Scientific Problem

Runoff Curve Number (CN) is an estimate of water runoff over a specific land cover type

CN is a static method that does not account for seasonal variability

Create LULC maps to highlight both detailed urban and agricultural land use

Objectives

Conduct and compare two methods of curve number calculation: traditional method and a dynamic method

Provide project partners with updated LULC maps

Provide project partners with a tutorial on how to calculate a dynamic, NDVI-based curve number

Study Period

Annual Rainy
Season

March

September

Early Rain
Season

NASA Earth Observations

Landsat 5 TM

► 2006 - 2012

Landsat 7 ETM+

► 2013

Landsat 8 OLI

► 2014 - 2020

Methodology

Results: Land Use Land Cover Change

LULC in 2008

LULC in 2016

- Water
- Grass/pasture
- Urban/developed
- Various agricultural

Results: Land Use Land Cover Change

LULC trends from 2006 to 2019:

- ▶ Grass/pasture decreased by 11%
- ▶ Agriculture increased by 13%
- ▶ Urban/developed increased by 6%

Results: Conventional CN Change

Change in average runoff between 2006 to 2019

- ▶ 10,600 acres showed increased runoff risk
- ▶ 9,500 acres showed decreased runoff risk
- ▶ 117,000 acres showed no change in curve number

Results: Dynamic Average CN Change

Change in average runoff
between 2006 to 2019

- ▶ Overall increase in average runoff risk
- ▶ Risk is displayed in increments

Results: Early vs. Late Rainy Season

Max CN Change

Early rainy season

Late rainy season

Results: HUC-12 Watershed Level Zonal Statistics

Results: HUC-12 Watershed Level Zonal Statistics

Eureka Lake - Kansas River

Kitten Creek - Wildcat Creek

Headwaters - Wildcat Creek

Cedar Creek - Big Blue River

Results: HUC-12 Watershed Level Zonal Statistics

Conclusions

- ▶ LULC for developed areas increased by 6%. Increases in impervious surface increase chances for runoff
- ▶ Runoff risk increased in 2.67% of the county over 13 years
- ▶ Dynamic CN shows more variability
 - ▶ Allows for seasonal analysis
 - ▶ Overall runoff increased across the county

Data Summary

Dynamic NDVI-based Curve Number Maps

Conventional Curve Number Maps & Tables

Land Use Land Cover Maps

Tutorial of Methods

Story Map

Future Work

- ▶ Incorporate precipitation data to understand the role intensity and frequency of rainfall may play in exacerbating runoff
- ▶ Include various farming techniques to determine changes in runoff for different tillage methods
- ▶ Model the area with the Soil and Water Assessment Tool (SWAT) to better quantify the impacts of land use and land cover practices over watersheds

In recent years, Riley County, Kansas has experienced unprecedented flooding potentially due to changes in land use. In order to get a more detailed picture of increases in floods, this study tracked land use/land cover (LULC) change to determine what impact these changes may have on curve number, which estimates runoff from rainfall events for specific LULC types. This project created maps and a conducted a comparative curve number analysis, which may help the end users make more informed decisions on resiliency strategies to address future flooding.
