# The Breathing Plasmasphere

- Study emphasizes a change in perspective from a local-view to a system-level view, that offers extensive quantitative information as well as a more encompassing perspective of the plasmasphere.
- A view of the plasmasphere's breath is a view of the system.
- An in situ measurement of density, temperature, or particle flux cannot realistically be knitted together to give the whole at any given time.
- However, both are critical for understanding the system behavior and the micro-processes that create that behavior.
- Technique enables detailed study of L-shell dependent corotation, inter-regional mass transport versus field-aligned flow, and can directly incorporate oxygen imaging.

60+ years of science this way

Just a pretty face?

10-Minutes of data

Came here once

4,800 EUV images – 2,800 “keepers”, nearly 60%

Most previous studies derive relative change in the magnetic equatorial density. To validate the results by mass and using remote EUV images it is necessary to compare to previous results.

To do that mass is correlated with the corresponding average equatorial mass in the integration volume and then fit with the function below. The mass-density value pairs as a function of the center L-value in the integration volume are separately fit and the fit parameters then fit versus L-value.

$$Pseudodensity = a_0 \cdot \cosh(a_1 \cdot Mass)$$

$$a_0 = (853 \pm 64) + (-133 \pm 16) \cdot L$$

$$a_1 = (0.27 \pm 0.002) + (-0.004 \pm 0.001) \cdot L$$

- The average equatorial density remaining in each integration volume versus L-value and compared to previous results.
- These new results are comparable.
- Note that previous results are mostly limited to one location in parameter space.
- **These results provide a more system-level result, yet are limited to only 3-events.**

PC: Park-73/Carpenter-95    C62: Carpenter-62  
 CL: Clilverd-00    CH: Chi et al-01

 R04: Reinisch et al-04    P17: Piersanti et al-17

- The 18 June 2001 event includes two extra minor erosion intervals
- Refilling starts, then there is erosion, then refilling, then erosion, followed by more extended refilling.
- The higher L-shell volumes are most responsive to changing conditions.
- **The innermost L-shells show much reduce, but still present response to these minor increases in erosion.**
- The physical mechanism must differ for plasma loss outside the penetrating convection seperatrix than inside, which might depend on change in the ionosphere that rebalance the pressure along inner magnetic field lines or plasmaspheric wind.

- Refilling followed for 3.5 to 12 days.
- **They fall for low L-shells and fall at higher L-shells**
- Even modest expansion of studied events may contribute much.
- **Even a few events offer system-level measurements.**

Mass in 1,000kg/day refilling rate as a function of L and average daily sum of Kp

$$RR_{mass}[Mt \cdot day^{-1}] = a_0 + a_1 \cdot L + a_2 \cdot \langle \sum_{daily} K_P \rangle \quad (3)$$
$$a_0 = 0.37$$

$$a_1 = (1.00 \pm 0.16) \cdot L$$

$$a_2 = (-0.15 \pm 0.3) \cdot \langle \sum_{daily} K_P \rangle$$

The multiple-linear correlation coefficient for Equations 3 is 0.77.

Average equatorial density refilling rate as a function of L and average daily sum of Kp

$$\log_{10}(RR_{Ne^-}[cm^{-3} \cdot day^{-1}]) = b_0 + b_1 \cdot L + b_2 \cdot \langle \sum_{daily} K_P \rangle \quad (5)$$
$$b_0 = -0.02$$

$$b_1 = (0.79 \pm 0.05) \cdot L$$

$$b_2 = (-0.09 \pm 0.01) \cdot \langle \sum_{daily} K_P \rangle$$

The multiple-linear correlation coefficient for Equations 5 is 0.95.

Minimum and Maximum  
Mass versus L-shell  
for 7-Events

# Minimum and Maximum Densities versus L-shell for 7-Events

CA92: Carpenter/Anderson-1992  
G00: Gallagher et al-2000  
S01: Sheeley et al-2001

## Summary of Results

- The use of images is capable of providing system-level quantitative measures of plasmasphere dynamics.
- The eroded plasmapause location is confirmed not to be a boundary for plasma loss or yet shown to suggest a boundary in the effectiveness of loss processes.
- The study of integrated plasma content, such as mass, is a new method of analysis that offers previously difficult or impossible to obtain measures of plasma transport through the magnetospheric system.

*While the solar wind and its coupling into the magnetosphere drive space weather impacts, it is the spatial and temporal dynamics of plasma mass in geospace that guides the magnetospheric conduits of energy and plasma transport in the inner magnetosphere.*
