STATIC LONGITUDINAL AND LATERAL STABILITY AND CONTROL

DATA OBTAINED FROM TESTS OF A 1/15-SCALE MODEL

OF THE GOODYEAR XZP5K AIRSHIP

TED NO. NACA DE 211

By Michael D. Cannon

SUMMARY

Static longitudinal and lateral stability and control data are presented of an investigation on a 1/15-scale model of the Goodyear XZP5K airship over a pitch and yaw range of $\pm 20^\circ$ and 0° to 30° , respectively, for various rudder and elevator deflections. Two tail configurations of different plan forms were tested and wake and boundary-layer surveys were conducted. Testing was conducted in the Langley full-scale tunnel at a Reynolds number of approximately 16.5×10^6 based on hull length, and corresponds to a Mach number of about 0.12.

INTRODUCTION

Current requirements for the use of airships in antisubmarine operations call for maneuver rates substantially higher than those used in past years. These maneuvers result in operation at high pitch and yaw attitudes which has caused some tail surface failures in service operations and which introduces new design problems for future airship configurations. Since the existing airship-loads data available for design purposes are limited to low-aspect-ratio surfaces and relatively low airship attitude ranges, the Bureau of Aeronautics, Department of the Navy, requested that a fin-loads investigation be conducted on a 1/15-scale model of the Goodyear XZP5K airship in the Langley full-scale wind tunnel.

UNCLASSIFIED

Tests were conducted for two types of tail surfaces representing current designs. Although the primary objective of the investigation was to obtain extensive fin-loads pressure data, model force data were also obtained over a pitch range of $\pm 20^\circ$ at yawed attitudes up to 30° for a full range of elevator and rudder deflections from which some of the static longitudinal and lateral stability derivatives can be determined. Also included were limited boundary-layer surveys and wake momentum surveys at the rear of the body to provide some data for stern propulsion design studies.

This paper presents only the model force test data and the boundary-layer and wake survey measurements. These data are presented without analysis to expedite publication.

SYMBOLS AND COEFFICIENTS

Force and moment coefficients are based on hull volume as in reference 1 and are referred to the stability axes the origin of which is the center of buoyancy. This point is located on the model center line 0.456l back of the nose.

C_L	lift coefficient,	$\frac{\text{Lift}}{q_0(V)^{2/3}}$
C_D'	drag coefficient,	$\frac{\text{Drag}}{q_0(V)^{2/3}}$
C_Y	side-force coefficient,	$\frac{\text{Side force}}{q_0(V)^{2/3}}$
C_m	pitching-moment coefficient,	$\frac{\text{Pitching moment}}{q_0 V}$
C_n	yawing-moment coefficient,	$\frac{\text{Yawing moment}}{q_0 V}$
C_l	rolling-moment coefficient,	$\frac{\text{Rolling moment}}{q_0 V}$
V	volume of hull,	192.8 ft ³

l	length of hull, 18.79 ft
q_0	free-stream dynamic pressure, $\rho U^2/2$, lb/ft ²
q	local dynamic pressure, $\rho u^2/2$, lb/ft ²
ρ	mass density of air, lb-sec ² /ft ⁴
U	free-stream velocity, ft/sec
u	local velocity, ft/sec
α	angle of pitch, positive when nose up, deg
ψ	angel of yaw, positive when nose to right, deg
δ_r	rudder angle, positive when trailing edge deflected to left, deg
δ_{eL}	left elevator angle, positive when trailing edge deflected down, deg
R	Reynolds number, based on hull length
δ_{eR}	right elevator angle, positive when trailing edge deflected down, deg

MODEL

The model used for this investigation was a 1/15-scale model of the Goodyear XZP5K airship. This corresponds to a model length of 18.79 feet and a volume of 192.8 cubic feet. Figure 1 shows the model installed in the tunnel and figure 2 presents some of the more pertinent geometric characteristics of the hull.

Two sets of tails were used in the investigation. Both sets were inverted Y-tail arrangements with a radial spacing of 120° between fins, but differed in plan form and area. The first, designated the standard tail, was of the conventional low-aspect-ratio design having a rudder area approximately 24 percent of the total area. The second, designated the high-aspect-ratio tail, was smaller in area and had a rudder area approximately 45 percent of its total area. Plan forms and pertinent geometric characteristics of the two tail configurations are shown in figures 3 and 4. All control surfaces were equipped with actuators allowing independent deflection of each control surface through a range of ±40°.

TESTS

Force test data were obtained for both the standard and high-aspect-ratio-tail configurations over a pitch range of $\pm 20^\circ$ for yawed attitudes from 0° to 30° . The rudder and left elevator controls were deflected independently $\pm 40^\circ$ for all model attitudes to provide separate effectiveness evaluation of each control. For the purpose of this report the rudder is considered the control surface of the top fin and the elevator the control surface of the side fins.

Measurements of the boundary-layer profile were made along the top and side center line of the hull at 0.60l, 0.75l, and 0.97l through the complete pitch range at zero yaw, and wake momentum surveys were conducted at yaw angles of 0° and 21° immediately in the rear of the hull. A region of approximately 42 inches square was surveyed.

The tests were conducted at a Reynolds number of approximately 16.5×10^6 based on hull length and corresponds to a Mach number of about 0.12. From consideration of model surface conditions, general tunnel turbulence, and high R, the hull boundary layer in the region of the tails would be expected to be turbulent in nature.

CORRECTIONS

All data presented in this paper have been corrected for tunnel stream angle and model buoyancy effects. Strut tare corrections have also been applied to all data, based on tare evaluations made using the image system at the zero yaw condition. Time did not permit such evaluations at yaw conditions and it should be noted that the zero yaw tares are probably conservative when applied to the highly yawed conditions.

PRESENTATION OF DATA

As stated in the introduction, these data are presented without analysis to expedite publication. This treatment is prompted by the specific nature of the tests.

The data of this investigation are presented as follows:

Longitudinal characteristics of the model with controls neutral for various yaw angles. (Standard and high-aspect-ratio tails installed).	Figure 5 and 6

Effect of rudder deflection on lateral characteristics for various pitch and yaw angles. (Standard tail installed) . . .	10
Effect of elevator deflection on lateral characteristics for various pitch and yaw angles. (Standard tail installed) . . .	11
Effect of rudder deflection on the lateral characteristics for various pitch and yaw angles. (High-aspect-ratio tail installed)	12
Effect of elevator deflection on the lateral characteristics for various pitch and yaw angles. (High-aspect-ratio tail installed)	13
Boundary-layer-velocity profiles along the top and side hull center line for various pitch angles.	14
Dynamic pressure surveys in the region of the tail cone at angles of yaw of 0° and 21°.	15 and 16

Profile irregularities noted in figure 14 at high angles of attack are probably due to the large relative angle between the local stream angle and survey rake. In the 0.97l position interference is likely from the tail surfaces.

The fin wakes are clearly defined for the zero angle of yaw case, figure 15, and the contours appear adequately defined. The break in contours in the lower middle portion marks the strut location. For an angle of yaw of 21°, figure 16, however, a considerable wake confused

the pressure profiles. At least the order of magnitude of gross wake influence is shown, although the strut wake is swept to the lower right and mixed in with the body wake.
