Spaceflight-induced Bone Loss: Is there a risk for accelerated osteoporosis after return?

Jean D. Sibonga, Ph.D.
Sr. Research Scientist, USRA
HRP Bone Discipline Lead
Recommendations of Institute of Medicine – Safe Passage: Astronaut Care for Exploration Missions

- Develop and use an occupational health model for the collection and analysis of astronaut health data, giving priority to the creation and maintenance of a safe work environment.

- Incorporate an evidence-based risk assessment and communication process into the risk identification and reduction approach.
The IOM approach for Bone Discipline Evidence Base Reports

4 identified risks of an adverse outcome due to space exploration.

1. Accelerated Osteoporosis
   Long-term health

2. Formation of Renal Stones

3. Intervertebral Disc Injury (or Damage)

4. Bone Fracture

#2-4 Risk for mission but more evidence required.
Overview
Evidence Base for #1 Risk of Accelerated Osteoporosis

- Involutional Osteoporosis
- Bone remodeling process
- Skeletal adaptation to space
- Skeletal changes: space vs. ageing
  - Circumstantial Evidence
- Gaps in our knowledge base
Two Risk Statements for Accelerated Osteoporosis

**Earlier:** Bioastronautics Roadmap 2005

“Osteoporosis associated with age-related bone loss may occur at an earlier age due to failure to recover bone lost during spaceflight.”

**Current:** Risk Statement in Human Research Program

“(If) mission-related bone loss cannot be corrected by post-mission rehabilitation; crew members could be at greater risk of osteoporosis-related fractures in later life.”

Is there recovery? Are the changes irreversible?

Overlap with involutional changes in bone.
“Involutional” Osteoporosis

The regressive alterations of a body or its parts characteristic of the ageing process

Age-related bone loss
Osteoporosis Definitions

- OLD: “...a reduced amount of bone that is qualitatively normal.”
  Albright F. Ann Intern Med. 1947

- MODERN: “...a systemic skeletal disease characterized by low bone mass and microarchitectural deterioration with a consequent increase in bone fragility with susceptibility to fracture ....”
  Am. J. Med. 1991

- NEWEST: “Osteoporosis is a skeletal disorder characterized by compromised bone strength predisposing to an increased risk of fracture. Bone strength reflects the integration of two main features: bone density and bone quality.”
  JAMA. 2001
Classifications of Osteoporosis

- **Primary Osteoporosis** - “Involutional Osteoporosis”
  - Menopause-induced Bone Loss – “Postmenopausal Osteoporosis”
  - Age-related Bone Loss – “Senile Osteoporosis”

- **Secondary Osteoporosis** – External causes
  - Glucocorticoid Medication
  - Alcohol-induced
  - Immobilization
  - Anti-seizure drugs
Bone Gain and Loss with Age is Sex-specific

Bone mass (g/calcium)

Age (yr)

Males

Females

Riggs BL, Melton LJ: Involutional osteoporosis
Oxford Textbook of Geriatric Medicine
Phase I (Bone Gain): Femoral Shaft areal BMD increases with age, but volumetric BMD is independent of age in young males and females.

Dispelling a Fallacy: NOT BMD, but Bone size increases in growing males.

Seeman, E. J Clin Endocrinol Metab 2001;86:4576-4584
Being Female is a risk factor for osteoporosis.

- Smaller bones
- Undergo two phases of bone loss: an earlier rapid phase of loss (menopause induced) followed by a slower phase of loss (induced by ageing) equivalent to the rate of bone loss in men.
How does the “Risk for Accelerated Osteoporosis” in crew members fit in with Involutional Osteoporosis?
Clarifying the “Risk for Accelerated Osteoporosis.”

1. **Accelerated**: “to bring about at an earlier time”

2. **Osteoporosis**: Occurrence of fractures under mechanical loading of normal activities “atraumatic”

3. **Evidence**: incidence of atraumatic fractures at an **earlier age** (relative to expected age of occurrence)

4. **Evidence**: **Greater** prevalence fractures in the former astronauts compared to peer group.

A STUDY EVALUATING FRACTURE AS THE OUTCOME IN ASTRONAUTS???
Age-Related Fractures: when and how many?

The influence of endocortical bone loss on # hip fractures in later life.

The influence of cancellous bone loss on wrist and spine fractures.

Cooper and Melton, 1992
Measuring surrogates to bone strength.

Supplementing DXA measures of areal BMD.

But, with which one?
Bone Volume Changes in the Adult Skeleton: The Bone Remodeling Process
Changes in the skeletal tissue occur through 3 regulated processes

- **Growth** - developing skeleton (BF>BR)

- **Modeling** - shaping of bone (e.g., elongation)

- **Remodeling** – repair, renewal, calcium homeostasis
  - 10% of skeleton/year
Remodeling in Discrete Packets of Bone
(Bone Remodeling Unit BRU – Basic Multicellular Unit BMU)

A. Quiescent Bone Surface
   - Lining cells
   - Osteocytes

B. Resorption Phase
   - Osteoclasts
   - Lining cells

C. Formation Phase
   - Osteoblasts
   - Cement line

D. Quiescent Phase
   - Cement line

Diagram illustrating the process of bone remodeling in discrete packets.
Remodeling at the level of the BRU

40 μm
Specific sites of bone remodeling.

- Cortical Bone
- Endocortical
- Intracortical
- Cancellous Bone
- Trabecular surface
- Endocortical
Bone Remodeling of Cancellous Bone  
(aka Trabecular Bone)

- For normal turnover, bone repair & tissue renewal, mineral homeostasis
- Bone Resorption (BR) precedes Bone Formation (BF)
- Time for BR < Time for BF
- Two phases of BF: matrix production and mineralization
- 4-6 months
- Bone Balance vs. Bone Coupling

Osteoporosis in the adult likely results from a perturbation in the remodeling process.

Sibonga et al. BONE 2007
Spaceflight Bone Loss vs. Age-related Bone Loss
BMD Loss vs. Age-matched Loss

Losses in 6 months in space far exceed 2-year losses on Earth in similarly age population.
Minimal BMD loss in forearms of males on earth.

Small n for females but suggest losses equivalent to postmenopausal losses on earth.
Circumstantial Evidence: Parallels
Menopause vs. SF

1. Reduction TbN, loss of connectivity in postmenopausal women (Kleerekoper, 1985)
2. Preferential cancellous bone loss (Riggs refs.)
3. BMD losses 2-3%/yr (Riggs refs)
4. Resorption on inside surface (endocortical) of cortex.
5. Activation Frequency high in postmenopausal women (Recker, 2004)

1. Biopsies after 120 days bed rest. TbN reduced (Thompsen, 2005)
2. Preferential cancellous bone loss in proximal femur (Lang, 2004)
3. Range BMD losses (3-9%) per ~6 months
4. Cortical thinning at femoral neck from endocortical surface.
5. Not quantified

Given the preferential loss in trabecular bone compartment and the rapid rate of loss in crew members, suspect that the impact on microarchitecture is at the very least equivalent to postmenopausal women.
Seventy percent reduction in remodeling rate does not look so alarming given that it results in activation frequency about equal to healthy premenopausal women.
Turnover in Crewmembers

- Loss in crewmembers at faster rate than postmenopausal females (months vs. years)
- High turnover with menopause leads to perforations of trabecular struts.
- At what time point with SF does irreversible perforation occur?
Normal vs. High Bone Turnover
Are crewmembers restored to preflight skeletal status? Recover bone that was lost in space?

- **DXA**: Restoration of areal BMD within ~ 3 years but cannot assess structure.
- **QCT**: Incomplete recovery of vBMD at 12 months postflight
- Geometrical changes at femoral neck indicate early onset of age-related changes (Riggs, JBMR 2004; 2008)
Histomorphometry of Bone Biopsies (Bed Rest Flight Analog)

- Vico (1987) a reduced mineralization, no change in matrix formation and increased resorption of bone (osteoclast parameters)
- Arnaud (1992) suppressed bone formation rate and reduced osteoblast activity in as short as 7 d experiment
- Zerwekh (1998) mild decrement in bone-forming osteoblasts concurrent with increased bone resorption in 12 wk study
- Thomsen (2006) deterioration of trabecular microarchitecture 120 d suggestive of aggressive resorption
Age-related Bone Loss

Sibonga et al, manuscript
Bone Gain and Loss with Age is Sex-specific

Riggs BL, Melton LJ: Involutional osteoporosis
Oxford Textbook of Geriatric Medicine
Incidence of Limb Fractures

The influence of previous bone loss on fractures in later life.
Summary: Spaceflight Evidence

- Negative calcium balance, reduced absorption and down-regulated calcitropic hormones

- Deficits in aBMD at weight-bearing sites, vBMD cancellous bone, thinning of cortical bone

- Increased bone resorption markers > formation markers

- Reductions in hip bone strength estimated by FEA, also in compressive and bending strengths at femoral neck after return

- Delayed and possibly incomplete restoration of preflight hip bone integrity.*
The evidence-to-date suggests that the rapid rate of site-specific bone loss in space, due to the unbalanced stimulation of bone resorption, may predispose crew members to irreversible changes in bone structure and microarchitecture.

No analyses conducted in the postflight period to assess microarchitectural changes.

There is no complete analysis of skeletal recovery in the postflight period to evaluate the structural changes that accompany increases in DXA aBMD.

Postflight analyses based upon QCT scans performed on limited crew members indicate reductions in hip bone strength and incomplete recovery at 1 year.

No recovery of trabecular vBMD after 1 year return (HRP IWG).

Time course of bone loss in space unknown.
Thank you.

GAPS: Factors Related to Fracture Risk Besides Bone Mass

1. **Energy released by fall or “injury”** (need to identify tasks to be performed; perform modeling to predict*)

2. **Neuromuscular protection of bone** (need to preserve postural muscle mass and motor coordination)

3. **Energy absorbed by soft tissue** (need to provide adequate “protective padding,” evaluate putative osteoprotective effect of EVA suit and partial gravity)

4. **Bone Strength: Quantity & Quality** (need supplement DXA bone mass measurements)

*Carpenter JBMR, 2005*
