Stoquastic Hamiltonians

Stoquastic Hamiltonian

A Hamiltonian whose off-diagonal entries are all real and non-positive.

- This is a basis dependent property
- In mathematics these are known as Z-matrices or negative Metzler matrices
- By the Perron-Frobenius theorem, the ground state is entirely real

$$\begin{pmatrix} d_1 & & & - \\ & \ddots & & \\ & & \ddots & \\ - & & & \ddots & \\ & & & & d_N \end{pmatrix}$$

The Sign Problem (Using Path-Integral Quantum Monte Carlo as an example)

Consider a Partition Function

$$\mathcal{Z} = \sum_{\mathbf{x}} \langle \mathbf{x} | e^{-\beta(\hat{H}_d + \hat{H}_o)} | \mathbf{x} \rangle$$

Use a Suzuki-Trotter expansion in diagonal basis

$$\mathcal{Z} = \lim_{T \rightarrow \infty} \sum_{\{\mathbf{x}_i\}} \prod_{i=1}^T \langle \mathbf{x}_{i+1} | e^{-\frac{\beta}{T}(\hat{H}_o + \hat{H}_d)} | \mathbf{x}_i \rangle$$

The Sign Problem (Using Path-Integral Quantum Monte Carlo as an example)

Consider a Partition Function

$$\mathcal{Z} = \sum_{\mathbf{x}} \langle \mathbf{x} | e^{-\beta(\hat{H}_d + \hat{H}_o)} | \mathbf{x} \rangle$$

Use a Suzuki-Trotter expansion in diagonal basis

$$\mathcal{Z} = \lim_{T \rightarrow \infty} \sum_{\{\mathbf{x}_i\}} \prod_{i=1}^T \langle \mathbf{x}_{i+1} | e^{-\frac{\beta}{T} \hat{H}_o} e^{-\frac{\beta}{T} \hat{H}_d} | \mathbf{x}_i \rangle$$

The Sign Problem (Using Path-Integral Quantum Monte Carlo as an example)

Consider a Partition Function

$$\mathcal{Z} = \sum_{\mathbf{x}} \langle \mathbf{x} | e^{-\beta(\hat{H}_d + \hat{H}_o)} | \mathbf{x} \rangle$$

Use a Suzuki-Trotter expansion in diagonal basis

$$\mathcal{Z} = \lim_{T \rightarrow \infty} \sum_{\{\mathbf{x}_i\}} \prod_{i=1}^T e^{-\frac{\beta}{T} H_d(\mathbf{x}_i)} \langle \mathbf{x}_{i+1} | e^{-\frac{\beta}{T} \hat{H}_o} | \mathbf{x}_i \rangle$$

The Sign Problem (Using Path-Integral Quantum Monte Carlo as an example)

Consider a Partition Function

$$\mathcal{Z} = \sum_{\mathbf{x}} \langle \mathbf{x} | e^{-\beta(\hat{H}_d + \hat{H}_o)} | \mathbf{x} \rangle$$

Use a Suzuki-Trotter expansion in diagonal basis

$$\mathcal{Z} = \lim_{T \rightarrow \infty} \sum_{\{\mathbf{x}_i\}} \prod_{i=1}^T e^{-\frac{\beta}{T} H_d(\mathbf{x}_i)} \langle \mathbf{x}_{i+1} | e^{-\frac{\beta}{T} \hat{H}_o} | \mathbf{x}_i \rangle$$

We want to interpret these as classical Boltzmann probabilities

$$p(\{\mathbf{x}_i\}) = \frac{1}{\mathcal{Z}} \prod_{i=1}^T e^{-\frac{\beta}{T} H_d(\mathbf{x}_i)} \langle \mathbf{x}_{i+1} | e^{-\frac{\beta}{T} \hat{H}_o} | \mathbf{x}_i \rangle$$

For stoquastic Hamiltonians, the $p(\{\mathbf{x}_i\})$ are positive

The Sign Problem (Using Path-Integral Quantum Monte Carlo as an example)

Consider a Partition Function

$$Z = \sum_{\mathbf{x}} \langle \mathbf{x} | e^{-\beta(\hat{H}_d + \hat{H}_o)} | \mathbf{x} \rangle$$

Use a Suzuki-Trotter expansion in diagonal basis

$$Z = \lim_{T \rightarrow \infty} \sum_{\{\mathbf{x}_i\}} \prod_{i=1}^T e^{-\frac{\beta}{T} H_d(\mathbf{x}_i)} \langle \mathbf{x}_{i+1} | e^{-\frac{\beta}{T} \hat{H}_o} | \mathbf{x}_i \rangle$$

We want to interpret these as classical Boltzmann probabilities

$$p(\{\mathbf{x}_i\}) = \frac{1}{Z} \prod_{i=1}^T e^{-\frac{\beta}{T} H_d(\mathbf{x}_i)} \langle \mathbf{x}_{i+1} | (I - \frac{\beta}{T} \hat{H}_o) | \mathbf{x}_i \rangle$$

For stoquastic Hamiltonians, the $p(\{\mathbf{x}_i\})$ are positive

Implications of the Sign Problem

- Simulating sign-problem Hamiltonians requires exponential slow-downs
- Non-stoquastic \neq Sign Problem

- Mostly¹², simulating stoquastic Hamiltonians is classically efficient
- Stoquasticity is tied into computational complexity

¹ M. B. Hastings, The power of adiabatic quantum computation with no sign problem, *Quantum* **5**, 597 (2021).

² J. Bringewatt and M. Jarret, Effective gaps are not effective: Quasipolynomial classical simulation of obstructed stoquastic Hamiltonians, *Phys. Rev. Lett.* **125**, 170504 (2020).

Curing Non-Stoquasticity

Curing

Finding a (local) basis in which the sign problem does not exist.

- Such a basis always exists (the eigenbasis)
- A local stoquastic basis might not exist
- Curing the sign problem is NP-Hard
- Mitigation and Avoidance algorithms exist

Quantum Annealing with Stoquasticity

Quantum Annealing

Adiabatic Quantum Annealing with a local stoquastic basis is no more powerful than classical computing

There are some caveats here

- 1 Adiabatic - Diabatic annealing can get around this
- 2 Local - Hastings has one example with a non-local basis
- 3 Basis - Annealing takes place in the same basis throughout

The Quantum Advantage rests either with locality or the basis interaction between the annealing Hamiltonians

Core Question

Simultaneous Stoquasticity

Assume I have a set of Hamiltonians

$$S = \{H_1, H_2, \dots, H_m\}$$

- m – Number of Hamiltonians in set
- d – Dimension of Hamiltonians

Does there exist a basis in which all $H_j \in S$ are stoquastic

$$UH_jU^\dagger = H_j^*$$

$$\begin{pmatrix} d_1^* & & & - \\ & \ddots & & \\ & & & \\ - & & \ddots & \\ & & & d_N^* \end{pmatrix}$$

Analogy to Simultaneous Diagonalizability

Our problem is analogous to simultaneous Diagonalizability

$$[H_i, H_j] = 0 \quad \forall H_i, H_j \in S$$

- Shared Eigenbasis
- No quantum advantage
- We want a condition like this
- Anything we do can apply to this similarity setting as well

Why is This Useful

Quantum Annealing

- Can the entire anneal be stoquastic
- Quantum annealing with stoquastic Hamiltonians seemingly lacks advantage*
- This can be useful in Monte Carlo simulation
- The question came up in some optimal control work

Quantum Complexity

- Stoquasticity plays into several complexity classes

What are the Limitations

Locality

- Our work currently doesn't consider locality
- Locality could be spatial or connectivity
- Monte Carlo and complexity results require locality
- Locality is the next extension

Feasibility

Geometricity

Results

$$S = \{H_1, \dots, H_m\} \quad \& \quad S' = \{H'_1, \dots, H'_m\}$$

Theorem (Existence)

The ordered sets S and S' are simultaneously unitarily similar iff $\text{Tr}[w(S)] = \text{Tr}[w(S')]$ for all words w in S, S' .

Theorem (Quick No-Go)

Every eigenvalue $\lambda \neq 0$ of $i[H_i, H_j]$ there is another eigenvalue $-\lambda$ of $i[H_i, H_j]$ (paired eigenvalue condition) for all $H_i \neq H_j \in S$.

Theorem (Frequency)

For almost every S with $m \geq 2$, $d \geq 3$, S is not simultaneously stoquasticizable.

Table of Contents

- 1 Stoquasticity
- 2 Core Question
- 3 Lie Algebras
- 4 Complete Conditions
- 5 Simplified Condition
- 6 Frequency of Satisfying Conditions
- 7 Conclusion

Lie Algebras

Structure of $\mathfrak{su}(d)$

Generalized Gell-Mann Basis

$$\hat{\lambda}_{jk}^{(x)} = |j\rangle \langle k| + |k\rangle \langle j|, \quad (1 \leq j < k \leq d)$$

$$\hat{\lambda}_{jk}^{(y)} = -i|j\rangle \langle k| + i|k\rangle \langle j|, \quad (1 \leq j < k \leq d)$$

$$\hat{\lambda}_j^{(\text{diag})} = \sqrt{\frac{2}{j(j+1)}} \text{diag}(\underbrace{1, \dots, 1}_j, -j, 0, \dots, 0)$$

Generalized Bloch Vectors

$$H = \vec{b} \cdot \vec{\lambda}$$

Stoquastic:

$$\{b^{(y)} = 0, b^{(x)} \leq 0\}$$

Simultaneous Stoquasticity in $\mathfrak{su}(2)$

$SU(2)$ is a double-cover of $SO(3)$

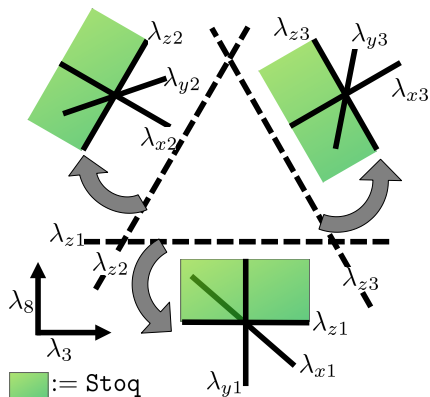

- Stoquasticity is the negative half-xz-plane
- It is always possible to rotate two vectors into a half-plane
- Simultaneous stoquasticity is always possible with $m = 2$

The Bloch Sphere is Misleading

SU(d) does not have nice relationships with SO

- Normal rotations do not apply
- Structure constants mix weirdly

| | | |
|----------------|----------------|----------------|
| λ_{xj} | λ_{yj} | λ_{zj} |
| λ_{xj} | λ_{yj} | λ_{zk} |
| λ_{xj} | λ_{xk} | λ_{yi} |
| λ_{yj} | λ_{yk} | λ_{yi} |

Complete Conditions

Words and Invariants

A word is some product of operators

$$w = \hat{B}^3 \hat{C} \hat{B} \hat{C}^2 \quad \ell = 7$$

- Words can be used to make up commutators
- $\text{Tr}(w)$ is an invariant under unitary rotations
- Provably the traces of all words describe every invariant property of a matrix

| | | | | |
|---|---|---|---|---|
| S | A | T | O | R |
| A | R | E | P | O |
| T | E | N | E | T |
| O | P | E | R | A |
| R | O | T | A | S |

Unitary Similarity

$$S = \{H_1, \dots, H_m\} \quad \& \quad S' = \{H'_1, \dots, H'_m\}$$

Theorem (Existence)

The ordered sets S and S' are simultaneously unitarily similar iff $\text{Tr}[w(S)] = \text{Tr}[w(S')]$ for all words w in S, S' .

- This is the known foundation of unitary similarity
- We only need to check finitely many words

$$\ell_{\max} = cd \sqrt{\frac{2(cd)^2}{cd-1} + \frac{1}{4}} + \frac{cd}{2} - 2 \in \mathcal{O}\left((\sqrt{md})^{3/2}\right)$$

$w/ (c^2 - 3c + 2 \geq 2m)$

System of Equations

We get a system of conditions for simultaneous stoquasticity:

$$\begin{aligned} \text{Tr}[w(S)] &= \text{Tr}[w(S')], & \forall |w| \leq \ell_{\max} \\ \text{Re}(H'_{j,k}) &\leq 0, & \forall j \neq k, H' \in S' \\ \text{Im}(H'_{j,k}) &= 0, & \forall j \neq k, H' \in S' \end{aligned}$$

This has $\mathcal{O}\left(m^{\mathcal{O}((\sqrt{m}d)^{3/2})}\right)$ equality constraints and $md(d-1)/2$ inequality constraints

- Many of these are redundant
- Determining if a solution exists is NP-Hard

Simplified Condition

Dynamical Lie Algebra (DLA)

Lie algebra generated from your Hamiltonians via nested commutation

For $n = 3$ Transverse Field Ising model

- The relative tree structure is invariant
- Incredibly useful for control theory

One Step Up

Go one step up the DLA

$$[\hat{H}_0, \hat{H}_1] = 2i\hat{H}_2$$

- ① The eigenvalues are all invariant
- ② If \hat{H}_0 and \hat{H}_1 can be simultaneously stoquastic, \hat{H}_2 is composed only of $\lambda^{(y)}$ in that basis
- ③ Then \hat{H}_2 is skew-symmetric and must have paired eigenvalues

| | |
|-------------|------|
| λ_1 | $-a$ |
| λ_2 | $-b$ |
| λ_3 | $-c$ |
| λ_4 | 0 |
| λ_5 | c |
| λ_6 | b |
| λ_7 | a |

Limitations

- This is a necessary but not sufficient condition
- This condition can be met by Hamiltonians that are not Simultaneously stoquastic*
- We are not looking at enough invariants
- This would be equivalent to the words if we looked at the entire DLA
- Related to the Cartan decomposition of $\mathfrak{su}(p)$

Frequency of Satisfying Conditions

Structure of $\mathfrak{su}(d)$

Generalized Gell-Mann Basis

$$\hat{\lambda}_{jk}^{(x)} = |j\rangle \langle k| + |k\rangle \langle j|, \quad (1 \leq j < k \leq d)$$

$$\hat{\lambda}_{jk}^{(y)} = -i|j\rangle \langle k| + i|k\rangle \langle j|, \quad (1 \leq j < k \leq d)$$

$$\hat{\lambda}_j^{(\text{diag})} = \sqrt{\frac{2}{j(j+1)}} \text{diag}(\underbrace{1, \dots, 1}_j, -j, 0, \dots, 0)$$

Generalized Bloch Vectors

$$H = \vec{b} \cdot \vec{\lambda}$$

Stoquastic:

$$\{b^{(y)} = 0, b^{(x)} \leq 0\}$$

Word Invariants with Bloch Vectors

We can express the trace invariants in terms of Bloch vectors

$$\mathrm{Tr}[w(S)] = \mathrm{Tr} \left[\prod_{j=1}^{|w|} \sum_{\mu_j=1}^{d^2-1} b_{\mu_j}^{(w_j)} \hat{\lambda}_{\mu_j} \right]$$

- This allows us to look at all possible invariants of a system in terms of combinations of Bloch vectors.
- All possible Bloch vectors generated by a set of Hamiltonians' invariants is denoted by \mathcal{B}
- We can show that a necessary condition for simultaneous stoquasticity is that $\dim(\mathrm{span}(\mathcal{B})) \leq (d^2 + d - 1)/2$

Dimension of Full Space

We can show that for almost all pairs of Hamiltonians

$$\dim(\text{span}(\mathcal{B})) = (d^2 + d - 1)$$

So almost all pairs of Hamiltonians have spans larger than can fit into simultaneous stochasticizability

- Cool ideas, but the proof is too long
- Equivalent to saying that almost all pairs of Hamiltonians have a DLA = $\mathfrak{su}(d)$ - full controllability
- A similar proof can be made for simultaneous diagonalizability

Conclusion

Summary

- Simultaneous Stoquasticity is rare
- Unpaired eigenvalues of $[\hat{B}, \hat{C}]$ imply no stoquasticity
- Stoquasticity is basis dependent but simultaneous stoquasticizability is basis independent
- Bloch vectors are a powerful geometric tool
