

Application of ASTM E-1559 apparatus to study H₂O desorption

MICHAEL WORONOWICZ RADFORD PERRY III GEORGE MEADOWS SGT, INC.

2015 CONTAMINATION, COATINGS, MATERIALS, AND PLANETARY PROTECTION WORKSHOP NASA GODDARD SPACE FLIGHT CENTER 29-31 JULY 2015

Outline

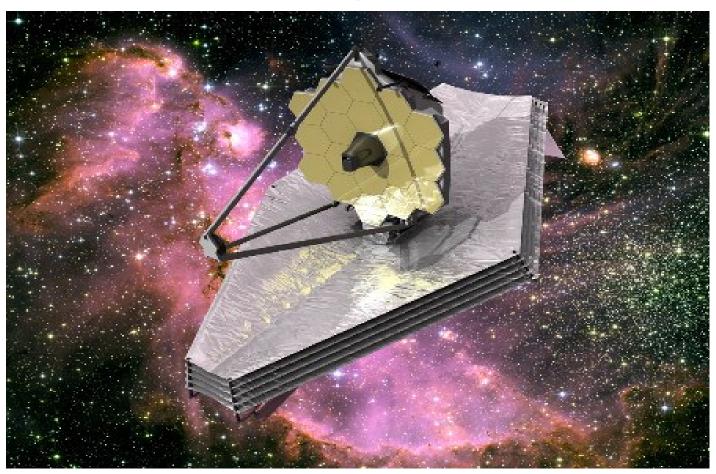

- Introduction
- Objectives
- Math model development
 - Clausius-Clayperon
 - Quantum Statistical Mechanics
- Selected candidate expressions
- ASTM E-1559 apparatus "MOLEKIT"
 - Physical description
 - Outgassing measurement procedure
 - Adaptation to desorption measurements
- Results & Discussion
- Concluding Remarks

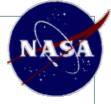

JWST Observatory

Introduction (2 of 3)

4

- James Webb Space Telescope (JWST)
 - Designed to operate for five years at L2
 - Contains four IR instruments operating below 50 K
 - Sunshield must reject nearly all solar input
 - **Radiative properties extremely sensitive to water vapor deposits**
- Electronics compartment on shadowed side will outgas more than enough water vapor to ruin sunshield effectiveness
 - Design vent to also collect sufficient fraction of water vapor
 - Account for temperature-dependent desorption of condensed material

Introduction (3 of 3)

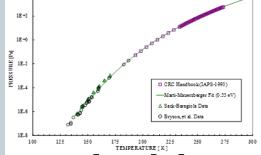

5

• Noted $p_{v,H2O}$ models tended to disagree at temperatures in

range of interest (120—140 K)

- Typically based on data above 150 K
- None found using data below 131 K
- What model to use?
- Researchers cited limits for thermal control stability
- Our group has experience with ASTM E-1559 apparatus used to collect volatile outgassing rates down to liquid nitrogen temperatures (~90 K)
 - Can measure source rates of picograms/s
 - Very stable thermal conditions
- Simple matter to adapt to H₂O desorption study at cryogenic temperatures

Objectives

- Review formulation of water vapor desorption models
 - Features of high-fidelity physical expressions
 - Selected candidates
- Discuss use of NASA-GSFC outgassing measurement apparatus
 - "MOLEKIT" = "Molecular Kinetics", ASTM E-1559 system
 - Sketch of operational procedures
 - Adaptation to desorption measurements

Outline

- Introduction
- Objectives
- Math model development

 - Adaptation to desorption measurements
- Results & Discussion
- Concluding Remarks

Clausius-Clayperon

8

- Thermodynamically, equilibrium condition for single species in multiple phases characterized by minimum value for Gibbs free energy *G*
 - Obtained when *G* per mole is equal for each phase
 - Consequence of this condition gives *p* as function of *T*

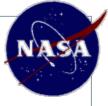

$$\frac{dp}{dT} = \frac{\Delta s}{\Delta v} = \frac{l}{T\Delta v} = \frac{p \, l}{RT^2}$$

 For constant heat of transformation I, obtain Arrheniustype expression

$$p_v(T) = p_{\text{ref}} \exp\left(\frac{-l}{RT}\right) = \exp\left(C - \frac{\Theta}{T}\right)$$

Quantum Statistical Mechanics

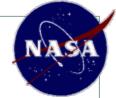

- On molecular scale, work with chemical potential μ , like Gibbs free energy per molecule
 - Determine chemical potentials for solid and gas are equal
- ullet Molecular ensemble described by number of energy states available to phases, increases with T
 - Somewhat convoluted path for solid phase 1, easier to describe gas phase 2 (monatomic)

$$\mu_{1}(T) = -\eta - T \int_{0}^{T} \frac{dT}{T'^{2}} \int_{0}^{T'} c(T'') dT'' \qquad \qquad \mu_{2} = -kT \ln \left[\frac{kT}{p_{2}} \left(\frac{2\pi mkT}{h^{2}} \right)^{\frac{3}{2}} \right]$$

$$p_{2}(T) = \exp\left\{\ln\left[\frac{(2\pi m)^{\frac{3}{2}}k^{\frac{5}{2}}}{h^{3}}\right] + \frac{5}{2}\ln(T) - \frac{\eta}{kT} - \int_{0}^{T}\frac{dT}{kT'^{2}}\int_{0}^{T'}c(T'')dT''\right\}.$$

Quantum Stat. Mech.—Diatomic Gas

 For a diatomic gas, must incorporate influence of internal degrees of freedom (rotational+vibrational)

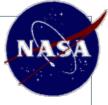

$$\mu_{2, \text{ diatomic}} \approx -kT \ln \left[\frac{kT}{p_2} \left(\frac{2\pi mkT}{h^2} \right)^{\frac{3}{2}} \frac{I_{\text{rot}}kT}{\hbar^2} \exp \left(-\frac{\hbar \omega}{2kT} \right) \right]$$

$$p_{2, \text{diatomic}}(T) \approx \exp \left\{ \ln \left[\frac{I_{\text{rot}} k^{\frac{7}{2}}}{\hbar^5} \left(\frac{m}{2\pi} \right)^{\frac{3}{2}} \right] + \frac{7}{2} \ln(T) - \frac{(\eta + \hbar \omega/2)}{kT} - \int_0^T \frac{dT}{kT'^2} \int_0^{T'} c(T'') dT'' \right\}$$

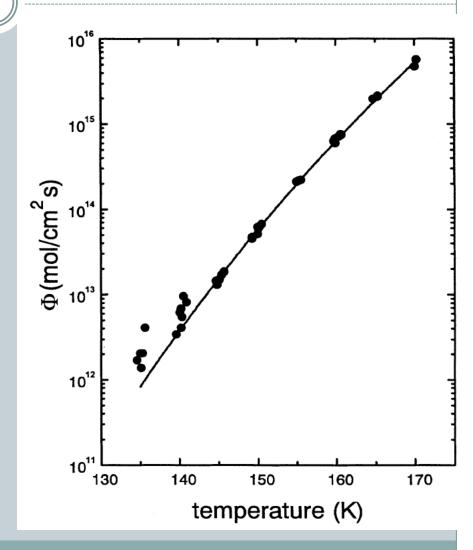

- Notice heat of transformation term becomes modified!
- Water vapor is polyatomic, approximate internal d.f. physical models become increasingly approximate
 - Punt—replace terms in exponential with fit parameters, functions of temperature

Sack-Baragiola Observations

- Sack & Baragiola managed to produce sublimation data down to 135 K
 - Very careful to distinguish between different types of solid phase ice
 - × Hexagonal crystalline
 - Cubic crystalline
 - **Amorphous**
- Noted that vapor deposited at low temperatures not necessarily in most equilibrium state, will relax with time, temp. dep.

Sack-Baragiola Formula

12

 Sack & Baragiola recommended the following formula for "stable crystalline" phase ice based on stat. mech. arguments:

$$p_{v,S-B} = BT^4 \exp\left(-E/kT\right) = \exp\left[\ln B + 4\ln\left(T\right) - \frac{E}{kT}\right]$$

- $o(B,E) = (29.3 \text{ Pa/K}^4, 10.375 \text{ kcal/mole})$
- \circ E identified as heat of sublimation = 0.45 \pm 0.03 eV
- Amorphous phase vapor pressure identified as being 100x higher
 - **Review of paper indicates this rate should be less than 30x higher**

Murphy-Koop Formula

13

 Murphy & Koop discussed review of various authors, devised vapor pressure fit claiming use of Clausius-Clayperon equation, but accounting for temperature dependent behavior:

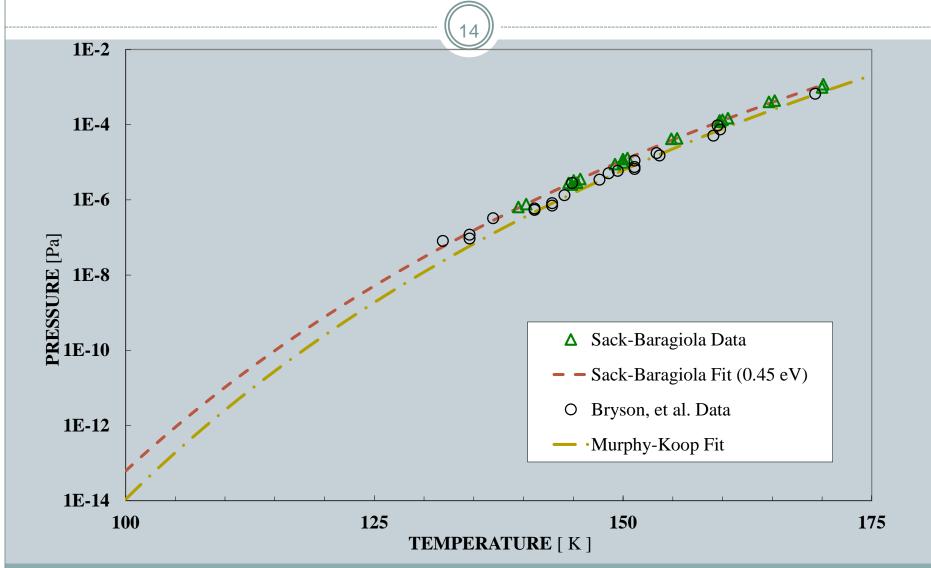

$$p_{v, \text{M-K}}$$
 [Pa] = exp $\left[9.550426 + 3.53068 \ln(T) - \frac{5723.265}{T} - 0.00728332 T \right]$

- based on
 - Solid phase ice specific heat data down to 110 K
 - ▼ Non-ideal gas behavior
 - Did M-K actually resort to stat. mech. arguments?
 - Not directly based on vapor pressure data

Model Comparison

Outline

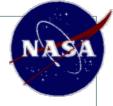

- Introduction
- Objectives
- Math model development
 - Clausius-Clayperon
 - Quantum Statistical Mechanics
- Selected candidate expressions
- ASTM E-1559 apparatus "MOLEKIT"
 - Physical description
 - Outgassing measurement procedure
 - Adaptation to desorption measurements
- Results & Discussion
- Concluding Remarks

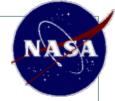

Rationale

- Found very little $p_{v. H2O}$ data below 150 K, none below 131 K
- Description of Sack-Baragiola apparatus mentioned sensitivity level of 5.0e-4 molecular monolayers/s
 - May translate to a QCM sensitivity exceeding 10 Hz/hr
- Test times typically limited to < 15 min
 - Certain runs lasted ~ 3 hrs.
- NASA GSFC possesses an ASTM E-1559 apparatus designed to measure outgassing from sample materials for gases condensable as low as LN₂ would allow
- Often exhibits measurement stability within 0.1 Hz/hr over days-long periods
 - o Could we measure vapor pressure levels two OOM below others?

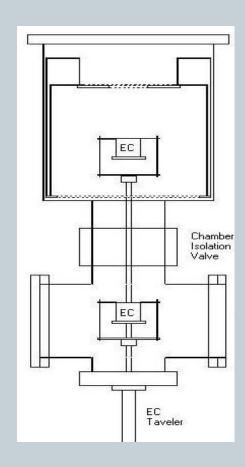

MOLEKIT Description (Genl.)

- Two vacuum chambers
 - Test chamber
 - Loading chamber
- Sample of test material inserted into Effusion Cell
 - Temperature controlled
 - Sample limited to < 2" cube</p>
- Heated, translated from loading chamber into test chamber

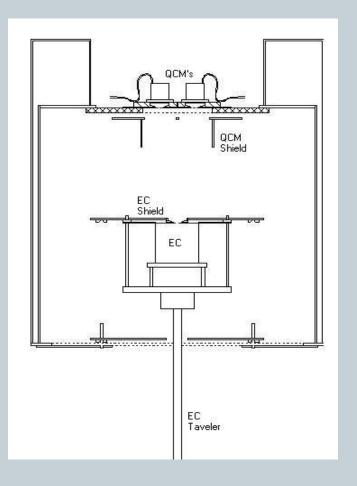

MOLEKIT Description (Test Chamber)

- $(d, L) \approx (36", 46")$
- LN₂ cooled walls
- Four QCM's
 - Cryogenically cooled (CQCM's)
 - Temperatures individually controlled
 - Fixed, known viewfactors to EC
 - Can relate QCM collection rate to source outgassing rate (translate from Hz/hr to g/cm²/s)
- Under equilibrium, $p_v = \dot{\phi} \sqrt{2\pi RT}$

General Test Procedure

- QCM's set to pre-selected temperatures
- Typically begins with thermal stability period (~15-20 hrs.)
 - Empty chamber, collect data on how frequency changes with time
 - Often exhibits variability at or below 0.1 Hz/hr
- Sample weighed, loaded into EC, loading chamber evacuated
- EC travels into test chamber position, warmed to $T_{
 m op}$
- Sample exposed to test conditions over pre-determined period or when QCM buildup rates have dropped below detectable limits
- Sample returned to loading chamber, chamber repressurized, sample removed and weighed

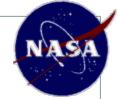

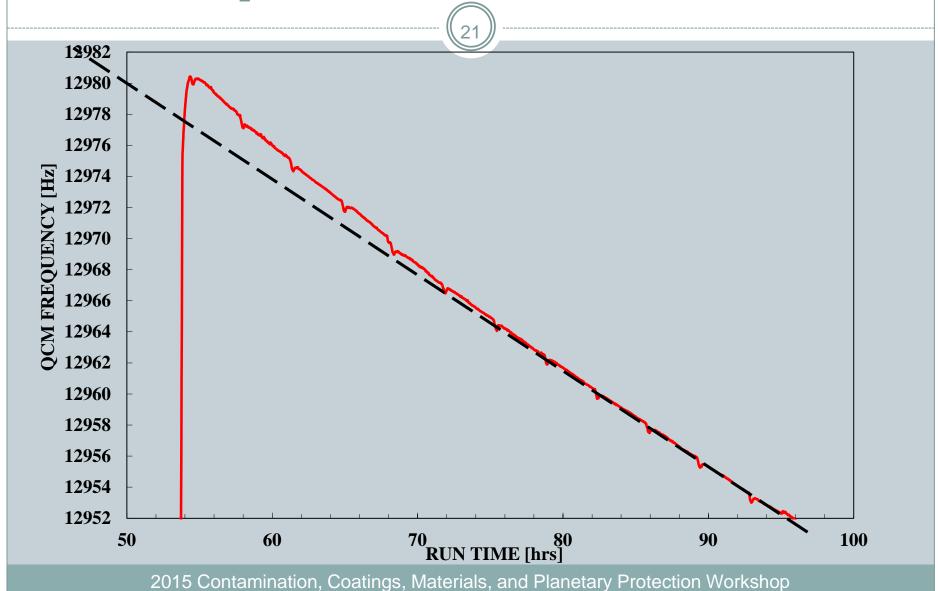

Desorption Test Procedure

- Select test sample that releases H₂O, not much else
 - From experience, chose G10 fiberglass block, exposed to atmospheric conditions
 - Similar to JWST electronics compartment material
- QCM's collect vapor at various, steady, cryogenic temps.
 - Chose temperatures between 90—140 K
- After sufficient amount of vapor collected, withdraw sample
 - Arbitrary minimum change in frequency ~ 10 kHz
- Continue operating QCM's at constant temperature, record desorption rates every minute over next 1-2 days

Sample Test Run Results (125 K)

Observation—Phase Change

- 22)
- Some results exhibited higher initial slopes that relaxed to lower, steady values over time (on order of one day)
 - Similar to behavior recorded by Sack & Baragiola, but rate enhancements were much lower here, less than 2x
 - Identified as solid phase transition to more stable form
 - S-B test runs lasted less than four hours apiece
 - x Typically 15 min
 - S-B noted that prior deposition rate factored into amount of amorphous phase desorption rate
 - Uncontrolled in this study

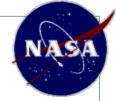

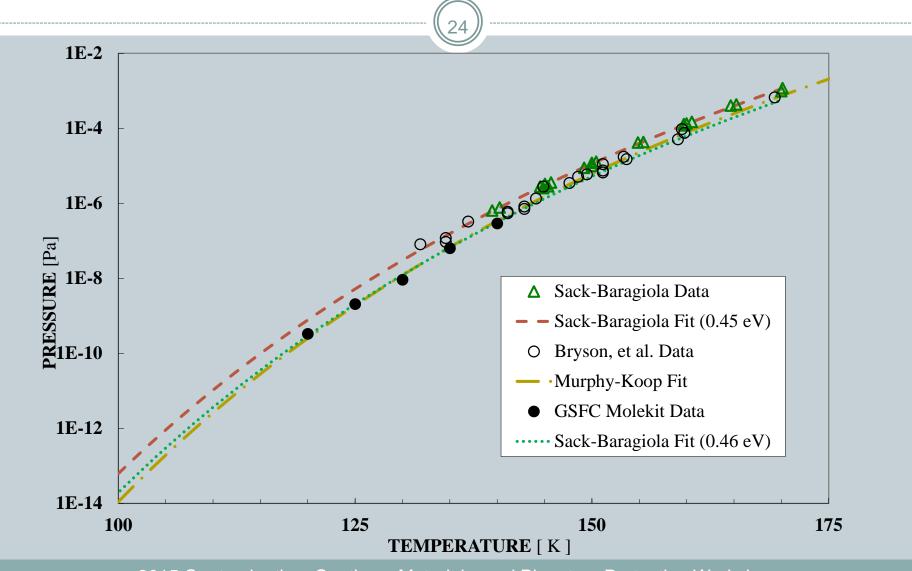

Results

- Performed two runs, attempted to collect data between 120 140 K, along with one QCM operating at coldest possible temperature (~90 K)
- Data collected on 90 K demonstrated massive out-of-family behavior, suggests current arrangement would have trouble obtaining useful data below 120 K
 - Could be interference from desorption of H₂O from test chamber walls at 90 K (big area compared to QCM sensor < 1 cm²)

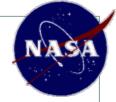

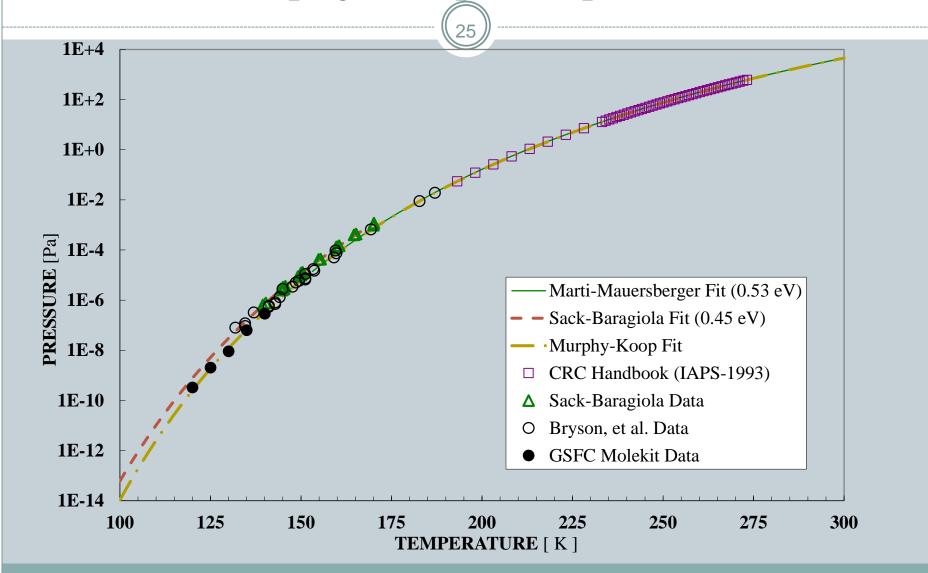

Model Comparison w/ Test Data

Murphy-Koop Comparison

Concluding Remarks

- Based on comparisons with other investigators, it appears test runs were long enough to firmly establish hexagonal crystalline water vapor desorption rates down to 120 K
- Narrow data set appears to confirm accuracy of Murphy-Koop model formulation
 - Established theoretical basis for form of equation
- JWST project may request further testing to confirm current data
