## PEM REGENERATIVE FUEL CELLS

## Larry L. Swette, Anthony B. LaConti, Stephen A. McCatty Giner, Inc. 14 Spring Street Waltham, MA 02154-4497

#### ABSTRACT

This paper will update the progress in developing electrocatalyst systems and electrode structures primarily for the positive electrode of single-unit solid polymer proton exchange membrane (PEM) regenerative fuel cells. The work was done with DuPont Nafion 117 in complete fuel cells (40 cm<sup>2</sup> electrodes). The cells were operated alternately in fuel cell mode and electrolysis mode at 80°C. In fuel cell mode, humidified hydrogen and oxygen were supplied at 207 kPa (30 psi); in electrolysis mode, water was pumped over the positive electrode and the gases were evolved at ambient pressure. Cycling data will be presented for Pt-Ir catalysts and limited bifunctional data will be presented for Pt, Ir, Ru, Rh and Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> catalysts as well as for electrode structure variations.

#### INTRODUCTION

In prior work [1, 2, 3], a large number of candidate bifunctional positive electrode catalysts were evaluated for chemical and electrochemical stability and for catalytic activity in 30% KOH at 80°C. As a result of this work, two potentially bifunctional catalyst systems were identified: 1)  $Na_xPt_3O_4$  [4] and 2) metal/metal oxide combinations of Rh, Pt and Ir [3]. More recently the scope of the program was expanded to include development of bifunctional positive electrode catalysts for the regenerative PEM fuel cell, focusing on many of the same catalysts.

In order to alternate between oxygen reduction and oxygen evolution on the same electrode, in addition to bifunctional catalysis, it is necessary to have an electrode structure that can perform in both of these modes. Some of the effort on this program was directed to the development of such structures. The approach taken was to develop catalyst/binder compositions optimized separately at the particulate level for either oxygen reduction (more hydrophobic) or oxygen evolution (more hydrophilic) and then combine these at an optimal ratio in a single electrode, referred to as an "integrated dual-character" (IDC) electrode. In this approach the catalyst for each function can be the same material if it shows bifunctional activity (e.g.,  $Na_xPt_3O_4$ ), or two different monofunctional catalysts (e.g., Pt for  $O_2$  reduction and  $IrO_2$  for  $O_2$  evolution). This approach, developed for the alkaline system, was extended to the PEMRFC by introducing a two-layer structure to achieve an appropriate interface to the more confined two-dimensional character of the proton exchange membrane.

## **EXPERIMENTAL**

#### **Catalyst Materials**

Pt black, used in both the positive and negative electrode structures, was fuel cell grade material obtained from Engelhard Industries. Metal oxide catalysts were prepared by proprietary modifications of Adams-type fusions of the metal salts in a nitrate flux [5]; metal/metal oxide catalysts (Pt-MO<sub>x</sub>) were prepared by co-fusion of the metal salts in a similar manner followed by electrochemical reduction of the PtO<sub>2</sub> to Pt, or were blends of separately prepared materials (Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub>).

 $Na_xPt_3O_4$  was typically prepared by firing mixtures of  $Na_2CO_3$  and  $PtO_2$  under oxygen at 650°C or higher for several hours. In most cases it was necessary to use a proprietary activation procedure to develop significant catalytic activity and acceptable conductivity. The surface areas of all materials were determined by the BET nitrogen adsorption method using a Micromeritics Flowsorb II 2300 instrument. The electrical conductivities of materials were estimated by a 2-point method measuring the resistance of the powders under moderate compression [2]. The compositions of the metal oxides prepared by nitrate fusion were determined in earlier work by X-ray diffraction analysis. Iridium chloride fusions yield IrO<sub>2</sub>, which becomes slightly oxygen deficient IrO<sub>2-x</sub> (x = ~0.05) if electrochemically reduced. Rhodium chloride fusions yield RhO<sub>2</sub>. The ruthenium salt fusions yield RuO<sub>2</sub>, which also becomes oxygen deficient RuO<sub>2-x</sub> (x = ~0.1) if electrochemically reduced. The Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> preparations were also analyzed by XRD for chemical characterization and determination of phase purity. The sodium content in Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> can be determined from the unit cell parameter,  $a_0$ :

$$x = (a_0 - 5.59)/0.11$$

Recent preparations of  $Na_x Pt_3 O_4$  have exhibited moderate surface areas and marginally acceptable conductivities without any post-synthesis treatment and have been tested in that form. Materials characterization data is summarized in Table 1.

### **PEM Regenerative Fuel Cell Testing**

A rechargeable fuel cell requires 1) a negative electrode that is active for both  $H_2$  oxidation and  $H_2$ evolution and 2) a positive electrode that is active for both  $O_2$  reduction and  $O_2$  evolution. The general approach to achieve bifunctional electrode structures was to partially distribute the charge and discharge functions to separate catalyst layers of a composite electrode each of which is optimized primarily for one function. A hydrophilic PEM-bonded layer supports the gas evolution functions; for oxygen evolution the selected catalyst, at a loading of 1-3 mg/cm<sup>2</sup>, was blended with 10-20 wt% of the ionomer and pressed onto the surface of the membrane. The gas-consumption discharge functions are supported by a separate more hydrophobic catalyst layer which was physically pressed against the PEM-bonded layer by the mechanical compression of the cell assembly.

Platinum is a good catalyst for the negative electrode reactions in both alkaline and acid electrolytes. We used the composite electrode structure for most of the PEM cell configurations. For the negative electrode the combination consisted of a platinum layer bonded directly to the PEM (optimized for hydrogen evolution) and a separate IDC electrode (optimized for hydrogen oxidation). The "free-standing" component of the composite electrode consisted of an IDC platinum composition bonded to wetproofed carbon paper.

The requirements for the positive electrode are more difficult to meet because of the scarcity of efficient bifunctional oxygen catalysts. In addition, a titanium current collector is required because carbon support materials are not stable under oxygen evolution conditions. Platinum is an excellent  $O_2$ -reduction catalyst for the fuel-cell mode, but is relatively poor for oxygen evolution.  $IrO_2$  is an excellent  $O_2$ -reduction catalyst, but a poor  $O_2$ -reduction catalyst. For electrolysis cells it is mixed or alloyed with Pt to improve the conductivity of the  $IrO_2$ . The general approach was to use Pt black for the oxygen reduction function in the free-standing component and to incorporate the more favorable oxygen evolution catalyst in the PEM-bonded layer, with Pt added to improve conductivity. For baseline performance data we used Pt or Pt-IrO<sub>2</sub> as the oxygen electrode catalyst. Three baseline cell types were fabricated and tested: a Pt/Pt fuel cell (also tested as an electrolyzer), a Pt/Pt-IrO<sub>2</sub> electrolyzer, and several Pt/Pt-IrO<sub>2</sub> bifunctional cell configurations; subsequently, Pt/Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> bifunctional cells of similar construction were also tested [6]. More recently, as the oxygen evolution catalyst, we have evaluated Pt-RuO<sub>x</sub>, RuO<sub>x</sub>-IrO<sub>x</sub> and RhO<sub>2</sub>, and we examined the performance of Pt-IrO<sub>x</sub> and Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> with repeated cycling.

÷

រូបសាក សេខម*ត*់ស្តែ**ក**ម

The baseline Pt/Pt fuel cell and the experimental bifunctional cells were fabricated with a Nafion 117 PEM and utilized composite electrodes (catalyst layer bonded to the PEM plus a free-standing IDC electrode) on both sides. The baseline fuel cell and all of the experimental bifunctional cells had the same negative (H<sub>2</sub>) electrode configuration. On the oxygen side, the PEM-bonded electrode was Pt, Pt-IrO<sub>2</sub>, Pt-RuO<sub>x</sub>, RuO<sub>x</sub>-IrO<sub>x</sub>, RhO<sub>2</sub> or Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub>, and the free-standing electrode was Pt or Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> on titanium mesh (Pt-plated). The baseline electrolysis cell had only the PEM-bonded electrode layers, optimized for gas evolution only (without ionomer

added). In electrolysis mode, the cells were run at ambient pressure with heated water pumped through the positive electrode chamber; in fuel-cell mode the gases were supplied at 207 kPa and the  $H_2$  stream was humidified at 90-120°C. The majority of testing was done at a cell temperature of 80°C.

## RESULTS

As described above, three different types of PEM cells were constructed and tested to establish a performance baseline for single-function cells (fuel cell or electrolyzer) and a bifunctional cell. Subsequently, bifunctional PEM cells with Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> positive electrodes were fabricated and tested to determine the relative performance of this potential catalyst in acid electrolyte. More recently we have evaluated Pt-RuO<sub>x</sub>, RhO<sub>2</sub> and RuO<sub>x</sub>-IrO<sub>x</sub> as the oxygen evolution components in bifunctional cells and investigated the performance of Pt-IrO<sub>x</sub> and Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> under limited cycling conditions.

## **Baseline Cells**

<u>Baseline Pt/Pt Fuel Cell</u>. - In fuel-cell mode, this cell ran at 0.874 V at 100 mA/cm<sup>2</sup> and at 0.714 V at 500 mA/cm<sup>2</sup> at 80°C. As an electrolyzer, performance was poor, as expected, primarily because Pt is not a very good catalyst for  $O_2$  evolution; 1.77 V at 100 mA/cm<sup>2</sup>, 2.00 V at 500 mA/cm<sup>2</sup> at 80°C. This cell was provided with the same positive electrode structure as used in the bifunctional cells (an IDC platinum composition at a loading of 8-10 mg/cm<sup>2</sup> on a Ti current collector mesh) so that the electrolyzer performance of Pt could also be measured. More recently a non-reversible Pt/Pt cell, optimized for fuel cell operation, was built and tested. In this cell the anode and cathode were of the same composition and configuration; the PEM-bonded layers consisted of Pt at a loading of 1 mg/cm<sup>2</sup> with 10 wt% ionomer, and the free-standing electrodes consisted of an IDC composition of Pt at a loading of 4 mg/cm<sup>2</sup> on wetproofed carbon paper (Toray HO-30). The fuel cell performance of these two cells is compared in Figure 1. It can be seen that the cell optimized for fuel cell optimized for these two cells is compared in Figure 1. It can be seen that the cell optimized for fuel c

<u>Baseline Pt/40Pt-60IrO<sub>2</sub> Electrolyzer</u>. - This cell ran at 1.50 V at 100 mA/cm<sup>2</sup> and at 1.671 V at 500 mA/cm<sup>2</sup>. This is fairly typical performance for a dedicated electrolyzer cell with Nafion and Pt/Pt-IrO<sub>2</sub> catalysts. This cell was not tested in fuel-cell mode. The performance is presented in Figure 2 in comparison to the baseline Pt/Pt fuel cell and the baseline Pt/Pt-IrO<sub>2</sub> bifunctional cell.

<u>Baseline Bifunctional Pt/Pt-IrO<sub>2</sub> Cell</u>. - Several Pt/Pt-IrO<sub>2</sub> cells with varying IrO<sub>2</sub> contents and electrode structures were evaluated initially to optimize bifunctional performance [6]. A Pt/40Pt-60IrO<sub>2</sub> cell (#5 in Tables 1 & 2) cell exhibited the best performance in both modes. At 500 mA/cm<sup>2</sup>, this cell ran at 1.587 V in electrolysis mode and at 0.723 V in fuel-cell (#5) mode. The comparable voltages for the baseline cells are 1.671 V for the electrolyzer and 0.714 V for the fuel cell. The performance is presented in Figure 2 in comparison to the baseline Pt/Pt fuel cell and the baseline Pt/Pt-IrO<sub>2</sub> electrolyzer.

#### **Catalyst Evaluation**

<u>Bifunctional Pt/Pt-Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> Cells</u>. - Two different bifunctional cells were constructed for the initial evaluation of Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> as a component of the oxygen electrode catalyst. The first cell (#6, Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> prep.#21, see Tables 1 & 2) used a two-layer oxygen catalyst structure bonded to the PEM consisting of very hydrophilic Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> (10% ionomer) and a less hydrophilic Pt transition layer. The balance of the composite electrode was a free-standing IDC electrode consisting of a 33/67 mix of Na<sub>x</sub>Pt<sub>3</sub>O<sub>4</sub> and Pt. This cell gave excellent fuel cell performance (0.74 V at 500 mA/cm<sup>2</sup>), as shown in Figure 2 and Table 2, better than the Pt/Pt cell (0.714 V) and the best Pt/40Pt-60IrO<sub>2</sub> cell (0.723 V). The cell performance in electrolysis mode was 1.697 V at 500 mA/cm<sup>2</sup>, better than Pt/Pt (2.00 V), but not as good as the best Pt/40Pt-60IrO<sub>2</sub> cell (1.587 V).

The second  $Na_{x}Pt_{3}O_{4}$ -containing bifunctional cell (#7,  $Na_{x}Pt_{3}O_{4}$  prep.#34A3) was constructed using a single layer of  $Na_{x}Pt_{3}O_{4}$  with 10% ionomer bonded to the PEM and the standard IDC Pt free-standing IDC electrode as the composite oxygen electrode. This cell showed reduced performance in both modes compared to

the first  $Na_x Pt_3 O_4$  cell (Figure 2 and Table 2). In the fuel-cell mode, the voltage at 500 mA/cm<sup>2</sup> was 0.657 V. In electrolysis mode, the voltage was 1.766 V at 500 mA/cm<sup>2</sup>, which is still a significant improvement over a pure Pt/Pt cell. The differences in performance between these two cells may be partly due to differences in catalytic activity since the materials, although very similar in physical characteristics, are from two separate and somewhat different preparations (see Table 1); a larger part of the differences, however, may be attributed to the changes in electrode structure in Cell #7 resulting in a higher resistance interface.

<u>Pt/Pt-IrO</u><sub>2</sub>. - Cell #8 was an attempt to repeat the build of the baseline bifunctional Pt/Pt-IrO<sub>2</sub> cell (#5) but with two slight differences: slightly more ionomer in the PEM-bonded layer and the introduction of a thin Pt transition layer between the bonded layer and the free-standing electrode. The cell had somewhat higher resistance and did not perform quite as well as Cell #5; the performance curves are shown in Figure 3.

 $\underline{RuO_x-IrO_x}$  was used as the PEM-bonded layer for oxygen evolution in Cell #9 and the Pt transition layer was included for comparison to Cell #8. The electrolysis performance was better than for Cell #8 but the fuel cell performance was not as good (see Figure 3). It is anticipated that a structural reconfiguration of the cell duplicating Cell #5 would significantly upgrade fuel cell performance with this catalyst.

<u>Pt-RuO<sub>x</sub></u> was used as the PEM-bonded layer for oxygen evolution in Cell #10 and the Pt transition layer was again included for comparison. The performance was quite similar to the performance observed for  $RuO_x$ -IrO<sub>x</sub> (see Figure 3).

<u>RhO<sub>x</sub></u> was used as the PEM-bonded layer for oxygen evolution in Cell #11 but the Pt transition layer was eliminated. This material was difficult to work with because of the very high surface area and more development would be required for a fair evaluation. Two performance points are shown in Table 2, but the cell was not very stable in either mode.

THE R. L.

NATE OF A DESCRIPTION OF A

#### **Repetitive Cycling Tests**

Cells #12 and #13 were attempts to reproduce the electrode structures and performance of the baseline bifunctional Pt/40Pt-60IrO<sub>2</sub> cell (#5) for the purpose of investigating tolerance to repetitive cycling. The first build (#12) had somewhat higher than typical internal resistance and showed lower performance than Cell #5 (Table 2). The cell was subjected to six charge/discharge cycles at 500 mA/cm<sup>2</sup>, shown in Figure 4, after which it developed a leak and testing was terminated.

Cell #13 came somewhat closer in performance to Cell #5; in fuel cell mode it was not quite as good as Cell #5 but in electrolysis mode it was somewhat better (see Table 2). This build was subjected to fifteen charge/discharge cycles, at which point it also developed a leak. The performance at 500 mA/cm<sup>2</sup>, shown in Figure 5, remained fairly constant for both modes of operation over the fifteen cycles.

Cells #14, #15 and #16 were attempts to fabricate bifunctional positive electrodes similar to that used in Cell #5 but based on  $Na_xPt_3O_4$ , also for the purpose of investigating tolerance to repetitive cycling. The first two builds (#14 & #15) did not give very stable performance and were not cycled (see Table 2). Cell #16 did not show any significant improvement in performance but was somewhat more stable (see Figure 6) and was subjected to five charge/discharge cycles. Neither the performance of Cell #5 nor the performance of the earlier  $Na_xPt_3O_4$  build (#6) was reproduced, but the cyclic performance was stable and better than Pt alone.

### CONCLUSIONS

فسأساد

Regenerative PEM fuel cells showing efficient bifunctional performance can be fabricated with traditional Pt and Pt-Ir catalysts if the electrode structures are properly designed. This investigation has also identified  $RuO_x$  as a catalyst with good potential for improving the oxygen evolution component of a bifunctional positive electrode.  $Na_x Pt_3O_4$  was identified in our earlier work as a catalyst with potential for bifunctional operation in

both alkaline and acid electrolytes; the current work has confirmed this with limited charge/discharge cycling but additional development will be required to achieve more reproducible catalyst properties and performance.

## **ACKNOWLEDGEMENTS**

This phase of the work was supported by NASA Lewis Research Center under the direction of Dr. Patricia Loyselle on Contract No. NAS3-24635. We would also like to acknowledge the assistance of Prof. B.L. Chamberland of the University of Connecticut in the selection and identification of numerous materials tested in this program.
