# **Executive Summary**

RESILIENCY IN FUTURE CISLUNAR SPACE ARCHITECTURES

#### December 1, 2022

#### **Purpose of the Study**

Resiliency is an aspirational metric, and it is a common goal for complex systems – be they engineered space architectures, geopolitical networks, or the human immune system. However, despite the ubiquitous desire for resiliency, the concept is surprisingly difficult to define and apply to future planning efforts. The objective of this work is to introduce and explore the concept of resiliency as it relates to future cislunar space architectures by 1) citing examples of its growing demand across government; 2) describing potential characteristics of resilient systems; 3) introducing a framework for evaluating the linkages between resilient capabilities and visions for future cislunar architectures; and 4) exercising the framework to identify and evaluate resiliency-enabling technical capabilities for cislunar space architectures. We assert that resiliency can emerge from a layered approach of deliberately chosen capabilities with overlap and flexibility that, in aggregate, result in a resilient system. The challenge is to identify capabilities that contribute to resiliency and to accurately characterize their value. Resiliency is discussed through the lens of future architecture planning, outlining how the National Aeronautics and Space Administration (NASA) can benefit from a shift in approach when transitioning focus to the cislunar environment.

#### **Key Findings**

In 2021, NASA facilitated a study exploring the concept of resiliency as it relates to cislunar architectures. Two working groups were established, an architecture working group and a technology working group. In initial working group discussions, participants recognized the value in characterizing resiliency to be inclusive of, but not focused solely on, reliability and mission assurance. Although several definitions of resiliency were proposed by participants or identified from industry and government, no single definition of resiliency was agreed upon by participants. However, there was general agreement that resiliency is inclusive of robustness, flexibility, agility and responsiveness, and the ability to evolve. Discussions also captured several characteristics of resilient systems, such as those that offer redundancy, disaggregation, self-healing abilities, situational awareness, and survivability.

Report ID

Rather than establishing a single definition, the working groups were able to characterize resiliency through a descriptive framework to provide a comprehensive assessment of resiliency. The framework, a matrix shown in Table 1, describes capabilities in terms of five aspects (i.e., the ways in which a system can be resilient) and four types of resiliency (i.e., the types of stressors to which a system can be resilient), detailing a tool to evaluate a technology's ability to preempt, withstand, react, recover, and evolve to known and unknown stressors including those originating within the environment, human, system, or support.

#### Table 1. Resiliency Framework

[Capabilities exist at the or Resiliency Types and Res	cross section of iliency	<b>Resiliency Aspects (Verbs)</b> High-level goals which define functions, methods, or actions used by a resilient system											
Aspects]		Preempt	Withstand	React	Recover	Evolve

Types of stressors to	Human	[Capability]	[Capability]	[Capability]	[Capability]	[Capability]							
which aspects of resiliency are applied	are applied System		[Capability]	[Capability]	[Capability]	[Capability]							
to ensure continued utility	Support	[Capability]	[Capability]	[Capability]	[Capability]	[Capability]							

Resiliency Types: Where does the stressor or disruptor originate?

- Environment: Inherent challenges and uncertainties from the natural environment
- Human: Human interaction
- System: System design, characteristics, or flaws internal to the system
- **Support:** Interaction with external supporting systems, infrastructure, or processes

Resiliency Aspects: Which functions, methods, or actions may be used and when?

- **Preempt:** Taking action, making choices, predictions, or allocations before a stressor
- **Withstand:** Maintaining full or partial capability during a stressor due to inherent qualities
- **React:** Taking action to avoid, affect, or mitigate the cause or impact of a stressor
- **Recover:** Taking action after a stressor to return to an original operating state
- **Evolve:** Changing a nominal state after a stressor to improve future performance

Once the framework was complete, the technology working group exercised the creativity matrix by identifying technical capabilities at the intersections of the Resiliency Aspects and Types. The brainstormed capabilities, such as 1) fast, efficient, and cheap dexterous robotics and 2) built in soft and hard stops, were compiled into a database of 52 resiliency-enabling technical capabilities. The listing and characterization of the technical capabilities in the database demonstrate preliminary utility of the Framework as a rubric to evaluate and

aggregate resiliency. By further using the framework to identify and evaluate resilient technical capabilities in connection to cislunar mission functions - building blocks of a functional architecture – the value of the framework may be fully realized. While we provide the key elements and outline the approach, additional work is necessary to further apply the Resiliency Framework and connect the Technical Capabilities Database to cislunar architectures.

## **About OTPS**

The Office of Technology, Policy, and Strategy (OTPS) is an independent office providing NASA leadership with data- and evidence-driven advice on technology, policy, and strategy. Established when the Office of Strategic Engagements and Assessments and the Office of the Chief Technologist combined in 2021, OTPS's trusted advice informs Agency-level decision making about NASA's activities across its six mission directorates. In this role, OTPS undertakes independent analyses and studies, such as the one described in this report, to provide leadership with a set of objective recommendations. For more information on the NASA Office of Technology, Policy, and Strategy to view publicly available reports visit https://www.nasa.gov/offices/otps/home/index.html.

## Introduction

This work introduces and explores the concept of resiliency as it relates to future cislunar space architectures by 1) citing examples of its growing demand across government; 2) describing potential characteristics of resilient systems; 3) introducing a framework for evaluating the linkages between resilient capabilities and visions for future cislunar architectures; and 4) exercising the framework to identify and evaluate resiliency-enabling technical capabilities for cislunar space architectures. We assert that resiliency can emerge from a layered approach of deliberately chosen capabilities with overlap and flexibility that, in aggerate, result in a resilient system. The challenge is to identify capabilities that contribute to resiliency and to accurately characterize their value. Resiliency is discussed through the lens of future architecture planning, outlining how the National Aeronautics and Space Administration (NASA) can benefit from a shift in approach when transitioning focus to the cislunar environment.

### Resiliency

Quality metrics of spacecraft and space architectures are often reliability, robustness, or even mission assurance. However, these metrics are bounded by definitive values calculated from engineered characteristics and only apply when operating within known limits. Resiliency is the ability for a component, subsystem, system, or architecture (a system-of-systems) to provide needed utility both within and outside anticipated limits.

Resiliency is an aspirational metric, and it is a common goal for complex systems – be they engineered space architectures, geopolitical networks, or the human immune system. However, despite the ubiquitous desire for resiliency, the concept is surprisingly difficult to define and apply to future planning efforts. The National Academies of Sciences, Engineering, and Medicine defines resiliency as "the ability to plan and prepare for, absorb, recover from, and more successfully adapt to adverse events."<sup>1</sup> In a different view, the Department of Defense's (DoD) definition of resiliency is focused more on straightforward utility to a wide range of applications and known and detectible failure modes that gracefully degrade with some continued utility.<sup>2</sup> Both approaches to the term recognize resiliency as a dynamic concept that adapts or evolves, but neither provides a clear yardstick by which to measure resiliency. Another noteworthy definition of resiliency derives from the study of complex ecological

 <sup>&</sup>lt;sup>1</sup> Committee on Increasing National Resilience to Hazards and Disasters; Committee on Science, Engineering, and Public Policy (COSEPUP); Policy and Global Affairs (PGA); The National Academies. Disaster Resilience: A National Imperative. The National Academies Press: http://www.nap.edu/catalog.php?record\_id=13457 (2012)
 <sup>2</sup> Goerger, Simon & Madni, Azad & Eslinger, Owen. (2014). Engineered Resilient Systems: A DoD Perspective. Procedia Computer Science. 28. 865-872. 10.1016/j.procs.2014.03.103.

systems in which resiliency is an emergent behavior of complex systems enabling continued system propagation in the face of new and unanticipated threats. For example, the human immune system builds resiliency by investing resources in randomly mutated lymphocytes that produce antibodies to protect against proteins that the body has never seen (and may never see) but could be present on future microbiological invaders. This "inefficiency" results in a greater overall system resiliency.

#### **Resiliency and Space**

The concept of resiliency is being incorporated into the lexicon of our national leadership as well as U.S. space agencies. The United States Space Priorities Framework released by the White House highlights the need for "[enhancing] the security and resilience of space systems that provide or support U.S. critical infrastructure from malicious activities and natural hazards."<sup>3</sup> In the commercial sector, resiliency is approached differently but is equally critical. Several low-Earth orbit (LEO) constellation companies are building in modularity, spiral upgrades, planned obsolescence, and low-cost constellation refreshes to achieve a systems-of-systems resiliency that supersedes individual satellite brittleness or fragility. This drive toward resiliency is due in part to increased complexity of space architectures (including LEO constellations), increased autonomy, and—at least for government systems—budgetary pressures driving the need to do more with less resources.

For cislunar architectures—including, but not limited to, areas such as space domain awareness, mobility and logistics, communications, and position, navigation, and timing<sup>4</sup> —we are concerned about continued utility in the face of known and unknown stressors. Put simply, a resilient system works as intended and continues to work (at least to some degree) when used as it is not intended. This is a critical property for deep space systems that require a significant investment in time and money, cannot be easily replaced, and must remain operational for decades. Such systems must also be designed with imperfect knowledge about the environment, needs of future users, and evolving stressors that can impact the designed utility. As it is impossible to know every potential challenge, interface, or future application for a cislunar capability, designing or testing for resilient behavior requires a deviation from the traditional system engineering tools. We assert that resiliency can emerge from a layered approach of deliberately chosen capabilities with overlap and flexibility that, in aggregate, result in a resilient system. The challenge is to identify capabilities that contribute to resiliency and to accurately characterize their value.

#### **Characterizing Resiliency**

In 2021, NASA facilitated a study, including a technology working group (TWG) and architecture working group (AWG), to explore the concept of resiliency as it relates to cislunar architectures. The agency recognizes the value in planning for resilient systems and the challenges of defining and characterizing resiliency through standard engineering tools. Through a working group approach, NASA looked at future plans such as NASA's Artemis architecture and potential pathways for resilient cislunar capabilities to improve our future resiliency posture. In initial working group discussions, participants recognized the value in characterizing resiliency to be inclusive of, but not focused solely on, reliability and mission assurance. Although several definitions of resiliency were proposed by participants or identified from industry (see Table 2), no single definition of resiliency was agreed upon by participants. However, there was general agreement that resiliency was inclusive of robustness, flexibility, agility and responsiveness, and the ability to evolve. Discussions also captured several characteristics of resilient systems, such as those that offer redundancy, disaggregation, self-healing abilities, situational awareness, and survivability. While the working groups did not finalize a common definition of resiliency due to the complexity and variation of perspectives, they were able to characterize resiliency through a descriptive framework. We suggest the use of this framework in place of a single definition to provide a comprehensive assessment of resiliency.

- **1 Resiliency** is the ability of a system architecture to continue providing required capabilities in the face of system failures, environmental challenges, or adversary actions
  - Resiliency and Disaggregated Space Architectures, Air Force Space Command, 2016<sup>5</sup>
- 2 **Resilience** is defined as the ability to deliver the mission in the face of manmade or natural interference Resiliency of Space Systems, The Aerospace Corporation, 2017<sup>6</sup>
- **3 Resilience** is the ability of an architecture to support the functions necessary for mission success in spite of hostile action or adverse conditions. An architecture is "more resilient" if it can provide these functions with higher probability, shorter periods of reduced capability, and across a wider range of scenarios, conditions and threats. **Resilience** may leverage cross-domain or alternative government, commercial, or international capabilities

Department of Defense (DoD) Fact Sheet, 2011

4 **Resilience:** The ability of an architecture to support the functions necessary for mission success with higher probability, shorter periods of reduced capability, and across a wider range of scenarios, conditions, and threats, in spite of hostile action or adverse conditions

**Resilience:** An internally-focused characteristic of an architecture that is extremely difficult to characterize in a closed form analysis... [developed into] the fewest categories into which resiliency could be sufficiently organized. We arrived at six discrete characteristics to describe resilience approaches: disaggregation, distribution, diversification, protection, proliferation, and deception

Space Domain Mission Assurance Resilience Taxonomy, Office of the Assistant Secretary of Defense for Homeland Defense & Global Security (2015)<sup>7</sup>

**5 Resilience**: *The ability to adapt to changing conditions and withstand and rapidly recover from disruption due to emergencies* 

Presidential Policy Directive 8: National Preparedness, Obama White House, 20118

**6** The characteristic or capability to maintain functionality and structure (or degrade gracefully) in the face of internal and external change

Mission Assurance Policy for the Defense Intelligence Enterprise, DoD, 20159

- System resilience is defined as the ability of the system to withstand a major disruption within acceptable degradation parameters and to recover within an acceptable time and composite costs and risks
   On the Definition of Resilient Systems, Haimes, et al., 2008; Haimes, 2009<sup>10</sup>
- 8 **Resilience** is designed to have systems self-heal with no intervention from humans. In the cyber context, a resilient cyber system must continue to operate as intended, even if compromised (for example, if unauthorized access is achieved)

Understanding Today's Cyber Challenges, TASC, 2011

**9** The ability to quickly adapt and recover from any known or unknown changes to the environment. **Resiliency** is not a process, but rather an end-state for organizations. The goal of a resilient organization is to continue mission essential functions at all times during any type of disruption. **Resilient** organizations continually work to adapt to changes and risks that can affect their ability to continue critical functions

Contingency Planning Guide for Federal Information Systems, National Institute for Standards and Technology (NIST), 2010<sup>11</sup>

The blue verbs inspired and informed the Resiliency Aspects of the Resiliency Framework. The green nouns inspired and informed the Resiliency Types of the Resiliency Framework.

### **Resiliency Framework**

With the assistance of the facilitation and analysis team, the working groups quickly acknowledged that some systems will be more or less resilient to different types of adverse events, or "stressors," and respond in different ways. Rather than a binary quality, resiliency may vary in degree and with respect to various stressors. In turn, an agency may make different design choices based on various aspects and types of resiliency. Expanding on previous resiliency taxonomy by MITRE and the Aerospace Corporation, the team established a Resiliency Framework (see Table 3) consisting of Resiliency Aspects (i.e., the ways in which a system can be resilient) and Resiliency Types (i.e., the types of stressors to which a system can be resilient). The Resiliency Aspects are inspired by the action verbs and descriptors of resilient systems mentioned in the resiliency references in Table 1. On the other hand, the Resiliency Types, are derived from the nouns and domains in which resiliency is applied. By dissecting the various resiliency definitions and references along these two axes, the framework emerged.

#### **Resiliency Aspects**

Resiliency Aspects can be defined as high-level goals which define functions, methods, or actions used by a resilient system. The working groups identified that systems could provide resiliency through multiple methods. Several actions were proposed with significant degrees of overlap and a loose temporal structure to describe actions taken before, during, or after a given stressor, as illustrated in Figure 1. For the purpose of the study, five resiliency aspects were identified and agreed to by working group participants: Preempt, Withstand, React, Recover, and Evolve.

Figure 1. Resiliency Aspects

**Preempt:** Actions taken, choices made, predictions made, or allocations made before a stressor begins. Preempt includes terms such as anticipate, prepare, avoid, deter, monitor, protect; however, it is not simply engineering to account for expected variances or reactive decisions. An example of Preempt in a resilient cislunar system is the ability to track and forecast micrometeoroid and orbital debris (MMOD) to ensure systems operate in orbits with the least risk of impact.

*Withstand:* Maintaining full or partial capability during a stressing event due to inherent qualities of the system. Withstand includes terms such as shield, harden, strengthen, throttle, hibernate, and graceful degradation. Withstand does not include actions taken by the system to change its state in response to a stressor. An example of Withstand in a resilient cislunar system is inclusion of additional MMOD shielding to provide additional protection for spacecraft.

**React:** An action taken to avoid, affect, or mitigate the cause or impact of a stressing event. React includes temporary state changes, counters, responses, reallocation of resources, and system transformations. It can occur during or immediately after an event but is not inclusive of repair or recover actions. An example of React in a resilient cislunar system is the ability to maneuver around detected debris or orientate the spacecraft to effectively utilize the additional MMOD shielding available.

**Recover:** Self correction or external actions that return the system to an original operating state. Recover includes terms such as restore, reconstitute, replenish, and rebuild. Recover, in the case of resiliency, is not replacement of an entire system or architecture, but could include expendable components that can be rapidly replenished. An example of Recover in a resilient cislunar system is self-healing materials that repair MMOD damage.

*Evolve:* Changes to a system's nominal state in response to a stressor to improve future performance. Evolve includes terms such as adaption, learning, experimentation, reconfigure, change, and redistribution. Evolve is not a temporary response such as an avoidance maneuver or upgrades to a spacecraft. An example of Evolve is a redesign of a constellation deployment to remove critical systems from congested orbital planes where MMOD risk is high.

#### **Resiliency Types**

Resiliency Types can be defined as types of stressors to which aspects of resiliency are applied to ensure continued utility. There is a wide variety of stressors that can disrupt cislunar systems and architectures. As illustrated in Figure 2 these stressors may originate in the **system** itself, in the **environment** (in which the system exists), in a **human** (either co-located with the system or in a different environment), or in a **support** system (either co-located with the primary system or in a different environment). Brainstormed examples ranged from manufacturing flaws to supply-chain failures to natural events. For this study, four Resiliency Types were identified: Environment, Human, System, and Support.

Figure 2. Resiliency Types

*Environment:* Stressor or disrupter resulting from inherent challenges and uncertainties from the natural environment. This includes space radiation, MMOD, and thermal challenges (note: space debris is part of the "natural" environment). Cislunar examples include a solar particle event that disrupts or damages electronics, a rocket body collision that places a new debris field in a system's path, or orbital alignment that results in a longer than typical period of darkness.

*Human:* Stressor or disrupter due to human interaction. This includes operator errors such as incorrect commands, misdiagnosed anomalies, processing and response delays, and incorrect software uploads. Cislunar examples include a mission operator sending an erroneous command to a spacecraft causing it to slew in an unexpected way or the crew making a mistake when following emergency protocols resulting in a system shutdown.

*System:* Stressor or disrupter resulting from system design, characteristics, or flaws internal to the system. This includes software bugs, unexpected performance characteristics, manufacturing flaws and system fatigue. Cislunar examples include large deployable structures failing to deploy due to a mechanical flaw or a tool failing due to inadequate knowledge of the performance requirements.

*Support:* Stressor or disrupter resulting from the interaction with external supporting systems, infrastructure, or processes. This includes communication network failures, supply-chain disruptions, or insufficient space domain awareness. Cislunar examples include lost position, navigation, and timing (PNT) or space situational awareness data during complex maneuvers or disruption of ground-based computing resources necessary to process spacecraft instrument data.

## **Resiliency-Enabling Technical Capabilities**

To date, the study team has developed the Resiliency Framework and applied the creativity matrix of Resiliency Aspects and Types by creating a list of desired technical capabilities for enhancing mission resiliency in cislunar space. The brainstorming occurred over several sessions with the technology working group and the analysis team. From these meetings, we obtained 177 capabilities covering all combinations of Resiliency Aspects and Resiliency Types, according the to the developed Framework. The Analysis Team then went through and grouped similar items by their broader category, e.g., capabilities referring to cybersecurity and encryption were grouped together. Additionally, since many capabilities overlapped with functions given in the 2021 On-orbit Servicing, Assembly, and Manufacturing (OSAM) State of Play<sup>12</sup>, we replaced these with the 11 OSAM areas for better coordination with other cross-agency efforts. The final result is a list of 52 capabilities, provided in Appendix A.

In Figure 3, we provide two examples of resiliency-enabling technical capabilities in our database: 1) Fast, efficient, and cheap dexterous robotics which were considered to be enabling in terms of preempting, recovering from, and evolving to stressors across the four Resiliency Types, and 2) Built in soft and hard stops which were considered to be enabling in terms of withstanding and reacting to disruptions in the human and support systems. These technical capabilities are further described in terms of cislunar benefits and considerations and NASA primary and secondary taxonomy<sup>13</sup> in Appendix A. As a demonstration of one utility that the framework offers, we show in Figure 3 how you may consider adding the two technical capabilities and their accompanying resiliency to better understand the ability of a total system to cover all aspects and types of resiliency.

This Resiliency Framework of aspects and types provides a matrix for discussing capabilities and their potential contribution to a system or architecture's aggregate resiliency. It is not a map for establishing requirements for resiliency, but instead assists with thinking creatively to understand potentially unexpected contributions or limitations and dependencies that are not expressed in traditional systems engineering. For example, a communication system that provides a sensing modality and a secondary PNT capability would address more aspect-type pairings than a higher-bandwidth but less-flexible alternative, thus increasing the system's overall resiliency. This analysis tool may also help identify when two seemingly unrelated capabilities are affected by the same stressors, potentially advocating for an overlapping Resiliency Aspect that supports both capabilities.

### Conclusion

Additional work is necessary to further demonstrate the value of the Resiliency Framework tool and apply it to architectures. Through this study process, we have characterized the need to think about resiliency along with mission objectives and system requirements. We note that while resiliency is challenging to define, it should be an aspirational goal for any design, particularly those with the potential for long-duration operations. Although there is not a clearcut approach to guarantee resiliency, there are characteristics that are indicative of resilient systems and architectures. Thinking proactively about how these characteristics, that are

enabled or enhanced by technical capabilities, can be applied to mitigate or neutralize potential stressors can assist in solidifying the role and utility of resiliency. The Resiliency Framework can thus be used as an analysis (or assessment) tool to identify gaps and dependencies in technical capabilities that must be considered (or addressed) to mature a system's resiliency for envisioned future cislunar space architectures.

## Appendix A - Resiliency-Enabling Technical Capabilities Database

For each item in the Resiliency-Enabling Technical Capabilities Database, the *Title* and *Description* give a quick overview of each capability. We were specifically interested in cislunar applications, referring to the region outside geostationary orbit where bodies are gravitationally affected by both the Earth and the Moon. *Cislunar considerations* refer to any potential difficulties or issues that apply in cislunar space, but not geostationary orbit. *Cislunar benefits* refer to technological abilities that specifically enable missions in cislunar space that would not otherwise be possible. *Primary/Secondary Taxonomy* gives the most relevant NASA technology taxonomy area(s)<sup>14</sup> for enabling this capability. Finally, the bottom of each box denotes the most relevant resiliency aspect/type combinations for the given resiliency.

#### Title: Advanced Encryption for Space Applications

Description: Next-generation encryption will be a critical capability for ensuring the safety and security of systems in all space domains. This includes novel encryption												<i>Cislunar considerations:</i> Distance between assets or from the GEO or LEO sphere may add additional challenges for cislunar applications.									
space domains. This includes novel encryption techniques, decentralized encryption, blockchain- dependent encryption, and any form of randomized or evolving encryption technologies that exceed the current (2021) state of the art. ## **Appendix B - Acknowledgements**

In its role as an independent office, OTPS relies on the inputs of a broad community of internal and external subject matter experts and stakeholders involved in NASA's future. For the study described in this report, OTPS considered many inputs while shaping the study itself and interpreting and reporting our findings. We thank the report reviewers and many contributors who shared these invaluable inputs, especially those that served on the technology and architecture working groups.
