Abstract

A space power amplifier composed of active linearly tapered slot antennas (LTSAs) has been demonstrated and shown to have a gain of 30 dB at 20 GHz. In each of the antenna elements, a GaAs monolithic microwave integrated circuit (MMIC) three-stage power amplifier is integrated with two LTSAs. The LTSA and the MMIC power amplifier have a gain of 11 dB and power added efficiency of 14 percent respectively. The design is suitable for constructing a large array using monolithic integration techniques.

Introduction

The power output as well as the dynamic range of microwave solid state devices decreases as the frequency of operation increases. Hence to obtain high power at fundamental frequencies of several tens of GHz, the output from all the devices have to be combined using either conventional power combiners or quasi-optical power combiners. In the case of conventional power combiners, the combining is done with Wilkinson, radial line, and hybrid coupled networks. In the case of quasi-optical combiners, oscillators constructed with IMPATT diodes, Gunn diodes, MESFETs, or HEMTs are integrated with microstrip patch antennas or linearly tapered slot antennas (LTSAs) to form an active antenna array which combines power radiatively in free space. The advantages of quasi-optical power combiners over conventional power combiners are that only a single stable lower power source is required (thus greatly simplifying the combiner construction) and that the amplifiers can be individually optimized. Figure 1 schematically illustrates a possible arrangement for space power amplification.

Active Antenna Module Characteristics

The experimental three-element array module is shown schematically in Figure 2. The array elements are constructed by integrating a GaAs MMIC multi-stage power amplifier between two nonplanar LTSAs.

Linearly Tapered Slot Antenna

The feed system of the nonplanar LTSA consists of a conventional microstrip with the ground plane tapered to form a balanced microstrip. The strip conductors of the balanced microstrip are gradually flared with respect to the antenna axis to form the nonplanar LTSA. The antenna is fabricated on a 0.02 inch thick RT-5880 Duroid substrate. The measured gain of the LTSA is about 11 dB at the center frequency of 20 GHz. The LTSA has a return loss $S_{11}$ of 10 dB (2:1 VSWR) over a bandwidth extending from 10 to 30 GHz.

Another way to obtain high power is to construct a spatial amplifier. One such scheme is the grid amplifier. Each unit cell of the grid amplifier consists of a pair of packaged GaAs MESFETs with the sources connected together to form a differential amplifier and with the gate and drain terminals extending radially to form a pair of orthogonal strip antennas. Radiation to and from a planar array of identical unit cells is quasi-optically coupled by a vertically or a horizontally polarized beam respectively.

This paper presents for the first time a spatial amplifier with GaAs monolithic microwave integrated circuit (MMIC) multi-stage power amplifiers. In this approach an array of active antenna modules constructed from nonplanar LTSAs and GaAs MMIC amplifiers receives signals at lower power, and after amplification re-radiates signals into free space. The two advantages of the spatial amplifier over the spatial oscillator are that only a single stable lower power source is required (thus greatly simplifying the combiner construction) and that the amplifiers can be individually optimized. Figure 1 schematically illustrates a possible arrangement for space power amplification.
Vg is -0.6 V. The measured gain ($S_{21}$) on a HP 8510B ANA with a 40 dB coaxial attenuator on the drain side of a typical amplifier is shown in Figure 4. The gain is greater than 10 dB over the frequency range of 18 to 21 GHz. The saturated output power measured on a Pacific Instruments scalar network analyzer at 20 GHz is about 1.8 W with a gain of 10 dB and power added efficiency of 14 percent.9

Experimental Results and Discussions

A simple measurement procedure has been developed to estimate the gain of the space amplifier. This procedure involves the LTSAs at the input terminals are space fed from a single horn antenna while those at the output terminals radiate into free space. The free space radiation is picked up by a second horn antenna which is placed at a far field distance from the array. The ratio of the measured received power with and without bias to the MMIC amplifiers provides an estimate of the gain of the space amplifier. In the set-up, the two horn antennas are orthogonally polarized but the LTSAs are oriented to have the same polarization as their respective horn antennas, thus good isolation between the transmitting and the receiving horn antennas is established. Also, for comparison purposes, a single LTSA was tested as a receive antenna. The H-plane pattern is shown in Figure 5 which exhibits a power gain of 6.7 dB with the MMIC amplifier turned ON.

Three-Element Array Module

In this experiment, the LTSAs at the amplifier input and output are oriented with the H and E vectors of the receiving horn, respectively as shown in Figure 6(a). This arrangement allows the horn to excite the three LTSAs with equal amplitude. The measured radiation pattern is shown in Figure 7(a) with the amplifiers turned ON and OFF, respectively. The gain increases by as much as 30 dB when the amplifiers are turned ON which is in good agreement with the measured gain of the amplifiers.

A second experiment, as shown in Figure 6(b), is carried out with the LTSAs at the input and output oriented with the H and E vectors of the receiving horn, respectively. The measured radiation pattern is shown in Figure 7(b). In this arrangement the gain increases by 25 dB when the amplifiers are turned ON. The gain is lower in this case because the LTSAs on either side of the center element are excited with a lower amplitude due to the amplitude taper of the electric field distribution of the transmitting horn. The experimental three element LTSA MMIC array module is shown in Figure 8.

Conclusions

A space power amplifier composed of active LTSA antennas has been demonstrated and shown to have a gain of 30 dB at 20 GHz. In each of the antenna elements, a MMIC three-stage power amplifier is integrated with two LTSAs. The GaAs MMIC power amplifier and the LTSA have a power added efficiency of 14 percent and a gain of 11 dB, respectively. The design is suitable for constructing a large array using monolithic integration techniques.
