SUTM 4 ARY

Rlunt-nose and elliptical-nose overhangs of 0.35 and 0.50 flap chord and a plain overhang on a flap having a chord of 0.20 airifoil chord have been tesied in two-dinersional flow on an HACA 0009 airfoil. The results of the tests are presented as aerodynamic. section'characteristics for sereral flap deflections with the gap: at the flap nose:sealed or unsealed. Tests were made also to determine the effectiveness of a tab of 0.20. flap chord on the plain sealed flap and: on a: sealed. flap having -an elliptical overhang of 0.35 flap-chord. The pressure difference acrose the flsp seal. was, also detemined for the piain sealed flap.

The resulte indicated, that the plain sealed filap had the largest ifift-curve slope, whereas the slopes for the 0.50-ilap-chord averhangs were the same a:s or slightly larger then for the $0.35-f l a p-c h o r d ~ o v e r h a n g s . ~$ A reduction-in slone caused. by unsealing trie flap gap increased with balance chord.

The change in Ifft coeffscient with flap derlection generally increased when the gap was sealed and when the balence nose shape was changed from elliptical to blunt.

Ssaing the flap gap generally made the variation of flap hinge-moment coefficient with angle of attack and with flap deflection more regative. Changing the nose shape from biunt to elliptical made the variation of the filap hinge-moment coefficient vith angle of attack more negative for the sealed gap. and more positive
for the unsealed gap. At small flap deflections, the variation of flap hinge-moment coefficient with flap deflection was more negative for the elliptical-nose than for the blunt-nose ilap; at large deflections, however, this variation was more negative for the bluntnose flap.

The change of flap hinge-moment coefficient with flap deflection for the unsealed blunt-nose overhang had a larger variation with balance chord than the change of flap hinge-moment coefficient with angle of attack; for the sealed blunt-nose overhang, these variations were about the same in the range of balance chord from 0.35 to 0.50 fiap chord. For the sealed and unsealed elliptical-nose overhangs, the change of flap hingemoment coefficient with argle of attack had a larger variation than the change of flap hinge-moment coefincient with flap deflection.

## -INTRODUCTTON

The NACA is conaucting an extensive investigation to determine the characteristics of verious types of flap arrangement suftable for use as control surfaces and to provide data for design purposes. The investigation, which was made in the Langley 4-by 6-foot vertical tunnel, has included tests-of modifications of flap profile, trailing-edge angle, gap size, flap nose shape, and balance chord; hovever, most.of these tests have been made in two-dimensional flow with a flap having a chord 30 percent of the airfoil chord ( 0.30 c ). The present tests have extended the investigation of balance chord and flap nose shape, which was reported in reference I for a. O. 40 c flap, to a 0.20 c flap. Data. on the pressure-across the flap nose seal and a method of applying these pressure data in the design of internal balances are presented. Tab data are presented for the plain flap and for a flap with aerodynamic balance.

## APPARATUS AND MODEL

The tests were made in the Langley 4- by 6-foot vertical tunnel described in reference 2 and modified as described in reference 3 .

The model, when mounted in the tunnel, completely spanned the test section except for $\frac{1}{32}$-inch clearance gaps between the model and the tumel walls. With this type of installation, two-dimensional flow is closely approximated and the section characteristics of the airfoil, flap, and tab may be determined. The model was attached to the balance frame by torque tubes that extended through the sides of the tunnel. The angle of attack was set from outside the tunnel by rotating the torque tubes with an electric drive. Flap deflections were set by an electrical position indicator, and tab deflections were set by a templet. The hinge moments of the flap were measured with a special torque-rod balance built into the model.

Tab finge moments were measured by an electrical strain gage installed in the model. For tests of the plain sealed flap, the pressure difference across the gap seal was measured on a manometer.

The model (fig. I), which had a chord of 2 feet and a span of 4 feet, was made of laminated mahogany (except for a steel tab), was عerodynamically smooth, and conformed to the NACA 0009 profile (table I). It was equipped with a 0.20 c flap and a $0.20 \mathrm{c}_{\mathrm{f}}$ plain tab. The flap had a plain nose with a radius that. was approximately one-half the airfoil thickness at the flap hinge axis or was fitted with $0.35 c_{f}$ or $0.50 c_{f}$ blunt-nose or elliptical-nose aerodynamic balances. The elliptical nose, the ordinates of which are given in table II, was a true ellipse tangent to the airfoil contour at the flap hinge axis. The radii shown in figure 1 determined the blunt and plain noses;

The various nose blocks were interchangeable and were fastened to the flap at the hinge axis. In order to keep the rap at the flap nose at 0.005 c , blocks corresponding to each balance chorc were attached to the airfoil just ahead of the balance. For the sealedgap tests, airtight fabric was fastened between the flap nose and the airfoil.

The $0.20 c_{f}$ tab. had a nose radius approximately one-half the airfoil thickness at the tab hinge axis. The tab gap was 0.001c for all the tests.

## TESTS

A dynamic pressure of 15 pounds per square foot, which corresponds to a velocity of about 76 miles per houp at standard sea-level conditions, was used throughout the tests. The test Reynolds number was $1,430,000$ and the effective Reynolds number was approximately 2,760,000: (Effective Reynolds number $=$ Test Reynolds number $x$. Turbulence factor. The turbulence factor for the Langley 4- by 6-foot vertical tunrel is 1.93.) The Mach number for the tests was about 0.10.

The maximum error in angle of attack appears to be $\pm 0.2^{\circ}$. It. is estimated that the flap and tab deflections were set within $\pm 0.2^{\circ}$.

An experimentally determined tunnel correction was applied to the lift coefficient. In accordance with a. theoretically derived analysis similar to that presented in reference 4 for finite-span models, the angle of attack and the hinge-moment coefficient were corrected for the effect of streamline curvature induced by the tunnel walls. . The increments of drag coefficient are believed to be reasonably independent of tunnel effect, although the absolute value is subject to an unknown correction. Inaccuracies in model construction and assembly of interchangeable blocks probably caused the small flap hinge moment at $\alpha_{0}=0^{\circ}$ and $\delta_{f}=0^{\circ}$.

A summary of information for convenience in locating the data for the various model configurations is presented in table III.

RESUITS AND DISGUSSION
Lift

The lift-coefficient curves for the plain flap and for the flaps with various overhangs are given in figures 2
to 11 for the flap gaps both sealed and unsealed. These curves were nonlinear at large flap deflections. The flaps with elliptical-nose overhangs generally developed lift to larger flap deflections than those with bluntnose overhangs.

Parameter values obtained from figures 2 to 11 are summarized in table IV. The variations with balance chord of the lift parameters ${ }^{c} \eta_{\alpha}, c_{\eta_{\delta_{f}}}$, and $a_{\delta_{f}}$ are given in figure 12.

With the gaps sealed and unsealed, the plain flap had the largest values of the slope of the lift curve cha, whereas the values of ${ }^{c} l_{\alpha}$ for the $0.50 c_{f}$ overhangs were the same as or langer than for the $0.35 c_{f}$ ovierhangs. This variation was similar for the $0.40 c$ flap (reference l). A reduction in $c_{2}$ caused by unsealing the gap increased with balance chord

The value of ${ }^{c} l_{\delta_{f}}$. was usually larger for the blunt than for the eillptical nose. Except for the flap with the $0.50 c_{f}$ blunt-nose overhang, sealing the gap increased ${ }^{c} Z_{\delta_{f}}$.

The filap lift effectiveness parameter $\alpha_{\delta_{f}}$ decreased as the balance chord increased, except for the flap with the unsealed blunt-nose overhang, and was'usually larger for the blunt-nose than for the elliptical-nose overheng. Sealing the gap increased $a_{\delta_{f}}$ for the elliptical-nose overhang and the plain flap but generally decreased it for the blunt-nose overhang. The values of $\alpha_{\delta_{f}}$ given in table IV and figure 12 were measured over a small flap deflection range at $c_{l}=0$ and therefore are mainly useful as a comparison of the various configurations tested.

## Finge Moment

The curves of flap hinge-moment coefficient as a function of angle of attack at constant flap deflections are presented in figures 2 to 11 for the plain flap and for the flaps with various overhangs. No appreciable flap oscillations were noticed throughout the flap.deflection range tested, although such oscillations occurred on the 0.40 c flap (reference 2 ).

The hinge-moment parameters $\quad c_{h_{f_{\alpha}}}$ and. $c_{h_{f \delta f}}$ presented in table IV and plotted against balance chord in figure 13 indicate that the $0.50 c_{f}$ blunt-nose overhang was overbalanced $\left({ }^{c_{h_{f}}}{ }_{\delta_{f}}\right.$ was positive $)$ and had a positive ${ }^{c} h_{f_{\alpha}}$ for the gap sealed and urisealed. (Values of $c_{h_{f_{\alpha}}}$ were determined at $\alpha_{0}=0^{\circ}$ and at $\delta_{f}=0^{\circ}$ and values of ${ }^{c} h_{f_{\delta_{f}}}$ were determined at $\alpha_{0}=0^{\circ}$ and small flap deflections.) The 0.20c flap was found to be overbalanced for conditions similar to those for which the 0.40 c flap tested on the same airfoil (reference 1) had been overbalanced. For the flap with the $0.50 c_{f}$ overhang, ${ }^{c} h_{f_{f}}$ could be made negative by the use of a tab deflected in the same direction as the flap:

The $0.50 c_{f}$ elliptical-nose overhang, with sealed and unsealed gap, had a positive $\mathrm{c}_{\mathrm{h}_{\mathrm{a}}}$. at $\delta_{\mathrm{f}}=0^{\circ}$; at larger flap deflections, however, an increase in angle of attack or flap deflection generally gave a negative increment of hinge-moment coefficient (figs. 10 and 1l). For the $0.50 c_{f}$ blunt-nose overhang, flap deflections up to approximately $15^{\circ}$ gave positive increments of hinge-moment coefficient; changing the flap to larger deflections gave negative increments.

Figure 13 indicates that, for the unsealed bluntnose overhäng, ${ }^{c} h_{f_{\delta f}}$ had a larger variation with balance chord than $c_{\mathcal{h}_{f_{a}}}$; for the sealed blunt-nose. overhang, the variations of ${ }^{c_{h_{f}}}$ and ${ }^{c_{h_{f}}}{ }_{\delta_{f}}$ were about the same in the range of balance chord from $0.35 c_{f}$ to $0.50 c_{f}$. For the sealed and unsealed elliptical-nose overhangs; $\quad{ }_{c_{r_{f}}}$ had a larger variation than ${ }^{c} h_{\mathcal{E}_{\delta_{f}}}$.

Changing the nose shape from blunt to elliptical made ${ }^{c} h_{f_{\alpha}}$ more negative for the sealed gap and more positive for the unsealed gap: Changing the nose shape from blunt to elliptical also made $c_{n_{f_{\delta_{f}}}}$ more negative at small flap deflections and less negative at large flap deflections.

Sealing the gap at the flap nose generally made $c_{h_{f \delta_{f}}}$ and
${ }^{c} h_{f_{\alpha}}$. more negative.
Since the aspect-ratio corrections for streamline curvature are always positive (reference 5) and since the hinge-moment parameters are very small and the signs are critical for several of the flaps with overhangs, the slopes may change from negative to positive and produce. an overbalanced flap on a finite-span wing.

Because the hinge-moment parameters shown in table IV represent the slopes of the curves at $\delta_{f .1}=0^{\circ}$ and $a_{0}=0^{\circ}$, these parameters should be used mainly a 'an indication of the relative merits of the different flap nose shapes. Because the tabulated slopes are valid for only a small range, the curves of hinge-moment coefficient should be used, rather than the tabulated parameters, in the calculation of the characteristics of a. control surface.

Pitching Moment
Values of the pitching-moment parameters $\left(c_{m_{c l}}\right)_{\delta_{f}, \delta_{t}}$ and $\left(c_{m_{C l}}\right)_{a, \delta_{t}}$ are shown in table IV and indicate the position of the aerodynamic center with respect to the $0.25 c$ point. When the lift was varied by changing the angle of attack at $\delta_{f}=0^{\circ}$, the aerodynamic center for the plain sealed flap was located at the $0.25 c$ point; the aerodynamic center for the balanced flap with sealed gap, regardless of balance chord or nose shape, was near the 0.24 c point. The effect of unsealing the gap was to move the aerodynamic center 0.01c forvard.

The center-of-lift positionsdue to flap deflections up to approximately $15^{\circ}$ are given in the following table:

NACA ARR No. L5FO6

| Gap | Center-of-lift position caused by flap deflection (percent c) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\begin{aligned} & \text { Plain } \\ & \text { overhang } \end{aligned}$ | $0.35 c_{f}$ overhang |  | $0.50 c_{f}$ overhang |  |
|  |  | Blunt nose | Elliptical nose | $\begin{gathered} \text { Blunt } \\ \text { nose } \theta \end{gathered}$ | $\begin{gathered} \text { Elliptical } \\ \text { nose } \end{gathered}$ |
| $\begin{aligned} & \text { Sealed } \\ & 0: 005 c \end{aligned}$ | 46 46 | .45 .44 | 44 47 | 44 43 | $\begin{aligned} & 46 \\ & 50 \end{aligned}$ |

This table indicates that the center-of-lift position was the same for the plain flap whether the gap was sealed or unsealed. The effect of unsealing the gap or of increasing the balance chord was to move the center-of-lift position due to flap deflection forward on the blunt-nose and rearward on the elliptical-nose flap. The center-of-lift position caused by flap deflection is. a function of the aspect ratio (references 5 and 6) and moves rearward as the aspect ratio decreases.

## Drag

Because of an undetermined tunnel correction, the measured values of drag cannot be considered absolute, but relative values of drag are thought to be independent of tunnel effect.

The increments of section profile-drag coefficient caused by flap deflection are presented in figure 14 for the plain flap and in figure 15 for the $0.55 c_{f}$ and $0.50 c_{f}$ blunt-nose overhangs.

Tab Characteristics
Because the characteristics for a tab on a flap with aerodynamic balance, in general, are similar to those for a tab on a plain flap (references 3 and 7) and are usually independent of flap nose shape (reference 7), only a limited investigation of tab characteristics has been made.

The aerodynamic section characteristics as a function of angle of attack, for a tab ratio $\frac{d \delta_{t}}{\partial \delta_{f}}= \pm 1$, are presented in figures 16 and 17 for the plain sealed flap and for the $0.35 c_{f}$ sealed elliptical-nose overhang, respectively. The values of $\mathrm{c}_{\mathrm{hf}_{\delta_{t}}}$ for the $0.35 \mathrm{c}_{\mathrm{f}}$ elliptical-nose overhang (figs. 7 and 17) were, in general, the same as or slightly less than the values for the plain flap (figs. 3 and 16). With the tab deflected and With $\delta_{f}=0^{\circ}$ (fig. l8), $\quad{ }^{c} l_{\delta_{t}}$ was 0.017 and ${ }^{c} h_{f_{\delta_{t}}}$ was -0.012 for the plain soalod flap. The tab, in general, was slightly more effective in producing lift on the plain flap than on the flap with the $0.35 c_{f}$ overhang. The effectiveness of the tab in changing the flap hinge moment decreased with tab deflection. A comparison of figures 3 and 16 with figure 18 showed that the tab effectiveness generally was the same whether the flap was at $0^{\circ}$ or deflected.

Pressure Difference across Plain-Flap Seal
The variation of resultant pressure coefficient across the plain-flap nose seal with angle of attack at constant flap deflections is shown in figure 19. The change in resultant pressure coefficient with angle of attack $\left(\frac{\partial P_{R}}{\partial a_{0}}\right)_{\delta_{f}, \delta_{t}}$ was found to increase with flap
deflection. deflection.

The data of figure 19 can be used with those of figure 3 to determine the flap section hinge-moment coefficient at a given angle of attack and flap deflection for a $0.20 c$ flap with an internal balance on an NACA 0009 airfoil. It can be shown that

$$
\begin{equation*}
\left(c_{h_{f}}\right)_{I B}=c_{h_{f}}+P_{R} K \tag{1}
\end{equation*}
$$

whère

The hinge-moment parameters $\quad{ }^{c_{h_{f}}}$ and ${ }^{c}{ }_{h_{f_{\delta_{f}}}}$ determined from flap hinge-moment coefficients obtained by equation (l) are plotted in figure 13 for internal balances of various chords.

CONGLUSIONS

Blunt-nose and elliptical-nose overhangs of 35 and 50 percent flap chord $\left(0.3 E c_{f}\right.$ and $\left.0.50 c_{f}\right)$ and a plain overhang on a flap having a chord 20 percent of the airfoil chord ( 0.20 C ) have been tested in two-dimensioral flow on an NACA 0009 airfoil. A limited investigation was also made of the cheracteristics of a $0.20 c_{f}$ plain tab. The results of the tests indicated the following conclusions:

1. The slope of the lift curve was largest for the plain sealed flap, whereas the slopes for the $0.50 c_{f}$ overhangs were the same as or slightly larger than for the $0.35 c_{f}$ overhangs. A reduction in slope caused by unsealing the gap increased wi.th balance chord.
2. The variation of lift coefficient with flap deflection generally increased when the gap was sealed and when the nose was changed from elliptical to blunt.
3. The flap lift effectiveness parameter $\alpha_{\delta_{f}}$ generally decreased when the overhang chord was increased and was usually`larger for the blunt-nose than for the elliptical-nose overhang. Sealing the gap increased $a_{\delta_{f}}$
for the plain flap and for the elliptical-nose overhang but generally decreased it for the blunt-nose overhang.
4. Sealing the gap at the flap nose made the variation of flap hinge-moment coefficient with angle of attack more negative; changing the nose shape from blunt to elliptical made this variation more negative for the sealed gap and more positive for the unsealed gap.
5. The variation of flap hinge-moment coefficient with flap deflection was generally more negative with a sealed gap than with an unsealed gap. Changing the nose shape from blunt to elliptical made this variation more negative at small flap deflections and less negative at large flap deflections.
6. The change of flap hinge-moment coefficient with flap deflection, for the unsealed blunt-nose overheng, had a larger variation with balance chord than the change of flap hinge-moment coefficient with angle of attack; for the sealed blunt-nose overhang, these variationa were about the same in the range of balance chord from $0.35 \mathrm{c}_{\mathrm{f}}$ to $0.50 c_{f}$. For the sealed and unsealed elliptical-nose overhangs, the change of flap hinge-moment coefficient with angle of attack had a larger variation then the change of flap hinge-moment coefficient with flap deflection.
7. For all conditions, unsealing the gap moved the aerodynamic center forward avout 1 percert airfoil chord. Unsealing the gap or increasing the balance chord moved tre center-of-lift. position due to flap deflection forvard for the blunt-nose and rearward for the elliptical-nose flap.
8. The tab was slightly more effective in changing the lift and the flap hinge moment on the plain flap than on the flap with $0.35 c_{\mathrm{f}}$ elliptical-nose overhang.
