctuating scalar data related to the observation. The relationship of the fluctuating data file names to the test condition and to the observation file and record within the observation file is specifically defined by convention. The use of a naming convention allows data reduction programs to associate all data files necessary for data reduction and for naming resultant fluctuating data files. Table 2 details the naming format.

The dynamic data samples digitized by the MULTITRAP digitizer hardware are stored by the waveform recorder function of ACQUIRE on a channel-per-file basis. Fluctuating data names are generated whenever a hot wire
calibration observation is logged, so that a naming convention is followed - should a request to digitize hot wire fluctuating data be processed.

2.2.7. Coefficient calculations

The process of providing the sensitivities necessary to convert three hot wire data arrays into velocity, density and temperature fluctuation arrays first requires that the calibration data be processed by multiple linear regression techniques to produce a set of coefficients for each of the three hot wires. Since the relationship of the performance of the hot wire is highly nonlinear in relationship to the velocity, density, and temperature, up to 10 coefficients are required (Eight are in use, as shown):

$$\log E = A_1 + A_2 \log u + A_3 \log \rho + A_4 \log T_0$$
$$+ A_5 \log u \log \rho + A_6 \log u \log T_0$$
$$+ A_7 \log \rho \log T_0$$
$$+ A_8 \log u \log \rho \log T_0$$

(1)

Since velocity, density, and temperature are all known for each observation (as collected by the DDAS form the tunnel data acquisition system - in the form of $P_T$, $P_S$, and $T_T$), the most direct solution is through multiple linear regression.

Whenever requested by the operator, a Multiple Linear Regression routine (which is a specifically modified version of the Hewlett Packard routine MLR which was purchased as part of a statistics package) is invoked, which calculates coefficients for each hot wire on each probe. These
coefficients can then be stored in a coefficient disk file related to each probe. (This internal MLR routine is not currently implemented.)

Alternatively, coefficients calculated in a separate multiple linear regression package may be read from a disk file generated by that package, or the coefficients may be manually entered through the keyboard.

2.2.7.1. Sensitivity calculations

The coefficients, which represent the hot wire relationship to velocity, density, and temperature, are combined with specific test conditions, which have been stored in an observation record of the observation file.

\[
\begin{align*}
S_u &= A_2 + A_5 \log \rho + A_6 \log T_0 \\
&+ A_8 \log \rho \log T_0 \\
S_\rho &= A_3 + A_5 \log u + A_7 \log T_0 \\
&+ A_8 \log u \log T_0 \\
S_{T_0} &= A_4 + A_6 \log u + A_7 \log \rho \\
&+ A_8 \log u \log \rho
\end{align*}
\]

(2a)  
(2b)  
(2c)

New ACQUIRE functions created in MODUSR2 allow the appropriate calibration file to be specified, and the beginning and ending observations and beginning and ending probes to be selected for the computations. For each observation and each probe, the log values of velocity, density and temperature are retrieved from the appropriate record in the observation file. Once the computation is completed for each probe, the resultant sensitivities are inserted into existing, but as yet unused variables in the previously recorded observation.
2.2.7.2. Calculating velocity, density, and temperature fluctuations

Once the sensitivities have been calculated, the operator may request that the dynamic data for a given set of observations and probes be processed in a way that yields dynamic waveforms representing fluctuating velocity, density and temperature (instead of 3 fluctuating voltages) and with turbulence figures and other statistical performance characteristics.

The equation that defines the relationship of voltages to turbulence parameters is:

\[
\begin{bmatrix}
\varepsilon' \\
\varepsilon' \\
\varepsilon'
\end{bmatrix} =
\begin{bmatrix}
S_{u_1} & \frac{U'}{U} + S_{\rho_1} \frac{\rho'}{\rho} + S_{T_0} \frac{T_0'}{T_0} \\
S_{u_2} & \frac{U'}{U} + S_{\rho_2} \frac{\rho'}{\rho} + S_{T_0} \frac{T_0'}{T_0} \\
S_{u_3} & \frac{U'}{U} + S_{\rho_3} \frac{\rho'}{\rho} + S_{T_0} \frac{T_0'}{T_0}
\end{bmatrix}
\]

To solve for the three unknowns \((\frac{U'}{U}, \frac{\rho'}{\rho}, \frac{T_0'}{T_0})\) in the three equations, rearrange, and organize for a matrix operation:

\[
\begin{bmatrix}
S_{u_1} & S_{\rho_1} & S_{T_0} \\
S_{u_2} & S_{\rho_2} & S_{T_0} \\
S_{u_3} & S_{\rho_3} & S_{T_0}
\end{bmatrix}
\begin{bmatrix}
\frac{U'}{U} \\
\frac{\rho'}{\rho} \\
\frac{T_0'}{T_0}
\end{bmatrix} = 
\begin{bmatrix}
\varepsilon' \\
\varepsilon' \\
\varepsilon'
\end{bmatrix}
\]
By rearranging again, which involves inverting the sensitivity matrix, solve for the three unknowns:

\[
\begin{bmatrix}
\frac{u'}{U} \\
\frac{e'}{\rho} \\
\frac{T_0'}{T_0}
\end{bmatrix} =
\begin{bmatrix}
S_{u_1} & S_{\rho_1} & S_{T_0_1} \\
S_{u_2} & S_{\rho_2} & S_{T_0_2} \\
S_{u_3} & S_{\rho_3} & S_{T_0_3}
\end{bmatrix}^{-1}
\begin{bmatrix}
\frac{e'}{E} & \frac{1}{G_w}
\end{bmatrix}_1
\]

\[
\begin{bmatrix}
\frac{e'}{E} & \frac{1}{G_w}
\end{bmatrix}_2
\]

\[
\begin{bmatrix}
\frac{e'}{E} & \frac{1}{G_w}
\end{bmatrix}_3
\]

The computation of the instantaneous velocity, density, and temperature is accomplished as shown:

for each probe and each observation to be processed,

for each of the three hot wires

the mean hot wire voltage (E) is retrieved

the gain (G) for the fluctuating hot wire voltage is retrieved

the three sensitivities (u,\rho,T_0) are retrieved and placed in the sensitivity matrix

the dynamic data file is retrieved from disk, and placed in memory

the sensitivity matrix is inverted

for each of the instantaneous samples

for each of the three hot wires

compute:

\[
\frac{e'}{E} \cdot \frac{1}{G_w}
\]

and store in the independent variable matrix
matrix multiply the inverted sensitivity array by the independent variable array, and place the instantaneous turbulence ratios \( \frac{U'}{U}, \frac{\rho'}{\rho}, \text{ and } \frac{T_0'}{T_0} \) in memory.

compute the RMS values of \( \frac{U'}{U}, \frac{\rho'}{\rho}, \text{ and } \frac{T_0'}{T_0} \)

store the RMS values of velocity, density, and temperature:

\[
\begin{bmatrix}
\frac{U'}{U} \\
\frac{\rho'}{\rho} \\
\frac{T_0'}{T_0}
\end{bmatrix}
\]

for each observation into existing, but as yet unused variables in the previously recorded observation.

store the fluctuating velocity, density, and temperature waveforms in disk files for later spectral investigations, utilizing existing functions of ACQUIRE.

2.2.8. Precision filter system control

The computer control of the filters and amplifiers allows adaptive processing of various hot wire signals, which are dependent upon a variety of operational parameters. The software interface allows full control of each functional module within the Precision Filter system - including the calibration module, and also allows the interrogation of all status and condition data - including the calibration module. The modules are connected to provide a full calibration sequence, and to allow full operator control, semiautomatic or automatic operation. (This feature not implemented as of April 88).
2.2.9. Utility Functions

Other utility functions were implemented to enhance operational characteristics of the system. The ability to eject plots, and the ability to plot "special" hot wire calibration data, are "plot utilities". The ability to list categories of files on the disk, to purge extraneous files - or groups of files, the ability to copy or move files - or groups of files - to another disk (or tape) are "file utilities".

Function LOGFILLE TO PC was used to transfer observation files containing logged and computed data to another system. A GPIB bus connects DDAS to the PC, where a GPIB card (National Instruments or HP) is installed. Appendix D contains the PC BASIC program used with the HP GPIB card to receive and store the data on the PC disk.

3. OPERATION

Operation of DDAS begins prior to the tunnel operation. Configuration of both the ACQUIRE software and the high speed digitizer is accomplished from within the software. Configuration files of various types are generated by the software and are recallable either at power on time or from within a sequence program.

3.1. System setup - hardware

The initial configuration of hardware is accomplished only once. The assignment of device addresses is as follows:

GPIB devices:

- printer 701
- 20Mb program disk 703,0
The ACQUIRE operating system was configured to operate within the memory constraints of 4Mbytes, and to be configured for 14 channels of digitizers, and 14 channels of data memory. Refer to the ACQUIRE operations manual for further details.

3.3. **ACQUIRE installation**

Upon receipt of the software, the installation procedure defined by the manufacturer allows the software to be configured for existing hardware, including amount of computer memory, number of digitizers in the digitizer chassis, and the maximum number of channels in the computer memory at any one time.

3.4. **System variables**
A file structure is maintained in the ACQUIRE software for containing a wide variety of currently selected operating parameters. This mechanism allows the operator to interactively select preferred operational conditions, and then store the "sysvars" on disk for later retrieval. These parameters include, but are not limited to, display format, memory length for each channel, waveform file names, waveform channel selection, system variables file name, binary switch name, plot file name, and sequence file name. To recall a specific set of system variables automatically at power on time, the system variables are stored in a file called "AUTOVARS".

3.5. **Binary switches - digitizer configuration - MULTITRAP**

The high speed digitizer is configured utilizing an interactive session to select sampling rates, gains, trigger modes, data block size, etc., and then the configuration of the binary switches within the digitizer are saved in a binary switch configuration file. To recall a specific configuration for the digitizer automatically at power on time, the binary switches are stored in a file called "AUTOSW".

3.6. **Plot setup**

The format of a plot is defined interactively and may then be saved on a plot file. The actual data is not saved in the file. Once the waveform channel in memory is selected, the position, scaling, and labeling of the axis is defined, and waveform labeling is determined. Once all channels are positioned and defined, the plot title is defined, and the plot configuration is saved to disk.

3.7. **Sequence program - initialization**
An initialization sequence program is interactively generated, which will determine a sequence of functions to be performed to set up DDAS to a configuration relevant to a specific wind tunnel test. See Appendix C for a listing of the initialization sequence used for the 8'TPT test. To recall the initialization sequence program at power on time, the sequence is stored in a file called "AUTOSEQ".

3.8. **Sequence program - acquisition**

A run sequence program is interactively generated, which will determine a sequence of functions to be performed to:

- log calibration data
- digitize and store fluctuating data
- plot hot wire mean voltages vs. mass flow, $\rho u$, (see Fig. 2)
- print a report displaying many parameters of the current observation whenever the operator presses a single button. See Appendix C for a listing of the run sequence used for the 8'TPT test. The run sequence program is automatically loaded by the initialization sequence program, so that once all configurations are defined, powering on the system, and pressing a button is all that is necessary to simultaneously acquire both calibration and fluctuating hot wire data.

3.9. **File transfer to PC**

The probe log data files - one or both - can be transferred to a PC via a dedicated GPIB cabled between DDAS and a PC. The PC BASIC program "XFR.HP" (see Appendix D) should be started first, and then, before providing the requested file name, invoke the DDAS function LOGFILE TO PC. Refer to the relevant function sheet in Appendix B for details on proper configuration prior to starting the transfer. When the file name is then
entered into the PC, which defines where the data is to be stored, the transfer will begin.

4. SYSTEM STRENGTHS

4.1. ACQUIRE

ACQUIRE, in combination with the hardware is a very versatile waveform recorder:

- It controls all the hardware associated with the system.
- It manages hardware and software configuration - via files.
- It manages process, or "sequence" files.
- It manages dynamic data files and internal arrays of data.
- It provides a choice of operator dialogue techniques, including: cursor, menu, and command line entry.
- It provides data display management.
- It provides the waveform plotting capabilities.

A Digital Signal Processing package is included which provides:

- Fast Fourier Transforms
- filters
- power spectrum
- transfer functions

The acquisition of the dynamic data, and the storing of the dynamic data is a very significant strength of ACQUIRE. But most importantly, the internal design allowed application routines to be written into ACQUIRE, which produces a set of software that appears to the user to be a single entity, without seams, and fully integrated.
4.2. **Data logging**

The internal log file format allows direct access by a commercially available statistics package, which includes a multiple linear regression analysis capability necessary to generate coefficients used in creating hot wire sensitivities.

4.3. **Computer link**

4.3.1. **DDAS to tunnel computer**

A software/hardware link is currently used with the MODCOMP data acquisition computer to receive mean data values, but a self-contained, accurate and reliable static data acquisition subsystem could be integrated, making the DDAS self-contained. The use of an existing data acquisition system for the collection of mean values transfers the instrument calibration requirements for those values to another system.

4.3.2. **DDAS to PC**

The LOGFILE TO PC function to transmit the logged and computed parameters to another system, where the data is reformatted and imported to a spreadsheet program (Lotus Symphony) for further analysis and data presentation.

5. **LIMITATIONS**

5.1. **Uncalibrated wires**
Hot wire calibration currently consumes the major portion of the tunnel operation time. Although not a limitation of the DDAS, the process of calibrating hot wire probes relative to temperature, density and pressure is currently the most expensive part of the three wire technique.

Pre-calibrated wires would allow real time processing of the voltages from the three wires into the velocity, density, and temperature components of turbulence. The facility would be much less expensive to construct and operate than the wind tunnel to be supported, since the size could be much smaller, and the tolerable turbulence levels could be higher, since only the mean values of velocity, density, and temperature are used in determining hot wire sensitivities.

For wind tunnels not capable of independently controlling velocity, density (or total pressure) and temperature, the three wire technique requires that the wires be pre-calibrated, since the sensitivities could not be properly determined in such a wind tunnel.

Although a hot wire calibration tunnel has been partially constructed, it is not yet operational due to manpower and funding constraints. A data logging program module developed for DDAS is available as a module for eventual integration with an instrumentation system expressly for the hot wire calibration facility.

5.2. Data storage

The acquisition of 2.5 seconds (50KHz bandwidth) of fluctuating data representing a single 3-wire probe hot wire output requires the rapid digitization, processing, display and storage, of 1.5Mb of data. 150Mb of data could easily be collected in 8 hours of transonic wind tunnel
testing. The hardware originally purchased with ACQUIRE can adequately
digitize 14 hot wire channels of the dynamic components. Modifications
have been made to rapidly transfer the digitized data to the computer.
adequate hardware exists to transfer the data to permanent storage. But
only 55Mb of conventional disk space is available for data. A Write Once,
Read Many (WORM) laser disk drive ($14K) would dramatically improve the
storage capability, since WORM drives can typically store 600-800Mb of
data per disc.

5.3. Compute speed

5.3.1. Hardware - central processing unit (CPU)

The real limitation of this system was - and is - in the processing speed
of the CPU. The original HP 9000/310 CPU was about as fast as an IBM
PC/AT, and often took minutes to perform a simple evaluation of a few
thousand points of dynamic data from a single channel. The upgrade to an
HP 9000/330 (for $13K) in the beginning of 1988 improved the processing
performance somewhat, but the array processing problem is still not being
met head on.

5.3.2. Data structure

For each computation the array structure requires an indexing algorithm to
access each sample. Through the indexing mechanism, and by representing
sample values in an integer format, at least a four-fold savings of
computer memory and disk space is realized. But the saving of space
(memory) has become an unnecessary and unacceptable tradeoff. All
generated data had been simply rescaled (as ratios) existing data, so the
linear coefficients were easily determined for the new integer data
arrays. However, the solution for three unknowns in three simultaneous equations does not allow for a simple determination for the linear coefficients to scale the integer data. To compute instantaneous turbulence fluctuation, each instantaneous voltage must be translated to floating point by applying first order coefficients. Then the floating point computations (a floating point matrix multiply operation is in itself not a fast operation) are accomplished for each instant in time. But the answers are in a floating point format and no linear coefficients have been determined to convert the floating point answers to a range of integer values. Therefore, the hot wire computations are accomplished twice - once to determine linear coefficients, and once to store the instantaneous turbulence fluctuation in an integer format. Both the integer format and the index algorithm produce excessively slow computing processes.

5.3.3. Operating system

The existing BASIC operating system is a single user, single task executive. It cannot support high speed communication via Ethernet. It cannot support concurrent operations; program development, data acquisition, data processing, and data communications cannot all be executing concurrently.

5.3.4. Programming language

The BASIC language is an interpreter, rather than a compiler, which trades off execution speed for ease of program development and maintenance. Although the ACQUIRE software takes advantage of some compiled and assembled subroutines - for speed - all of the application software is still interpreted.
6. RECOMMENDATIONS

Several solutions exist - they all require much larger investments of time and money than a mere doubling of financial resources.

6.1. Improvement options

6.1.1. Array processor hardware

A dedicated array processor is available from Analogic Corp ($27K) which is designed to interface to both the HP 9000/330 and the HP software. Modifications to the ACQUIRE Digital Signal Processing software (DSP), or development of a user-provided DSP routine to replace the ACQUIRE DSP software (3 man-months, est.) would be required.

6.1.2. Faster CPU

A larger HP 9000/350 CPU ($29K) would quadruple the processing speed, and still be able to run the existing ACQUIRE software.

A combination of the Analogic array processor and the HP 9000/350 would provide the best performance possible - without abandoning the ACQUIRE software.

6.1.3. Utilize UNIX operating system

Provide the multitasking, multiuser environment necessary to support concurrent operations, Ethernet (TCP/IP) communications, a choice of programming languages - including interpretive and compiled, and a wider marketplace for software and hardware solutions like nine track magnetic
tape support, laser printer support, graphics and statistics support, and data management support.

6.1.4. **Abandon ACQUIRE**

Abandon the ACQUIRE software system, and actively search for a software system that operates in the UNIX environment, has the potential for supporting the high speed digitizer, can acquire, process, display, and save both the mean data and fluctuating data more rapidly than ACQUIRE.

6.1.5. **Remote processing**

Processing the data elsewhere: ACD, MODCOMP or other larger computer resource. The solution is suggested by the existence of other computational resources that may be made available, including the tunnel computer, and would provide parallel processing of the DDAS data once the hot wire sensitivities are available, and once the instantaneous data has been acquired and transferred to the other resource. This approach assumes that a viable communications link like Ethernet is available. At NASA LaRC, this capability is called LaRCNET. Although this link is proposed for the East Area of LaRC - where 8'TPT is located, its presence is still about 2 years distant. LaRCNET also implies - by its very existence - that the ACD computational resources will be in great demand. The MODCOMP connection, however, proposes a much closer solution. Although not an array processor machine, and not yet capable of communicating via LaRCNET, the access via a local Ethernet (to eventually be a part of LaRCNET) is scheduled for the forth quarter of 1988.

6.2. **Preferred solution**
The preferred solution is: abandon ACQUIRE for a UNIX compatible set of software, translate existing hot wire programs to the UNIX environment, purchase new statistical software, and purchase an array processor and a faster CPU (the HP 9000/350). About 1 man-month would be required for conversion of the hot wire software, and about 3 man-months would be required to integrate all the various software and hardware modules. This solution minimizes the engineering integration risks attendant in any system of this complexity.

The ACQUIRE software module MODUSR2 has been written to utilize the fluctuating data file naming conventions described above.

The ACQUIRE software module MODGEN (provided by Data Laboratories) was modified to not automatically add a sequence number in column 9 if not necessary to differentiate between two files with the same name (in columns one through eight).

Table 2. Fluctuating Data File Name Format
APPENDIX A. Program Listings

This appendix contains the DDAS program listings for all the application specific code to acquire, process, display, store and transmit the hot wire data.

The program is separated into two modules: MODUSR1 provides general utility functions. MODUSR2 provides all hot wire specific functions.
This program becomes a part of "ACQUIRE", and provides additional utility functions. As the need for additional functions increases, so will the functions implemented in this program.

This routine logs mean value data received from another CPU via the HP-IB bus. This bus is SC-8, and the primary address is 01. This end is NOT System Controller!

The variables are logged in a disc file that contains a header record, a variable names record, and 100 observation records. It is an ASCII file.

This routine also computes coefficients of calibration for multiple 3 wire probes thru the use of multiple linear regression. Alternatively, the coefficients can be entered either by reading a coefficient file, or by manually keying in the coefficients -

With the calibration coefficients, this routine can generate sensitivities for the designated probe for each observation previously logged.

This routine can then apply the sensitivities to dynamic HOTWIRE data!

in trace and returns:

1 HOTWIRE 1 fluctuating velocity \((u)\) in trace 4
2 HOTWIRE 2 fluctuating density \((p)\) in trace 5
3 HOTWIRE 3 fluctuating temperature \((T_o)\) in trace 6

These calculations are performed only between cursor positions - if - both cursors of trace 1 are active; or from the only cursor to the end of the memory. Otherwise, sensitivity coefficients are applied to the entire sample.

Traces 1, 2, and 3 are automatically loaded from disk files that were previously recorded using a naming convention defined here:

If the log filename is of the format "XXX"

then the hotwire data disk file names would have the format:

"MPXXXYYZZnn"

(where XXX is the test number)

(where M is the mode as follows:
R = Real time digitization
P = Playback digitization
P is the probe selection as follows:
A = probe A
B = probe B
XX is the RUN number
YY is the POINT number

of the data most recently logged, and therefore most likely to define related mean conditions, and will contain calculated sensitivities, gains of the fluctuating voltages, etc
ZZ is the digitizer channel number (this naming convention assumes a 1-to-1 relationship:

probe "A"
ch 1 = hotwire 1
2 2
3 3

probe "B"
5 1
6 2
7 3

nn is the "serial number" automatically applied (unfortunately) by ACQUIRE, and must be ignored.

NOTE: the hotwire data disk file name is defined by ACQUIRE function "FILENAME".

Using the sensitivities, mean voltages, and gains from the "A" or "B" probe file,
traces 4, 5, and 6 are scaled and created to represent the ratios:

trace 4 = velocity fluctuations / mean velocity
trace 5 = density fluctuations / mean density
trace 6 = temperature fluctuations / mean temperature

The mean value is removed from these ratios, and an rms value of the three ratios is stored as variables 47, 48, and 49 of the appropriate probe file - "A" or "B".

Additionally, the ratios above can be retrieved and used to compute correlations between velocity, density, and temperature fluctuations, and then, using these correlations, go on and compute massflow and pressure fluctuations. These results are stored much as the ratios above are stored.

THIS ROUTINE IS THE ACQUISITION AND DATA LOGGING PORTION OF THE HOTWIRE
DYNAMIC DATA SYSTEM.

STEVE CLUKEY, VIGYAN RESEARCH ASSOCIATES, SEPTEMBER, 1987

DATA IS RECEIVED FROM ANOTHER COMPUTER (MODCOMP) VIA HP-IB IN ASCII.
ON DISK AS AN OBSERVATION IN AN X-Y ARRAY. SOME VALUES ARE CALCULATED
AND STORED ALONG WITH THE DATA RECEIVED FROM THE OTHER COMPUTER.

THESE DATA OBSERVATIONS WILL BE USED TO COMPUTE HOTWIRE SENSITIVITIES,
AND THEREFORE THE FORMAT OF THE DISK FILE SHOULD BE COMPATIBLE WITH
THE COMPUTATIONAL PROGRAMS.

FOR EACH OBSERVATION, "Max_vars" VARIABLES ARE STORED:

THE PROCESS IS:

1. CREATE AN OBSERVATION FILE, OR DECLARE AN EXISTING FILE, AND SET UP
2. WHEN REQUESTED BY THE OPERATOR, DATA IS READ FROM THE OTHER COMPUTER
3. WHEN REQUESTED BY THE OPERATOR, THE FILE IS CLOSED.

AT SOME LATER TIME, THE FILE WILL BE PROCESSED TO PROVIDE A HOTWIRE
SENSITIVITY FILE.

CALL Pline(0,"OBSERVATION LOGGING STARTED")
WAIT 1

APPENDIX B. Function definitions

This appendix contains the DDAS functions added to ACQUIRE by the user to provide the necessary functionality to acquire, process, display, store and transmit the hot wire data.

The function definition sheets provide essential definition data for each function. Full documentation for each function is contained within the program source code listings.
Function Name: CALC VEL etc
Function Number: 4104
Module: MODUSR2

This function computes velocity, density and temperature fluctuations as ratios of the fluctuating quantities to the mean quantities:

\[ \frac{u'}{U} \quad \frac{p'}{P} \quad \frac{t'}{T} \]

The log file for each observation in the range of INITIAL OBS to ENDING OBS is processed for each probe in the range of INITIAL PROBE to ENDING PROBE.

For each observation, and each probe, the three fluctuating data files related to the Run and Point (variables 2 and 3 in the observation record) are loaded into traces (and memories) 1, 2, and 3.

The computations retrieve mean values, sensitivities, and gains related to the data in channels 1, 2, and 3.

For each simultaneous sample in each of the three traces (the beginning and ending samples are defined by the cursors on trace 1) the instantaneous value is divided by the equivalent mean value and the gain. Then the three ratios are matrix multiplied by the nmatrix inversion of the sensitivities. This process essentially solves a set of simultaneous equations for three unknowns: \( \frac{u'}{U} \), \( \frac{p'}{P} \), and \( \frac{t'}{T} \).

The solutions are placed in traces (memories) 4, 5, and 6. The mean value is removed, and the RMS (root mean square) value of each of the answers is stored in the logfile for the appropriate observation and probe. Traces 4, 5, and 6 are then stored in separate disk files.

[ CALC VEL etc ]------------------|

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: CAT GROUP
Function Number: 4021
Module: MODUSR1

This function catalogs all selected files. The selection criteria is defined in detail in the HP BASIC language reference manual for HP function CAT (SELECT).

```
[ CAT GROUP ]-----------------------------
    | [ - ] [ name ] |

Item      | Description           | Range
name      | string expression     | any valid characters that are allowed in a file name
```

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
This function computes actual voltage gains from gain codes. The fluctuating data is gained to provide adequate voltage for filtering and digitization, and the gain codes are sent in a data packet from the static data computer during the logging of a data point. For the probes in the range INITIAL PLROBE to ENDING PROBE, and for observations in the range INITIAL OBS to ENDING OBS, the gain codes are retrieved from the observation file, and through a table lookup algorithm, the actual gains are retrieved, and stored back into the appropriate place in the log file for the probe and observation being processed.

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues through April, 1988.
Function Name: COEF FILENAME
Function Number: 4101
Module: MODUSR2*

This function selects the file name relevant to the hotwire coefficient file being processed. See functions LOAD COEFS and STORE COEFS.

[ COEF FILENAME ]---------------------

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
This function computes hotwire coefficients for the probe previously selected - by function INITIAL PROBE - utilizing a custom multiple linear regression routine that generates up to 10 coefficients based on calibration data already in the logfile. These coefficients are then stored - by function STORE COEFS - in a coefficient file whose name has been previously defined - by function COEF FILENAME. Function COMPUTE SENS utilizes these coefficients to generate sensitivities necessary to compute velocity, density and temperature turbulence ratios - by function CALC VAL etc.

This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: COMPUTE R etc  
Function Number: 4132  
Module: MODUSR2

This function computes the correlations between velocity, density and temperature fluctuations and then computes mass flow fluctuation \([m'/M(rms)]\) and pressure fluctuation \([p'/P(rms)]\) using the correlation between velocity, density, and temperature fluctuations.

The log file for each observation in the range of INITIAL OBS to ENDING OBS is processed for each probe in the range of INITIAL PROBE to ENDING PROBE.

For each observation, and each probe, the three fluctuating data files related to the Run and Point (variables 2 and 3 in the observation record) are loaded into traces (and memories) 2, 3, and 4.

As each pair of traces is multiplied together, the resulting trace ends up in trace 1. The correlation of the two traces multiplied is the ratio of the rms value of the first trace multiplied by the rms value of the second trace to the mean value of trace 1. The rms values of the first and second traces have been previously calculated by function CALC VEL etc, and were called \(u'/U\), \(p'/P\), and \(t'/T\).

The correlation between these three components of turbulence are stored in the appropriate observation record for the observation and probe being processed as \(R(\rho U)\), \(R(UTO)\), and \(R(\rho T0)\).

Massflow and pressure fluctuations are then computed from the correlations just computed, and these are also stored in the appropriate logfile as \(M'/M\) and \(P'/P\).

[ COMPUTE R etc ] ---------------------

This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April 1988.
**Function Name:** COMPUTE SENS

**Function Number:** 4111

**Module:** MODUSR2

This function computes hotwire sensitivities for the probes in the range INITIAL PROBE to ENDING PROBE for all observations in the range INITIAL OBS to ENDING OBS. The hotwire coefficients previously defined - see functions GET COEFS, COEF FILENAME, LOAD COEFS, ENTER COEFS, EDIT COEFS, STORE COEFS, AND COMPUTE COEFS.

The computed sensitivities are stored in the appropriate probe file for each appropriate observation.

These sensitivities are read from the logfile - by function CALC VAL etc - to compute velocity, density and temperature turbulence ratios.

This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: EDIT COEFS
Function Number: 4133
Module: MODUSR2*

This function allows the operator to manually edit hot wire calibration coefficients (up to 10) for three wires. These coefficients have been previously generated. The operator views a list of the entered coefficients, and, by responding to prompts, select the coefficient to be edited. After each coefficient is edited, the operator may accept the coefficients, or be prompted to select another coefficient to be edited. The operator should then invoke function STORE COEFS.

NOTE: This function is highly interactive, and is not recommended for inclusion in a SEQUENCE PROGRAM.

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: ENDING OBS
Function Number: 4113
Module: MODUSR2

This function declares the ending observation to be processed by other MODUSR2 functions - see function INITIAL OBS.
Functions utilizing this feature to define the range of observations to be processed are: COMPUTE SENS, LOG DATA POINT, CODE TO GAINS, CALC VEL etc, COMPUTE R etc, Remake probe and LOGFILE TO PC.

| [ ENDING OBS ] | | |
| | | |
| | | |
| | | |

Item | Description | Range
value | numeric integer | 1 to 300, the max number of observations

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: ENTER COEFS  
Function Number: 4103  
Module: MODUSR2*

This function allows the operator to manually enter hot wire calibration coefficients (up to 10) for three wires. These coefficients have been previously generated elsewhere, and are not available for entry via disc (see function LOAD COEFS). The operator is prompted for each coefficient by wire, number, and name. Once all 30 coefficients are entered (unused coefficients should be set to 0.0), the operator views a list of the entered coefficients, and chooses to accept or reject the coefficients. If they are accepted, the function is complete. The operator should then invoke function STORE COEFS. If the coefficients are not accepted - because they are not correct, this function automatically enters the EDIT COEFS function.

NOTE: This function is highly interactive, and is not recommended for inclusion in a SEQUENCE PROGRAM.

*This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: FILE COPY  
Function Number: 4025  
Module: MODUSR1

This function serves merely as a label for the path for accessing other related functions via the softkeys.

[ FILE COPY ]-------------------

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: FILE GROUP
Function Number: 4028
Module: MODUSR1*

This function defines the files to be selected for copying - function COPY FILES - or moving - function MOVE FILES. The files selected will begin with, or be equal to the character(s) defined by this function. For example, if this function defines "ABC", then all of the files in the TO DISK device that begin with "ABC" would be selected for copying or moving. Note that this function only defines the character(s): no selection is done until COPY FILES or MOVE FILES is invoked.

[ FILE GROUP ]---------------------------|

Function Name: LOAD COEFS
Function Number: 4102
Module: MODUSR2*

This function loads coefficients previously stored by function STORE COEFS.

The coefficient filename must have been previously defined - see function COEF FILENAME.

[ LOAD COEFS ]-----------------

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: LOAD LOGFILE
Function Number: 4106
Module: MODUSR2*

This function loads the files used to log hotwire calibration observation data. The function LOG FILENAME declares the file name, and function DISC DEVICE declares the Mass Storage Identifier. See LOG FILENAME for a description of the files loaded into memory.

NOTE: This function must be performed before the function LOG DATA POINT can be invoked.

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: LOAD LOGFILE  
Function Number: 4106  
Module: MODUSR2*

This function loads the files used to log hotwire calibration observation data. The function LOG FILENAME declares the file name, and function DISC DEVICE declares the Mass Storage Identifier. See LOG FILENAME for a description of the files loaded into memory.

NOTE: This function must be performed before the function LOG DATA POINT can be invoked.

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: LOG DATA
Function Number: 4109
Module: MODUSR2*

This function serves merely as a label for the path for accessing other related functions via the softkeys.

This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: LOG DATA POINT  
Function Number: 4108  
Module: MODUSR2*

This function logs the hotwire calibration observation data into the logfile(s). The function LOG FILENAME declares the file name, and function DISC DEVICE declares the Mass Storage Identifier. See LOG FILENAME for a description of the files which receive the data.

The hotwire calibration data is received from a static data acquisition system - MODCOMP, other HP, etc - thru a GPIB interface in the form of an ASCII data packet. The static data system is regularly sending about 1 packet per second, and it contains the necessary data in engineering units, including test conditions and test identification.

This function also calculates various data items for inclusion in some of the data files.

This function also generates fluctuating data file names base on the RUN, POINT and channel of the data. These names relate to the data being logged, and allow storing of the fluctuating data in appropriately named files. See functions STORE or TF/STORE ALL.

Example: "RA031701"
R = Realtime digitization
A = probe A
03 = RUN
17 = POINT
01 = data channel 1

[ LOG DATA POINT ]-------------------|

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: LOGFILE TO PC
Function Number: 4127
Module: MODUSR2*

This function transfers logfile data to another computer via a GPIB. The information transmitted is all in ASCII to assure compatibility between systems.

For each probe in the range INITIAL PROBE to ENDING PROBE and for observations in the range INITIAL OBS to ENDING OBS, the appropriate observations records are transmitted. Prior to transmitting the set of each probes observations, the names of the variables contained in the observation record are transmitted.

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
This function defines the files to be selected for moving, and then copy the selected files from a disk device to a disk device using the HP COPY command. When the files are selected, a report is generated on the printer which declares the number of files selected, the from device, the to device, and the files selected for copying. As each file is actually copied, a message is displayed on the CRT, and printed on the printer. Once all selected files have been copied, all successfully copied files are purged from the from device, completing the "move". Functions FROM DISK, TO DISK, AND FILE GROUP all effect the results of this function. Selection of files by indicating a group name with this function overrides the group name selection previously made by function FILE GROUP.

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: PICTURE LOG E
Function Number: 4006
Module: MODUSR1

This function generates x-y plots on the CRT which represent the Log(RhoU) vs. Log(E) for each hotwire. The axes, titles, etc. are internally generated using a plot file called "RhoU" - see function PLOT NAME. (It should be noted that this 'RhoU' picture is actually generated for dynamic channels 8 and 9 - which are assumed to be 1 point long, - and offscale as well.)

This function represents data from all observations in the range INITIAL OBS to ENDING OBS for all probes in the range INITIAL PROBE TO ENDING PROBE.

[ PICTURE LOG E ]--------- ]

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: PLOT EJECT  
Function Number: 4002  
Module: MODUSR1

This function sends a "PG" command to the plot device (if the plot device is not the CRT device).

This function also resets the 'number of observations plotted' pointer, the number of observations printed' pointer, and the 'ending observations' pointer, which affects the operation of functions ENDING OBS, PRNT LOGFILE, PLOT LOG_E and PICTURE LOG_E.

*. This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: PLOT LOG E
Function Number: 4005
Module: MODUSR1*

This function generates x-y plots on the Plotter which represent the Log(RhoU) vs. Log(E) for each hotwire. The axes, titles, etc are internally generated using a plot file called "RhoU" - see function PLOT NAME. (It should be noted that this 'RhoU' picture is actually generated for dynamic channels 8 and 9 - which are assumed to be 1 point long, - and offscale as well.)

This function represents data from all observations in the range INITIAL OBS to ENDING OBS for all probes in the range INITIAL PROBE TO ENDING PROBE.

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: PLOT UTILITIES
Function Number: 4001
Module: MODUSRI*

This function serves merely as a label for the path for accessing other related functions via the softkeys.

*This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: PRNT LOGFILE  
Function Number: 4107  
Module: MODUSR2*

This function prints the data hotwire calibration observation data currently in the logfile(s). The function LOG FILENAME declares the file name, and function DISC DEVICE declares the Mass Storage Identifier. See LOG FILENAME for a description of the files which contain the data printed. The format of the printout is customized to best demonstrate the hotwire calibration data. This function prints all observations beginning with INITIAL OBS, and ending with ENDING OBS unless previously printed. When the program first starts, and when the PLOT EJECT function is invoked, the number of observations printed is reset to zero, causing all observations already logged to be printed when PRNT LOGFILE is invoked. This technique allows the easy implementation of a sequence program loop including both function LOG DATA POINT and PRNT LOGFILE without having to manipulate observation pointers.

[ PRNT LOGFILE ]-------------------|

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: PURGE
Function Number: 4022
Module: MODUSR1*

This function serves merely as a label for the path for accessing other related functions via the softkeys.

[* PURGE ]-------------------]

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
**PURGE FILE**

Function Name: **PURGE FILE**  
Function Number: **4024**  
Module: **MODUSRI**

This function defines the file to be selected for purging (deleting) from the disk, and then purges the selected file.

```
[ PURGE FILE ]----------------------------------------|
|                                                   |

Function Name: Remake Probe
Function Number: 4128
Module: MODUSR2

This function reproduces the computations normally accomplished during the execution of the function LOG DATA POINT, but without actually acquiring any new data. The purpose is to recompute data should modifications to the computations become necessary.

This function performs these calculations for all probes in the range INITIAL PROBE to ENDING PROBE, and for all observations in the range INITIAL OBS to ENDING OBS.

NOTE:

This function permanently overwrites previous data in the logfiles.

[ LOG DATA POINT ]-----------------|

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: SAMPLES TO AVG
Function Number: 4110
Module: MODUSR2*

This function declares the number of data samples to be included in an average of the hotwire calibration data. See LOG DATA POINT for a description of the actual data acquisition process.

[ SAMPLES TO AVG ]------------------ |

* This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: STORE COEFS
Function Number: 4124
Module: MODUSR2

This function stores coefficients previously defined by functions ENTER COEFS, LOAD COEFS, COMPUTE COEFS, etc.

The coefficient filename must have been previously defined - see function COEF FILENAME.

[ STORE COEFS ]----------|

This routine - MODUSR2 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: TAG PICTURE  
Function Number: 4004  
Module: MODUSR1

This function "tags" the picture with the first few parameter names and values from the current observation. These few values are intended to identify the environment from which the "picture" was taken. This function is therefore intended to be invoked just after function REDRAW PICTURE or PICTURE LOG E.

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: SELECTOR
Function Number: 4129
Module: MODUSR2*

This function serves merely as a label for the path for accessing other related functions via the softkeys.

[* This routine - MODUSR2* - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.]
Function Name: TAG PLOT
Function Number: 4003
Module: MODUSR1

This function "tags" the plot with the first few parameter names and values from the current observation. These few values are intended to identify the environment from which the plot was taken. This function is therefore intended to be invoked just after function REDRAW PLOT or PLOT LOG E.

[ TAG PLOT ]-----------

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: TO DISK
Function Number: 4027
Module: MODUSR1*

This function defines the mass storage device to which the files will be copied - function COPY FILES - or moved - function MOVE FILES.

<table>

* This routine - MODUSR1 - was written by Steven J. Clukey of Vigyan Research Associates, Inc. for NASA LaRC TAD/FDB under contract NAS1-17919, Task 36. This work was done beginning in October, 1986 and continues thru April, 1988.
Function Name: UTILITY
Function Number: 4000
Module: MODUSR1*

This function serves merely as a label for the path for accessing other related functions via the softkeys.

This report describes the high speed Dynamic Data Acquisition System (DDAS) which provides the capability for the simultaneous measurement of velocity, density, and total temperature fluctuations. The system of hardware and software is described in context of the wind tunnel environment.

The DDAS replaces both a recording mechanism and a separate data processing system. The data acquisition and data reduction process has been combined within DDAS. DDAS receives input from hot wires and anemometers, amplifies and filters the signals with computer controlled modules, and converts the analog signals to digital with real-time simultaneous digitization followed by digital recording on disk or tape. Automatic acquisition (either from a computer link to an existing wind tunnel acquisition system, or from data acquisition facilities within DDAS) collects necessary calibration and environment data. The generation of hot wire sensitivities is done in DDAS, as is the application of sensitivities to the hot wire data to generate turbulence quantities. The presentation of the raw and processed data, in terms of root mean square values of velocity, density and temperature, and the processing of the spectral data is accomplished on demand in near-real-time with DDAS.

A comprehensive description of the interface to the DDAS and of the internal mechanisms will be presented. A summary of operations relevant to the use of the DDAS will be provided.
