# ABSTRACT

Since the beginning of its routine science operation in March 2015, the NASA SMAP observatory has been returning interference-mitigated brightness temperature observations at L-band (1.41 GHz) frequency from space. The resulting data enable frequent global mapping of soil moisture with a retrieval uncertainty below 0.040  $\text{m}^3/\text{m}^3$  at a 36 km spatial scale.

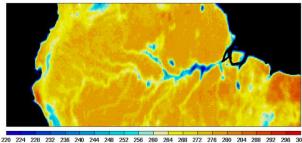

This paper describes the development and validation of an enhanced version of the current standard soil moisture product. Compared with the standard product that is posted on a 36 km grid, the new enhanced product is posted on a 9 km grid. Derived from the same time-ordered brightness temperature observations that feed the current standard passive soil moisture product, the enhanced passive soil moisture product leverages on the Backus-Gilbert optimal interpolation technique that more fully utilizes the additional information from the original radiometer observations to achieve global mapping of soil moisture with enhanced clarity. The resulting enhanced soil moisture product was assessed using long-term in situ soil moisture observations from core validation sites located in diverse biomes and was found to exhibit an average retrieval uncertainty below 0.040 m<sup>3</sup>/m<sup>3</sup>. As of December 2016, the enhanced soil moisture product has been made available to the public from

the NASA Distributed Active Archive Center at the National Snow and Ice Data Center.

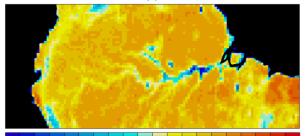

## **1. INTRODUCTION**

Since the beginning of its routine science operation in March 2015, the NASA Soil Moisture Active Passive (SMAP) observatory [1] has been returning interference-mitigated brightness temperature (T<sub>B</sub>) observations at L-band frequency (1.41 GHz) from space. The resulting data enable the production of the standard SMAP Passive Soil Moisture Product (L2\_SM\_P) [2] that provides frequent global mapping of soil moisture with a retrieval uncertainty below  $0.040 \text{ m}^3/\text{m}^3$  at a 36 km spatial scale [3].

Given the scanning geometry of the radiometer onboard the SMAP observatory, the time-ordered  $T_B$  observations in the standard Level 1 Brightness Temperature Product (L1B\_TB) [4] are oversampled (i.e., exceeding the Nyquist sampling rate) in the along-scan direction. By applying the Backus-Gilbert (BG) optimal interpolation technique [5][6] to L1B\_TB, additional radiometric information that was not readily available in the current standard Level 1 Gridded Brightness Temperature Product (L1C\_TB) [7] can be more fully utilized for the development of higher-level geophysical products, such as the SMAP Enhanced Passive Soil Moisture Product (L2\_SM\_P\_E). The development of L2\_SM\_P\_E begins with the application of the BG optimal interpolation technique to the time-ordered  $T_B$  observations in L1B\_TB. This technique makes use of the antenna gain pattern information specific to the 6-meter reflector assembly onboard the observatory to achieve optimal data interpolation on a fine grid from the original data. The interpolation is considered optimal in the sense that it aims at producing interpolated values closest to what would have been measured had the instrument actually made its measurements at the interpolation points [5]. A comparison between the standard L1C\_TB on a 36 km grid and the SMAP Level 1 Enhanced Gridded Brightness Temperature Product (L1C\_TB\_E) on a 9 km is shown in Fig. 1.

(a)

220 224 228 232 236 240 244 248 252 256 260 264 268 272 276 280 284 288 292 296 300 (b)

Figure 1: SMAP horizontally polarized TB observations during December 15-17, 2016 over the Amazon basin. The application of BG interpolation in L1C\_TB\_E (Fig. 1a) results in enhanced spatial features of the scene that are often concealed or not immediately obvious in the standard L1C\_TB product (Fig. 1b).

It is clear from the comparison that the enhanced  $L1C_TB_E$  product (Fig. 1a) reveals spatial features of the scene that are concealed or not immediately obvious in the current standard L1C\_TB product (Fig. 1b). Overall, the L1C\_TB\_E image presents a less pixelated representation of the original data, offering a higher acuity and contrast compared with the L1C\_TB image. Because the information in the along-scan oversampled measurements in the original time-ordered T<sub>B</sub> data is more completely captured in L1C\_TB\_E, the product provides a more optimal representation of the original data for the production of L2\_SM\_P\_E.

# 2. PRODUCT DEVELOPMENT

The development of the enhanced L2\_SM\_P\_E follows that of the standard L2\_SM\_P [3]. A flowchart of the L2\_SM\_P\_E processing is shown in Fig. 2.

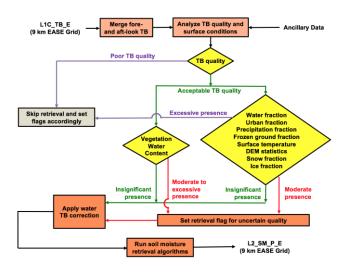

Figure 2: Processing flow of the L2\_SM\_P\_E processor. The processor uses the L1C\_TB\_E product as the primary input, along with other ancillary data on finer grid resolutions, to retrieve soil moisture.

Both products share the same baseline soil moisture retrieval algorithm - the single channel algorithm that uses the vertically polarized T<sub>B</sub> channel (SCA-V) and the same set of ancillary data. The fore- and aft-look T<sub>B</sub> observations in L1C TB E are first combined to provide the primary input data to the L2\_SM\_P\_E processor. External static and dynamic ancillary data preprocessed on finer grid resolutions are then brought into the processing to evaluate the feasibility and subsequent estimated quality of the When surface conditions favorable to soil retrieval. moisture retrieval are identified at a given grid cell, retrieval is performed. Corrections for water contamination, surface roughness, effective soil temperature, and vegetation water content are applied to produce the final output soil moisture retrieval field on the same 9 km EASE Grid 2.0 global projection [8][9] as the input L1C\_TB\_E. The resulting data contents of the L2\_SM\_P\_E output files are described in the Product Specification Document [10] of the product.

Compared with the standard L2\_SM\_P that is posted on a 36 km grid, the enhanced L2\_SM\_P\_E is posted on a 9 km grid. As such, the processing for L2\_SM\_P\_E is (36/9)<sup>2</sup> or 16 times more intensive than that for L2\_SM\_P. Despite this increase in computation time, L2\_SM\_P\_E processing remains relatively swift on the SMAP Science Data System (SDS).

# **3. PRODUCT VALIDATION**

The retrieval performance of L2\_SM\_P\_E was assessed using the same set of validation methodologies described in [3]: Long-term ground truth consisting of properly scaled aggregations of in situ soil moisture observations from core validation sites serves as a primary way for product Agreement between the L2 SM P E soil assessment. moisture estimates and in situ data over space and time are reported in time-series correlation coefficient, bias, rootmean-square difference (RMSD), and unbiased root-meansquare difference (ubRMSD). Together, these metrics provide a more comprehensive description of product performance than any one alone. Among these metrics, the ubRMSD (in units of  $m^3/m^3$ ) is the metric adopted by SMAP for stating product accuracy across all Level 2 through Level 4 soil moisture products. The SMAP Level 1 mission requirement for the active/passive soil moisture product accuracy is ubRMSD =  $0.040 \text{ m}^3/\text{m}^3$  or better. The same accuracy target was also adopted for the standard L2 SM P.

*In situ* soil moisture observations from a total of 15 core validation sites were used to assess the retrieval performance of L2\_SM\_P\_E at a spatial scale similar to the effective field-of-view (EFOV) of the SMAP radiometer. Performance metrics were evaluated using 19 months (April 1, 2015 through October 31, 2016) of *in situ* soil moisture observations from core validation sites and the corresponding L2\_SM\_P\_E granules from both 6:00 am descending passes and 6:00 pm ascending passes. Tables 1 and 2 provide a list of the core validation sites used in this assessment and the corresponding performance metrics, tabulated separately for the 6:00 am / 6:00 pm L2\_SM\_P\_E data.

Table 1: Assessment of 6:00 am descending L2\_SM\_P\_E based on a 19-month matchup with *in situ* soil moisture observations from 15 core validation sites. The units for ubRMSD, RMSD, and bias are  $m^3/m^3$ .

Sites	ubRMSD	Bias	RMSD	Corr
Reynolds Creek	0.040	-0.023	0.046	0.598
Walnut Gulch	0.024	0.011	0.026	0.813
TxSON	0.032	-0.015	0.036	0.921
Fort Cobb	0.028	-0.056	0.062	0.883
Little Washita	0.022	-0.027	0.035	0.920
South Fork	0.054	-0.062	0.082	0.646
Little River	0.028	0.087	0.092	0.887
Kenaston	0.022	-0.040	0.046	0.854
Carman	0.056	-0.088	0.104	0.611
Monte Buey	0.051	-0.020	0.055	0.840
REMEDHUS	0.042	-0.007	0.042	0.872
Twente	0.056	0.013	0.057	0.885
HOBE	0.036	-0.009	0.037	0.863
MAHASRI	0.036	-0.006	0.037	0.728
Yanco	0.043	0.020	0.048	0.964
L2_SM_P_E	0.038	-0.015	0.054	0.819
L2_SM_P	0.037	-0.014	0.052	0.822

A few observations can be drawn from the performance metrics listed in Tables 1 and 2. First, the enhanced L2\_SM\_P\_E and the standard L2\_SM\_P showed great similarity in all performance metrics; both demonstrated an average ubRMSD below 0.040 m<sup>3</sup>/m<sup>3</sup> and thus met the SMAP Level 1 mission requirement for soil moisture retrieval accuracy. The performance of the 6:00 am data is slightly better than that of the 6:00 pm data. This is within expectations because the current correction in geophysical inversion for effective soil temperature described in [3] had been optimized primarily for the 6:00 am data only. Despite this limitation that led to slight degradation in retrieval accuracy the performance metrics for both 6:00 am data and 6:00 pm data are nonetheless similar.

Table 2: Assessment of 6:00 pm ascending L2\_SM\_P\_E based on a 19-month matchup with *in situ* soil moisture observations from 15 core validation sites. The units for ubRMSD, RMSD, and bias are  $m^3/m^3$ .

Overall, the development of L2\_SM\_P\_E results in a 9 km global soil moisture product that benefits from the enhanced information available in the oversampled timeordered  $T_B$  observations in the original data, while retaining decent retrieval performance (ubRMSD below 0.040 m<sup>3</sup>/m<sup>3</sup>) as the standard L2\_SM\_P.

## 4. CONCLUSION

In this paper, the development and validation of the SMAP Enhanced Passive Soil Moisture Product were discussed. Posted on a 9 km grid on EASE Grid 2.0 global projection, the new product leverages on the Backus-Gilbert optimal interpolation technique that more fully utilizes the additional information from the original radiometer observations to achieve global mapping of soil moisture with enhanced clarity. Assessment of the enhanced product based on 19 months of *in situ* soil moisture observations from core validation sites showed that the enhanced product exhibits a level of retrieval performance (ubRMSD below 0.040  $m^3/m^3$ ) that met the SMAP Level 1 mission requirement for soil moisture retrieval accuracy. As of December 2016, the enhanced soil moisture product has been made available to the public from the NASA Distributed Active Archive Center (DAAC) at the National Snow and Ice Data Center (NSIDC).
