NASA's IV&V Program

- NASA's IV&V Program: established in 1993
- Founded under the NASA Office of Safety and Mission Assurance (OSMA) as a direct result of recommendations made by the National Research Council (NRC) and the Report of the Presidential Commission on the Space Shuttle Challenger Accident
- IV&V is an objective examination of safety and mission critical system and software processes and products

Three Key Parameters:

- Technical Independence
- Managerial Independence
- Financial Independence

Three Questions (3Qs) of IV&V:

Q1 - Will the system's software do what it is supposed to do? Q2 - Will the system's software not do what it is not supposed to do? Q3 - Will the system's software respond as expected under adverse conditions?

IV&V Technical Framework

- Objectives include the verification and validation of:
 - Concept Documentation
 - Requirements
 - Design
 - Implementation
 - Test Documentation
 - Operations and Maintenance

 Risk-significant adverse condition awareness brings forth off-nominal analysis threads aligned with hazards, dependability, emergent behavior, security, and testing

IV&V plays a role in the overall risk mitigation strategy applied throughout the lifecycle to improve the quality, reliability, safety, and security of critical software systems

Adverse Conditions

- Examining Q2 and Q3 are major challenges of FM software
- An *adverse condition* is considered a subset of an offnominal state that prevents a return to nominal operations and compromises mission success unless an effective response to the causal fault is employed
- How a system is architected to handle faults and adverse conditions is crucial for the satisfaction of functional and performance requirements for mission success.

Adverse condition awareness strengthens software assurance

Assurance Strategy

Raising adverse condition awareness identifies areas of significant risk to apply an adaptive, iterative analysis approach for software assurance

Capability-Based Assurance

- Enables software assurance workflow in an adaptive, risk-informed manner
- Identifies IV&V scope and rigor by prioritizing and framing analysis
- Infuses agility in order to accommodate change
- Crosses all lifecycle phases
- Influences static and dynamic test coverage
- Communicates findings and assurance conclusions more comprehensively
- Provides the mapping of critical capabilities to adverse conditions or hazard causes that are prevented or mitigated by software controls and verifications
- Reveals dependencies or vulnerabilities in capabilities that may indicate missing requirements, weak design, incomplete implementation, or a need for expanded test coverage, either static or dynamic

The goal of defining capabilities at the mission level is to be able to adequately understand and mitigate the riskiest aspects of the mission

Hazard Analysis

- Maintaining the health and safety of a system, or fault management, is a cross-cutting capability that is an integral part of assurance
- A system's prevention, detection, isolation, response, or tolerance of multiple faults and failures maintains mission capabilities despite adverse conditions
- Assessing hazard causes, controls, mitigations and verifications is part of adverse condition awareness that can not be "done and forgotten" at the outset of a project, or worse, left to the end during system integration testing
- Evaluating multiple project artifacts, sources of adverse conditions to which the system should be capable of responding, occurs throughout the lifecycle
- Identifying unforeseen adverse conditions that may impede mission success or inhibit safety is an assurance service of great value to a project, ensuring that coverage is complete with respect to safety, security, and dependability

Independent analysis based on solid system understanding and experience with similar systems allows analysts to generate adverse conditions to be considered

Adverse Condition Database

- Centralizes and compiles a comprehensive listing of adverse conditions in a cross-project repository with correlated data relevant across NASA missions
- Incorporates adverse condition awareness into all phases or for all objectives of analysis, throughout the development lifecycle, expanding Q3 coverage
- Provides the ability to map critical capabilities to adverse conditions or hazard causes that are prevented or mitigated by software controls
- Improves analysis by tracking adverse conditions and allowing queries based on project, mission type, domain/component, causal fault, and other key characteristics for cross-project fault management knowledge sharing
- Alerts analysts of vulnerabilities, architectural design weaknesses, and unforeseen or undesirable system behaviors in reaction to faults
- Identifies risk-significant scenarios that may be selected for dynamic testing

The Adverse Condition Database promotes assurance at a higher level of rigor with the goal of reducing risk and increasing confidence in NASA mission success

Value to NASA

- Collaboration and infusion of results will continue as the Adverse Condition Database is deployed to a wider audience and methods are enhanced to take advantage of the tool as a dynamic, living resource tailored to improve workflow in the ultimate goal of reducing risk and increasing confidence in NASA mission success
- As research progresses, the Adverse Condition Database and supporting assurance methodologies seek to:
 - Improve capability-based assurance from the provision of more comprehensive data
 - Provide more rigorous IV&V analysis from identification of off-nominal scenarios
 - Increase efficiency of analyst workflow and enable broader test coverage
 - Allow greater focus on FM and project areas of vulnerability or significant risk
 - Deliver support for reliability and resiliency for critical system safety

The complexity of fault management and the importance of effectively providing assurance that NASA safety- and mission-critical software will operate reliably, safely, and securely demands rigorous attention to risk-significant adverse conditions
