I. SUMMARY

This midterm report describes the progress to date on the Analysis and Design of a High Power, Digitally Controlled Spacecraft Power System. Two quarterly presentations have already been made to NASA Goddard. This report contains the presentation material as well as a summary of the accomplishments to date.

The Statement of Work is divided into two phases.

1. Phase I:

    - Task 1. Battery Discharger Topology Trade-off

2. Phase II:

    - Task 1. ORU Level Modeling and Control
    - Task 2. DC Bus Regulation and Mode Control
    - Task 3.Example Design of Digitally Controlled Spacecraft
    - Task 4.Bus Performance Verification With Model

This report describes the progress on Phase 1, Task 1 and Phase 2 Tasks 1 and 2. The remaining two tasks have just been started.

II. Phase 1, Task 1: Battery Discharger Topology Trade-off

Several battery discharger topologies have been compared for use in the space platform application. The task originally called for a comparison of the following candidate topologies:

1. Boost Converter

2. Tapped-Boost Converter

3. Voltage-Fed Push-Pull with Auto-transformer

4. Current-Fed Push-Pull with Auto-transformer

Updated information has since been provided on the battery voltage specification. Initially it was thought to be in the 30 to 40 V range. It is now specified to be 53 V to 84 V. This eliminated the tapped-boost and the current-fed auto-transformer converters from consideration. After consultations with NASA, it was decided to trade-off the following topologies:

1. Boost Converter

2. Multi-Module, Multi-Phase Boost Converter

3. Voltage-Fed Push-Pull with Auto-transformer

A non-linear design optimization software tool developed by VPEC was employed to facilitate an objective comparison. Non-linear design optimization insures that the best design of each topology is compared.

The results indicate that a four-module, boost converter with each module operating 90 degrees out of phase is the optimum converter for the space platform.

Phase 2, Task 1 : ORU Level Modeling and Control

Large-signal and small-signal models have been generated for the shunt, charger, discharger, battery, and the mode controller. The models were first tested individually according to the space platform power system specifications supplied by NASA. The battery ORU model consists of the battery, charger, and discharger models integrated together. This model was used to investigate issues such as interfacing, control, and paralleling of ORU's.

The effect of battery voltage imbalance on parallel dischargers was investigated with respect to dc and small-signal responses. Similarly, the effects of paralleling dischargers and chargers were also investigated. A solar array and shunt model was included in these simulations. A model for the bus mode controller (power control unit) was also developed to interface the ORU model to the platform power system.

Phase 2, Task 2 : DC Bus Regulation and Mode Control

The small signal models were used to generate the bus impedance plots in the various operating modes. The large signal models were integrated into a system model, and time domain simulations were performed to verify bus regulation during mode transitions. Some changes have subsequently been incorporated into the models. The changes include the use of a four module boost discharger, and a new model for the mode controller, which includes the effects of saturation The new simulations for the boost discharger show the improvement in bus ripple that can be achieved by phase-shifted operation of each of the boost modules.

CONCLUSIONS

A MULTI-MODULE BOOST CONVERTER OFFERS THE LOWEST WEIGHT BATTERY DISCHARCHER

97% EFFICIENCY IS OBTAINABLE AND PRACTICAL

FLIGHT QUALIFIED PARTS CAN BE USED

BOTH THE VFPPAT AND THE BOOST DESIGNS REQUIRE CIC. VFPPAT FOR FLUX BALANCING, AND THE BOOST FOR DYNAMIC PERFORMANCE AND STABILITY

THE STABILITY MARGIN OF THE BOOST DESIGN CAN BE MADE EQUAL TO THE VFPPAT DESIGN

OUTPUT IMPEDANCE AND LOAD TRANSIENT RESPONSE OF THE BOOST DESIGN CAN BE MADE EQUAL TO OR BETTER THAN THE VFPPAT DESIGN

REVIEW OF SPACE PLATFORM POWER SYSTEM MODELING

INTRODUCTION

Modeling and simulation :

Large and small signal component models have been developed for the following, using the EASY5 analysis program :

- Solar cells/solar array
- Solar array shunt switching units
- DC-DC converters (buck, boost, flyback, forward)
- Error amplifiers, PWM controllers
- Battery dischargers (boost, tapped-boost) and output filter
- Battery charger (buck) and input filter
- Battery
- Loads
- Mapham inverter
- Spacecraft power system models (for both AC and DC bus)

These models have been used to study

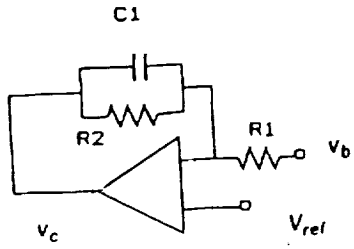
- Transient response to step change of load
- Mode transitions with changes of illumination level
- Paralleling of chargers and dischargers
- Stability study using frequency response plots (small signal models)

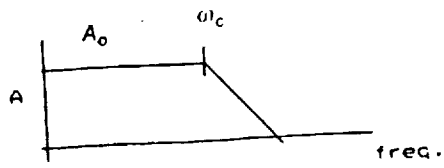
Design and analysis :

- Battery charger design
- Battery discharger topology trade-off study
- Battery discharger design
- Analysis of bus impedance, stability and ripple in the shunt regulation mode
- Analysis of bus impedance in charger and discharger regulated modes

Proposed future work :

- Modeling, analysis, design
- Hardware system testbed



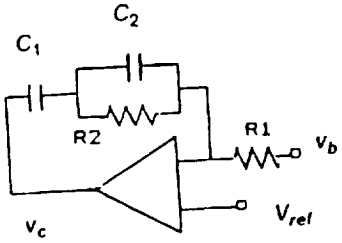


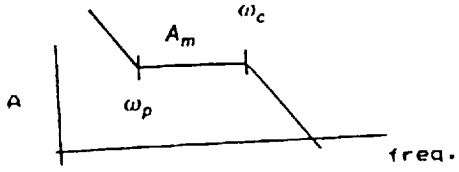
$$A = \frac{v_c}{v_b} = \frac{A_o}{1 + \frac{s}{\omega_c}}$$

$$\omega_c = \frac{1}{C_1 R_2}$$

$$A_o = \frac{R_2}{R_1}$$

Proportional gain compensator (select PG = 1)





$$A = \frac{v_c}{v_b} = \omega_m \frac{(1 + \frac{s}{\omega_p})}{s(1 + \frac{s}{\omega_c})}$$

$$A_m = \frac{R_2}{R_1}(1 + \frac{C_2}{C_1})$$

$$\omega_p = \frac{1}{R_2(C_2 + C_1)} \qquad \omega_c = \frac{1}{C_2 R_2} \qquad \omega_m = \frac{1}{C_1 R_1}$$

Integrator type compensator (select PG = 0)

Fig. 2.1-5 Compensators for [SR] model

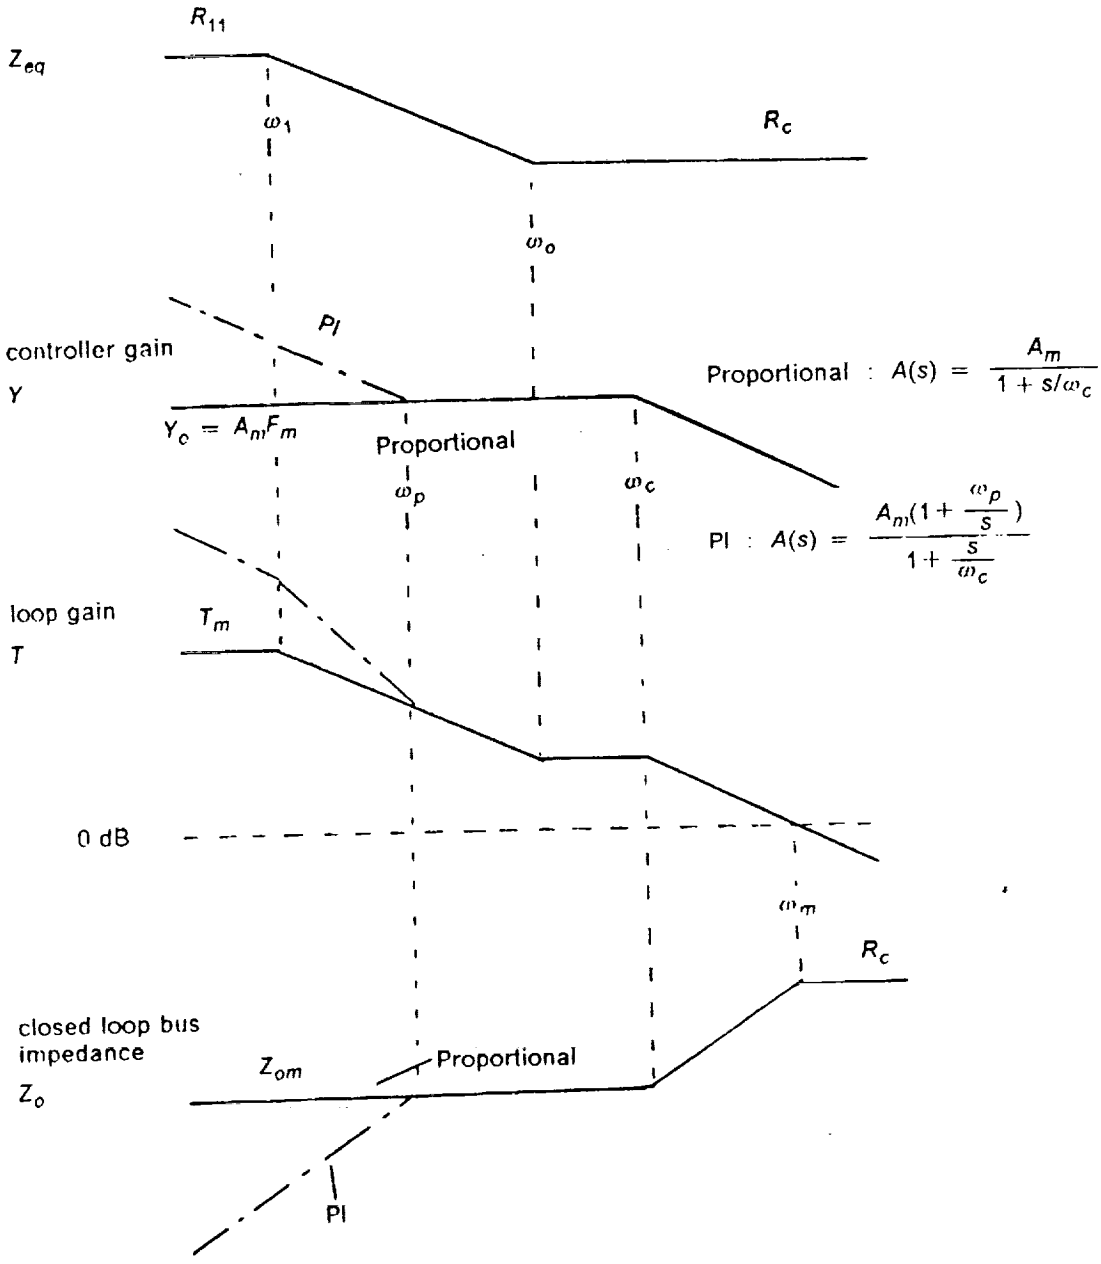


Fig. 4 Loop gain and bus impedance plots

Salient design features for shunt unit and bus capacitor

- For a properly designed system, the peak bus impedance is the ESR of the bus filter capacitor (this determines the overshoot for a step load change)
- A proportional controller has fast transient response but has a load dependant bus voltage error (a voltage "band" requirement)
- An integrator type compensator can decrease the voltage band requirement, but the zero required to reduce phase lag results in a low frequency pole in the bus impedance. This may make the transient response slower.
- The bus ripple depends on the following factors :

  Switching frequency
  Bus capacitor ESR
  Bus capacitance
  Current per parallel switch

$$V_{pp} = I_p R_c + D(1 - D)\frac{T_s I_p}{C}$$

where

D = duty ratio modulation
R_c = bus capacitor ESR
I_p = current from one set of NPS strings
T_s = switching period
C = bus capacitor

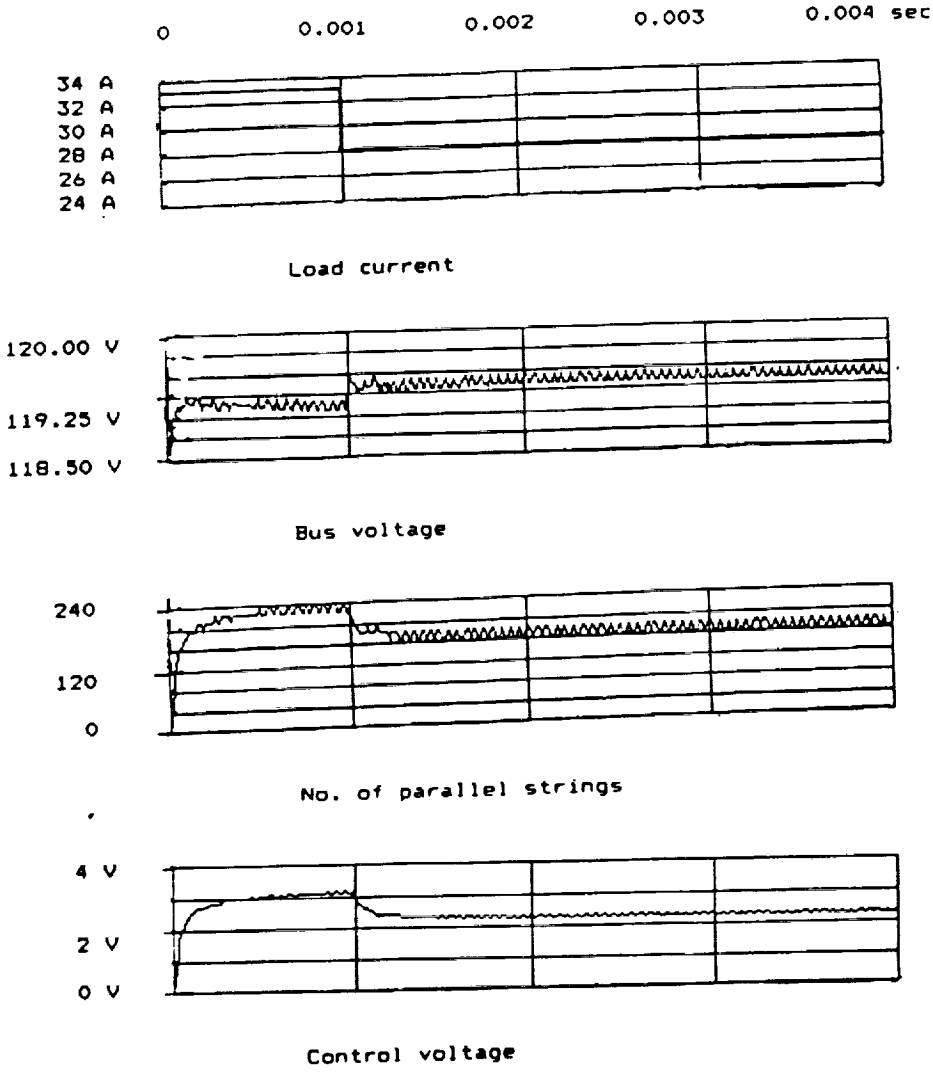

Fig. 5a Simulation for proportional compensator

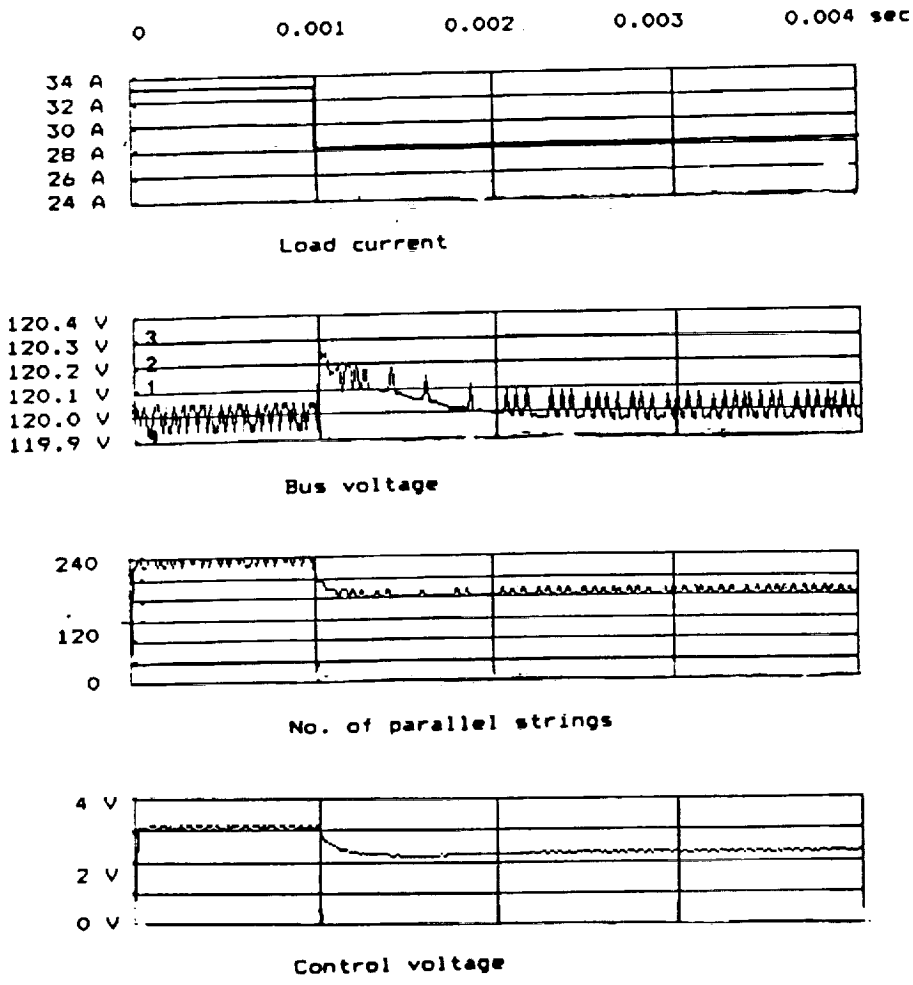

Fig. 5b Simulation for PI compensator

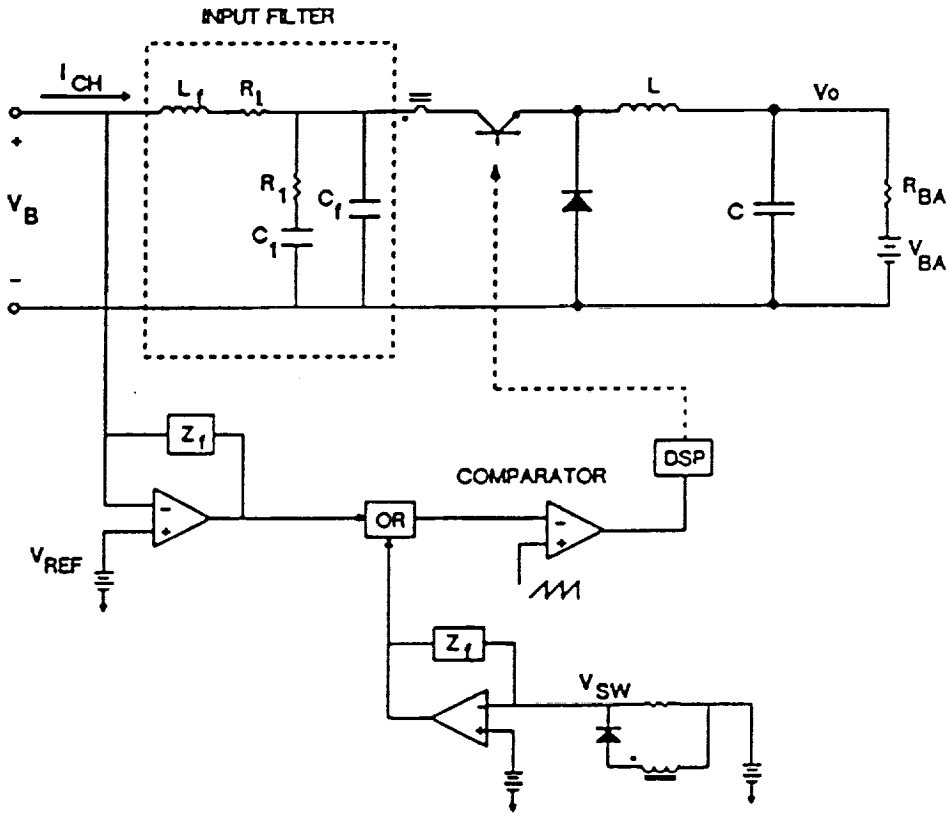
Battery charger circuit (Buck) with input filter



- An input filter is added to smooth the pulsating current drawn by the buck converter
- The circuit can be made to function in two modes.
- In the bus voltage regulation mode, the current is less than the maximum battery charge current and the charger regulates the bus
- When the array has sufficient illumination to provide the maximum charge current, the charger current is limited to this maximum value. The bus voltage rises and the array shunt switching unit regulates the bus

Salient design features for the charger

- Input filter corner frequency is one decade below the switching frequency to lower the ripple to 1% of output side ripple
- An integrator type compensator (2 poles, 2 zeroes) is used.

$$H_v = \frac{w_m}{s} \frac{(1 + s/w_{z1})(1 + s/w_{z2})}{(1 + s/w_p)}$$

- The low frequency compensator zero is the dominant pole for bus impedance and determines transient response. It is kept as large as possible. However, placing it beyond the low frequency pole of the power stage can cause conditional instability
- The peak overshoot is determined by the ESR of the bus filter capacitor
- The second zero approximately determines the settling speed of the system
- These transient response features have been verified from the step load simulation

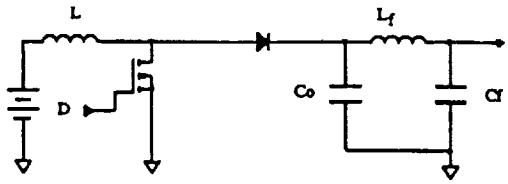
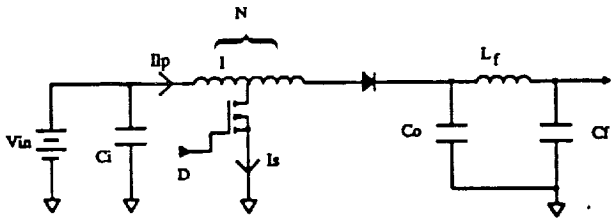
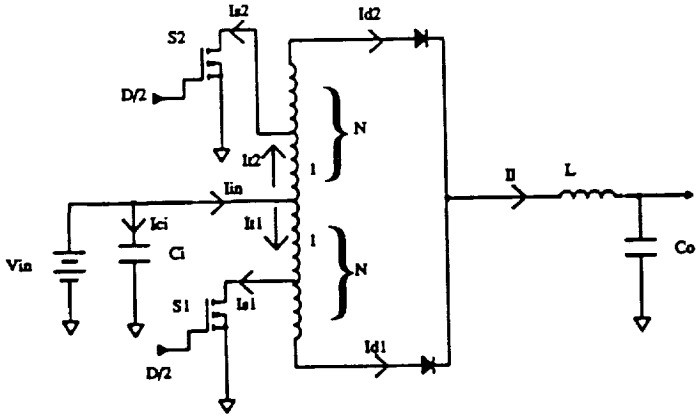
Topologies considered for discharger



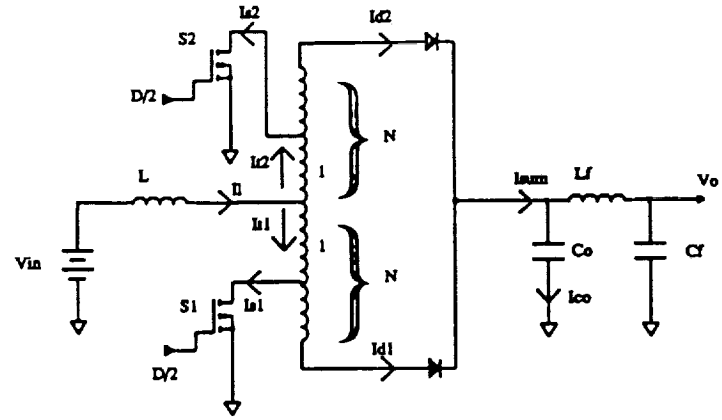
Boost



Tapped boost



Voltage fed push pull with tapped auto transformer (VFPPTAT)



Current fed push pull with tapped auto transformer (CFPPTAT)

	Boost	T-Boost	VFPPTAT	CFPPTAT
Inductor Tap Ratio	1	2	1	1
X-former Tap Ratio	n/a	n/a	3	3
Conversion Frequency	25kHz	25kHz	50kHz	50kHz
Inductance (15% Ripple)	$59\mu H$	$140\mu H$+	$65\mu H$	$5.5\mu H$
Peak Inductor Current	66 A	42.5 A	19.2 A	66 A
Inductor Energy ($\frac{1}{2} LI_p^2$)	.13 W-S	.13 W-S	.010 W-S	.012 W-S
Max. Duty Cycle	73%	56%	41% *	47% *
Peak Q current	66 A	85 A	57.6 A	49.5 A
RMS Q current	49 A	55 A	37 A	30 A
Peak Q Voltage	120 V	82.5 V	90 V	120 V
Peak Diode Current	66 A	42.5 A	19.2 A	33 A
Peak Diode Voltage	120 V	165 V	210 V	180 V
Input Cap RMS Current	0	18.4 A	19.7 A	0
Output Cap RMS Current	26 A	19 A	0	10.3 A
Pri. Leakage L delta I	0	42.5 A	38.4 A	16.5 A

+ This is the whole inductance. The primary inductance is $35\mu H$.

* This is the duty cycle per switch. The duty cycle seen by the inductor is twice.

Results of comparison : choice of discharger topology

- the boost converter is simple, has only one switch, one diode and no transformer, and continuous input current
- it however has disadvantages (specially if the step up ratio is high). These are the RHP zero in the control/output voltage transfer function, high output current stress in the output capacitor, and difficulty in control loop design at high transformation ratios (i.e., high duty ratio)
- the tapped boost allows a lower duty ratio for a given voltage step up, the RHP zero is at a higher frequency and more manageable
- the VFPPTAT is buck derived so it provides continuous output current, well behaved control characteristics, and a lower current stress than the boost or tapped boost
- the VFPPTAT however needs two diodes and two switches, and the circuit is sensitive to transformer saturation
- CFPPTAT has many desirable features such as lowest switch current stress.
- the CFPPTAT however needs two switches, and it is expected that that it may not compare favorably with 2 tapped boost converters operating in parallel and out of phase by 180 degrees
- the tapped boost topology was therefore selected for modeling as discharger

Comparison of bus impedances in different modes

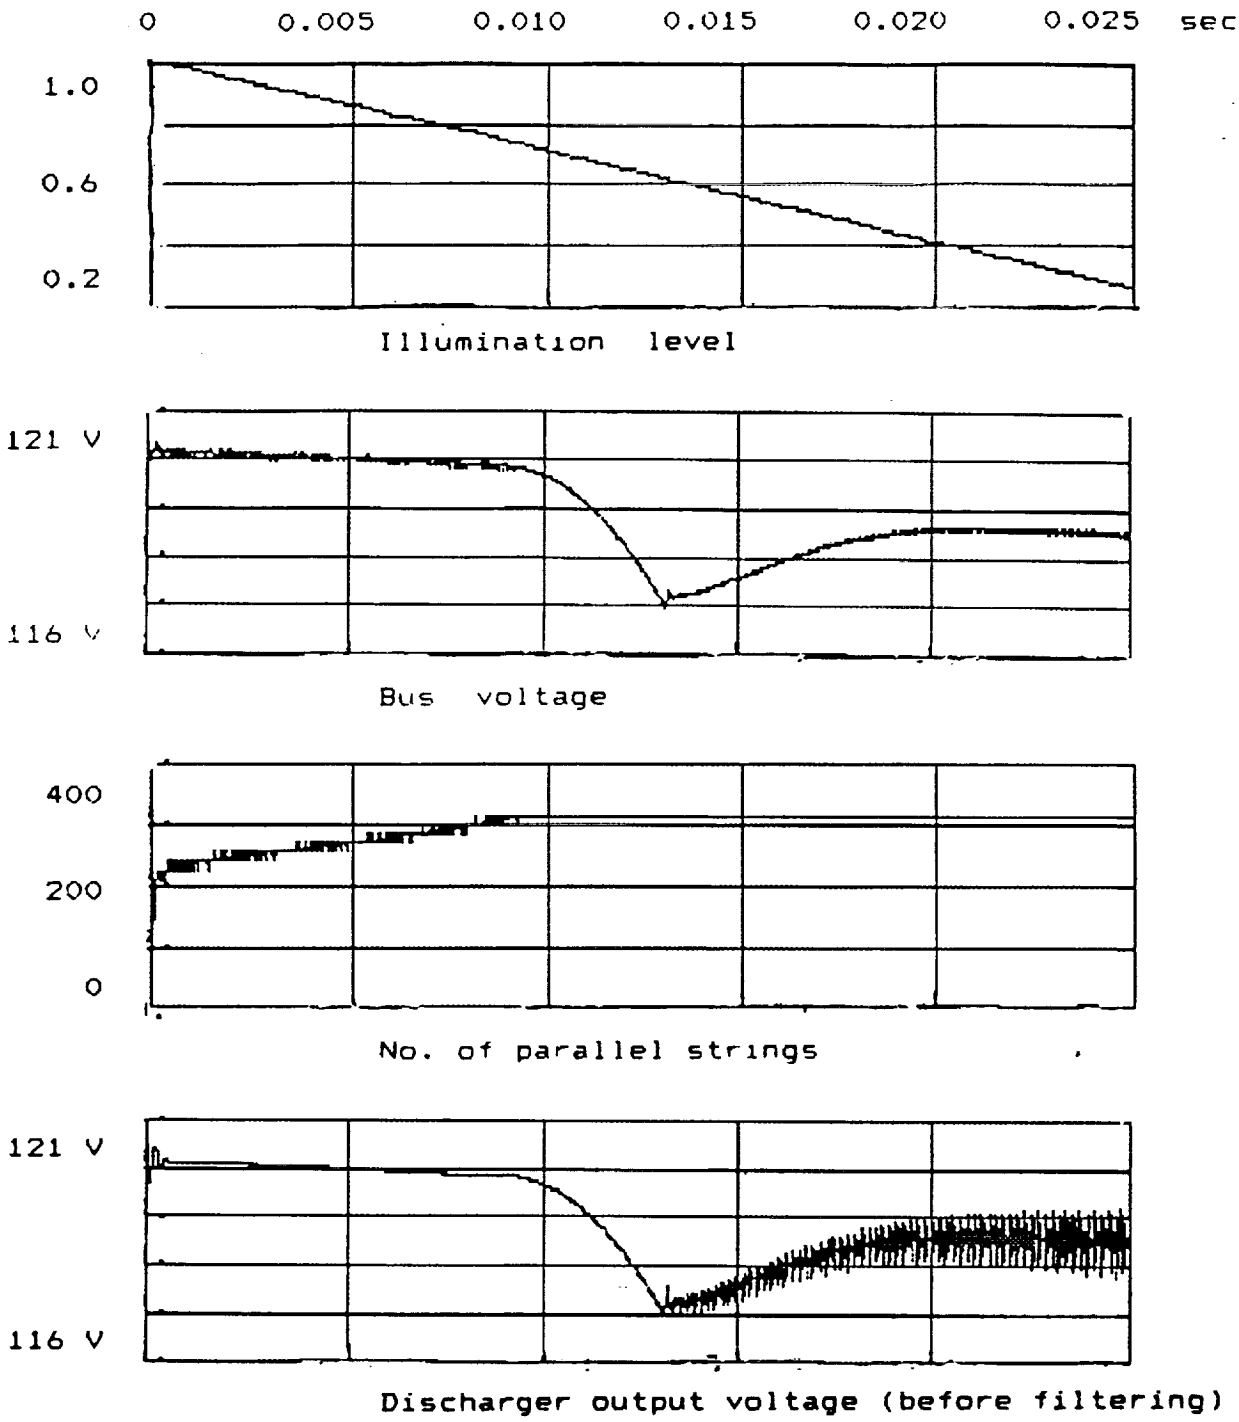

Fig. 4.1-5 Sunlight to eclipse transition

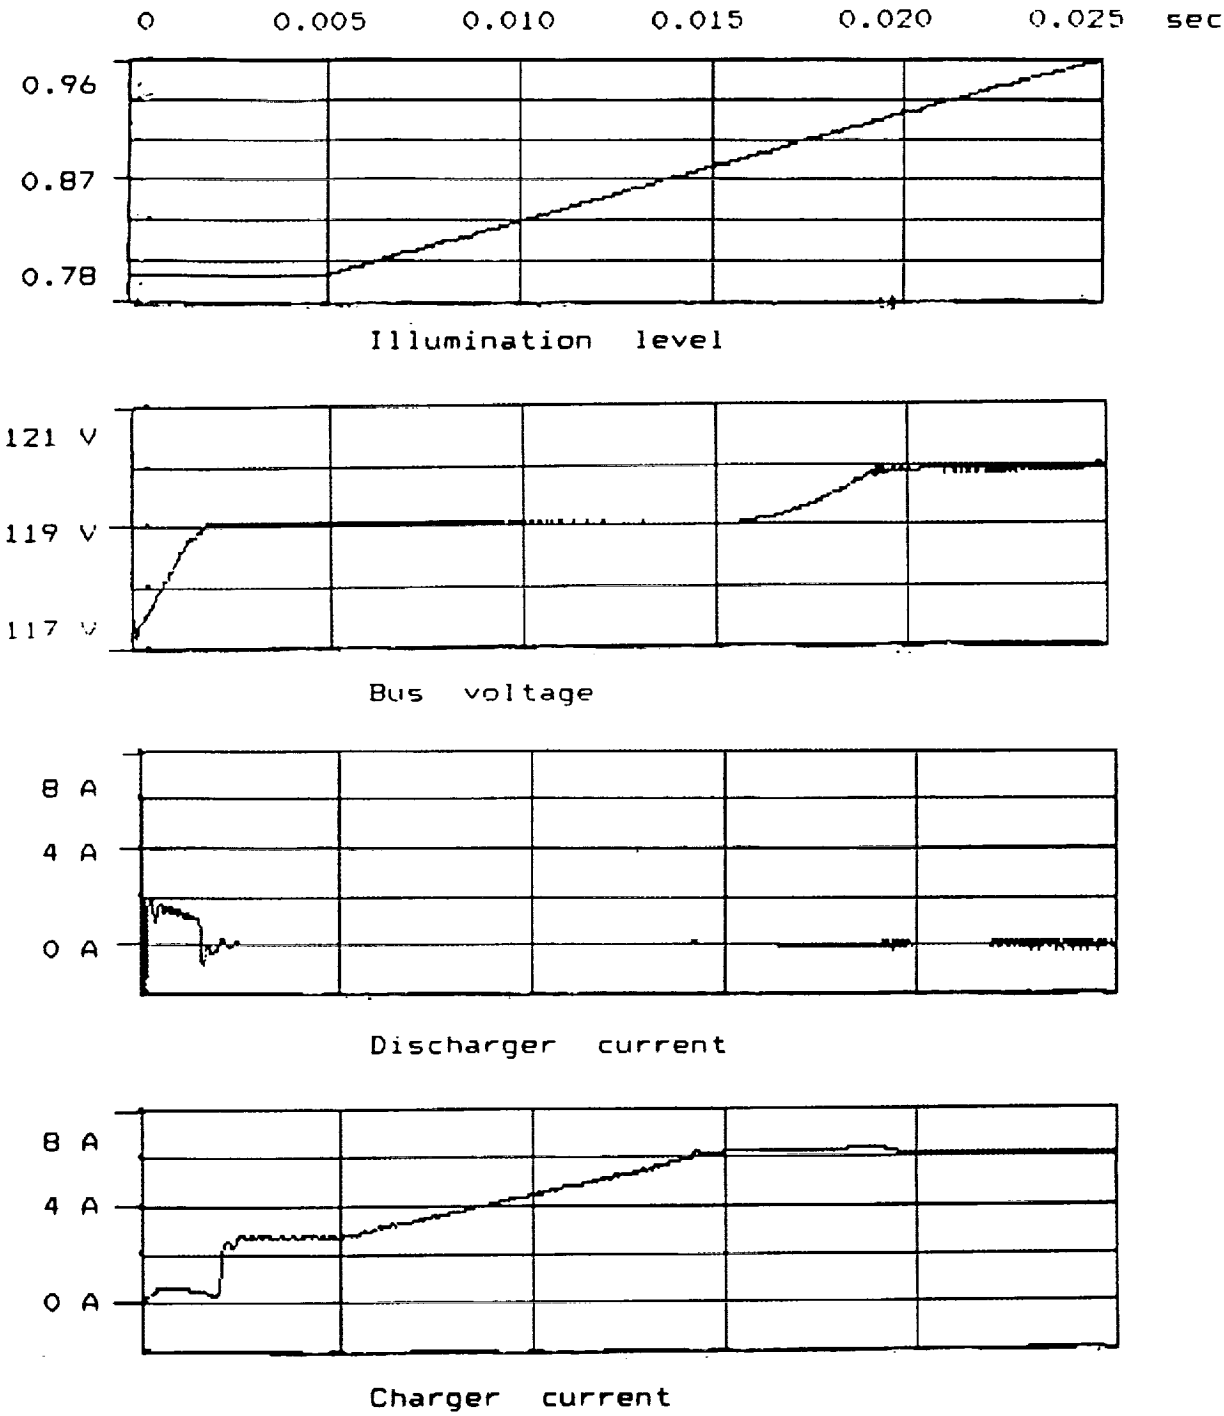

Fig. 4.1-6 Eclipse to sunlight transition

Proposed future work : Hardware system testbed

Objectives :

- To enable verification and improvement of existing EASY5 computer models
- To provide experimental confirmation of analytical design procedures

Proposed hardware work :

The following are to be designed, built and tested. The designs will be optimized by VPEC's power converter optimization (CADO) software.

- battery charger
- battery discharger (boost, and an alternate topology)
- mode controller

These are to be tested with :

- a simple solar array simulator
- battery simulator
- load bank

These will allow verification of simulations for many of the system modes. Future work could incorporate a solar array shunt switching unit for verification of the shunt mode.

CHARACTERISTIC EQUATION

(Note: C2 = CBUS)

$$S^4 + S^2\left[\frac{1}{L2\,C1} + \frac{1}{L2\,C2}\right] + \frac{1}{L1\,L2\,C1\,C2} = 0$$

$$\left[S^2 + \frac{1}{L1\,(C1 + C2)}\right]\left[S^2 + \frac{1}{L2\,C1} + \frac{1}{L2\,C2}\right] \approx 0$$

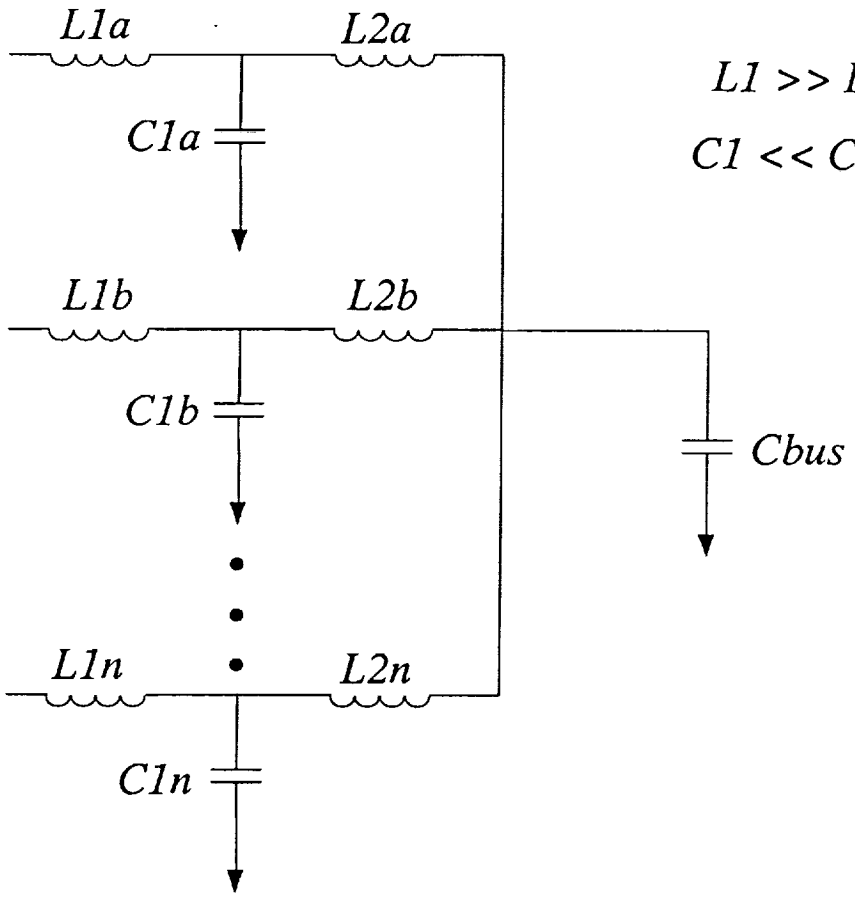
RESONANT FREQUENCIES

$$W_{o1} = \frac{1}{\sqrt{L1\,(C1 + C2)}} \approx \frac{1}{\sqrt{L1\,C2}}$$

$$W_{o2} = \frac{1}{\sqrt{L2\left[\frac{C1\,C2}{C1 + C2}\right]}} \approx \frac{1}{\sqrt{L2\,C1}}$$

PARALLEL CONVERTERS WITH TWO STAGE FILTERS

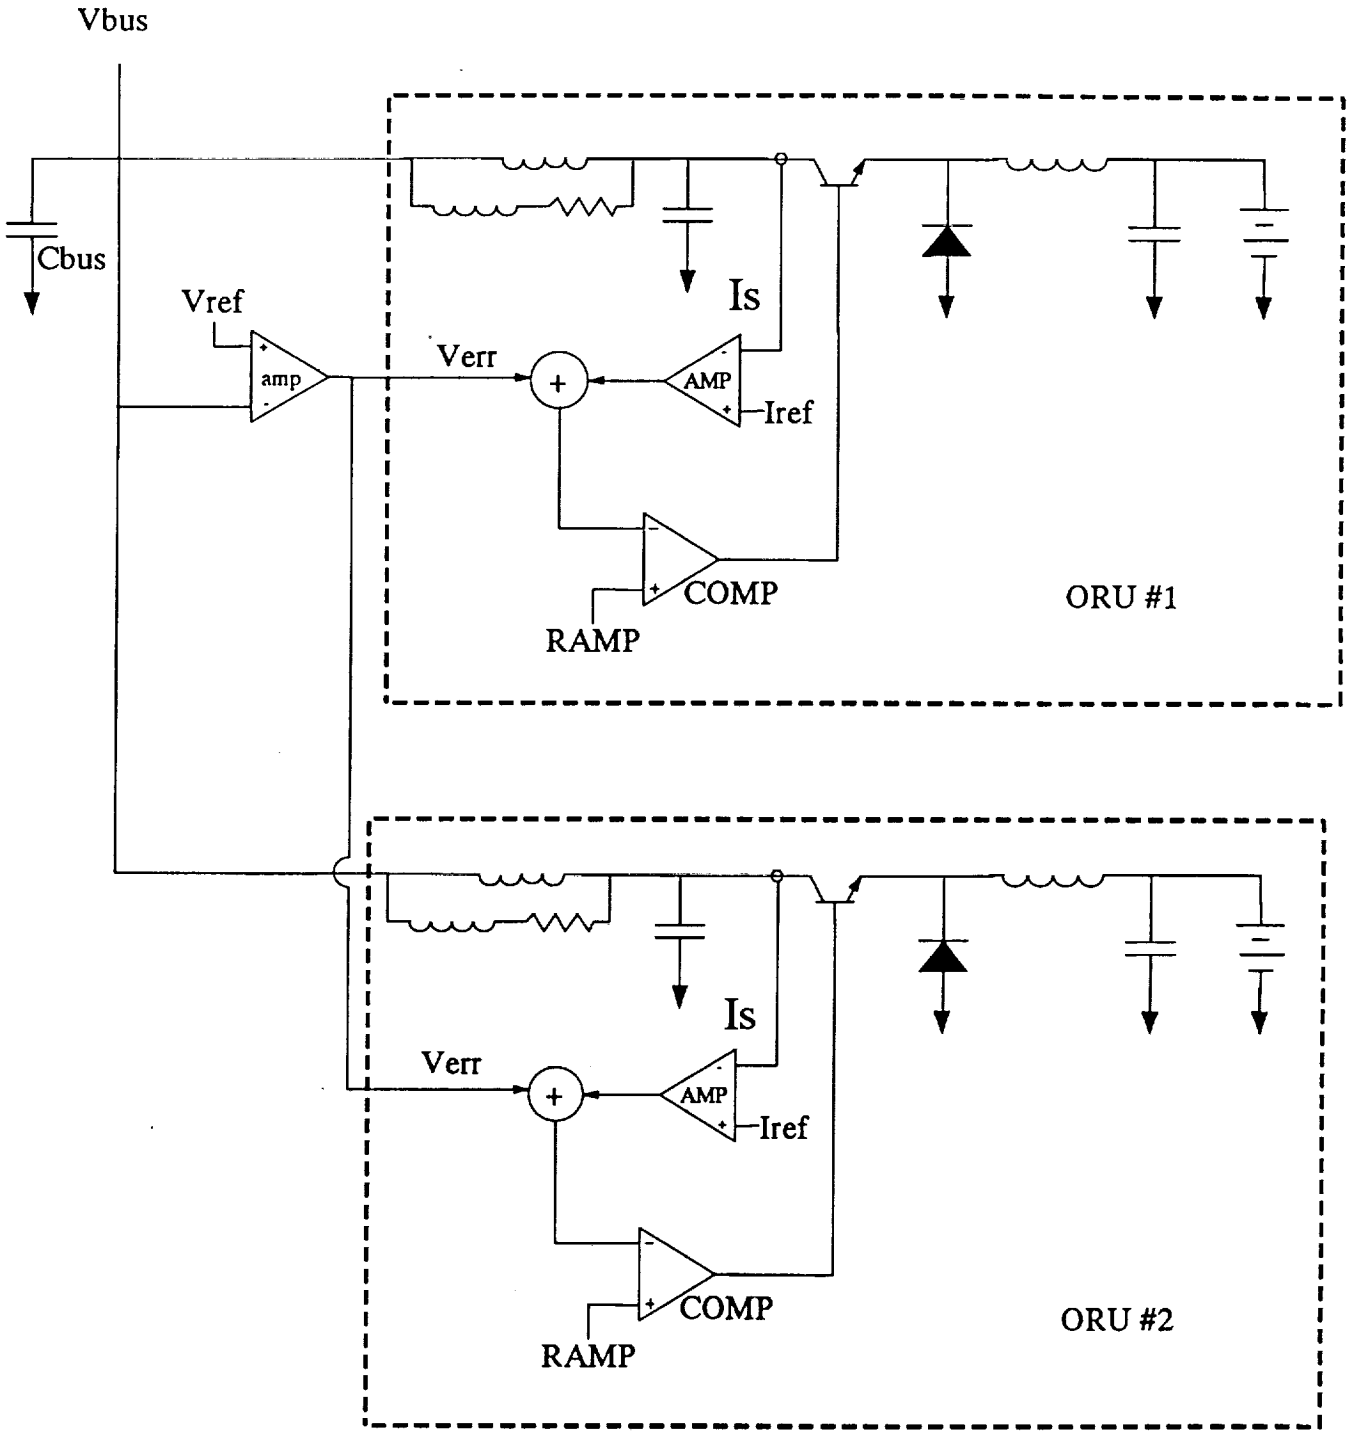
(BUCK OR BOOST EQUIVALENT)



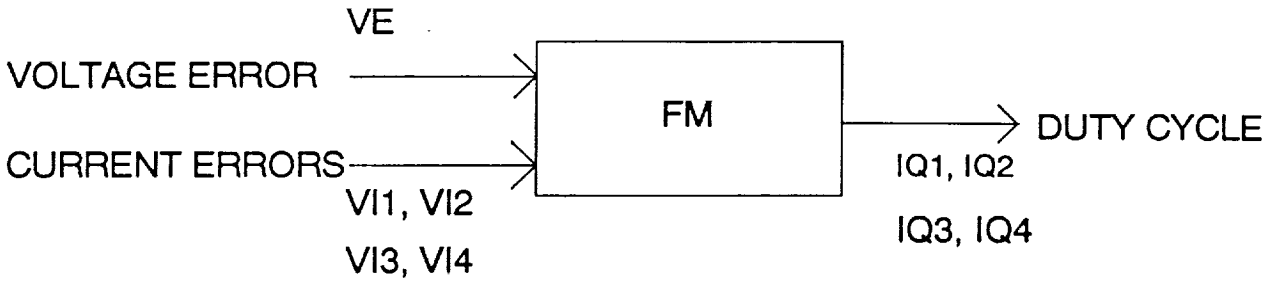
$$W_{o1} = \frac{1}{\sqrt{\frac{L1}{n}(n\,C1 + Cbus)}} \approx \frac{\sqrt{n}}{\sqrt{L1\,Cbus}}$$

$$W_{o2} = \frac{1}{\sqrt{\frac{L2}{n}\left[\frac{n\,C1\,Cbus}{n\,C1 + Cbus}\right]}} \approx \frac{1}{\sqrt{L2\,C1}}$$

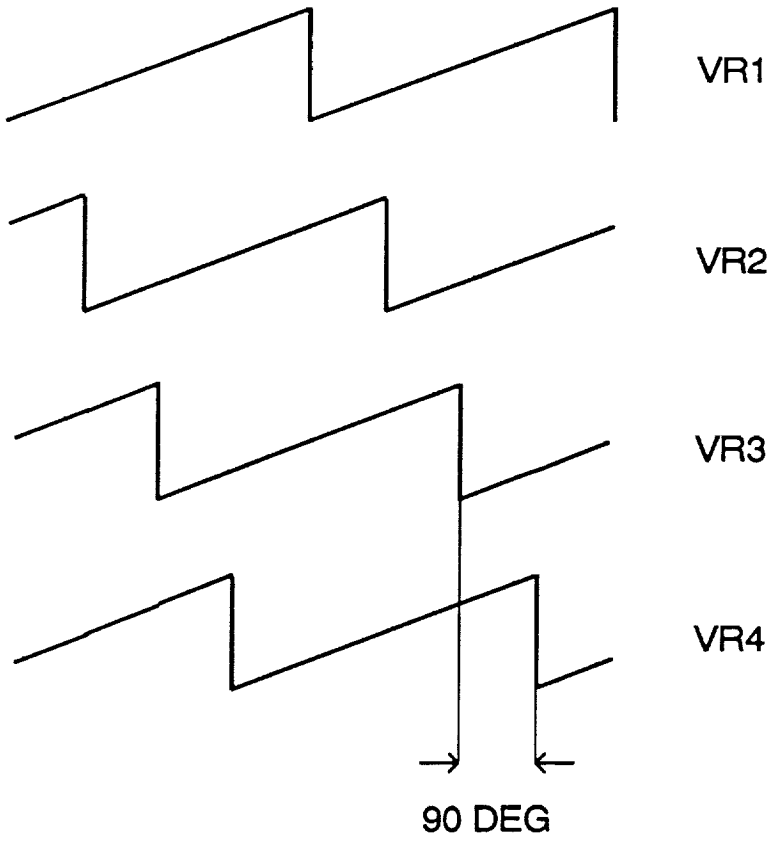
PARALLEL CHARGER MODEL



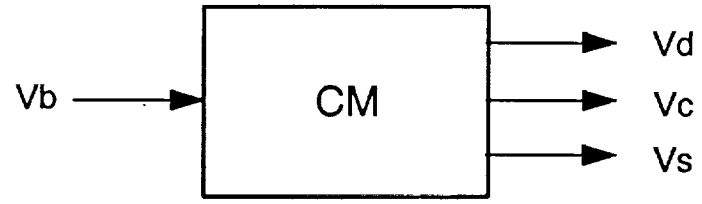
EASY5 FOUR PHASE MODULATOR MODEL

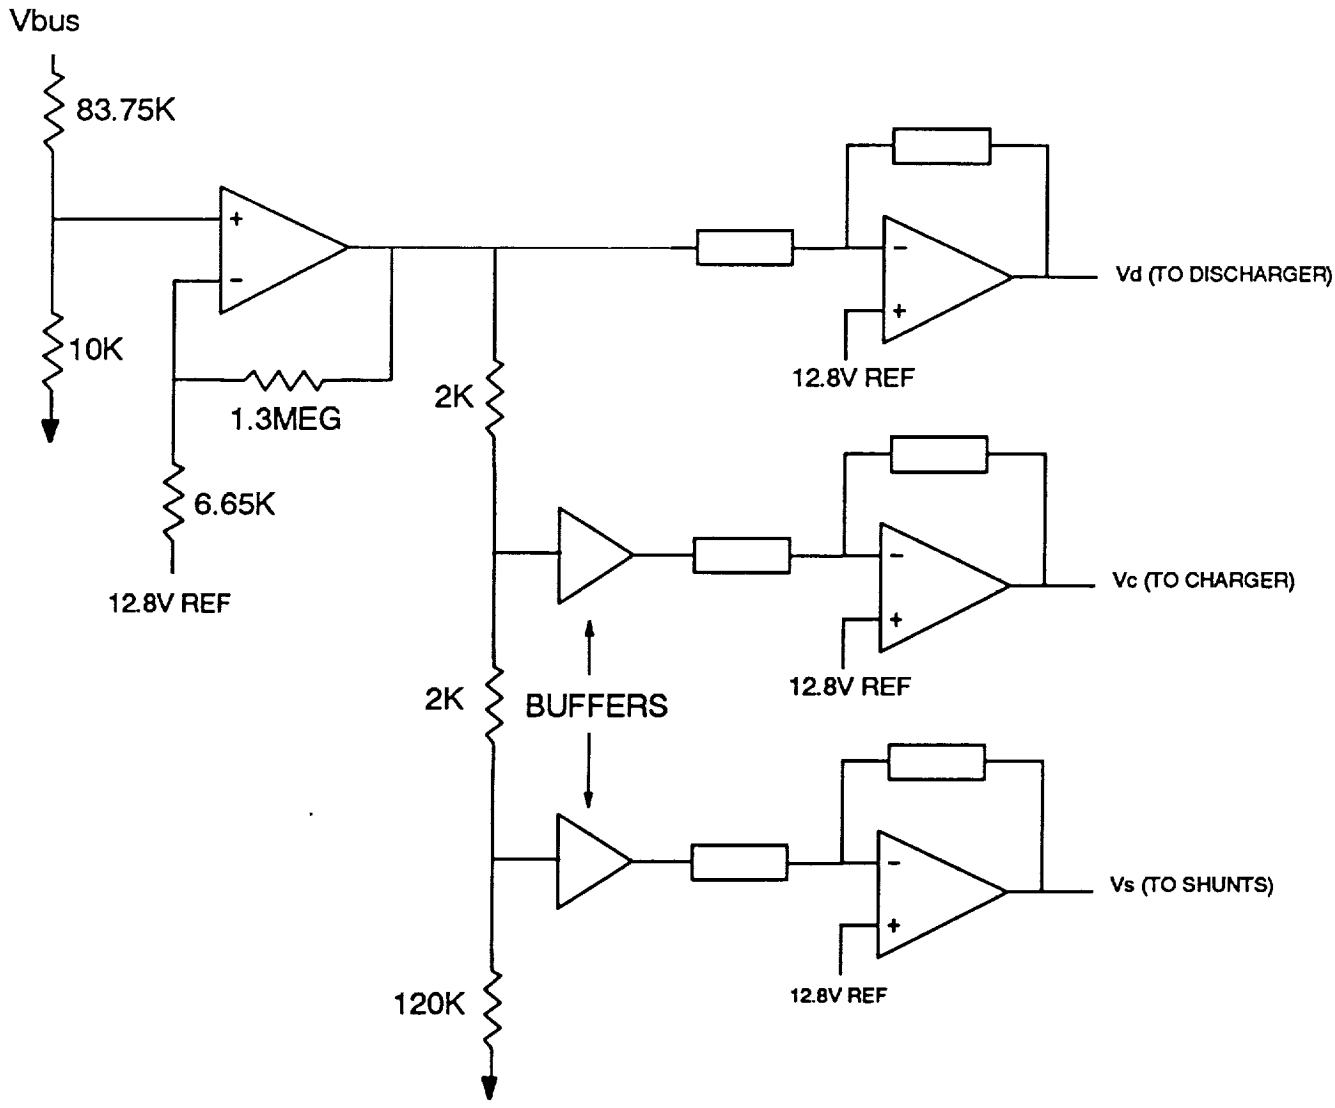


THE FOUR MODULATOR RAMPS ARE ALL SHIFTED BY 90 DEG :



EASY5 MODE CONTROLLER MODEL



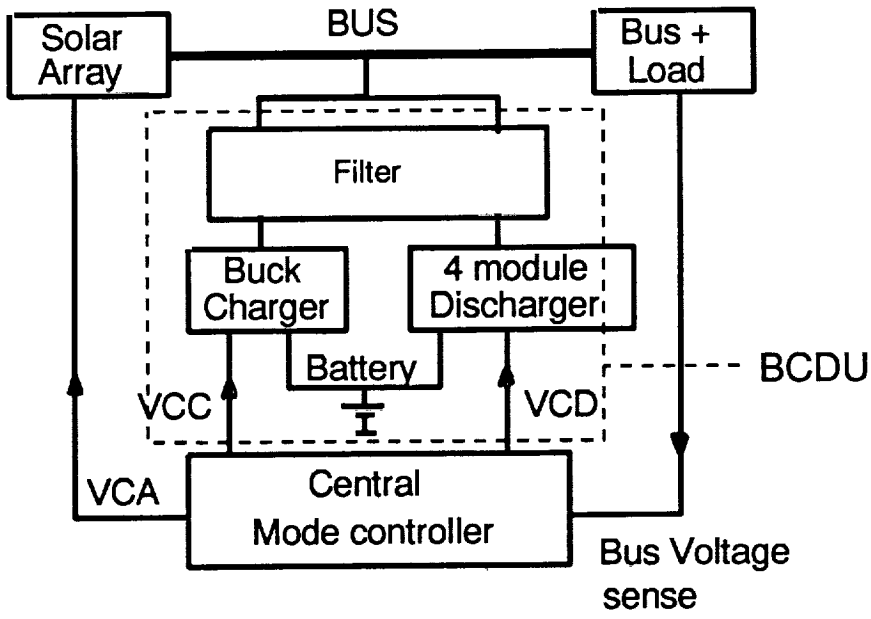


NOTE: ALL OP-AMPS HAVE ONE COMMON 12.8V REFERENCE

MODELING AND SIMULATION OF POWER SYSTEM

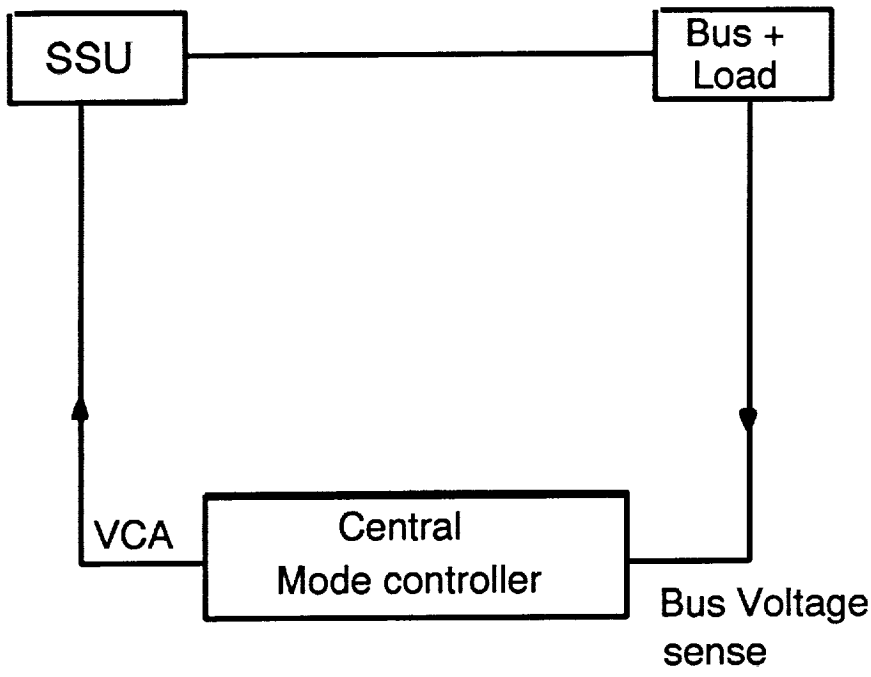
- System block diagram
- Operation of solar array
- Operation of 4-module discharger
- Operation of charger
- Mode transition from array to discharger

SYSTEM BLOCK DIAGRAM



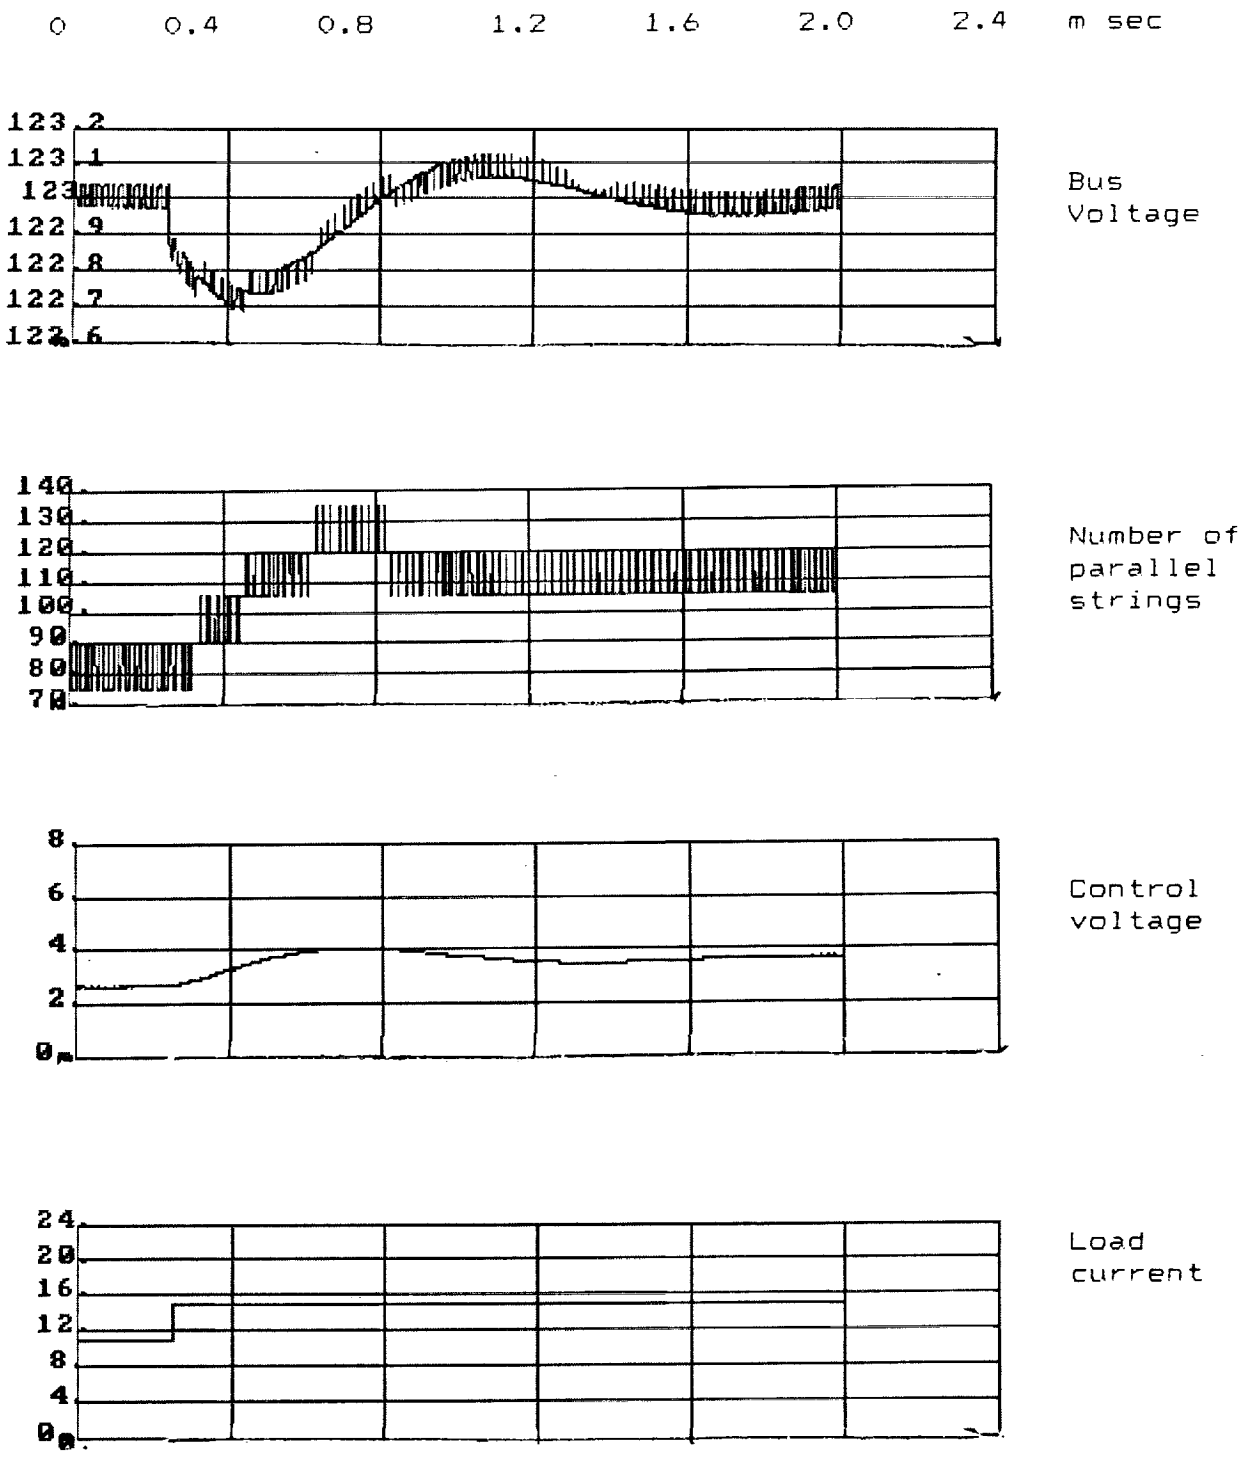
- New models are controlled by a central mode controller
- New discharger is a 4-module boost converter
- Models are set up as per the proposed hardware design
- Details are shown in the subsequent simulations
- Each mode is tested with a step load change
- Mode transition is induced by changing the illumination level

SOLAR ARRAY SWITCHING UNIT OPERATION

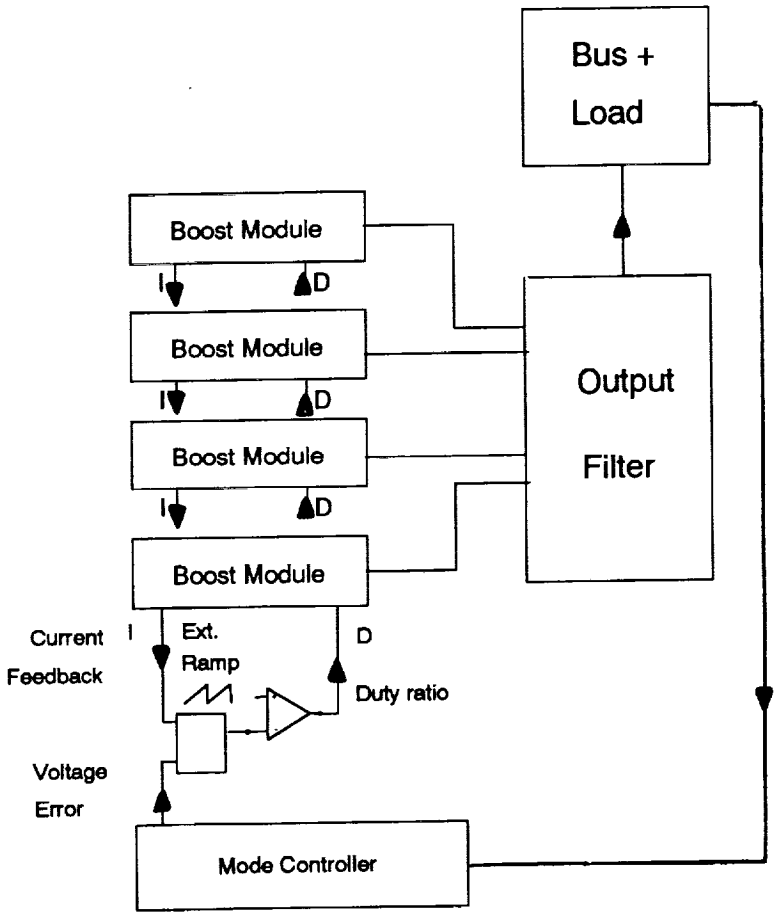


- The solar array is controlled by a central mode controller
- The bus is regulated by the array
- The simulation shows a change in parallel strings with load

SOLAR ARRAY OPERATION FOR LOAD STEP CHANGE

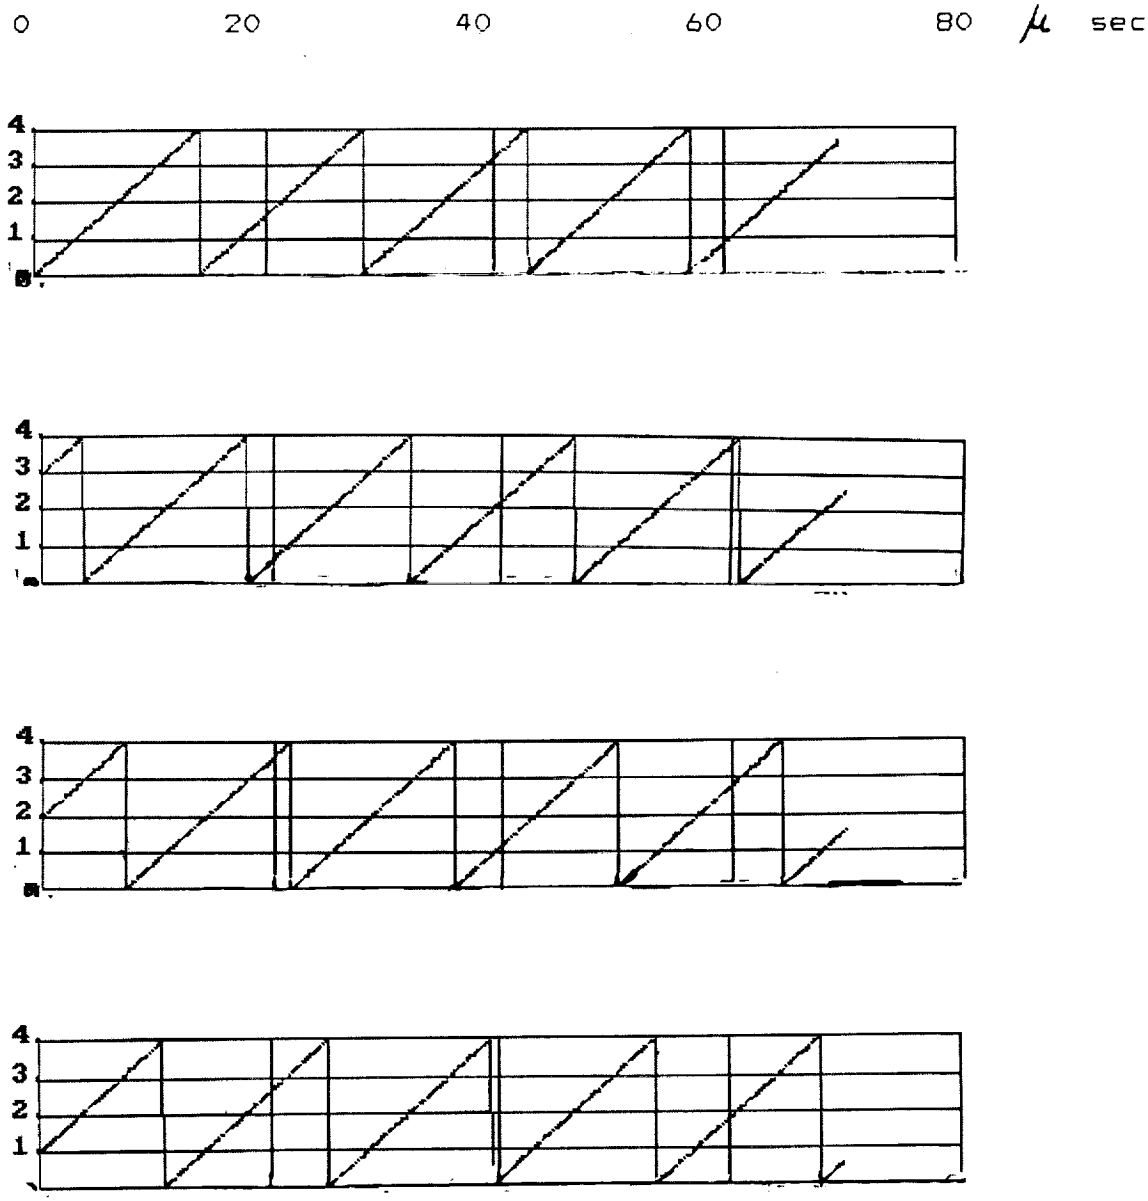


DISCHARGER MODEL TEST SIMULATION

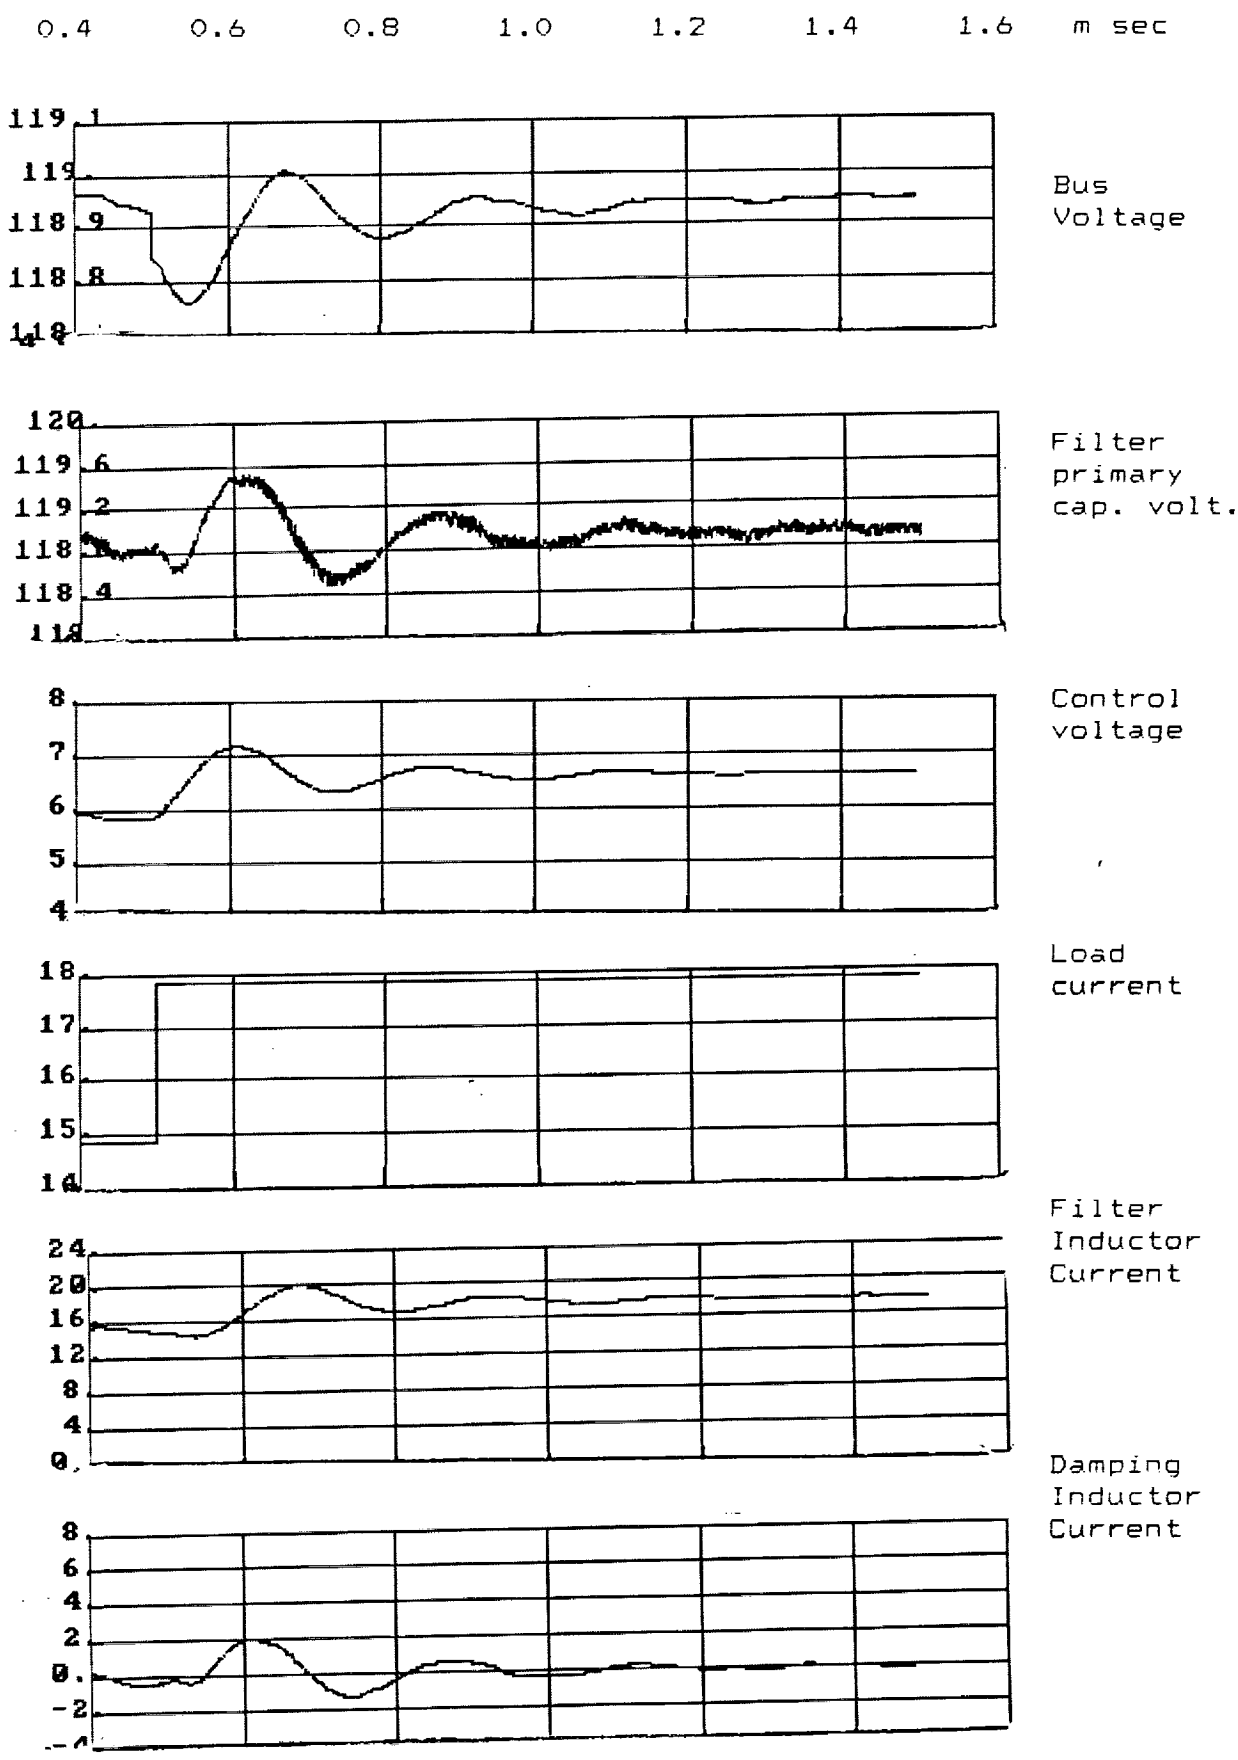


- The voltage error is common to all modules
- Each module has it's own phase shifted PW modulator
- Current feedback is applied separately to each module

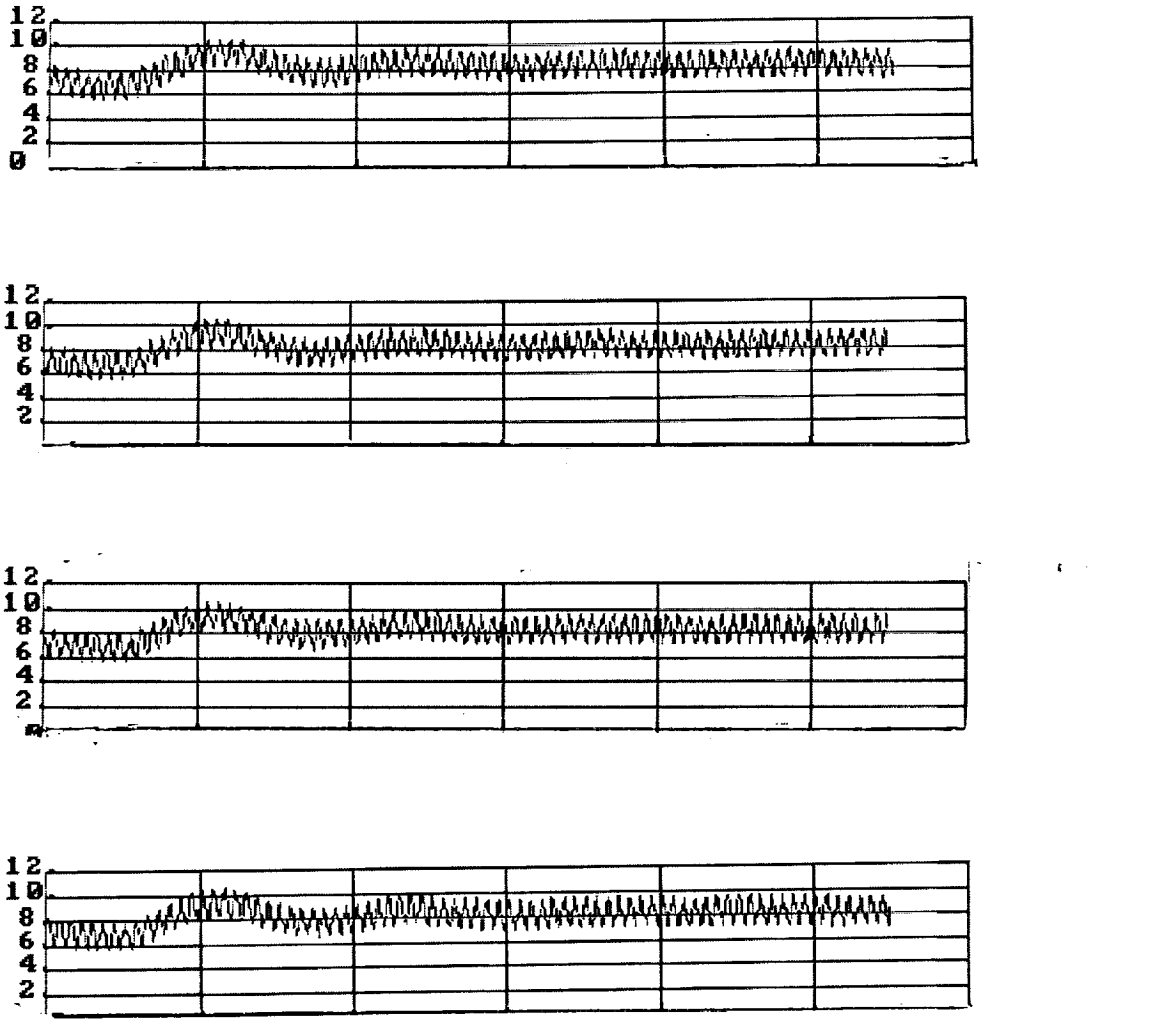
PHASE-SHIFTED RAMPS FOR MULTIMODULE BOOST DISCHARGER



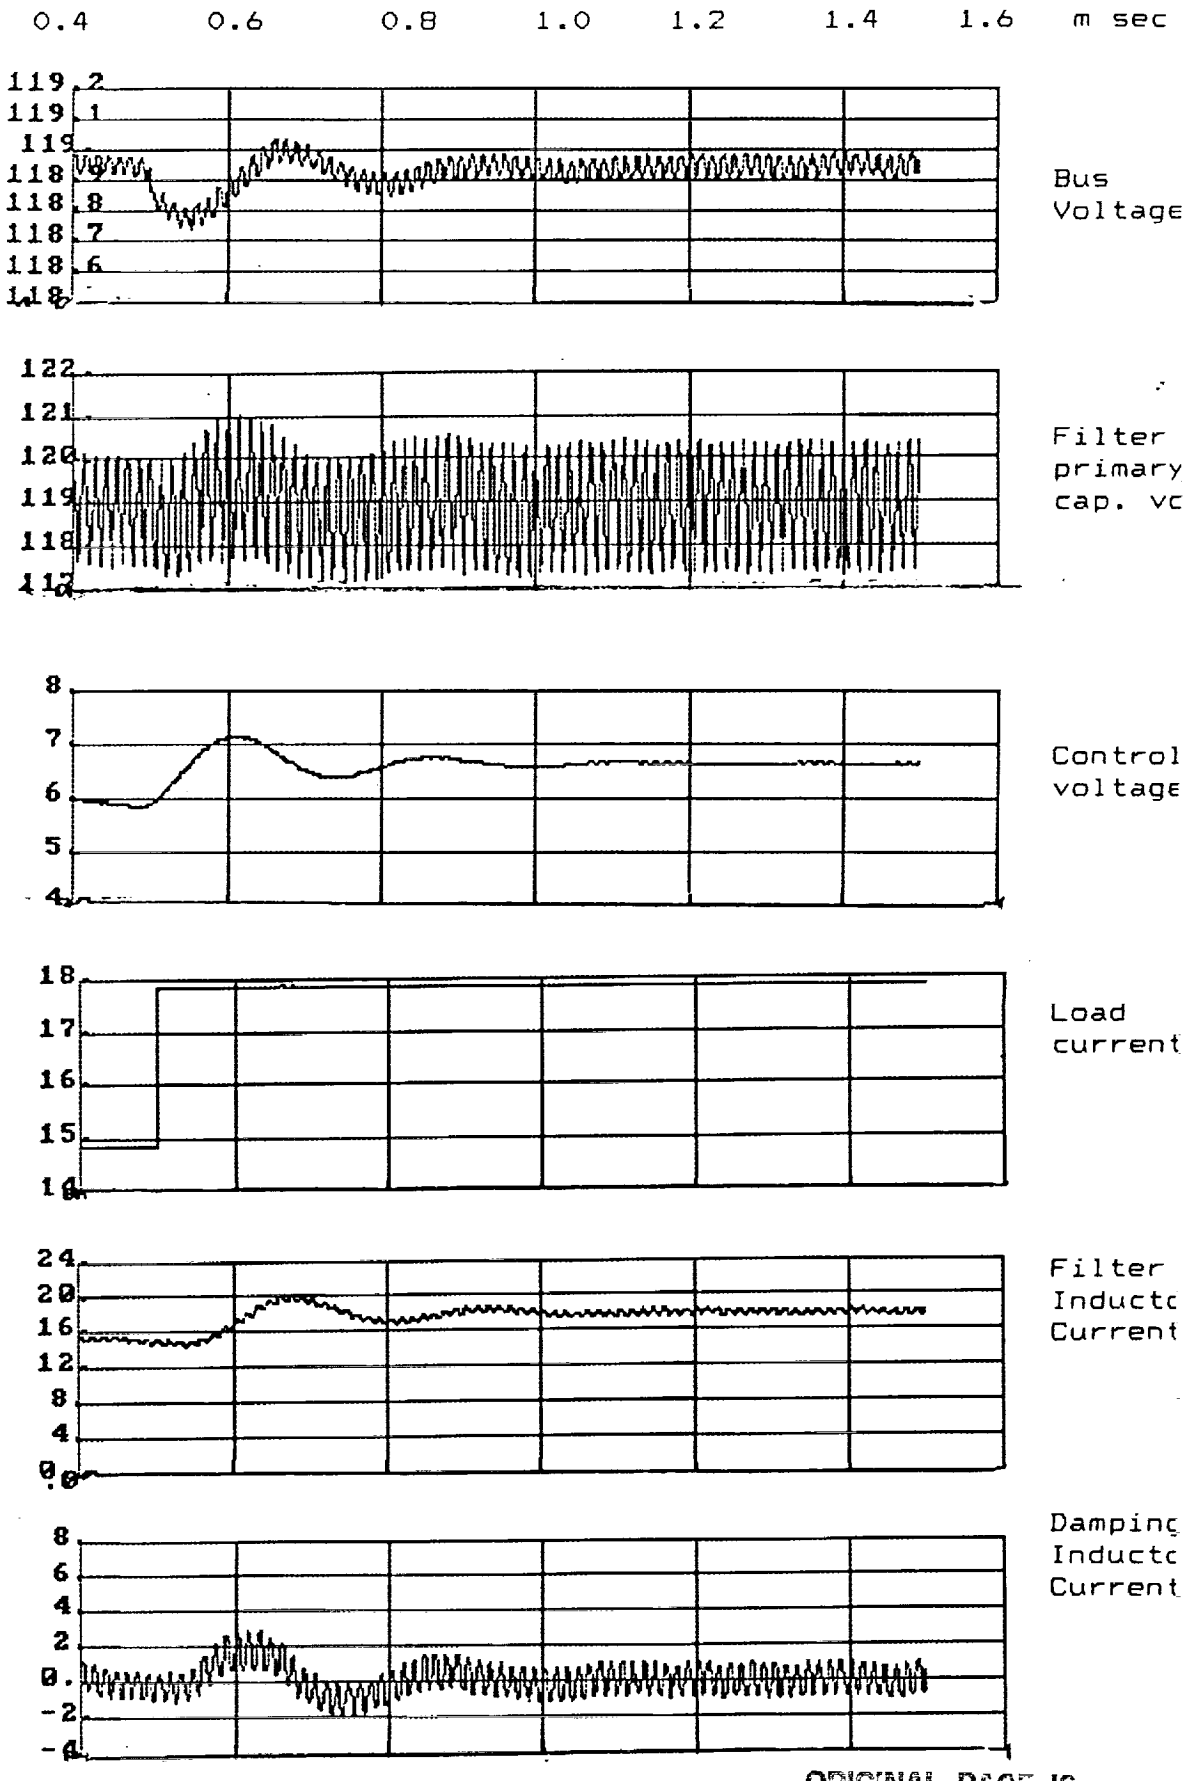
DISCHARGER OPERATION FOR A LOAD STEP CHANGE



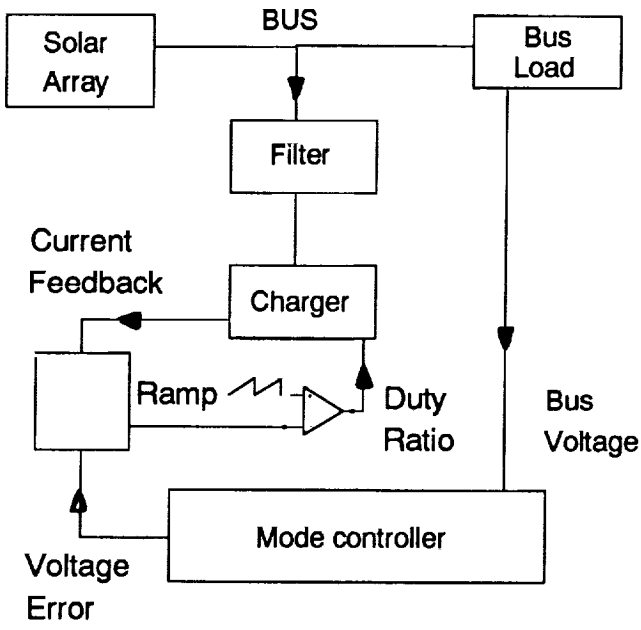
EQUAL SHARING OF CURRENT BY THE FOUR MODULES



DISCHARGER OPERATION WITHOUT PHASE SHIFTED RAMPS

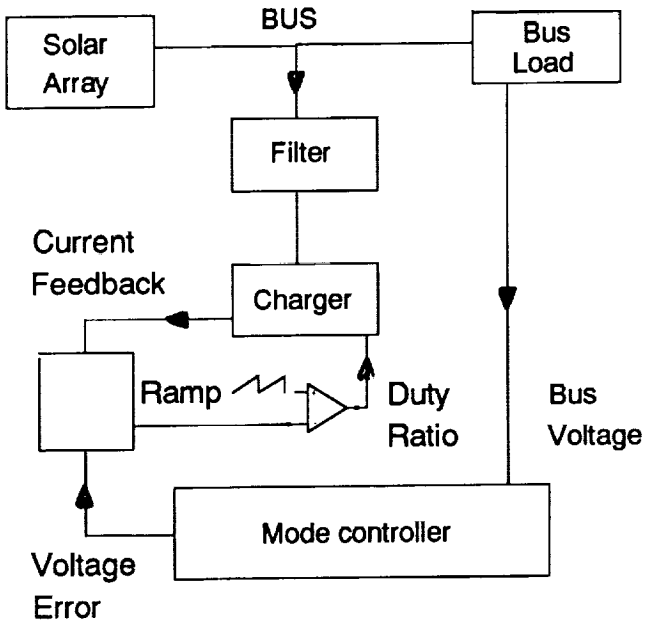


CHARGER MODEL TEST SIMULATION 1



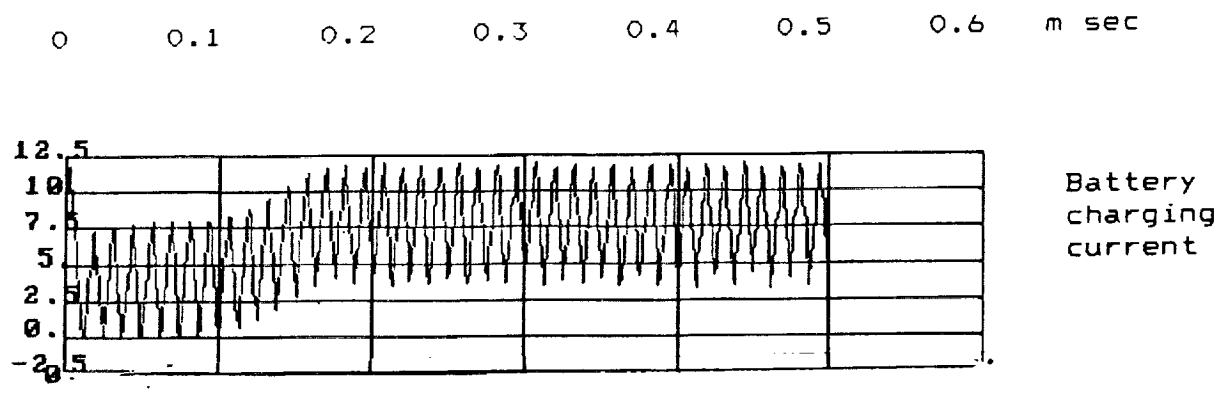
- In the voltage regulation mode, the charger regulates the bus
- The bus is regulated by changing the charging current

CHARGER MODEL TEST SIMULATION 2



- In the current regulation mode, the array regulates the bus
- The charger regulates the charging current at the limiting value

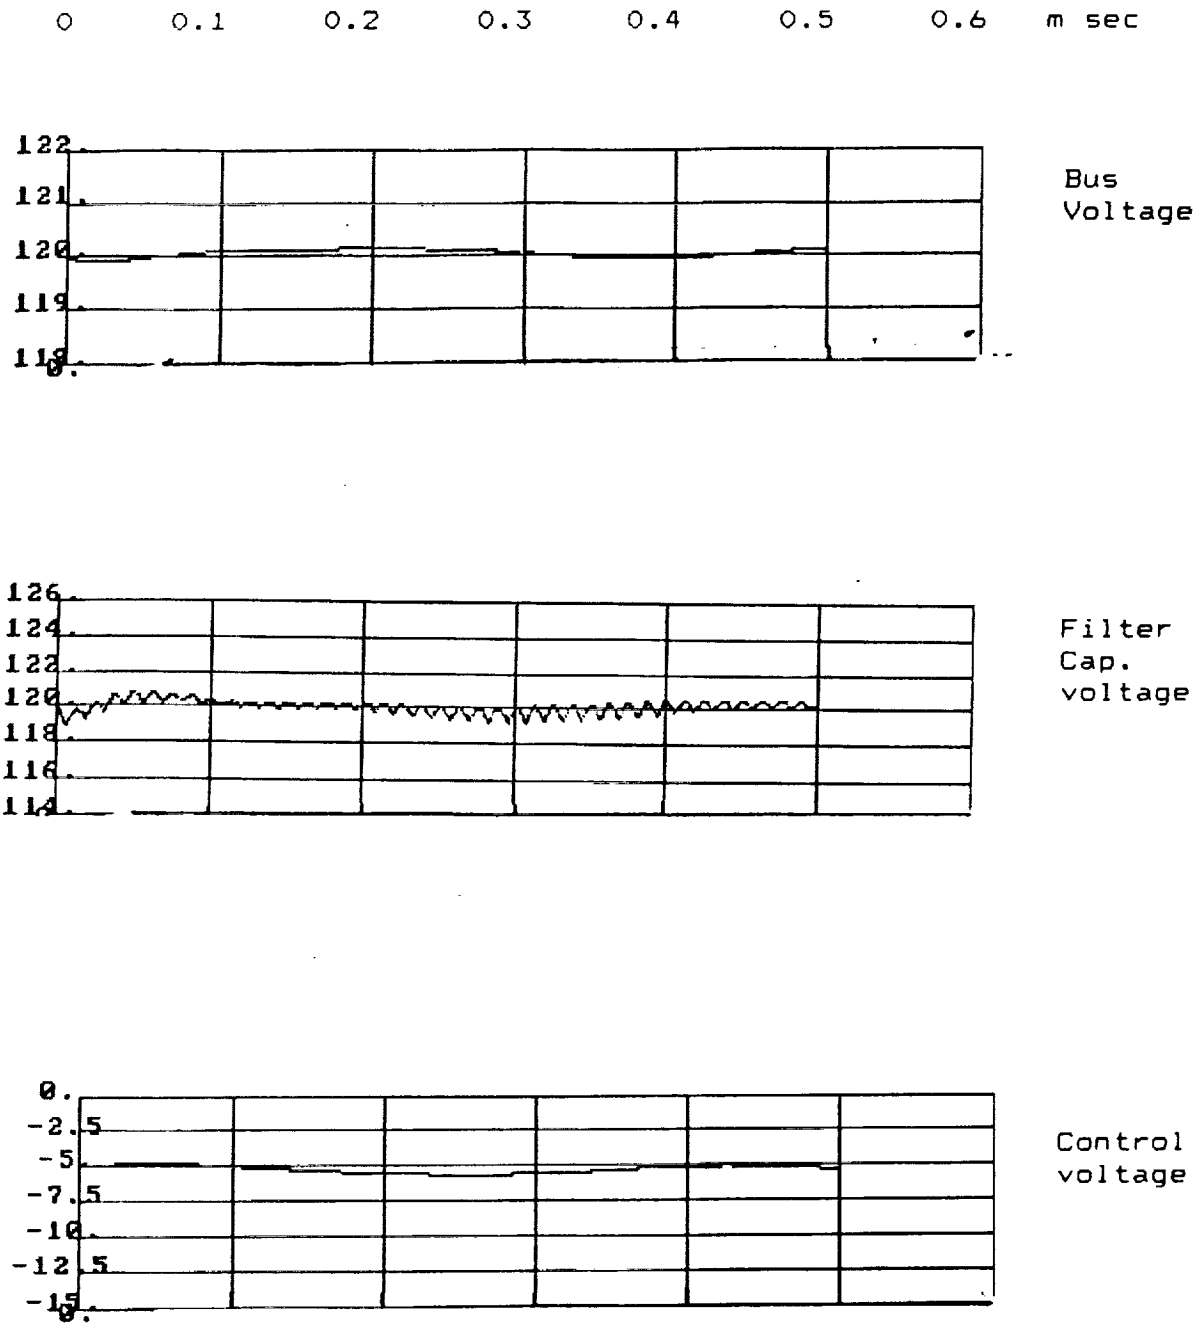
CHARGER IN CURRENT REGULATION MODE



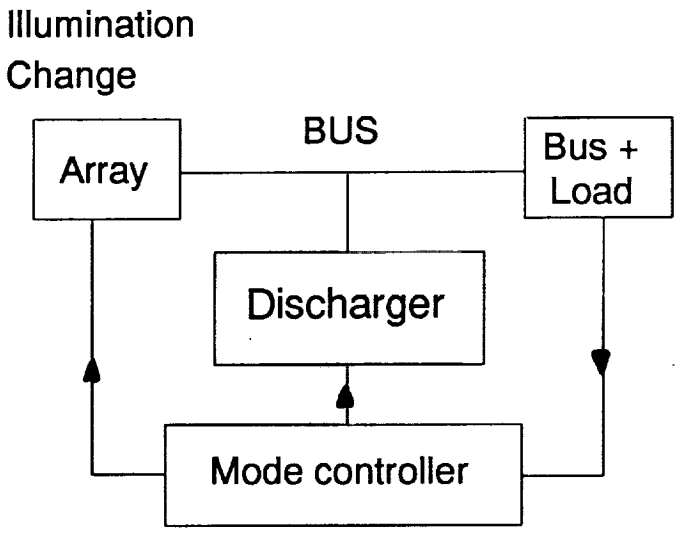
1.2 - 20A

C-2

CHARGER IN VOLTAGE REGULATION MODE

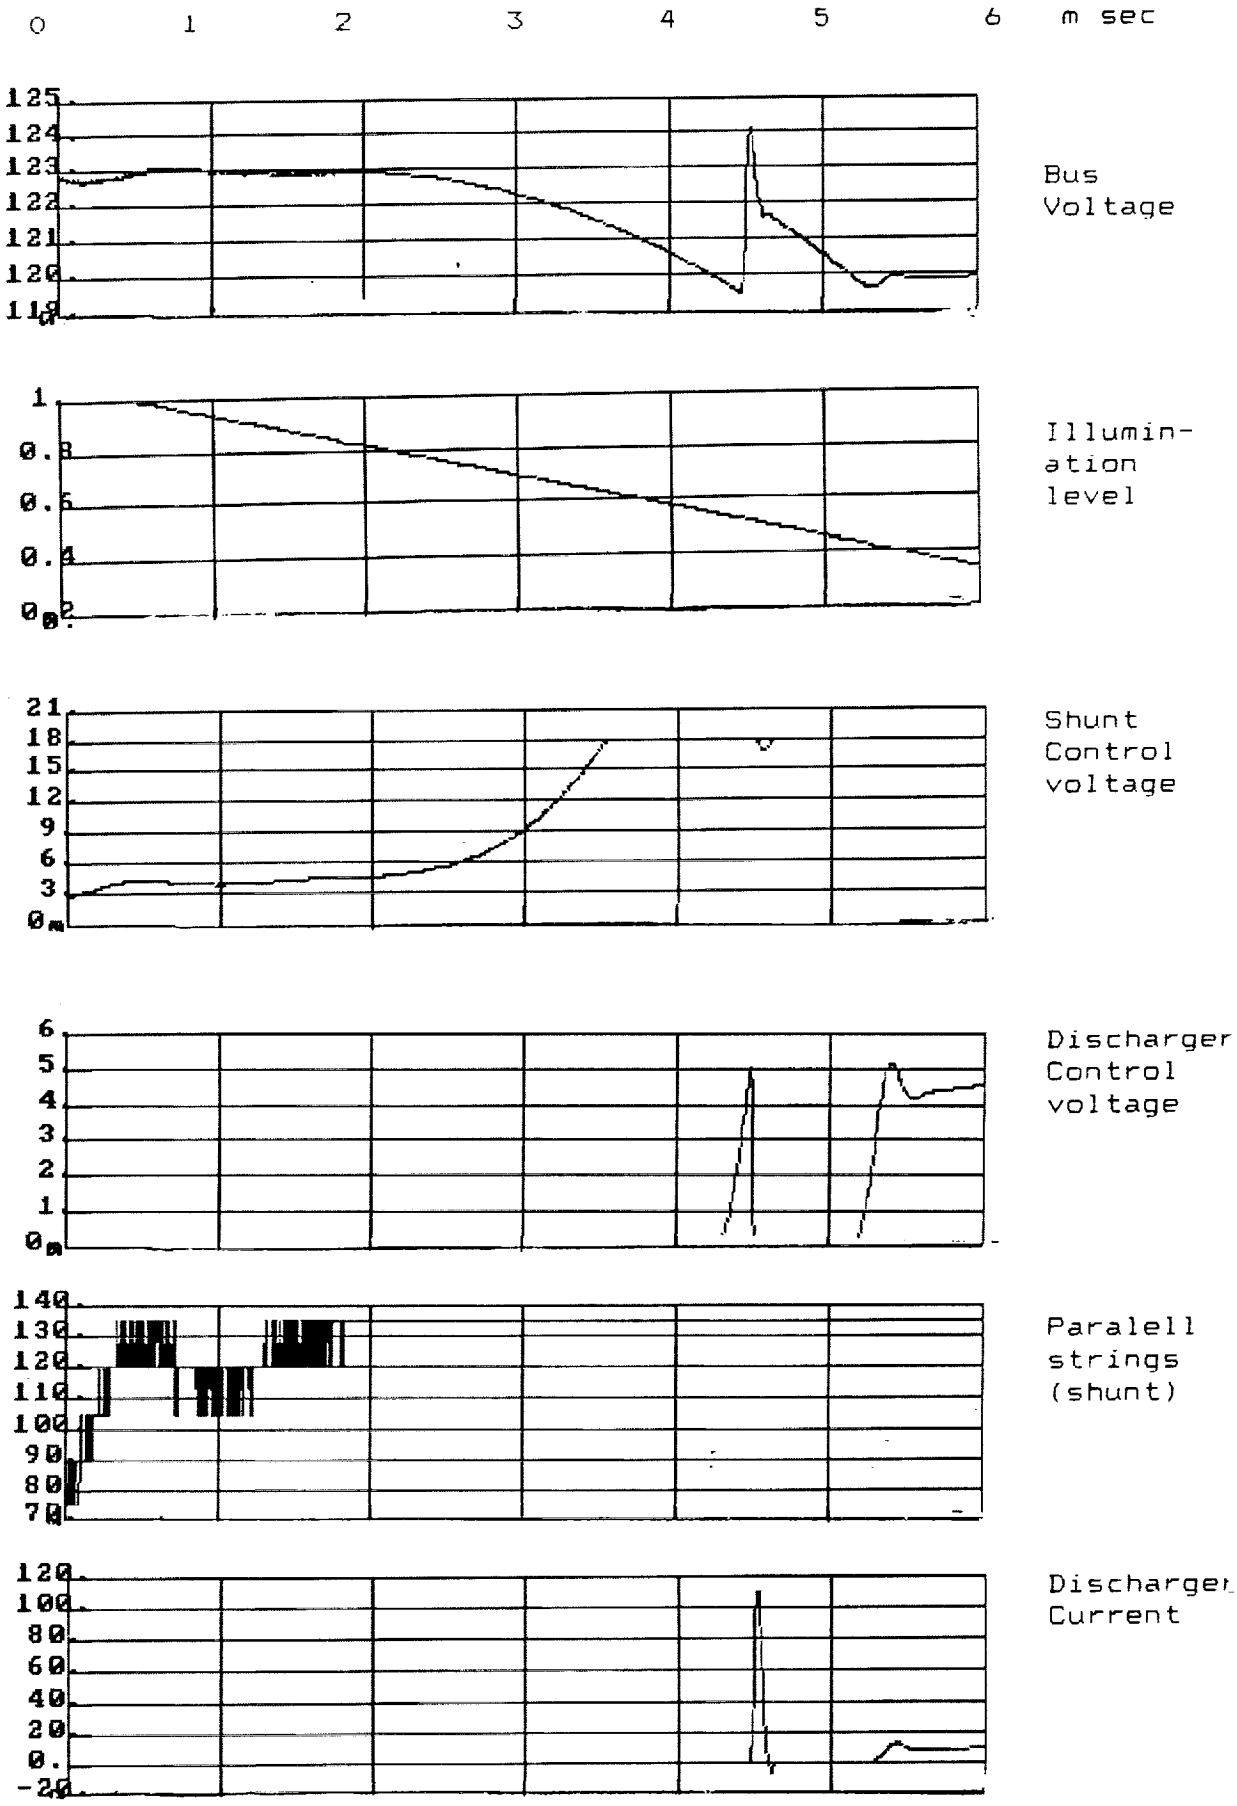


MODE TRANSITION SIMULATION



- Mode transitions are induced by changing the illumination level
- With sufficient illumination, the array regulates the bus
- At low illumination level, the discharger regulates the bus

SIMULATION FOR TRANSITION FROM SUNLIGHT TO ECLIPSE



2. SPACE PLATFORM

POWER SYSTEM TEST BED

NASA/GSFC Space Platform Testbed

Year 1 Tasks

1.	Design Multi-Module Boost Converter	DS
2.	Design VFPPAT Converter	DS
3.	Build Multi-Module Boost Converter	DS
4.	Build VFPPAT Converter	SD
5.	Design Battery Charger	TS
6.	Bild Battery Charger	TS
7.	Test Multi-Module Boost Converter (Open-Loop)	DS/JI
8.	Test VFPPAT Converter	SD
9.	Select Optimum Discharger & Design Control Loop	DS/SI
10.	Build Discharger Controller, Integrate & Tester	DS/SI
11.	Test Batter Charger	TS
12.	Design Charger Controller	TS
13.	Build Charger Controller & Integrate	TS
14.	Integrate Charger & Discharger (W/Mode Controller)	DS
15.	Test ORU System	DS
16.	Investigate Bi-directional Converter

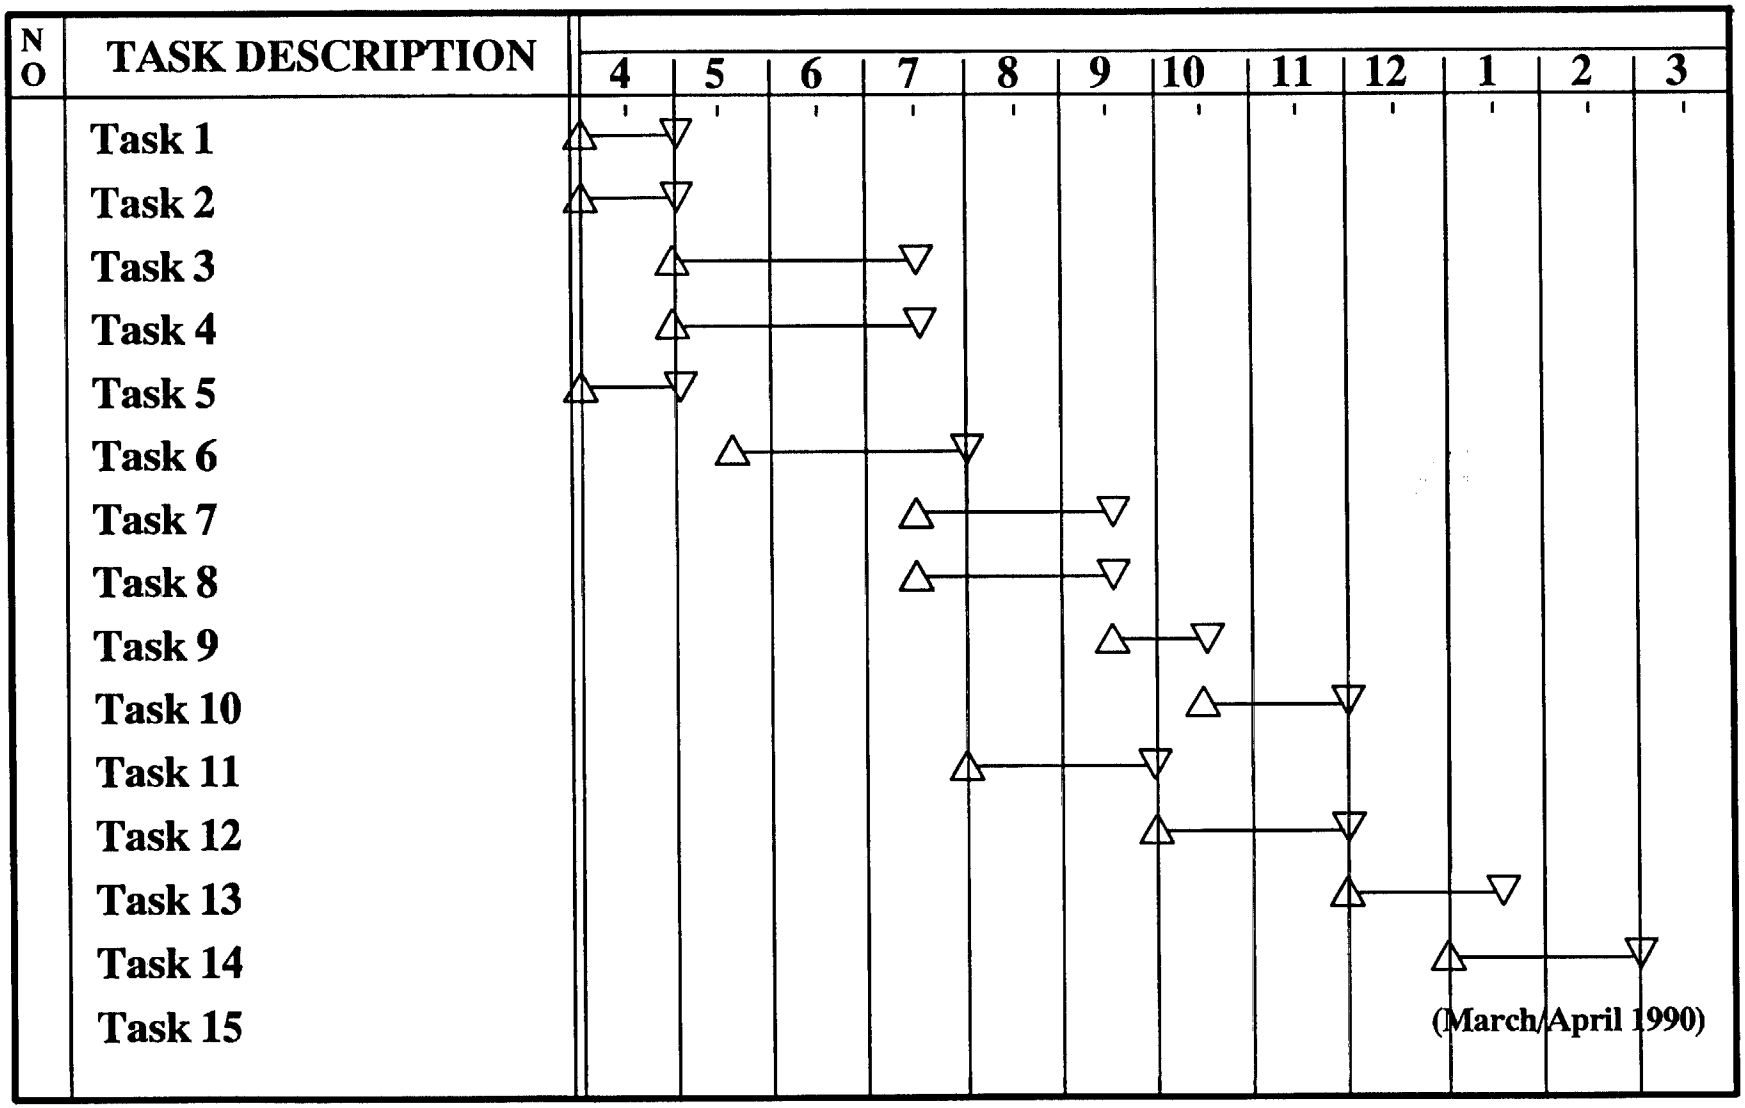
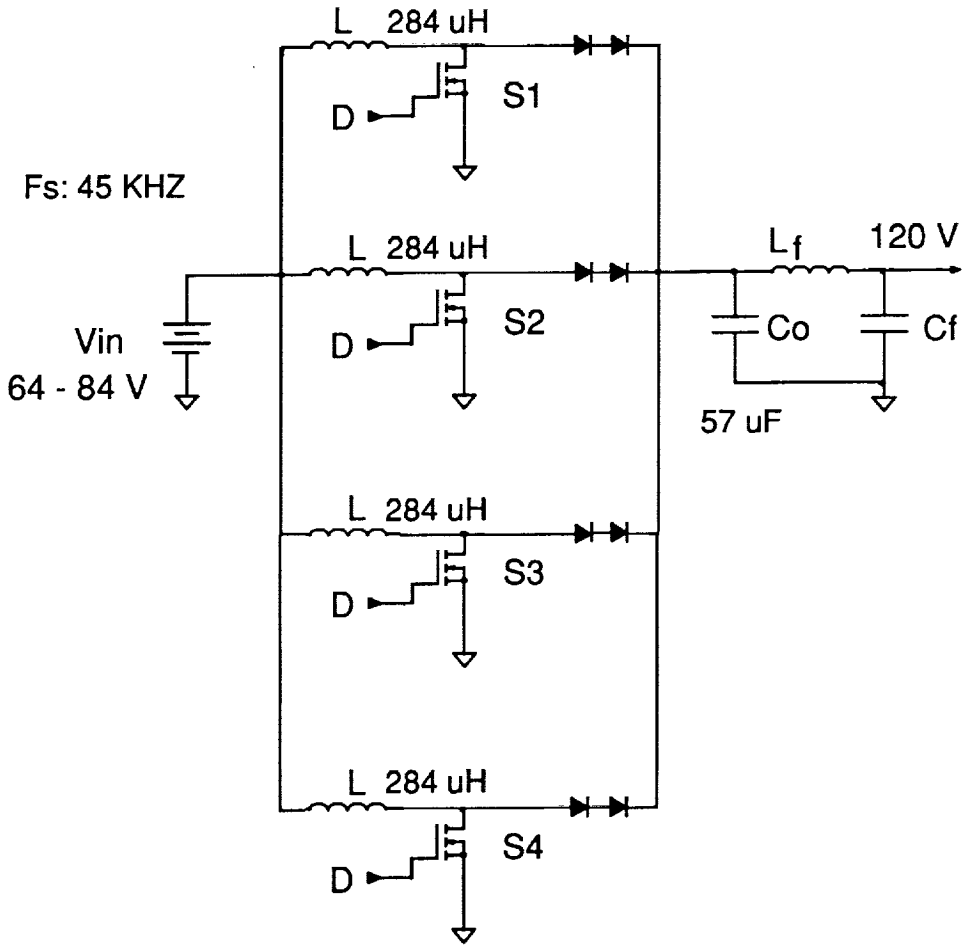
Space Platform Testbed Schedule



97% EFFICIENT FOUR MODULE BOOST DESIGN



INDUCTOR DESIGN

INDUCTOR TURNS: 31
INDUCTOR CORE WIDTH: 8.6E-3 M
INDUCTOR WINDOW WIDTH: 8.9E-3 M
INDUCTOR AIR GAP: 9 MILS
INDUCTOR WIRE SIZE: 1.54E-6 M^2

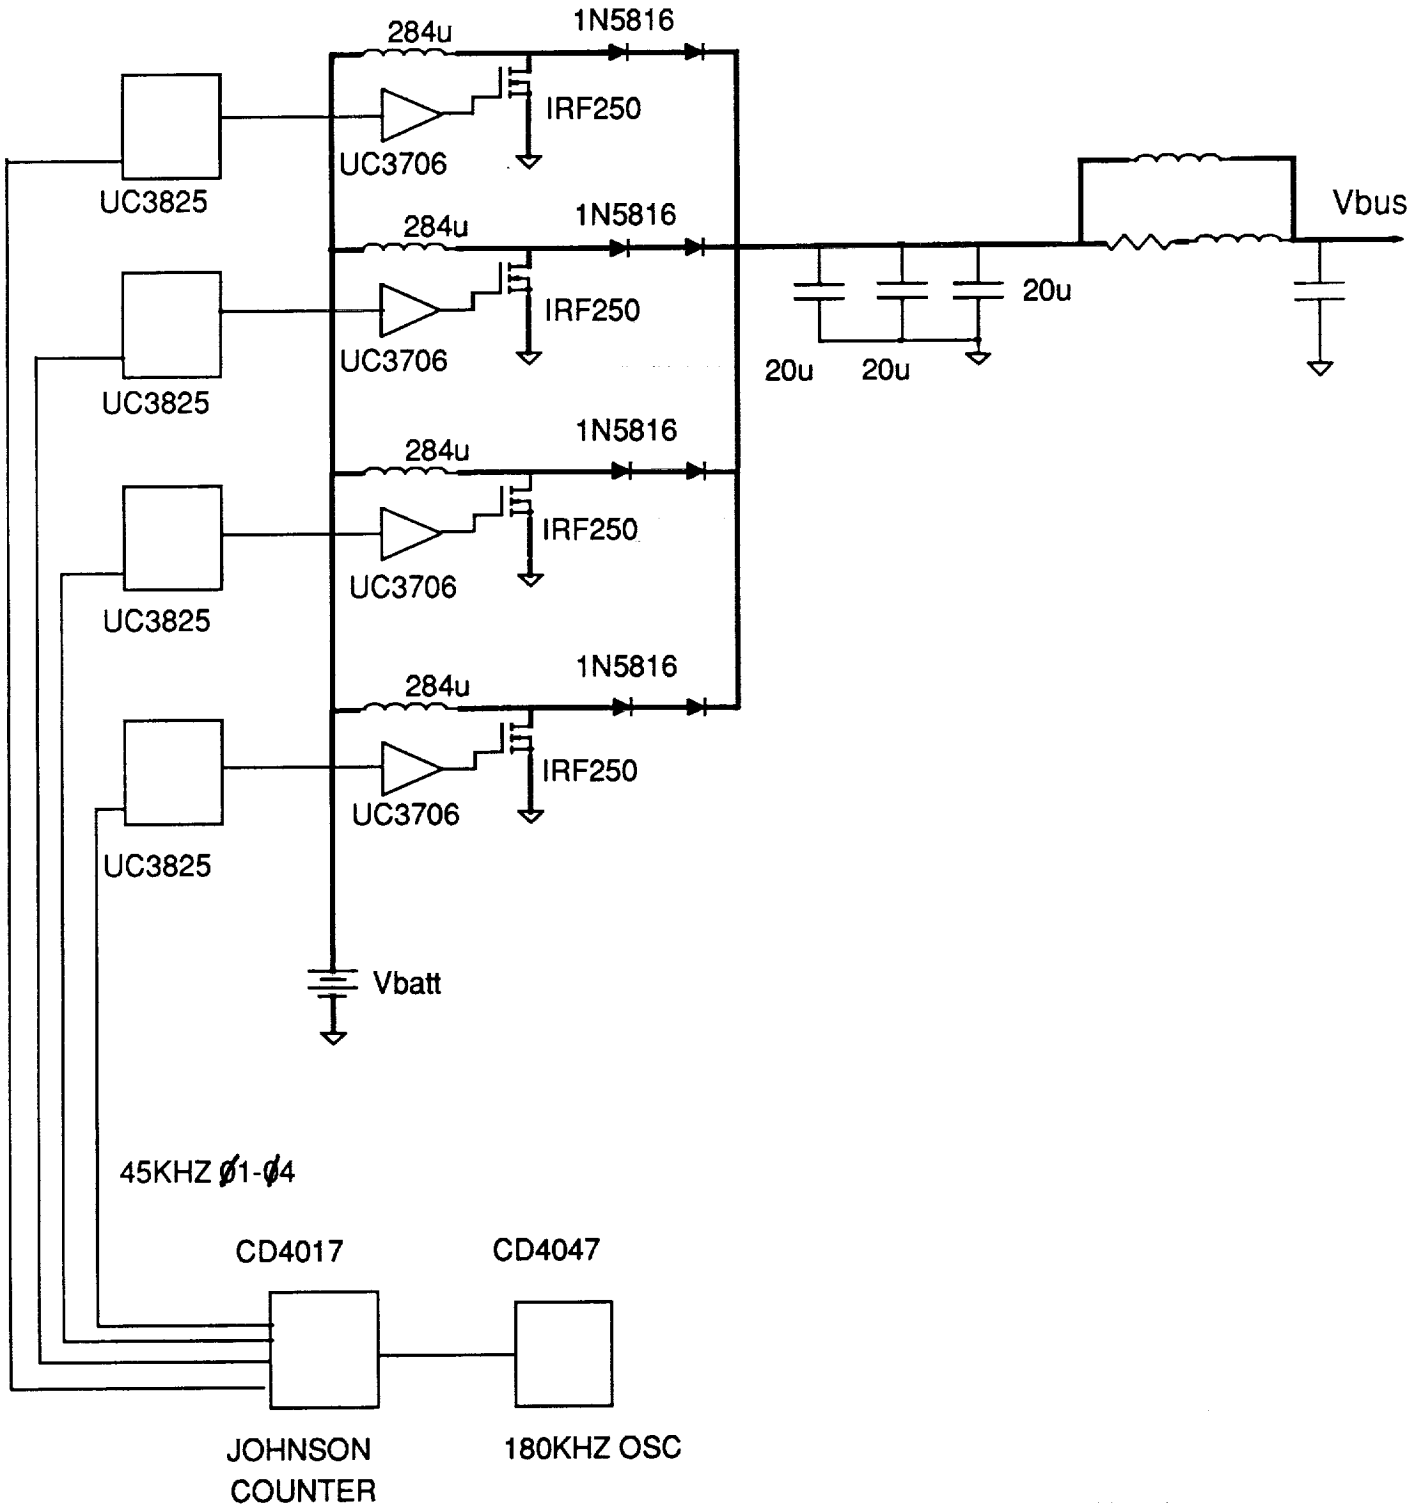
WEIGHT BREAKDOWN

INDUCTOR WEIGHT: 0.16 KG
CAPACITOR WEIGHT: 0.16 KG
TOTAL: 0.32 KG

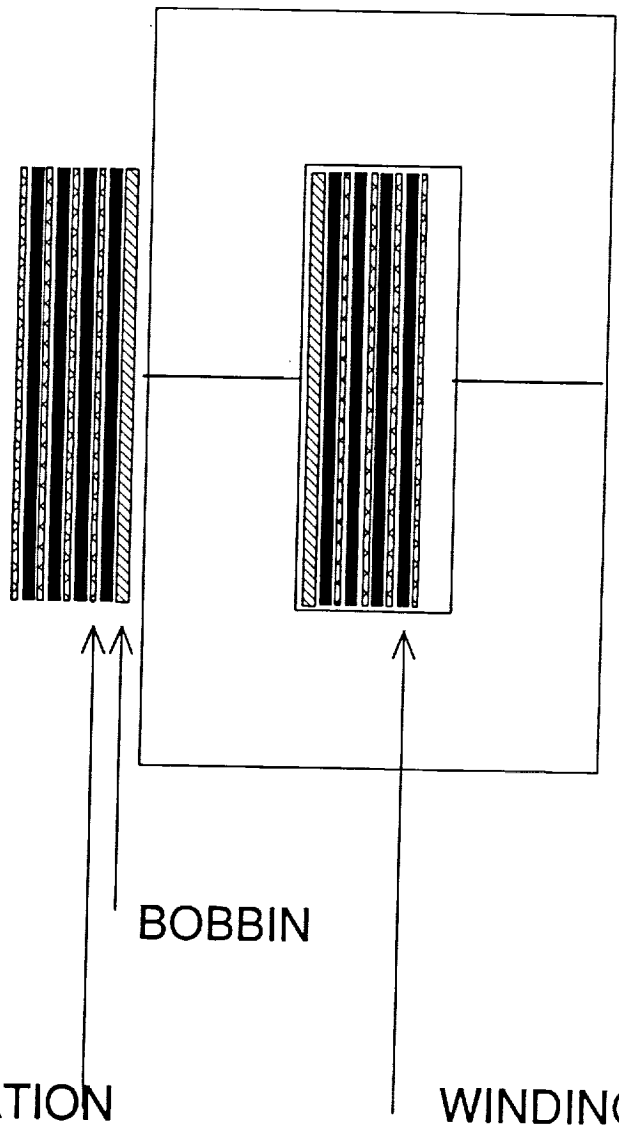
LOSS BREAKDOWN

FET CONDUCTION LOSS: 9.1 W
FET SWITCHING LOSSES: 11.8 W
DIODE CONDUCTION LOSS: 22.5 W
DIODE SWITCHING LOSSES: 3.7 W
INDUCTOR COPPER LOSS: 5.9 W
INDUCTOR CORE LOSS: 4.8 W

MULTI-MODULE BOOST HARDWARE DEVELOPMENT



FOUR MODULE BOOST INDUCTOR



CORE: MC1200-1B (METGLAS)

40 TURNS 4 MIL X 1 INCH COPPER FOIL

13 MIL AIRGAP

FOUR MODULE BOOST CONVERTER
BATTERY DISCHARGER STRESS ANALYSIS

COMPONENT PARAMETER	APPLIED VALUE	RATED VALUE	STRESS RATIO
MOSFET CONTINUOUS DRAIN CURRENT	9 AmpS	33 Amps	27%
PEAK TRANSISTOR DRAIN-TO-SOURCE VOLTAGE	120 Volts	200 Volts	62%
PEAK TRANSISTOR GATE VOLTAGE	10 Volts	±20 Volts	50%
PEAK DIODE CURRENT	9 AmpS	20 Amps	45%
PEAK DIODE REVERSE VOLTAGE	60 Volts	150 Volts	40%
OUTPUT CAPACITOR VOLTAGE	120 Volts	200 Volts	60%
OUTPUT CAPACITOR RMS CURRENT	1.1 Amps	22 Amps	5%

VOLTAGE-FED, PUSH-PULL, AUTOTRANSFORMER, (VFPPAT) BATTERY DISCHARGER

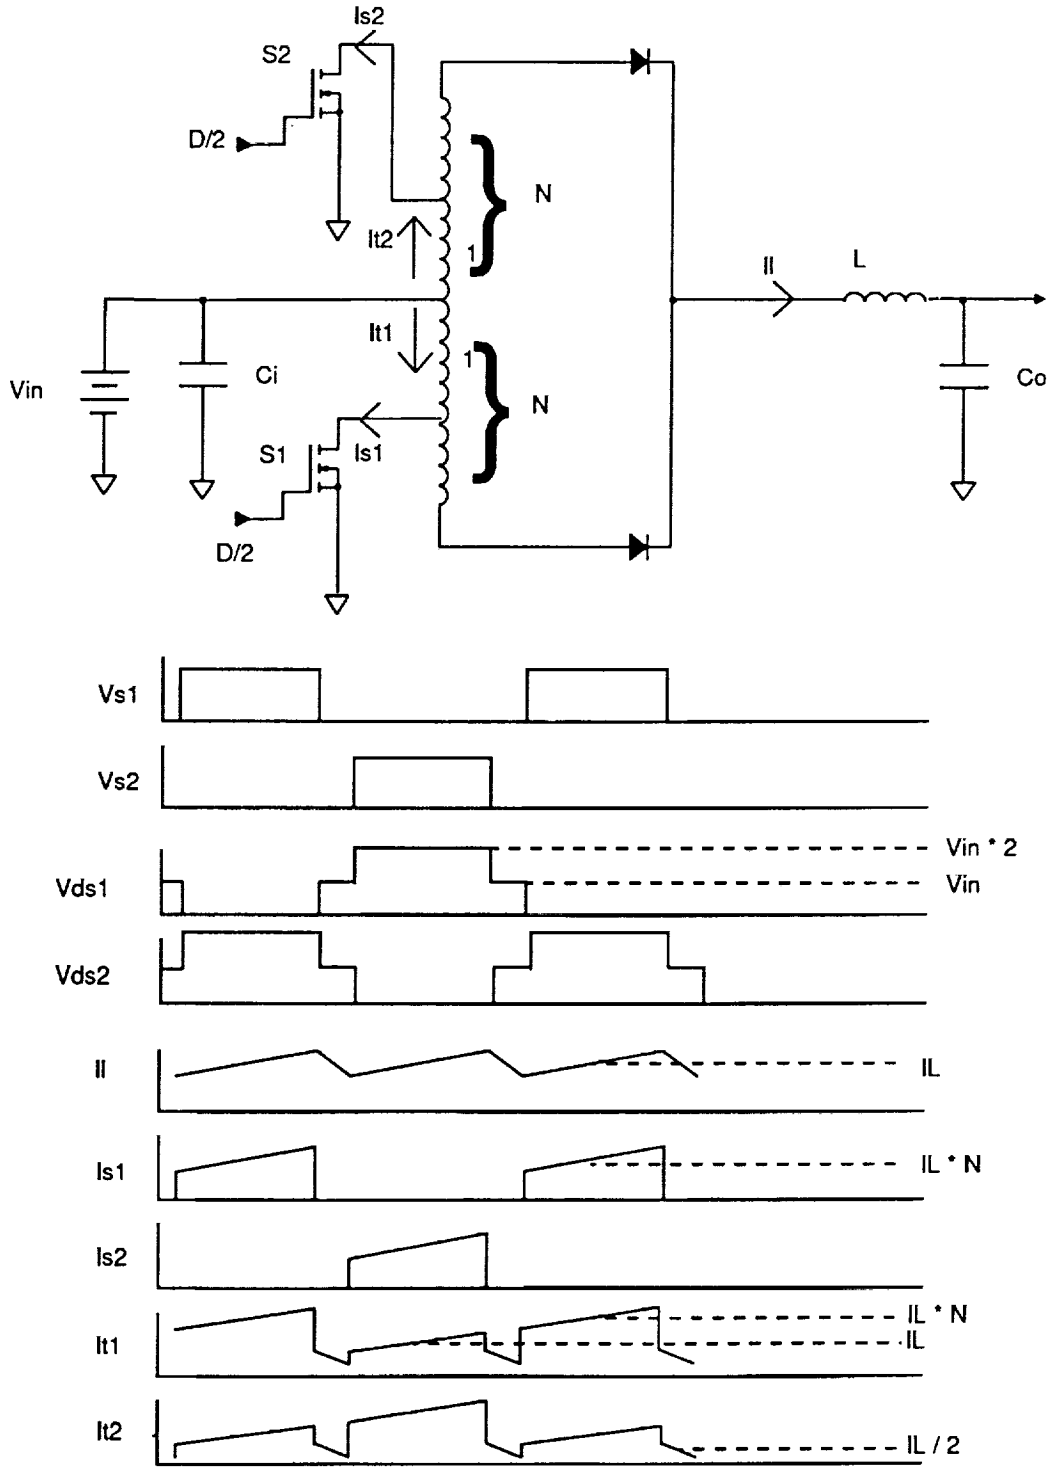
HARDWARE DESIGN TOPIC LIST

VFPPAT

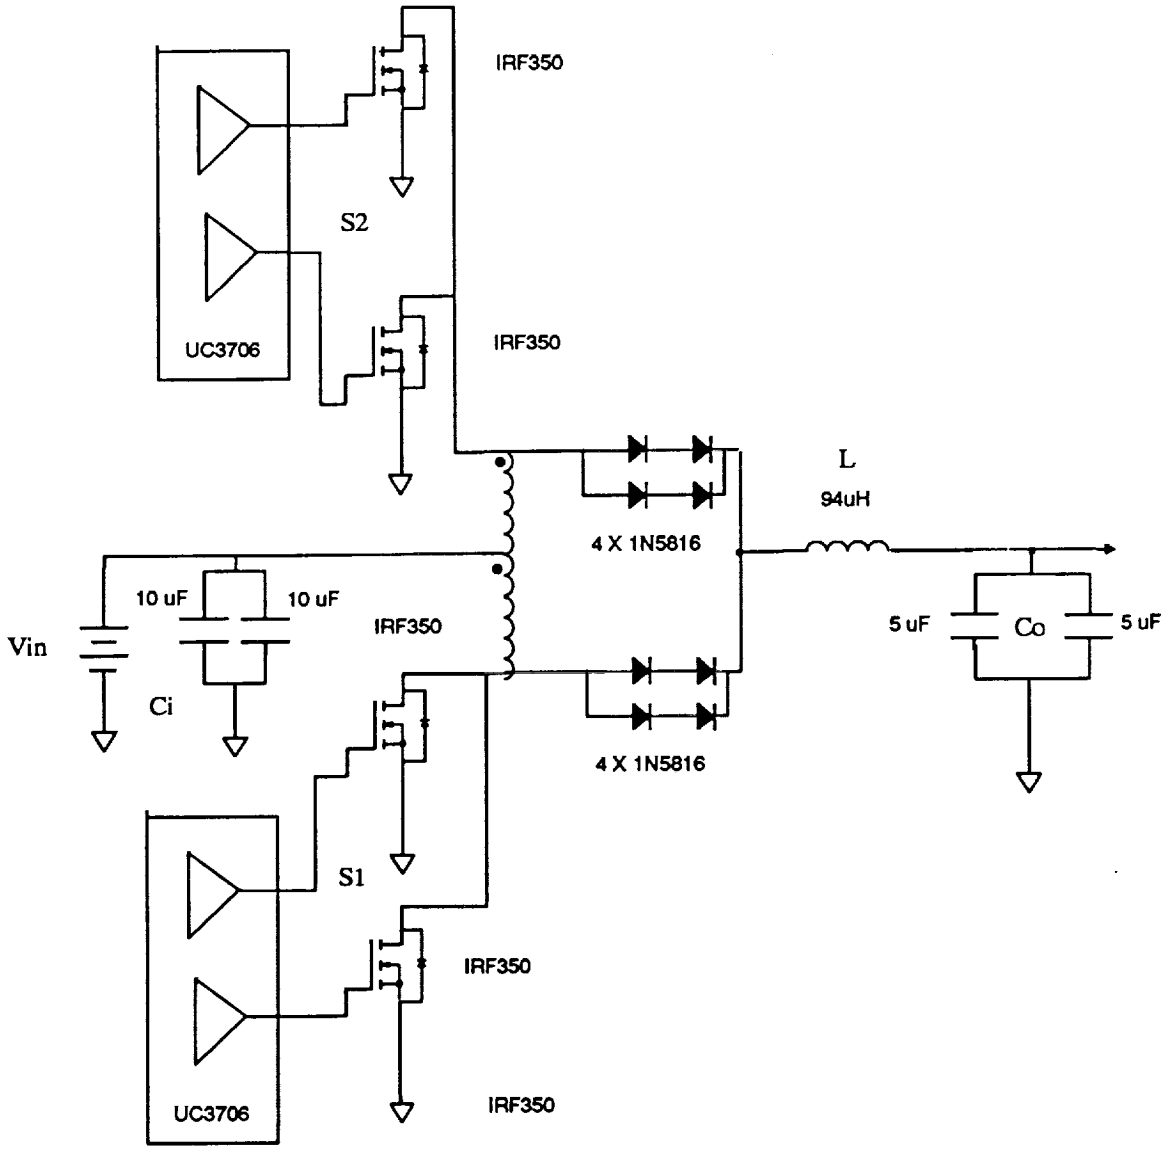
BATTERY DISCHARGER DESIGN SPECIFICATIONS

PARAMETER	SPECIFICATION
INPUT VOLTAGE RANGE	64 VDC to 84 VDC
OUTPUT VOLTAGE RANGE	120 VDC ± 4%
OUTPUT VOLTAGE RIPPLE	200 mV peak to peak
OUTPUT POWER RANGE	0 Watts to 1800 Watts
SWITCHING FREQUENCY	40 kHz
EFFICIENCY GOAL	96%
TRANSIENT PERFORMANCE	
OUTPUT VOLTAGE PEAKING RANGE	115.2 VDC - 124.8 VDC
OUTPUT SETTLING TIME	10 msec

VOLTAGE-FED, PUSH-PULL WITH TAPPED AUTOTRANSFORMER (VFPPAT) CONVERTER



VFPPAT SCHEMATIC WITH ACTUAL COMPONENTS



DISCHARGER POWER STAGE COMPONENTS

POWER SWITCH

- IRF350, INTERNATIONAL RECTIFIER
- TWO IN PARALLEL FOR HIGH EFFICIENCY
- Rdson = 250 mOHM

POWER DIODE

- 1N5816, UNITRODE
- Trr = 35 nS

INDUCTOR

- MC0007 METGLAS CUT C-CORE, MAGNETICS, INC.
- L = 94 uH

INPUT AND OUTPUT CAPACITORS

- POLYPROPYLENE, ELECTRONIC CONCEPTS, INC.
- LOW ESR
- LIGHTWEIGHT

DRIVER IC

- UC3706, DUAL OUTPUT DRIVER, UNITRODE
- PEAK OUTPUT CURRENT = 1.5 A

VFPPAT MAXIMUM COMPONENT STRESS EVALUATION

STRESS PARAMETER	** APPLIED VALUE	RATED VALUE	PERCENT USEAGE
PEAK TRANSISTOR DRAIN CURRENT*	8.3 Amps	60 Amps	14%
PEAK TRANSISTOR DRAIN-TO-SOURCE VOLTAGE	168 Volts	400 Volts	42%
PEAK TRANSISTOR GATE VOLTAGE	10 Volts	±20 Volts	50%
PEAK DIODE CURRENT*	8.15 Amps	20 Amps	41%
PEAK DIODE REVERSE VOLTAGE*	82 Volts	150 Volts	55%
OUTPUT CAPACITOR VOLTAGE	120 Volts	200 Volts	60%
OUTPUT RMS CURRENT*	0.4 Amps	22.5 Amps	2%
INPUT CAPACITOR VOLTAGE	84 Volts	200 Volts	42%
INPUT CAPACITOR RMS CURRENT*	3.25 Amps	15 Amps	25%

* 50% DIVISION OF PARAMETER ASSUMED

INPUT CAPACITOR VOLTAGE	120 Volts	200 Volts	60%
INPUT CAPACITOR RMS CURRENT	4.2 Amps	15 Amps	28%

CHARGER POWER INDUCTOR DESIGN

MATERIAL : METGLAS

- HIGH Bsat ALLOWS SMALL INDUCTOR SIZE
- LOW LOSS
  -1 MIL LAMINATION : HIGH RESISTIVITY & LOW EDDY CURRENT LOSS
- HIGH PERMEABILITY
- LOW Bsat DRIFT OVER TEMPERATURE

CONDUCTOR AND INSULATION

- COPPER FOIL : 5 MIL THICKNESS
  * HIGH WINDOW UTILIZATION
  * LOW SKIN EFFECT LOSS
  * LOW PROXIMITY LOSS
- INSULATION : 2 MIL KAPTON TAPE

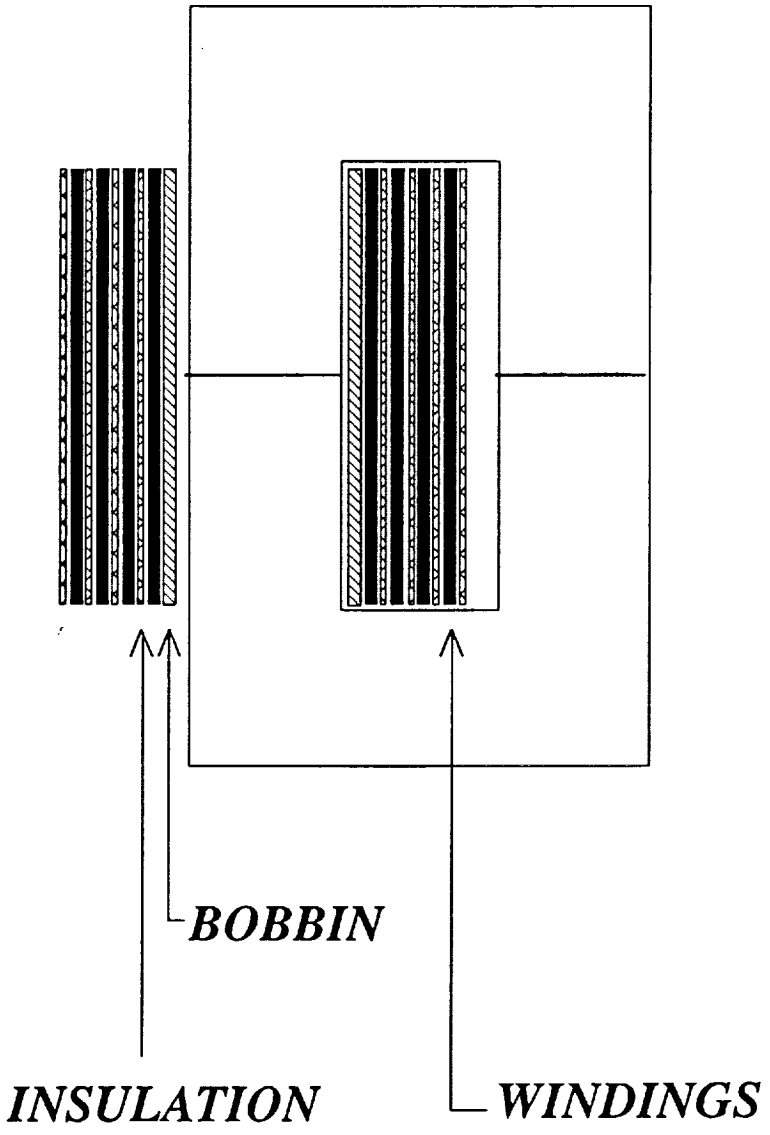
CORE

- MAGNETICS, INC. MC1603 CUT C-CORE
- 14 MIL GAP FOR L = 46 uH
- DISADVANTAGE : GAP LOSS AND PROXIMITY LOSSES

DESIGN

- SPREAD SHEET PROGRAM
- AREA PRODUCT APPROACH
- TRADE-OFFS : LOSSES AND WEIGHT
- CONSIDERATIONS : STANDARD FOIL AND TAPE DIMENSIONS

CHARGER POWER INDUCTOR DESIGN



CORE : MC1603-1B (METGLAS)

21 TURNS COPPER FOIL (5 MIL X 1 INCH)

14 MIL AIR GAP (PER LEG)

CHARGER PWM AND DRIVE CIRCUITS

ISOLATED GATE DRIVE

DRIVE TRANSFORMER

- CORE RESET
- FERRITE TOROID
- 1:1 TURNS RATIO FOR HIGH COUPLING

FOUR SEPARATE DRIVE CIRCUITS

- MOSFET TURN-ON CURRENT SHARING
- ELIMINATING PARASITIC OSCILLATIONS

UNITRODE UC3706 DRIVER CHIPS

- Ipeak = 1.5 AMPS
- SWITCHING SPEED

UNITRODE UC1825 PWM IC

CHARGER REGULATION CIRCUITS

CHARGE CURRENT REGULATION

- RESISTIVE CURRENT SENSING
  - * 25 mOHM IN SERIES WITH THE BATTERY
  - * ADVANTAGE : SIMPLICITY
  - * DISADVANTAGE : LOSSES
    - 10 A CHARGE = 2.5W LOSS
    - 20 A CHARGE = 10W LOSS
- ADJUSTABLE CHARGE CURRENT REFERENCE

BUS VOLTAGE REGULATION

- IMMEDIATELY AFTER ECLIPSE
- DURATION
- ERROR SIGNAL FROM MODE CONTROLLER (PCU)

CURRENT/VOLTAGE MODE SELECTION

- DIODE OR-ING CIRCUIT
- CHARGE CURRENT REFERENCE LEVEL
- MODE CONTROLLER THRESHOLDS
