25 Supplementary discussion: temperature response in ThickIce and ThinIce experiments

26 In ThickIce, a cooling is observed in summer and in regions in winter close to the ice edge compared  
27 to the reference experiment (Fig. S5) due to the larger sea ice extent. However, this does not  
28 overwhelm the effect of the larger winter sea ice formation (Fig. 4) and thus the larger heat fluxes to  
29 the atmosphere within the pack that leads to an air temperature increase that dominates the regional  
30 mean (Fig. 8).

31 The opposite should occur in the ThinIce experiments. The lower sea ice formation (Fig. 4) and oceanic  
32 heat losses in ThinIce should lead to a cooling of the atmosphere within the ice pack, while the smaller  
33 ice extent should be associated with an atmospheric warming in the regions that are ice free in ThinIce  
34 and ice covered in the reference experiment. However, we find that the atmospheric warming due to  
35 a reduced ice extent expands to most of the pack in ThinIce, even in winter with cooling restricted to  
36 some regions close to the continent (Fig. S5). This extended warming is likely due to the strong changes  
37 in albedo and absorbed solar radiation in ThinIce (Fig. S4). The dominant role of the albedo is consistent  
38 with the generally colder temperatures in the first winter of ThinIce\_PARA\_Mar (Fig. 8), when the  
39 albedo effect did not yet have the time to act given that the experiments start at the end of summer.  
40 The larger fraction of leads within the ice pack also contributes to the warming in ThinIce.

42

43 Figure S1. Anomaly of Antarctic sea ice extent (in  $10^{12} \text{m}^2$ ) compared to the corresponding reference  
 44 simulation in the group of experiments starting in March (top row) and September (bottom) for the  
 45 NEMO (left column) and PARASO configurations (right column).

46

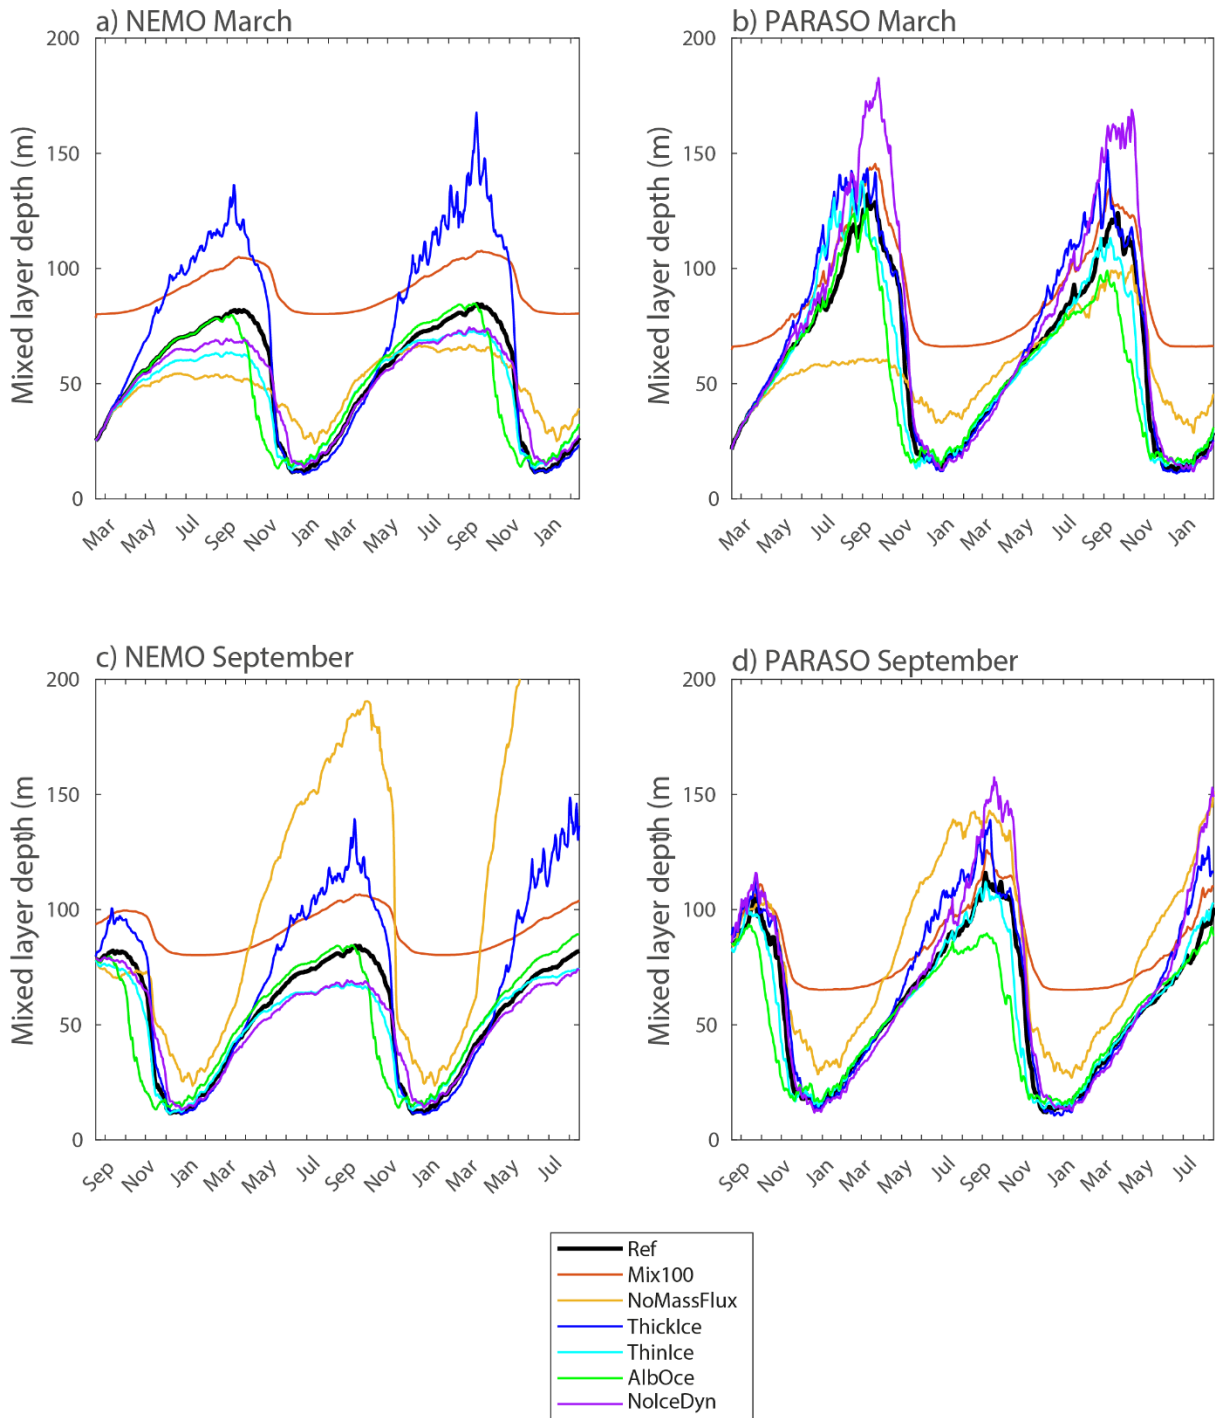

47

48

49 Figure S2. Anomaly of mass flux due to sea ice growth and melt (counted positive for melting)  
 50 integrated over the Southern Ocean (in  $10^{11} \text{m}^3 \text{d}^{-1}$ ) compared to the corresponding reference  
 51 simulation in the group of experiments starting in March (top row) and September (bottom) for the  
 52 NEMO (left column) and PARASO configurations (right column).

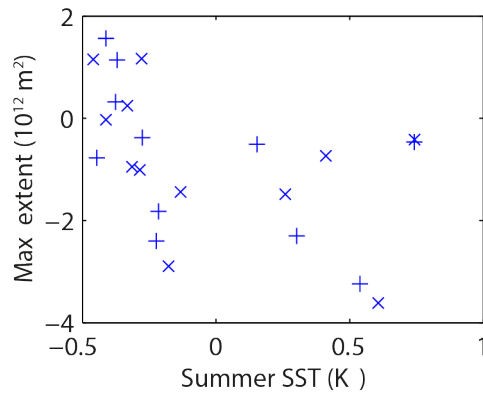

53

54

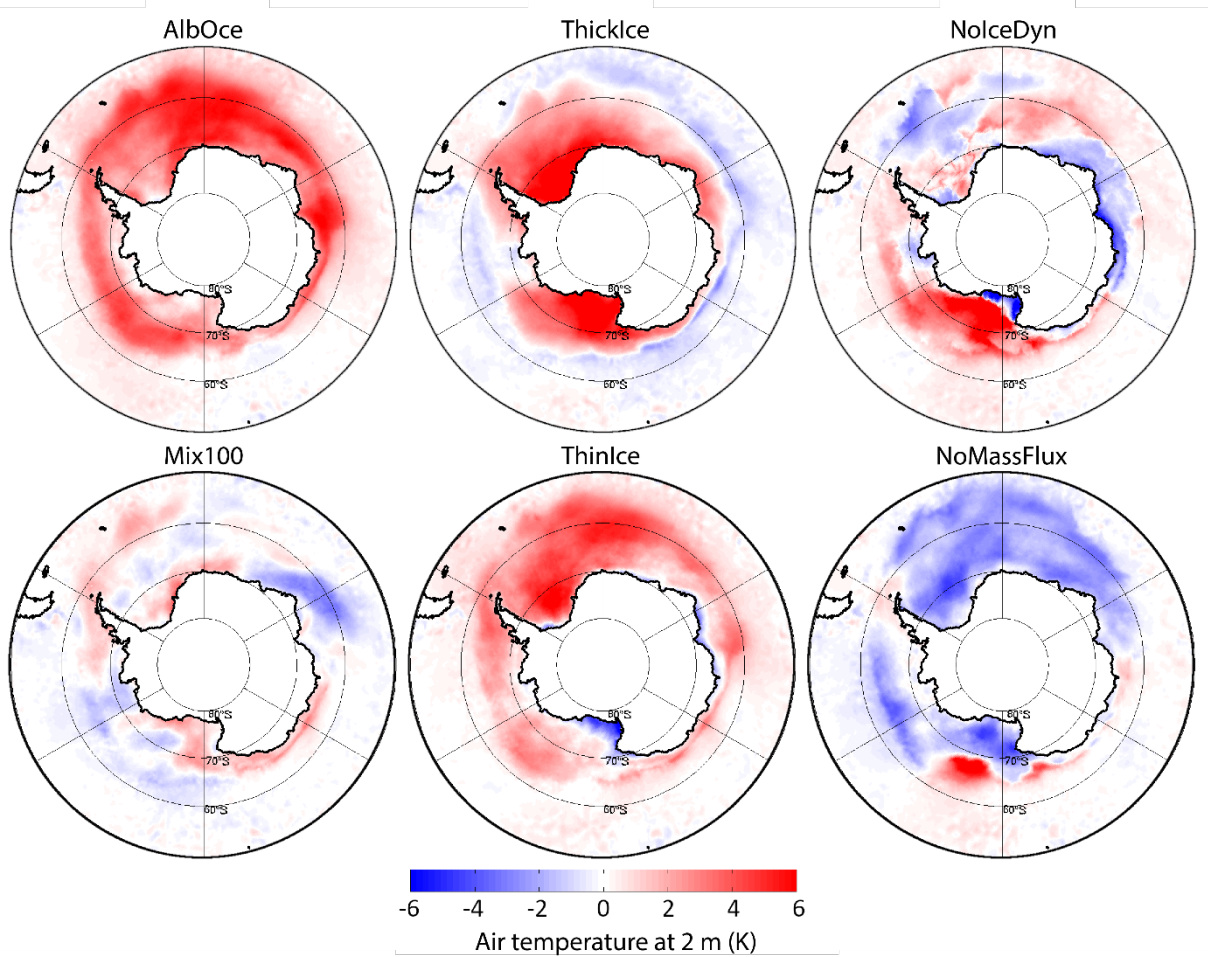

55 Figure S3. Mixed layer depth (in m) averaged over the ocean region south of 60°S in the group of  
 56 experiments starting in March (top row) and September (bottom) for the NEMO (left column) and  
 57 PARASO configurations (right column).

58

59

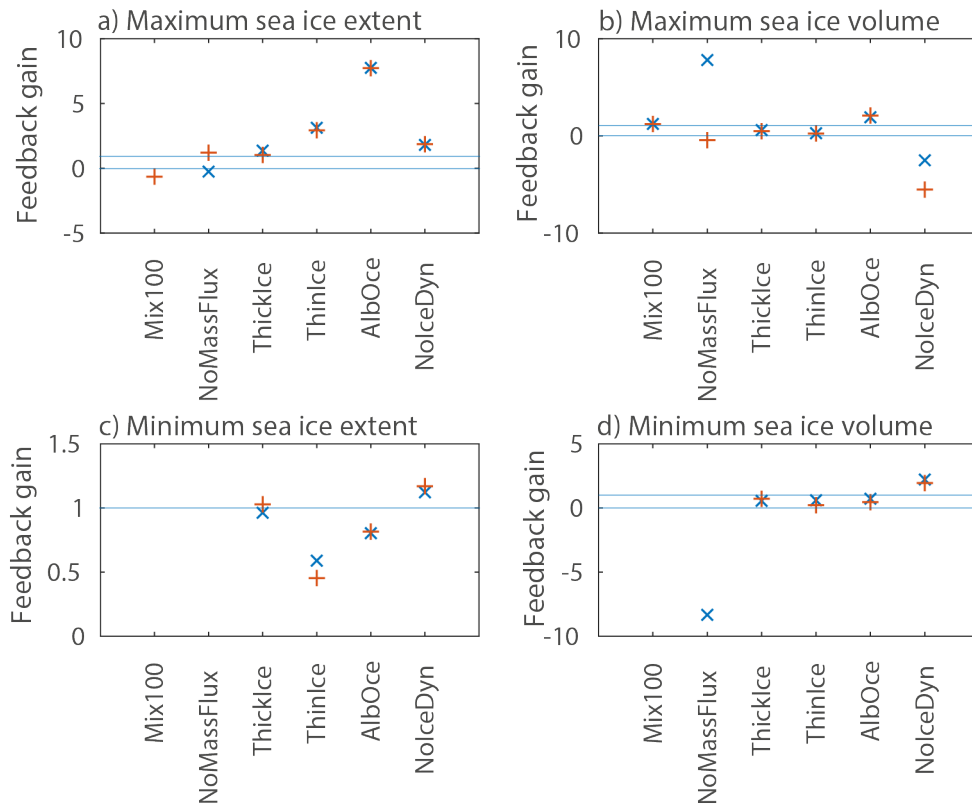

60 Figure S4. Maximum sea ice extent anomaly (in  $10^{12} \text{ m}^2$ ) compared to the reference experiment as a  
 61 function of the sea surface anomaly averaged over the region south of  $60^\circ\text{S}$  (in K) in the previous  
 62 summer for the second year in the experiments starting in March and for the first minimum and second  
 63 maximum for the experiments starting in September.

64

65 Figure S5. Difference in surface air temperature (in K) between the PARASO experiment in winter (July-  
 66 August-September) of the second year of the experiment starting in March and the corresponding  
 67 reference experiment.

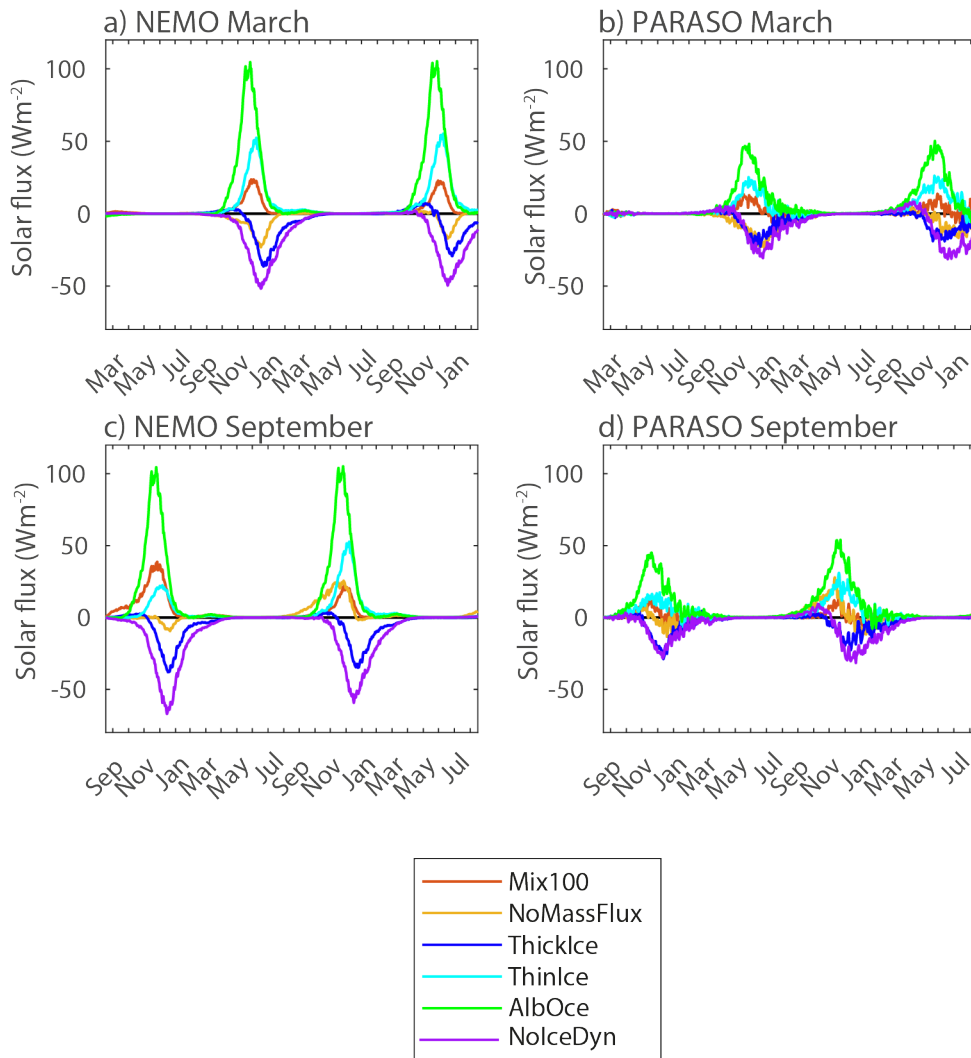

68

69

70 Figure S6. Feedback gain for experiments starting in March (blue x) and September (red +) for the a)  
 71 maximum sea ice extent, b) maximum sea ice volume, c) minimum sea ice extent and d) minimum sea  
 72 ice volume. We have not displayed the feedback gain when the uncoupled response is smaller than  
 73 0.2 million km<sup>2</sup> for sea ice extent or 0.2 thousand km<sup>3</sup> for sea ice volume to avoid large numbers of the  
 74 feedback gains, as this value is used in the denominator of  $G$ . Light blue lines are drawn at values of 0  
 75 and 1.

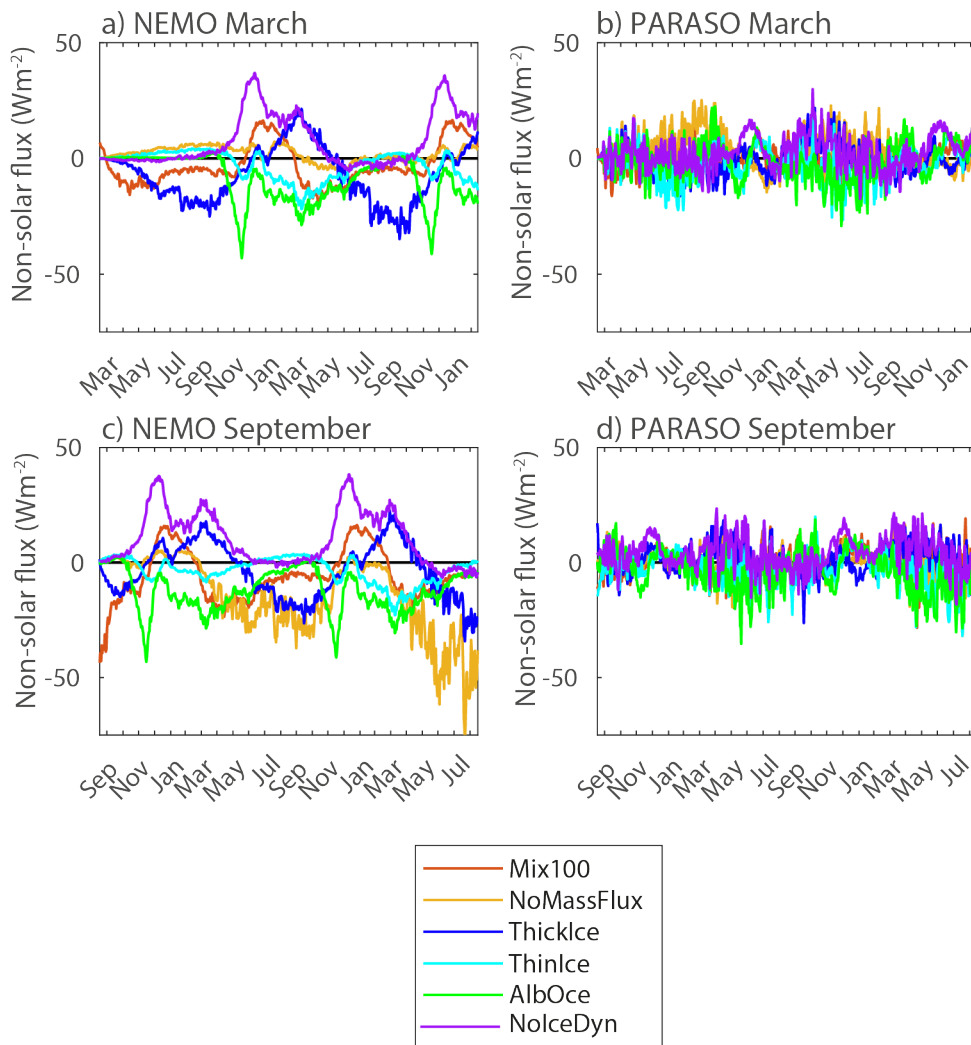

76

77

78 Figure S7. Anomaly of net solar radiation at the top of the ocean (in  $\text{W m}^{-2}$ ) averaged over the ocean  
 79 region south of  $60^\circ\text{S}$  compared to the corresponding reference simulation in the group of experiments  
 80 starting in March (top row) and September (bottom) for the NEMO (left column) and PARASO  
 81 configurations (right column).

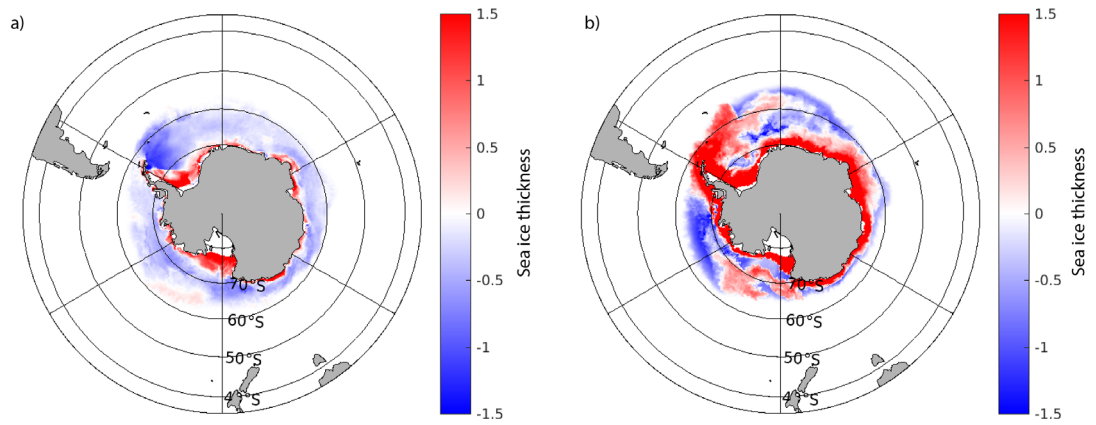

82

83 Figure S8. Anomaly of net non-Solar heat flux at the top of the ocean (in  $\text{W m}^{-2}$ ) averaged over the  
 84 ocean region south of  $60^{\circ}\text{S}$  compared to the corresponding reference simulation in the group of  
 85 experiments starting in March (top row) and September (bottom) for the NEMO (left column) and  
 86 PARASO configurations (right column).

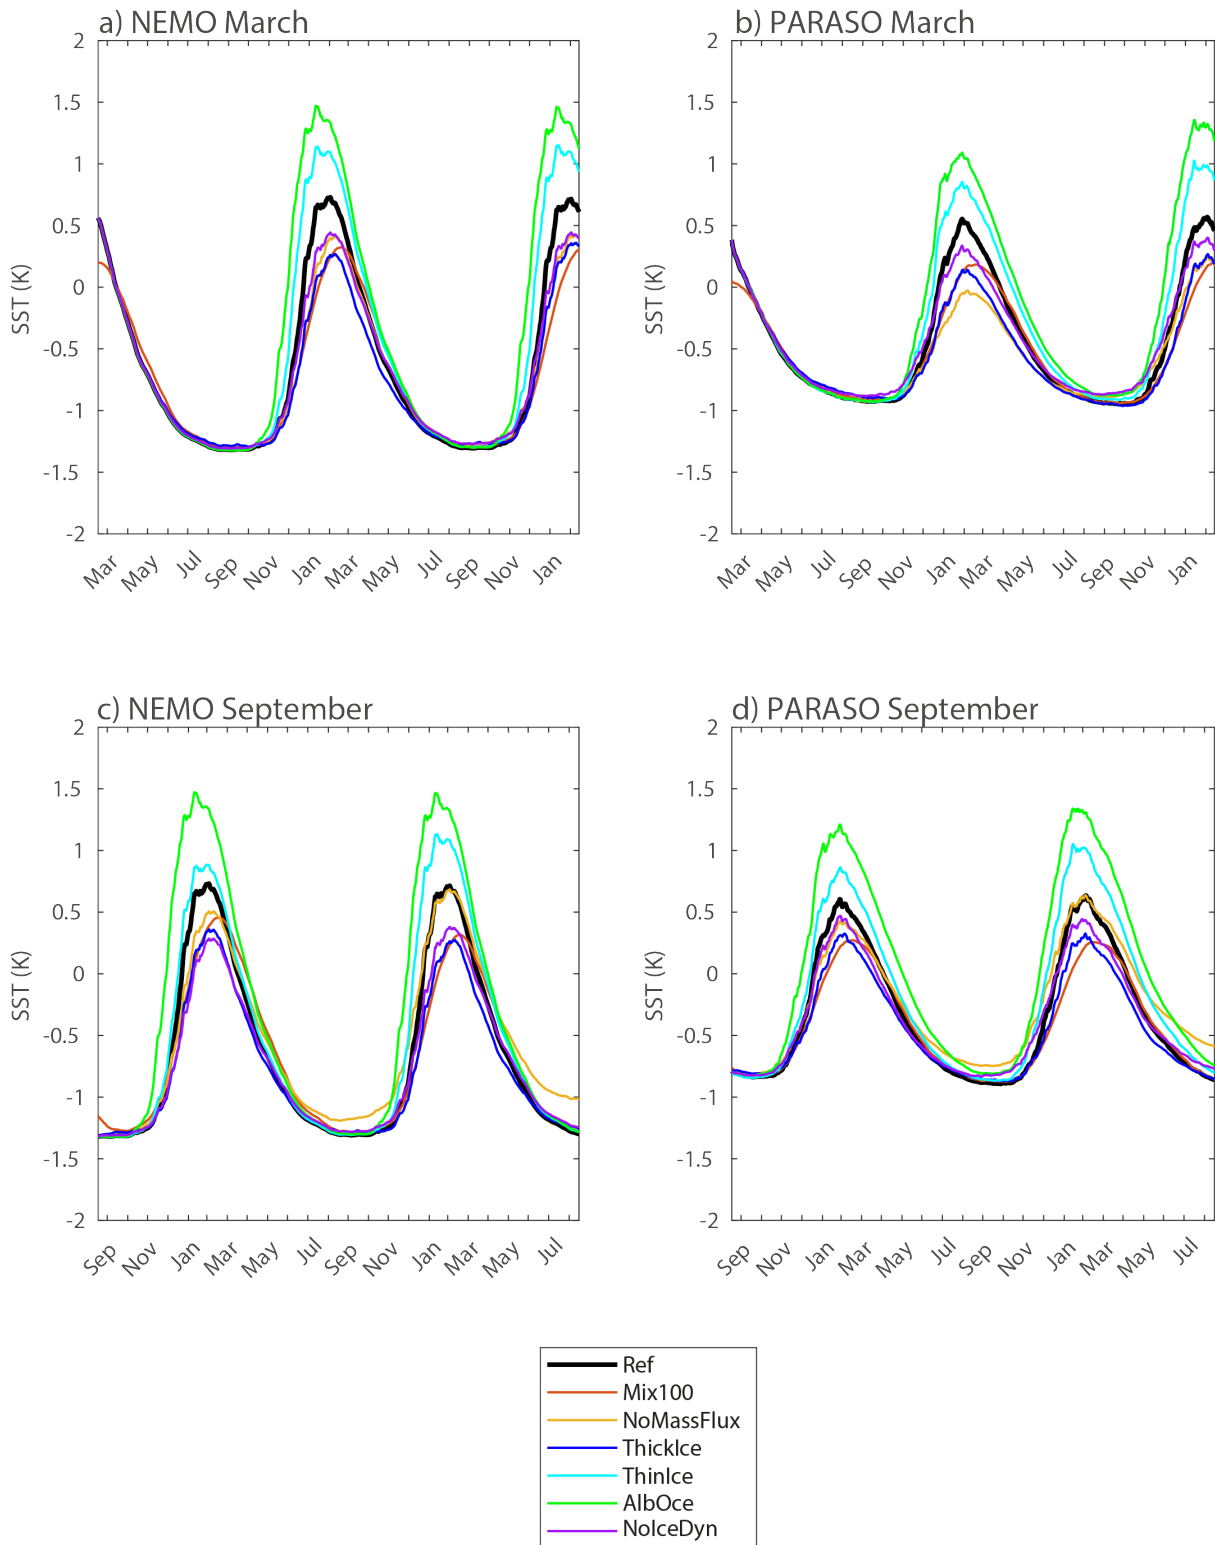

87

89

90 Figure S9. Difference in sea ice thickness (in m) in September of the second year between  
91 NolceDYN\_NEMO\_Mar (left) and NolceDYN\_PARA\_Mar (right) and the corresponding reference  
92 experiments.

93

94

95 Figure S10. Sea surface temperature (in K) averaged over the ocean region south of 60°S in the group  
 96 of experiments starting in March (top row) and September (bottom) for the NEMO (left column) and  
 97 PARASO configurations (right column).
