Practical Applications of Cosmic Ray Science: Spacecraft, Aircraft, Ground Based Computation and Control Systems and Human Health and Safety

ICED 2012 Mars Habitat Design Program - Sustaining Humans in Mars.
Blackstone Valley Tech.
December 12, 2012

First presented at CR 2012 Symposium, University of Denver, Denver, Colorado
June 26 - 28, 2012

William Atwell - Boeing Research & Technology, Houston, Texas
Steve Koontz - NASA, Johnson Space Center, Houston, Texas
Eugene Normand - Boeing Research & Technology, Seattle, Washington
Outline

• Outline and Abstract
• 1) Cosmic ray interactions with matter
  – Direct Ionization/Excitation Particle Tracks
  – Nuclear Reactions and Secondary Particle Showers (and more ionization tracks)
• 2) Cosmic Ray Exposure Environments
  – Earth surface and atmosphere
  – Low Earth Orbit (International Space Station)
  – Interplanetary Space
• 3) Cosmic ray effects on contemporary electronic technology
  – Ground based computation and control system effects
  – Commercial and military aircraft electronics systems effects
  – Spacecraft electronic systems effects
• 4) Cosmic ray effects on human health and safety
  – Earth Surface Environments
  – Commercial and Military Aircraft Environments
  – Manned Spaceflight Environments
• 5) Summary and Conclusions
• 6) Supporting Information and References
The natural space radiation environment consists primarily of energetic charged particles: Galactic cosmic rays, solar cosmic rays, and magnetically trapped radiation (2,4)

**Energetic charged particle interactions with target materials:**
**three basic processes**

1. **Energy loss** (dE/dx) by direct ionization/excitation of material along the particle track
   - Direct ionization effects – linear energy transfer (LET) – “slowing down”
   - Primary cause of single event effects (SEE) in susceptible electronic devices
   - Primary cause of total ionizing dose effects in susceptible electronic devices
   - Primary cause of human health effects

2. **High energy collisions** (inelastic/hadronic) triggering nuclear reactions
   - Nuclear hadronic reactions initiate secondary particle showers in the target mass
   - Further collisions of secondary particles with target nuclei lead to expansion and propagation of the secondary particle shower
   - Secondary particles can produce direct ionization and more nuclear reactions

3. **Collisions with material nuclei that produce displacement damage**
   - Displacement of target atoms so as to disrupt crystal structure (solids only – not considered further here, but important for some spacecraft optoelectronics)
1.1: GCR Exposure Environments: Earth Surface and Atmospheric Environments: Dominated by secondary particle showers

Earth surface/atmospheric environments
- 1000 grams/cm² air shielding mass at sea level
- Latitude dependent geomagnetic shielding
- GCR secondary particle shower products dominate

Commercial and military aviation environments
- Altitude dependent air shielding mass
- Latitude dependent geomagnetic shielding
- Solar cycle modulation of GCR environment
- Latitude dependent solar particle event exposure
- Pfotzer secondary shower particle maximum at about 20 km altitude (mid latitudes)
- Average ISS hourly crew dose rates are on the order of 20 µSv/hr - comparable to commercial aircraft dose rates on polar routes at solar minimum

Image Credit - The Boeing Company

1.2: GCR Exposure Environments: Low Earth Orbit (LEO) – Primary CR and secondary particle showers

The differential LET spectra [#/(cm² week LET)] at various shielding depths in a concentric spherical shell model spacecraft is shown to the right.

LET spectra are calculated, using the FLUKA (1) Monte Carlo radiation transport code, as the number of particles entering each of the Si detector shells placed at various depths in the concentric spherical shell model (see the table below).

All secondary particle shower processes are enabled and full shielding mass distribution function for each Si shell is utilized in a fully three dimensional calculation. Total ionizing dose and nuclear reactions “star” density is also calculated but not reported here.

2.0: Cosmic Ray Effects on Contemporary Electronic Technology

Solid state electronic devices as charged particle detectors: Single Event Effects (SEE)

Schematics of a solid state charged particle detector (right) and a MOSFET transistor (left) illustrating the particle counting or single event upset process. Direct ionization by CR charged particles and charged particles produced by nuclear reactions in the device can produce counts in the detector and SEE events in the transistor only if the devices are powered, i.e. only if an electric field is applied to force charge collection.

Solid state electronic devices as charged particle detectors: Total Ionizing Dose (TID) Effects

Schematic of n-channel MOSFET illustrating radiation-induced charging of the gate oxide: (a) normal operation and (b) post-irradiation. The electrostatic field produced by trapped charge in SiOx layers changes device characteristics. TID damage accumulated even if the device is unpowered.

• **Ground based computation and control systems**
  • SEE caused principally by GCR shower generated secondary neutrons
  • TID effects negligible in the natural environment

• **Aircraft electronic systems**
  • SEE caused principally by GCR shower generated secondary neutrons and protons
  • TID Effects negligible in the natural environment

• **Spacecraft electronic systems**
  • Single event effects caused principally by GCR heavy ions, GCR protons, trapped protons, and solar particle events (SPE)
    • Neutrons and other secondary shower particles increasingly important as spacecraft shielding mass increases, especially when the electronic device contains heavy elements - e.g. Pb, Hf, W
  • TID effects are important in specific high-dose-rate natural environments, e.g. planetary radiation belts and/or solar particle events
2.1: Ground based computational and control systems - History

- **Observations of satellite electronic anomalies lead to the first report of SEE effects in solid state electronics**

- **Memory parity errors observed in the first Cray supercomputer at Los Alamos in 1976 were later determined to be SEUs caused by atmospheric neutrons**

- **Alpha particles emitted from thorium impurities in chip packaging materials were identified as an SEU cause by May and Woods in 1978**

- **Modeling and prediction of cosmic ray effects on computer memories**

- **Summary of IBM investigations into soft errors in microelectronic devices**

- **JEDEC Standard developed for test and measurement of alpha particle and atmospheric cosmic ray shower induced soft errors in semiconductor devices**
  - Measurement and Reporting of Alpha Particle and Terrestrial Cosmic Ray Induced Soft Errors in Semiconductor Devices, JEDEC Standard JESD89A, October 2006
2.2: Atmospheric Neutron Effects on Ground Based and Aircraft Electronic System Reliability

Ever increasing microelectronic system size, complexity, and capability can lead to overall decrease in Mean Time Between Failure (MTBF) (increase in failures in time (FIT). In 2002, Actel predicted a significant decline in FPGA MTBF with both operational altitude and the scale of the technology node (see below) for Actel field programmable gate arrays (FPGAs).

<table>
<thead>

In contrast, XILINX FPGA field performance measurements (the Rosetta Experiment, 2009 - 2012), show soft error rates (MTBF/Mb in \(10^6\) hrs) decreasing with technology node size for both Configuration and Block RAM, however the advantages of a smaller node can be easily offset by much larger increases in the number of bits in device memory.

2.4: Spacecraft Electronic Systems

- The reliability and safety of spacecraft electronic systems are often determined, in practice, by the mission space radiation environment
  - SEE rate depends on the primary particle flux and the extent of secondary particle production in spacecraft shielding mass
  - TID effects lead to slow degradation of device performance characteristics as dose accumulates during a mission, leading, ultimately, to wear-out like device failure

- Mitigating SEE/TID effects in spacecraft electronic systems
  - Selection of electronic parts resistant to SEE/TID
    - Military Class S parts or equivalent
    - Silicon-on-insulator (SOI) device structure for reduced SEU and latch-up sensitivity
    - Not always possible – susceptible complex parts may be the only option for the required performance
  - Design of robust system architectures
    - Triple (or more) module redundancy
    - Error detection and correction firmware and software
    - Fault detection isolation and recovery (FDIR) software systems

- A rigorous component and integrated system test and analysis program is essential to demonstrate the reliability of the spacecraft electronic system before flight.
  - Accurate definition of worst-case natural cosmic ray, solar energetic particle event, and trapped radiation flight environments
  - Applicable component and system ground based accelerated test methods
  - Understanding the relationship between ground based test results and expected on-orbit electronic system failure rates
2.5: Estimating SEE rates: Verifying Spacecraft System Safety and Reliability

Direct Ionization

References (2 – 10)

Differential LET distribution function (spectrum) calculated for the shielding mass distribution function applicable to the electronic device location in the spacecraft

SEU Rate = \[ \int \int \int f(\text{LET}) \times \sigma(\text{LET}, \Theta, \Phi) \, d(\text{LET})d(\Theta) \, d(\Phi) \]

Electronic device heavy ion accelerator test data - Measured device cross section (\(\sigma_{\text{let}}(\Theta, \Phi)\)) vs. Heavy ion effective LET value expressed as an integral Weibull or the integral (cumulative) log normal distribution function, or the tabulated test results data

In-Device Nuclear Reactions

References (2 – 10)

Nuclear reactions internal to the microelectronic device can be triggered by primary and secondary particle (especially those producing little or no direct ionization e.g. neutrons, protons, and pions) inelastic collisions with microelectronic device nuclei to produce high-LET, short-range fragments.

SEU Rate = \(\sigma_{\text{let}}(\text{device-particle}) \times \text{Flux} \times \text{number of devices}\)
GCR and trapped proton single event upsets detected and corrected by Error Detection And Correction (EDAC) firmware in ISS computer system Dynamic Random Access Memory (DRAM). EDAC operation is part of the nominal system design, not an anomaly.
2.6: In-flight vs. calculated spacecraft device SEU rates

**Shielding Mass Rate Ratio**

\[
\text{Shielding Mass Rate Ratio } = \frac{(10 \text{ g/cm}^2 \text{ Rate})}{(40 \text{ g/cm}^2 \text{ Rate})}
\]

Note that only FLUKA correctly quantifies the shielding mass (i.e. secondary particle shower) effects for the ISS TI CMOS DRAM.

Using the same device parameter, the FLUKA based rate calculations show the smallest least squares error and overall acceptable performance compared to CREME-96 and the Peterson FOM, providing some validation for the FLUKA based methods described here.
2.7: FLUKA calculation of the increase in high LET particles entering a thin (10 micron) Si layer from a thin (1 micron) high Z element (W) over-layer as a function of spacecraft aluminum shielding masses (Mercury Messenger SRAM, interplanetary environment)

For Mercury Messenger SRAM, an SEU rate calculation, based on FLUKA LET spectra calculated for the concentric spherical shell spacecraft model (see back-up), predicts that including a 1 micron Tungsten over-layer above the 10μ Si detector shell should result in a dramatic increase in SEU caused by high LET particles affecting this high threshold device.

Y axis – Mercury Messenger SRAM upsets per bit day

X axis – g/cm² Al median shielding mass (concentric spherical shell target with cosine and solid angle corrections)
2.8: FLUKA calculation of the increase in high LET particles entering a thin (10 micron) Si layer from a thin (1 micron) high Z element over-layer at two different spacecraft aluminum shielding masses

![Graph showing particle flux and fission probability normalized to Tungsten = 1](image)

**Explanation**

The number of high LET (> 10 MeV cm²/mg (Si)) particles entering the 10μ Si shells at **median shielding masses of 31 and 77 g/cm² Al** correlates with the atomic number of the 1μ high Z element over layer on the Si shell through the fissility parameter, \(Z^2/A\).

Increasing high Z element content in modern semiconductor device structures can lead to unexpectedly high upset or latch-up rates at high spacecraft shielding mass. Fission of high Z element nuclei by secondary particle shower species is the probable cause.

### 3.0: CR effects on human health and safety

Some comparative (Earth environment) radiation doses and their effects

3.1: Biological Effects of Cosmic Radiation – Earth Surface Environments

- Earth surface ionizing radiation dose environments are dominated by natural radioisotope decay and man-made radiation source
  - Radon gas is the most important contributor
- CR contributions are on the order of 10% of the natural environment

Sources of Radiation Exposure in the United States

- Cosmic (Space) - 5%
- Terrestrial (Soil) - 3%
- Internal - 5%
- Medical Procedures - 36%
- Industrial and Occupational - 0.1%
- Consumer Products - 2%
- Nuclear Medicine - 12%

Natural Sources - 50% (~310 millirem (0.31 rem))
Manmade Sources - 50% (~310 millirem (0.31 rem))

Full report is available on the NCRP Web site at www.NCRPpublications.org.

http://www.world-nuclear.org/info/inf05.html
3.2a: Biological Effects of Cosmic Radiation – Commercial and Military Aviation Environments – CRs determine the dose rate at high latitude/altitude

http://sol.spacenvironment.net/~nairas/Dose_Rates.html
The figure at right shows the NAIRAS prediction of the radiation exposure quantity related to biological risk - Effective dose rate (uSv/hr). To put the exposure rates into perspective, one chest X-ray is about 100 uSv, and a CT scan is about 8,000 uSv. The exposure rate on ISS ≈ 18-20 μSv/hr.
3.3a Biological Effects of Cosmic Radiation – Manned Space Flight Environments

**GUIDELINES**

- Code of Federal Regulations
- Crew & Area Dosimetry
- ALARA – “As Low As Reasonably Achievable”
- NASA Flight Rules, e.g., No EVAs in South Atlantic Anomaly
- Crew annual and career dose limits

**CREW DOSE LIMITS**

<table>

BFO – BLOOD-FORMING ORGAN
CNS – CENTRAL NERVOUS SYSTEM
cGy-Eq. (centi Gray-Equivalent) = cSv (centi Sievert)

Based on a limit of 3% radiation exposure induced (premature) death (REID) with 95% confidence level (Code of Federal Regulations).

Also, the new Crew Exploration Vehicle (CEV) design objective is 150 mSv per year, down from historical 500 mSv per year as driven by uncertainty in the dose-REID relationship in the primary CR dominated space radiation environment.
3.3b Biological Effects of Cosmic Radiation – Manned Space Flight Environments

**Spaceflight Radiation Examples - Human Spaceflight Mission Type Radiation Dose:**

Assuming 20 to 50 g/cm$^2$ Al shielding and not including secondary particle shower effects internal to the human body which can increase effective dose by about 50%.

- **Space Shuttle Mission 41-C**
  (8-day mission orbiting the Earth at 460 km)  
  5.59 mSv

- **Apollo 14**
  (9-day mission to the Moon)  
  11.4 mSv

- **Skylab 4**
  (87-day mission orbiting the Earth at 473 km)  
  178 mSv

- **International Space Station (ISS) Mission**
  (up to 6 months orbiting Earth at 353 km)  
  160 mSv

- **Estimated Mars mission (3 years)**  
  1200 mSv

Slow accumulation of whole body dose from GCR (expressed in Effective equivalent Sv) and including secondary particle showers in the human body presently limits the duration of manned space operations outside earth’s magnetosphere to times on the order of 180 days (assuming 20 to 30 g/cm$^2$ shielding mass). The overall programmatic cost of the available active or passive shielding needed to extend that limit is likely prohibitive at this time. (Francis A. Cucinotta, Myung-Hee Y. Kim, Lei Ren; “Evaluating shielding effectiveness for reducing space radiation cancer risks,” Radiation Measurements 41 (2006) 1173 – 1185)
Spacecraft shielding mass estimates for career dose limits of: 1) 150 mSv (x - new) and 2) 1000 mSv (Δ - old) and mission durations of 1 to 4 years (median atmospheric shielding mass)
NASA HZETRN 2010 estimates of crew dose vs. shielding mass for a 3 year interplanetary mission assuming solar Maximum and solar minimum GCR environments and no SEP event contributions and both the 10 and 100 cSv career dose limits.
Assumed Hybrid DSH Dimensions

• Pressurized Core Volume (excludes any inflatable envelope outside)
  – Cylinder
    • 4.5 meters (450 cm) diameter
    • 6 meters (600 cm) long
    • Volume = 95.43 cubic meters
    • Lateral surface area = $8.48 \times 10^5$ square centimeters
    • Total end cap surface area = $3.18 \times 10^5$ square centimeters

• Crew quarters located on one end of the pressurized core volume
  – Cylinder
    • 4.5 (450 cm) meters diameter
    • 3 meters (300 cm) long
    • Volume 47.7 cubic meters
    • Lateral surface area $4.24 \times 10^5$ square centimeters
    • End cap (2 of) surface area = $3.18 \times 10^5$ square centimeters
### Shielding mass total (kg) for a specific DSH hybrid habitat (minimum atmospheric shielding mass estimate)

<table>
<thead>
<tr>
<th>Mission Duration (years)</th>

</tr>
</tbody>
</table>

Combinations with launch costs less than 2 billion dollars are highlighted in red. Note the cost benefit of building the spacecraft in LEO for departure from LEO (or launching to LEO and transporting to an earth-moon LaGrange point using relatively low cost ($1 to $3 billion) reusable solar electric tugs)!
The effects of energetic cosmic ray, solar particle event, and trapped radiation charged particles on contemporary electronic systems as well as human health and safety depends on:

- The production of ionization/excitation tracks in target materials
- Collisions with target material nuclei to initiate secondary particle showers

CR secondary particle shower species, especially neutrons, dominate effects on electronic systems and human health at high shielding mass

- Earth surface operating environments
- High altitude aircraft operating environments
- Heavily shielded manned spacecraft
- In massive targets, like the human body, secondary particle showers can contribute on the order of 50% of the total body dose expressed in Sv

SEE effects on electronic systems can be managed by: 1) selection of resistant parts, 2) EDAC and FDIR functions, and 3) robust/highly redundant system architectures

Shielding mass can mitigate electronic system TID and SEE effects from SPE and trapped radiation but is largely ineffective against GCR

Slow accumulation of whole body dose (expressed in Sv) from GCR presently limits the duration of manned space operations outside earth’s magnetosphere to times on the order of 180 days. The overall programmatic cost of the available active or passive shielding needed to extend that limit is prohibitive at this time
5.0 Supporting Data: Modeling and Calculation Methods

Energetic Particle Interactions with Materials
Direct ionization & excitation of target substance

- High speed charged particles decelerate by losing energy to target substance electrons during coulombic collisions leaving an ionization/excitation damage track
  - Nuclear collisions make little contribution to deceleration except at the lowest kinetic energies near end of track.
- \( \frac{dE}{dx} \) is the rate of energy transfer: keV/micron or MeV-cm\(^2\)/mg in a particular target substance
  - Linear and nearly constant over most of the particle range - hence the term linear energy transfer (LET)
  - Nonlinear near end of track – most of the energy is deposited near the end of track in the “Brag Peak”; basis of accelerator hadron therapy for certain cancers
- Quantified by the relativistic Bethe-Bloch equation

\[
\frac{dE}{dx} = \frac{4\pi}{m_e c^2} \cdot \frac{n z^2}{\beta^2} \cdot \left( \frac{e^2}{4\pi \varepsilon_0} \right)^2 \cdot \ln \left( \frac{2m_e c^2 \beta^2}{\gamma (1 - \beta^2)} \right) - \beta^2
\]

 Projectile (cosmic ray particle) dependencies
\( \beta = \frac{v}{c} \); \( v = \) velocity of the particle; \( E = \) energy of the particle; \( x = \) distance travelled by the particle in the target; \( c = \) speed of light; \( z = \) particle charge; \( \varepsilon_0 = \) vacuum permittivity

 Target substance dependencies
\( I = \) mean excitation potential of the target = 10eV(Z), \( n = \) electron density of the target = \( \frac{N_A Z \rho}{A M_u} \); \( \rho = \) density of the target; \( Z = \) target atomic number; \( A = \) target atomic mass number; \( N_A = \) Avogadro number; and \( M_u = \) Molar mass constant = 1 in Si units; \( e = \) charge of the electron; \( m_e = \) rest mass of the electron

Photographic/nuclear emulsion tracks - Image Credit - PROF. P. FOWLER, UNIVERSITY OF BRISTOL

CR-39 (polycarbonate thin plastic sheet) solid state nuclear track detector SSNTD – ISS
Tracks are revealed by etching the plastic post flight
Nuclear Reactions and Secondary Particle Showers

- Inelastic collisions attenuate the primary flux exponentially and generate secondary particle showers via nuclear reactions
  - \( N(l) = N(0) \exp(-l/\lambda) \)
    - \( \lambda \) = inelastic collision length (grams/cm\(^2\))
    - \( l \) = thickness in g/cm\(^2\)
  - \( \lambda \) ranges from 42 g/cm\(^2\) to 118 g/cm\(^2\) for protons in various materials
  - At fixed target mass, number of collisions decreases with increasing atomic weight (i.e. fewer target nuclei per gram)
    - \( \lambda \) Scales as (projectile atomic number)\(^{0.77}\)
    - \( \lambda \) increases with target atomic number
  - \( <n_{\text{event}}> \) = average number of secondary particles per collision event
  - \( <n_{\text{collision}}> \) is proportional to \( A(\text{projectile}) \times A(\text{target}) \times \) (average nuclear thickness function)
  - \( <n_{\text{shower}}> \) is proportional to primary projectile energy

False-color emulsion photo of a cosmic ray sulfur nucleus (red) colliding with a nucleus in the emulsion. The collision produces a spray of other particles: a fluorine nucleus (green), other nuclear fragments (blue) & 16 pions (yellow). The length of the sulfur track is 0.11 mm. The curlicues which adorn the track of the sulfur nucleus are electrons which it has knocked out of atoms in passing. The photograph was taken in 1950 by Cecil Powell, the English physicist who pioneered the use of photographic emulsions to record the tracks of electrically charged particles.
Solid State Devices as Charged Particle Detectors

1) Solid state electronic devices as charged particle detectors: Single Event Effects (SEE)
   - Solid state ionizing radiation detectors and most modern microelectronic devices share a common basic physical feature – the reverse biased P-N junction and corresponding depletion region.
   - Energetic charged particles traversing the device depletion region cause ionization, i.e. a large number of mobile charge carriers, along the particle track
   - The applied reverse bias voltage rapidly collects the mobile charge carriers so that:
     • A current pulse appears in the external circuit
     • The voltage across the depletion region collapses briefly and that voltage appears as a voltage pulse elsewhere in the external circuit leading to data corruption or even hardware failure

2) Solid state electronic devices as charged particle detectors: Total Ionizing Dose (TID) Effects
   - Driven by accumulation of trapped charge in SiOx isolation layers in the device
   - Both Si based bipolar and Si based MOS Technologies are affected
   - Accumulation of trapped charges in SiOx layers leads to changes in device characteristics and eventually device failure
   - TID to failure varies widely with device type, elemental composition, and device architecture – SiOx layer location and thickness is important for Si devices
   - Failure dose ranges from $10^3$ rad (Si) to more than $10^7$ rad (Si) depending on the degree of TID hardening by design for each device type and elemental composition
CR effects on human health and safety

- Exposing cells to ionizing radiation leads to lethality, mutation induction, and carcinogenesis
- Primary and secondary cosmic ray particles transfer energy, proportional to charged particle LET \( = \frac{dE}{dx} \), to atoms and molecules in the cellular structure along the particle ionization track so as to:
  - Produce free radicals
  - Break chemical bonds
  - Produce new chemical bonds and cross-linkage between macromolecules
  - Damage molecules and molecular assemblies that regulate vital cell processes (e.g. DNA, RNA, proteins, and membrane lipid structures)
- Ionizing radiation induces both direct biomolecule damage and indirect biomolecule damage through the radiolysis of water.
  - At low doses (i.e. damage rates), such as what we receive every day from background radiation, the cells repair the damaged molecules rapidly enough to survive
  - At higher doses (up to 1000 mSv), the cells might not be able to repair the damage rapidly enough, and the cells may either be changed permanently or die.
- Cells changed permanently may go on to produce abnormal cells when they divide. In the right circumstance, these cells may become cancerous. This is the origin of our increased risk in cancer, as a result of radiation exposure.
  - Bystander cells can also be affected via intracellular signal transduction pathways

http://www.pnas.org/content/102/40/14127/F1.large.jpg
Natural Environment Definitions: CREME 96, Peterson Figure of Merit, and FLUKA Natural Environment Parameters

- CREME 96 and FOM input natural environments for calculations (16)
  - GEO/Interplanetary Fluxes, Solar Minimum, Z=1-92
  - ISS: 362km/51.6°, Solar Minimum,

- FLUKA input natural environments for calculations
  - Uses a subset of the CREME-96 Environments as shown below
    - H, He, C, O, Mg, Si, Fe
    - Accounts for 98% + of total GCR flux
    - Increases computational speed and efficiency with negligible impact on accuracy
FLUKA Methods Overview

- **FLUKA Monte Carlo nuclear reaction and transport code (1)**
  - Theory driven and benchmarked with data - Based on original and verified microscopic interactions models
    - FLUKA is not a tool kit, rather a transport code with fully integrated physics models
    - First principle model – no adjustable parameters – does not rely on extrapolated empirical look-up tables
      - Nucleus-nucleus interactions from 100 MeV/n to 10000 TeV/n
      - Hadron-hadron and hadron-nucleus interactions 0–10000 TeV
      - Exact dE/dx ionization (LET) calculation with delta ray production and statistical fluctuations
      - No limitation on projectile/target composition or combination

- **Simple 3D spacecraft model**
  - Concentric spherical shells – simple shielding mass distribution function for each shell
    - 10 μ thick Si “detector” shells at various shielding mass depths – optional 1 μ metallization layers on outward facing Si shell surface (a generic microelectronic device structure)
    - Report TID and nuclear reaction rates for each Si or metallization shell
    - Report LET spectra entering outward facing surface of Si detector shell

- **SEE rate calculations**
  - Calculate SEE rates with:
    - Differential LET spectrum entering each Si detector shell at each shielding depth in the concentric sphere structure (Includes all secondary particle production in “spacecraft shielding mass and metallization layers”)
    - Directional cross section function, \( \sigma(\text{LET,}\Theta,\Phi) \), from device heavy ion test data
  - Same \( \sigma(\text{LET,}\Theta,\Phi) \) in FLUKA, CREME-96, and Petersen Figure of Merit (FOM) calculations
• Spacecraft shielding simulated using FLUKA 3D concentric spherical shells

• 10 micron Si detector shells are inserted at different shielding depths with optional 11 micron heavy element shells (over-layers) on the silicon shells

• Each concentric shell is a FLUKA “region” with specific boundary surfaces.

• The volume of the sphere at radii smaller than 5000 cm is treated as a perfect particle absorber in all FLUKA calculations reported here.

• FLUKA reports the number of particles of LET X entering the 10μ Si detector shells per primary particle, as well as the number of nuclear reactions and total energy deposition (TID), also per primary particle, internal to each of the concentric spherical shell shielding shells, 10μ Si shells, or 1μ metal shells on the Si shells.
• FLUKA launches randomly directed energetic particles into the 3D concentric spherical model spacecraft structure, thereby sampling the full shielding mass distribution function of the model.
  • Simulates an isotropic particle flux on a concentric spherical shell structure.
• The shielding mass distribution function metrics (Table 1 below) corresponding to each of the 10µ Si detector shells (or 1µ over layer shells) are used for data reporting and comparison.
• Example – shielding mass distribution function metrics values in g/cm² Al for each Si shell in the concentric spherical spacecraft model. Metrics for another shielding material, X, can be obtained by multiplying the density ratio, ρₓ/ρ_{Al}.

Spacecraft shielding mass and secondary particle shower effects are calculated using the FLUKA (FLUktuierende Kaskade) (ref. 1) Monte Carlo nuclear reaction and transport code applied to a hollow concentric spherical shell spacecraft model and the natural LEO and interplanetary primary particle environments on the previous slide.

The generic spacecraft structure model consists of a hollow spherical shell structure (shown in cross section to the right) with an inner radius of 5000 cm and an outer radius of 5037 cm.

Various thicknesses of Al shielding material overlay eight thin Si detector (scoring shells) labeled SiDet1 to SiDet 8, moving from the exterior of the sphere to the interior. See Table 1 for the median Al shielding mass overlying each Si detector shell.

FLUKA 2008.3b Calculation Details - Estimating the in-flight SEU rate from the FLUKA LET Spectrum and the Device Heavy Ion Test Data

- FLUKA simulations produce the differential form of the LET spectra entering each 10μ Si shell
  - Forward going particles only reported here – backward going particle fluxes are also calculated, but do not contribute significantly to the result
  - FLUKA “USRYIELD” utility used to recover LET spectra of particles crossing boundaries
  - Results reported on a per geometric region or region boundary and per primary particle basis
  - Scaling to on-orbit primary particle flux/fluence

- Use the integral form of the microelectronic device directional cross section \( \sigma(LET, \Theta, \Phi) \) and the following \( \sigma(LET, \Theta, \Phi) \) approximations as determined by the test/flight data sources

  - The x y plane is the plane of the microelectronic device die

  - \( \Theta \) and \( \Phi \) define the entry angle of a particle in the microelectronic device coordinate system
  - \( \sigma(LET, \Theta, \Phi) \) represented as a simple geometric solid with a specific aspect ratio (width/thickness)
    - Isotropic Target, (17) \( \sigma(L, \theta) = \sigma_N(L) \) for all \( \theta \) sometimes observed especially for CMOS DRAM
    - Cosine Law Target, (17), \( \sigma(L, \theta) = |\cos \theta| \sigma_N( L / |\cos \theta| ) \) up to \( \theta = 60 \) degrees, commonly observed, (17)
    - Right Circular Cylinder (RCC) Target, (18-21). Note that we use the average (first moment) cord length for a given \( \theta \), not the full chord length distribution

- The on-orbit rate estimate is then given by: \( \text{Upset Rate} = \iiint f(LET) \times \sigma(LET, \Theta, \Phi) \, \text{d}(LET)\text{d}(\Theta) \text{d}(\Phi) \)
Estimating Total Ionizing Dose (TID) and nuclear reaction (star) rates per unit volume
- FLUKA “SCORE” utility reports total ionizing dose and nuclear reactions (“stars”) caused by all:
  - Protons
  - Neutrons
  - Pions
- SCORE also reports expected in-flight total ionizing dose and “star” density using concentric spherical shell model dimensions and with scaling to on-orbit primary particle flux/fluence values

How do we know all this works (method validation/success metric)?
- Calculate least squares error metric – \( \Sigma (\text{in-flight rate} - \text{estimated rate})^2 \) as a generic quality assessment of the various SEE rate estimate methods
- If in-flight rate predictions are within “a factor of a few” of the pre-flight predictions the method is usually considered more than adequate for practical work (17)
- As a minimum, the on-orbit SEE rate calculation method should provide SEE rate estimates accurate to within a factor of 10 at one standard deviation when compared to available in-flight data (22-24)

Run-to-run variability and error bars in Monte Carlo calculations
- Monte Carlo models simulate real physical experiments or measurements including natural (random) quantum and statistical fluctuations, so the results of two statistically independent runs are not expected to be equal.
- As is the case for radioisotope decay, and other Poisson processes, the uncertainty in a Monte Carlo particle or event count is equal to the square root of the number of particles or events in the result
- In the following, plot symbols are always selected to be larger than or equal to the expected error of the numbers plotted unless two statistically independent FLUKA runs are plotted, in which case the error plot represents the spread in the data points directly

Supporting Data: References & Device Parameters
Abstract

In this paper we review the discovery of cosmic ray effects on the performance and reliability of microelectronic systems as well as on human health and safety, as well as the development of the engineering and health science tools used to evaluate and mitigate cosmic ray effects in earth surface, atmospheric flight, and space flight environments.

Three twentieth century technological developments, 1) high altitude commercial and military aircraft; 2) manned and unmanned spacecraft; and 3) increasingly complex and sensitive solid state micro-electronics systems, have driven an ongoing evolution of basic cosmic ray science into a set of practical engineering tools (e.g. ground based test methods as well as high energy particle transport and reaction codes) needed to design, test, and verify the safety and reliability of modern complex electronic systems as well as effects on human health and safety.

The effects of primary cosmic ray particles, and secondary particle showers produced by nuclear reactions with spacecraft materials, can determine the design and verification processes (as well as the total dollar cost) for manned and unmanned spacecraft avionics systems. Similar considerations apply to commercial and military aircraft operating at high latitudes and altitudes near the atmospheric Pfotzer maximum. Even ground based computational and controls systems can be negatively affected by secondary particle showers at the Earth’s surface, especially if the net target area of the sensitive electronic system components is large.

Accumulation of both primary cosmic ray and secondary cosmic ray induced particle shower radiation dose is an important health and safety consideration for commercial or military air crews operating at high altitude/latitude and is also one of the most important factors presently limiting manned space flight operations beyond low-Earth orbit (LEO).

  - 1000 grams/cm² air shielding mass at sea level
  - latitude dependent geomagnetic shielding
  - GCR secondary particle shower products dominate

- **Commercial and military aviation environments**
  - Altitude dependent air shielding mass
  - latitude dependent geomagnetic shielding
  - Solar cycle modulation of GCR environment
  - Latitude dependent solar particle event exposure
  - Pfotzer secondary shower particle maximum at about 20 km altitude (mid latitudes)

Relative variation of cosmic ray flux at the earth's surface as a function of altitude and latitude (Cosmogenic Nuclide Laboratory - University of Glasgow - [http://web2.ges.gla.ac.uk/~dfabel/CN_explain.html](http://web2.ges.gla.ac.uk/~dfabel/CN_explain.html))

Biological Effects of Cosmic Radiation – Commercial and Military Aviation Environments

**NAIRAS** Operational Distributed Network System Architecture

*NAIRAS - Nowcast of Atmospheric Ionizing Radiation for Aviation Safety*
Discovery of GCR – observations from developing electrical technology (1785 to 1926)

- 1785 - Coulomb: reports spontaneous discharge
- 1835 - Faraday: confirms spontaneous discharge
- 1879 - Crooks: reduced discharge rate at reduced pressure
- 1896 - Bequerel/Curie: radioactivity discovered
- 1910 - Wolf climbs Eiffel tower with electroscope
- 1910 - Pacini: Discharge rate lower under water
- 1912 - Hess: After an initial drop, discharge rate increases steadily with altitude during balloon flights
- 1920s – Compton and Millikan: particles or photons?
- By 1926 a consensus was reached on what cosmic rays are (mostly energetic charged particles with some small number of energetic photons), and it all began with observations that capacitors can discharge in an unexpected way.
