## ORDINATES AND THEORETICAL PRESSURE-DISTRIBUTION DATA FOR NACA 6- AND 6A-SERIES AIRFOIL SECTIONS WITH THICKNESSES FROM 2 TO 21 AND FROM 2 TO 15 PERCENT CHORD, RESPECTIVELY <sup>1</sup>

By ELIZABETH W. PATTERSON and ALBERT L. BRASLOW

### SUMMARY

Basic thickness forms of the NACA 63-, 64-, 65-series and NACA 63A-, 64A-, 65A-series airfoil sections are tabulated for thicknesses of 2, 3, 4, and 5 percent chord. Also presented for these thin airfoil sections are theoretical values of pressures and velocity ratios required to obtain theoretical airfoil pressure distributions. In addition, for each family of airfoil sections, cross plots are presented from which ordinates and pressure distributions can be easily obtained for airfoil sections of thicknesses intermediate to those presented in this report, in NACA Report 824 (from 6 to 21 percent chord for the NACA 6-series), and in NACA Report 903 (from 6 to 15 percent chord for the NACA 6A-series).

### INTRODUCTION

In order to minimize the wave drag of supersonic aircraft, the wings and tail surfaces are designed with the use of airfoil sections thinner than 6 percent chord. Ordinates for only a few of these thin airfoils are published and these are not conveniently located in a single report. This report will supplement the information presented in references 1 and 2 and provide the ordinates of additional airfoil sections useful in design of supersonic aircraft.

The information presented in this report includes tabulated ordinates for symmetrical NACA 6- and 6A-series airfoil sections with thicknesses of 2, 3, 4, and 5 percent chord and a simplified method of obtaining ordinates for any thickness intermediate to published values from 2 to 21

percent chord for NACA 63-, 64-, and 65-series and from 2 to 15 percent chord for NACA 63A-, 64A-, and 65A-series airfoil sections. In addition, a simplified procedure is presented for obtaining the pressure distributions about airfoil sections of intermediate thicknesses.

### SYMBOLS

$c$	chord of airfoil
$t$	maximum thickness of airfoil
$V_{\infty}$	free-stream velocity
$V$	local velocity at any point on airfoil surface
$\Delta V$	increment of local velocity
$\Delta V_a$	increment of local velocity caused by additional type of load distribution
$x$	distance along chord from leading edge
$y$	distance perpendicular to chord

### DISCUSSION

The basic thickness forms for the NACA 63-, 64-, 65-series and NACA 63A-, 64A-, 65A-series airfoil sections with thicknesses of 2, 3, 4, and 5 percent chord are presented in the tables of figures 1 to 24. For the 6A-series airfoil sections, where a trailing-edge radius is specified, an ordinate is presented for the 100-percent-chord station to serve as a guide in fairing the rear portion of the airfoil. The theoretical methods of references 1 and 2 were used to derive the 2-percent-thick airfoil sections of the NACA 63-, 64-, 65-series and the NACA 63A-, 64A-, 65A-series families, respectively. Although not exactly correct, ordinates for thickness ratios intermediate to those presented in references 1 and 2 and in the

<sup>1</sup> Supersedes NACA Technical Note 4322 by Elizabeth W. Patterson and Albert L. Braslow, 1958.

present report can be obtained for all practical purposes by the following method which was used to obtain the ordinates for the 3-, 4-, and 5-percent-thick airfoil sections tabulated herein. For each family of airfoils, the ratio obtained by dividing the ordinate  $y$  at each chordwise station by the maximum thickness  $t$  is plotted against the airfoil maximum thickness in percent airfoil chord as presented in figures 25 to 30. From these cross plots, the ratio  $y/t$  at each chordwise station can be obtained at the desired value of maximum thickness. Values of the ratio of the leading-edge radius to the maximum thickness squared as a function of maximum thickness  $t$  are presented for the NACA 6-series and 6A-series airfoil sections in figures 31 and 32, respectively. Addition of a cambered mean line to the basic thickness form is accomplished with the use of the mean-line data of references 1 and 2.

The theoretical pressure distributions, indicated by  $(V/V_\infty)^2$ , for each of the symmetrical airfoil sections presented are also tabulated in figures 1 to 24. In order to obtain the theoretical pressure distributions for these airfoil sections at angles of attack and/or with cambered mean lines, the procedure described in reference 1 can be used. In this method of calculating the pressure distributions, the velocity distribution about an airfoil section is considered to be composed of the following three separate and independent components:

(1) The distribution corresponding to the velocity distribution over the basic thickness form at zero angle of attack ( $V/V_\infty$ )

(2) The distribution corresponding to the design load distribution of the mean line ( $\Delta V/V_\infty$ )

(3) The distribution corresponding to the additional load distribution associated with angle of attack ( $\Delta V_a/V_\infty$ )

Values of the velocity-increment ratio  $\Delta V/V_\infty$  are presented in references 1 and 2 and values of the velocity ratio  $V/V_\infty$  and the velocity-increment ratio  $\Delta V_a/V_\infty$  are tabulated in figures 1 to 24. For each family of airfoil sections, values of  $(V/V_\infty)^2$  and  $\Delta V_a/V_\infty$  for intermediate thicknesses can be obtained from figures 33 to 44. In these figures,  $(V/V_\infty)^2$  and  $\Delta V_a/V_\infty$  are plotted as a function of the maximum airfoil thickness  $t$  in percent chord for each chordwise station.

Careful comparison of the ordinates and pressure ratios tabulated in references 1 and 2 with the faired cross plots of figures 25 to 44 shows some discrepancies. Although these discrepancies are small enough to be disregarded for all practical purposes, the values obtained from the faired cross plots are preferred for design considerations.
