# Radiation Onboard Aircraft

- Passengers of a commercial aircraft at around 37,000 feet (~11 km) absorb about 30 times more ionizing radiation than people at sea level
- On average, the absorption onboard the aircraft is about 1 chest X-ray per each 10,000 miles flown
- Pilots and aircrew are classified as “occupational radiation workers”
- The Radiation Data Portal (RDP) provides an interactive web-based application for convenient search and visualization of in-flight radiation measurements.
- <https://data.nas.nasa.gov/helio/portals/rdp/>
- Mirror: <https://solarflare.njit.edu/RDP/>

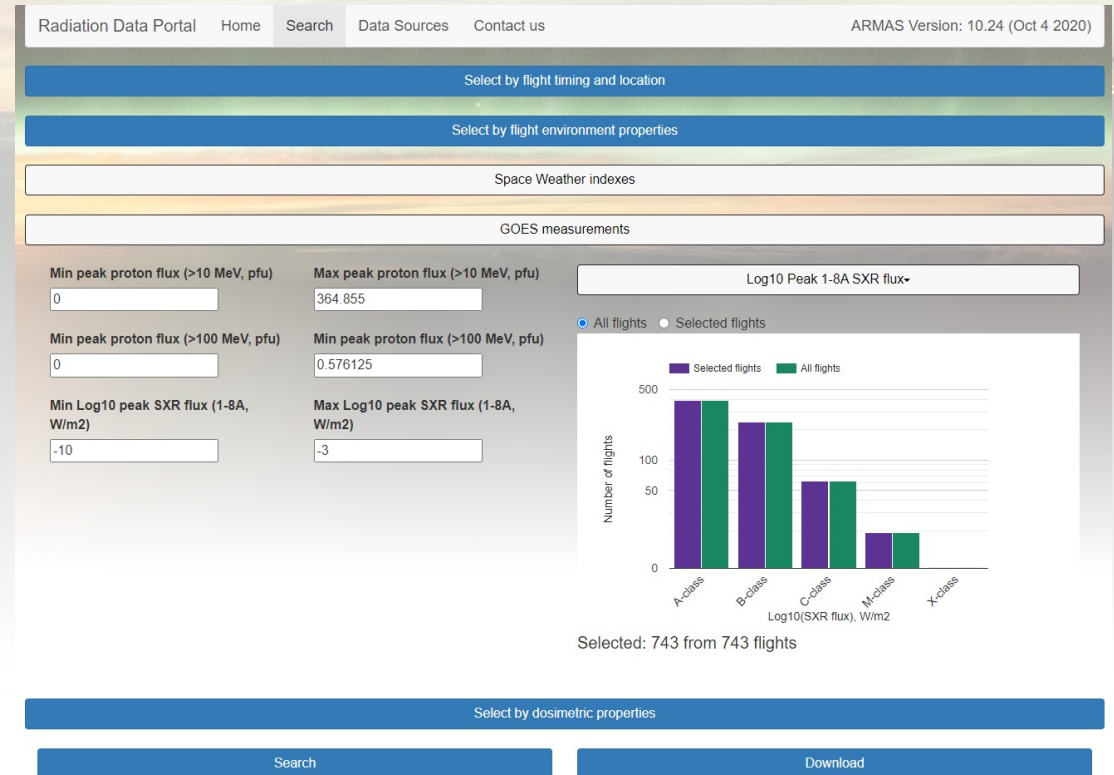

# Integrated Data Sources

- The Automated Radiation Measurements for Aerospace Safety (ARMAS) augmented with the integrated properties of the flight and environment (more than 750 flights at the moment of deployment; more than 1000 after the updates in late 2024)
- Geostationary Operational Environmental Satellite (GOES) Soft X-ray (SXR) radiation measurements in the 0.5-4 Å and 1-8 Å channels.
- Integrated GOES/EPEAD proton flux measurements
- The data sources are loaded to MySQL relational database. The API is developed to handle the requests to the database.

# Radiation Data Portal Front-End

- The search filters include flight time and location properties, environment characteristics, and dosimetry measurement properties
- The search results visualized in the form of dynamic histograms and quick-look light curves for the flight measurements are implemented using the Google Charts API.

## Radiation Data Portal

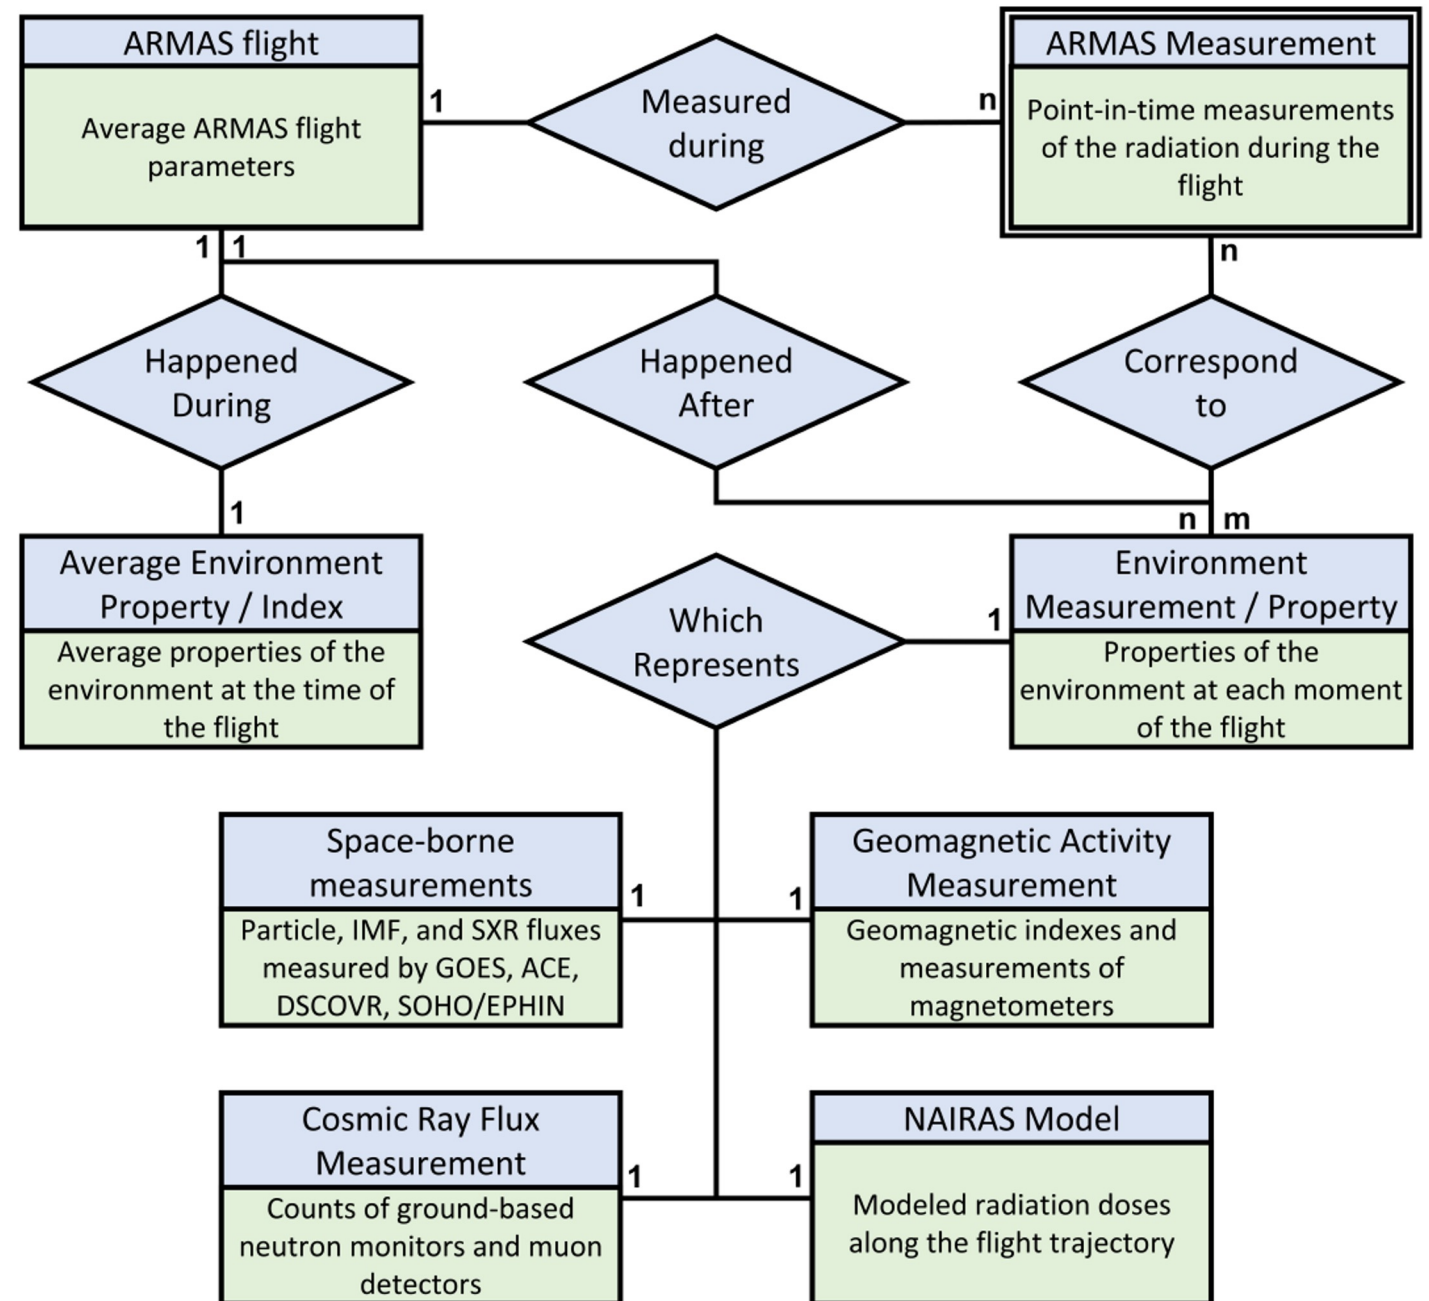

The Earth's radiation environment is a subject of primary importance in the study of Space Weather from scientific, operational, and commercial points of view. A decision-impacting example of using advanced scientific knowledge to improve human safety is to obtain accurate estimates of the radiation doses received during aircraft flights. To increase the accessibility of the relevant data, we provide intuitive access to the radiation measurements obtained from the Automated Radiation Measurements for Aerospace Safety (ARMAS) project.

# Expanding RDP

Within the new NASA HITS 2022 program grant, are expanding the portal:

- Inclusion of additional radiation measurement sources (measurements of radiation, solar wind, geomagnetic activity, etc.)
- Adapting the existing data visualization capabilities to the new data sets and improving the search engine
- Creating ML-ready data set for in-flight radiation prediction
- Including in-house GSU muon detector measurements in the portal

# Expanding RDP: Current Status

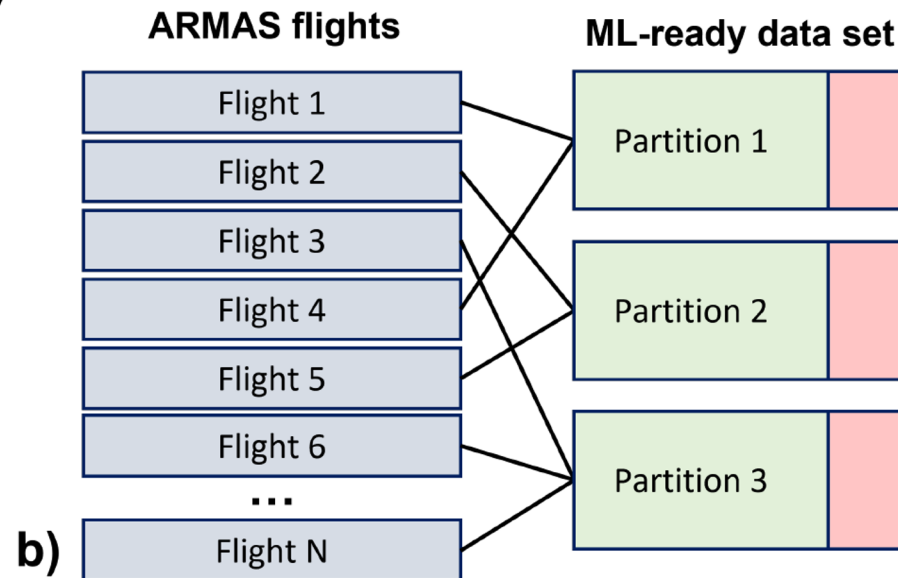

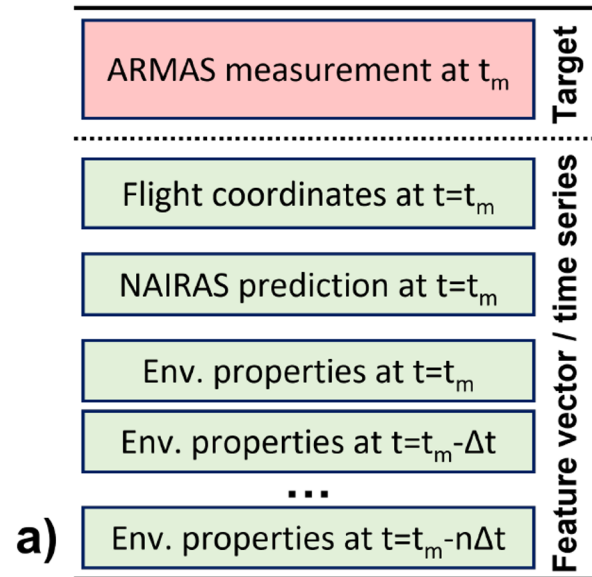

- The data for the following sources have been uploaded (with the capability to update for the desired period, if applies):
  - Updated ARMAS flight data for more than 1000 flights
  - Updated SXR and proton flux data from GOES spacecraft series
  - SOHO/EPHIN proton and alpha particle flux measurements
  - Curated solar wind and geomagnetic activity data from OMNI Web
  - Ground-based neutron monitors (currently Oulu and Dome C)
- The RESTful API was developed to interact with the DB
- The related front-end updates are in progress

# ML-Ready Data Set for Radiation Prediction

- To enhance the efforts targeted on the prediction of the radiation environment, we propose to arrange the data which is directly suitable for the ML applications
- The data set structure is presented below. The ML-ready data set versions will be available via the Radiation portal website.

**ML-ready Data Set Point (flight point)**

A schematic representation of the flight partitioning

# ML-Ready Data Set for Radiation Prediction

- Large dataset with many features
- Cannot split flight between different partitions
- Large variation in data quality
- Dense clusters of data

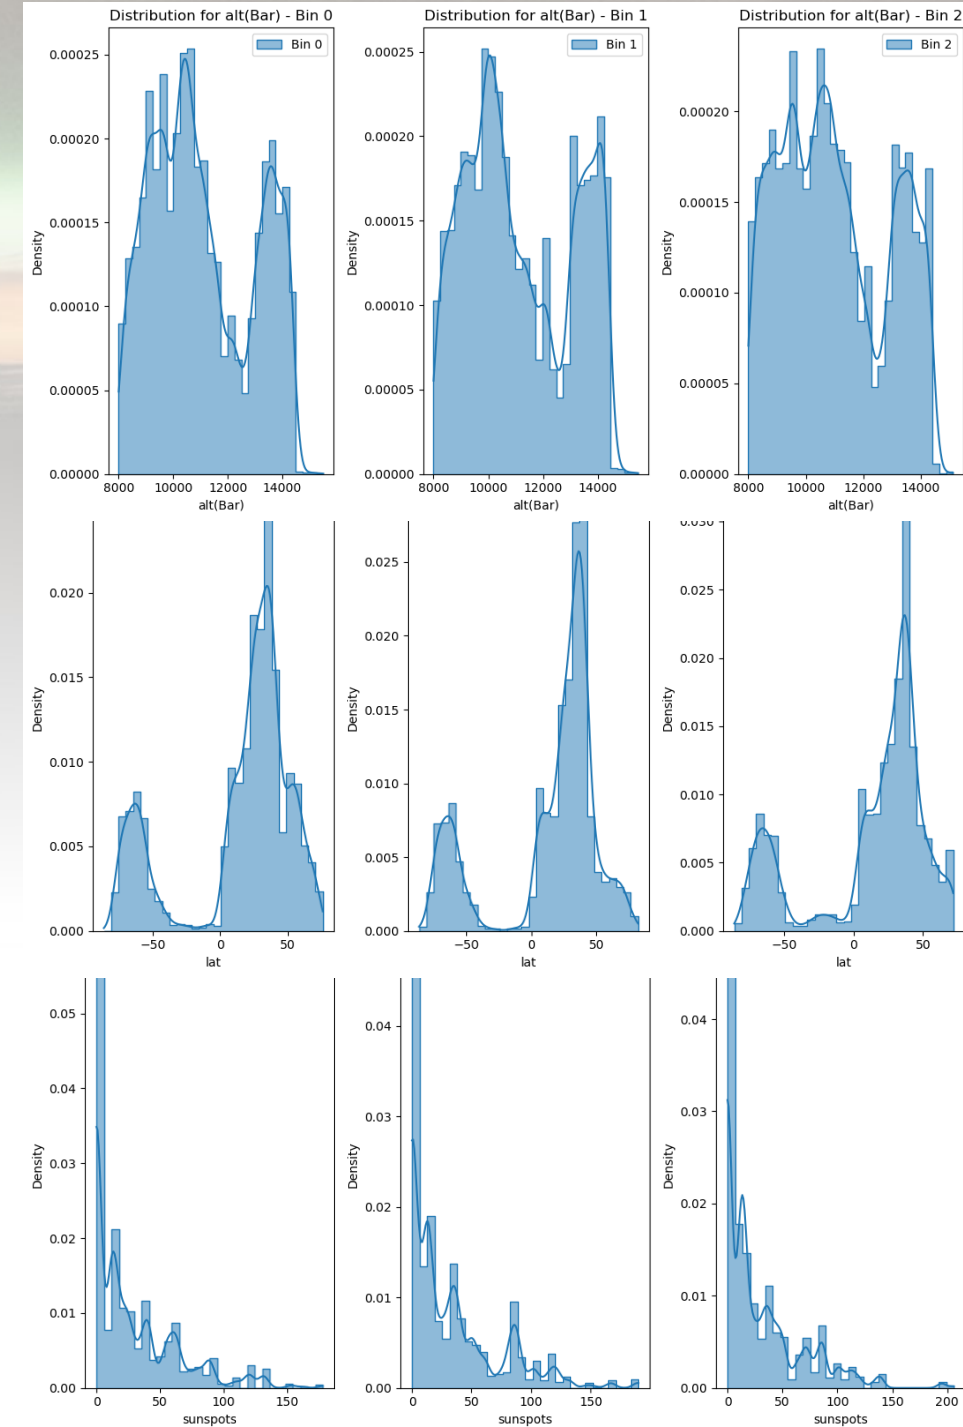

# ML-Ready Data Set for Radiation Prediction

- Large dataset with many features
  - Find independent features and divide along those lines
- Cannot split flight between different partitions
  - Keep flights together through splitting algorithm
- Large variation in data quality
  - Use curating algorithm based on known valid data
- Dense clusters of data
  - Use probabilistic data so that points that pass through dense cluster aren't automatically considered part of that cluster

# Testing Partitioning Algorithm

- Testing how good the data has been partitioned:
  - Good sign #1: the distributions of the parameters (flight locations and solar/geo activity properties) look alike (right)
  - Good sign #2: the data point cannot understand what data set it belongs to!

Predicted	0	1	2	Accuracy: 0.3343
Actual				Precision: 0.3343
0	21973	21898	21979	Recall: 0.3343
1	22250	22216	22228	F1 Score: 0.3343
2	21512	21444	21442	

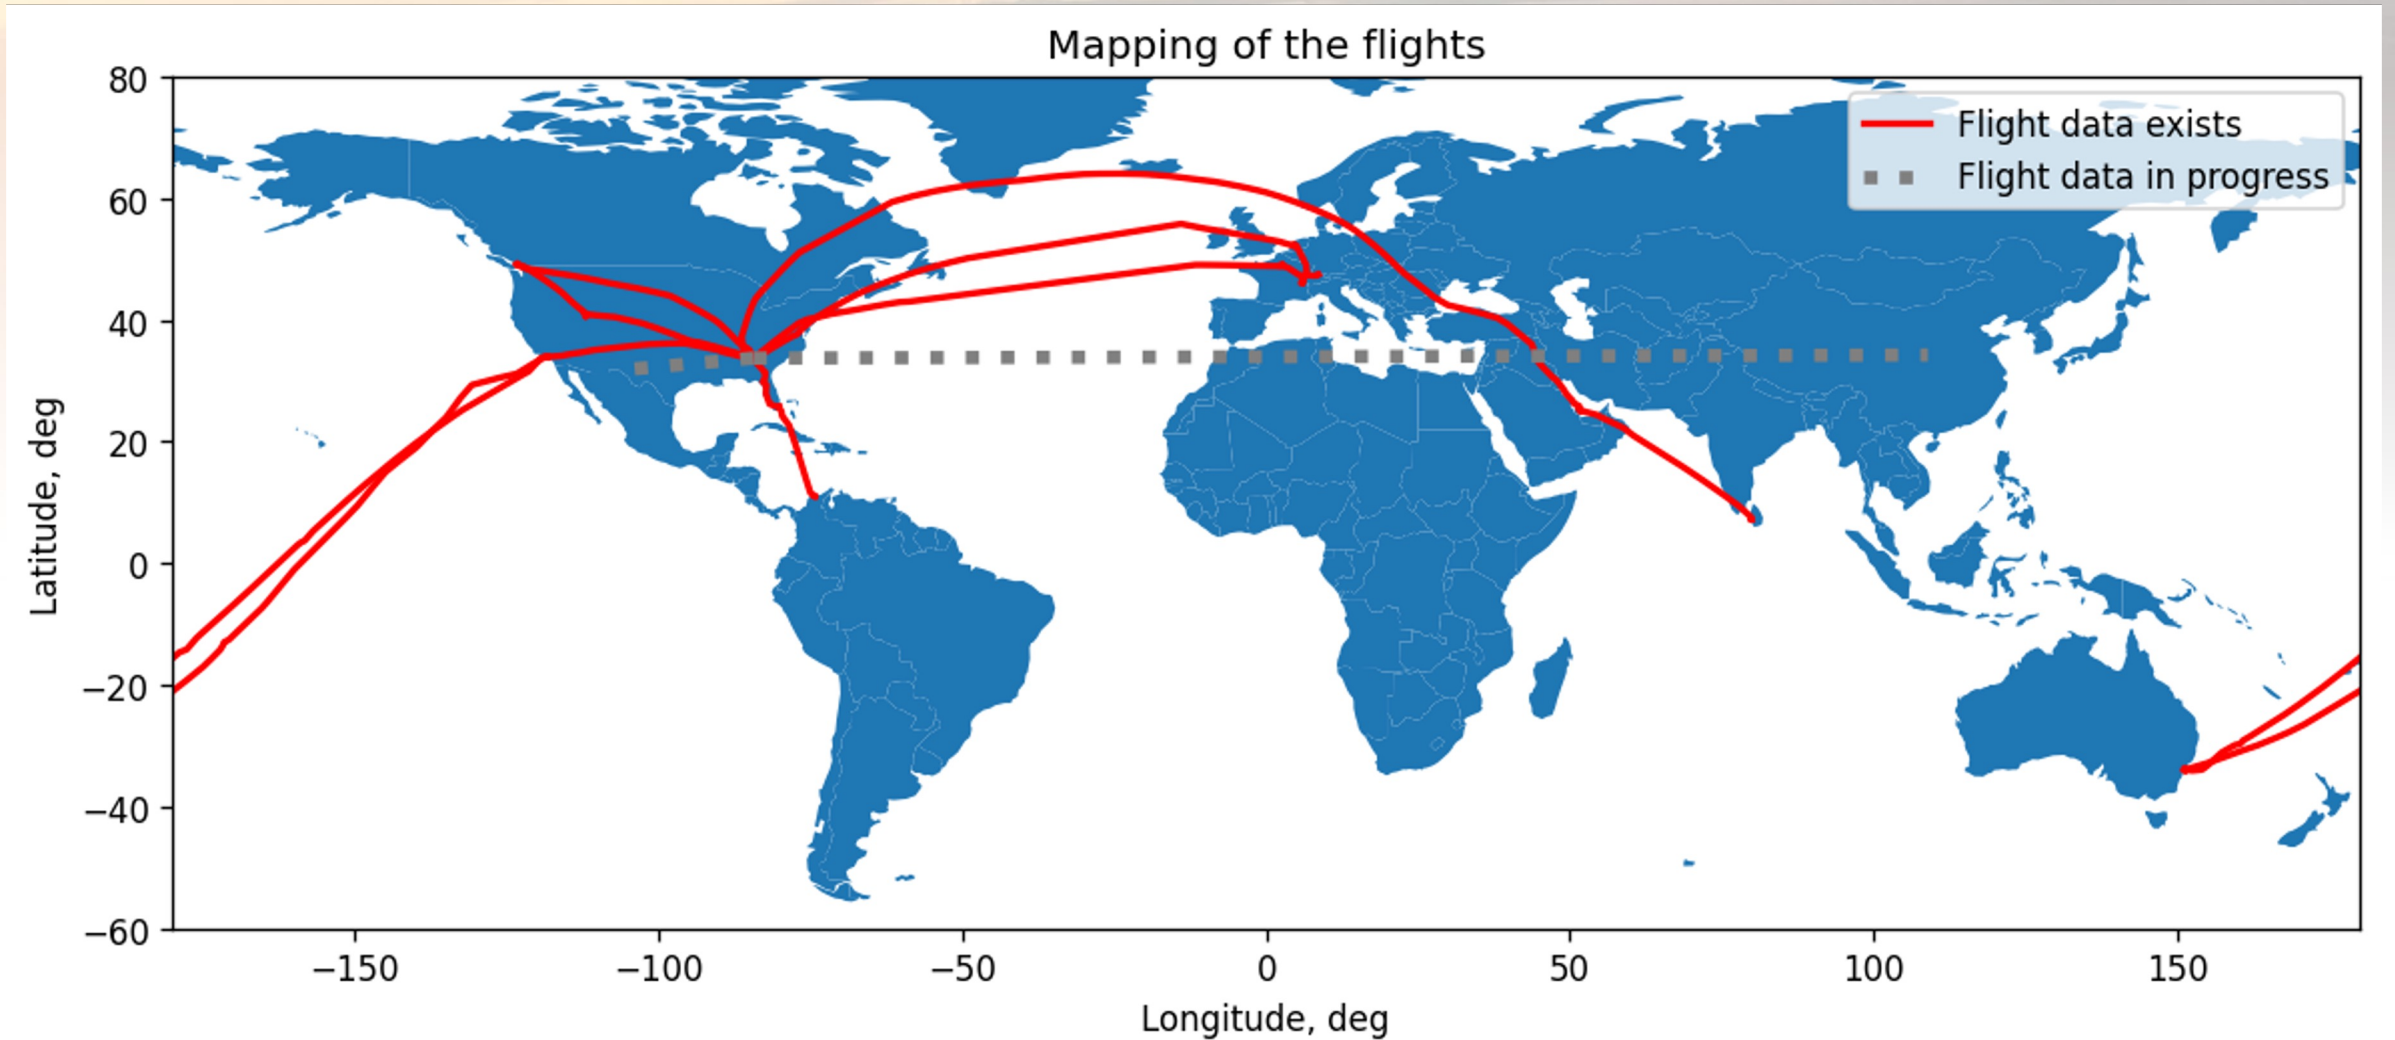

# In-Flight Muon Measurements at GSU

- A CubeSat-size prototype of the cosmic ray muon detector was developed by Nuclear physics and CS colleagues at GSU
- The prototype was taken on more than 15 commercial airplane flights. The data analysis is ongoing.
- The measurements are planned to be featured at the portal at the designated page

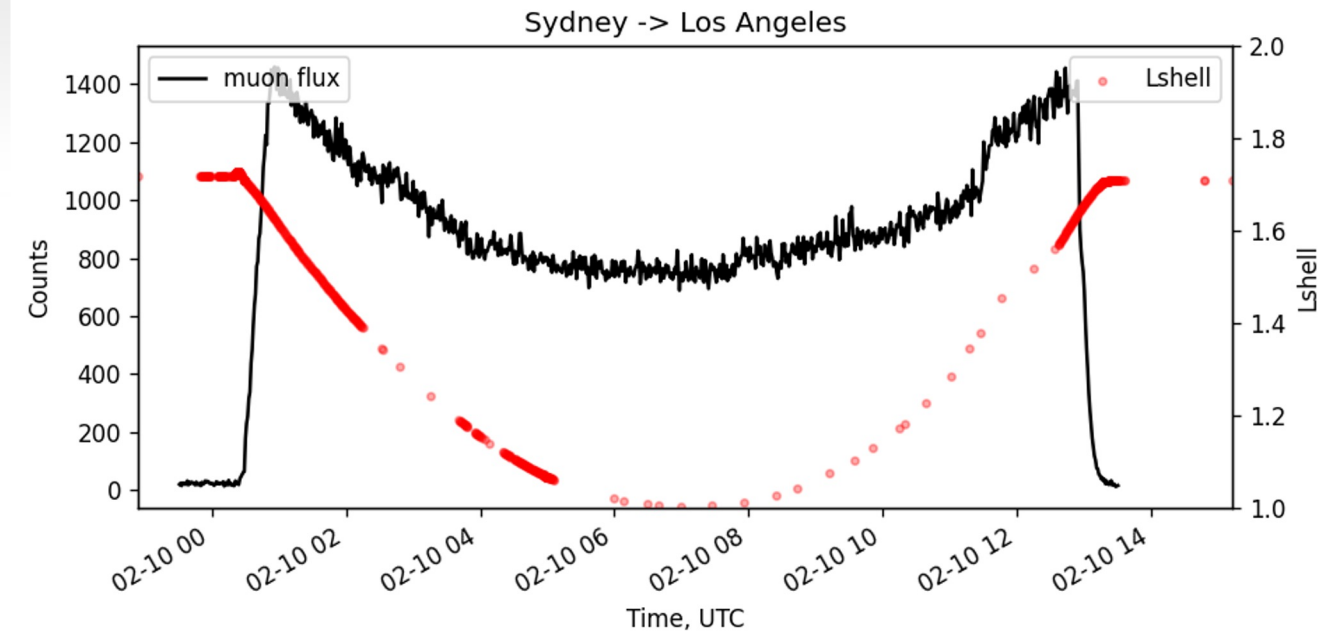

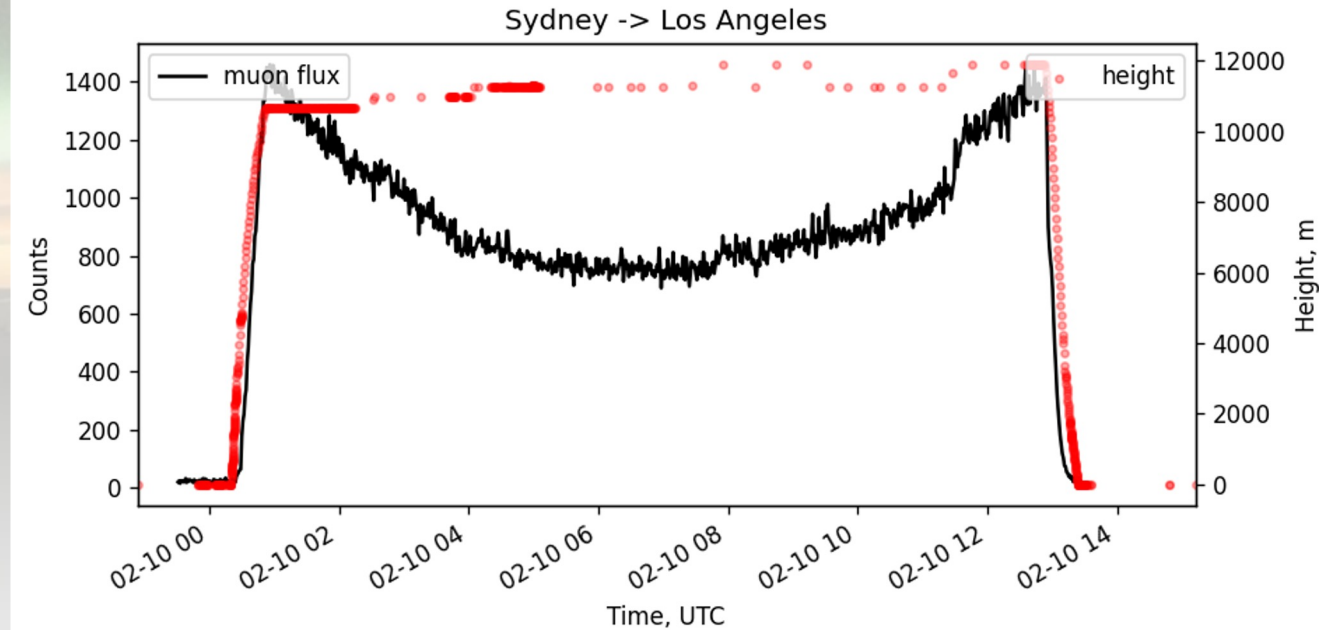

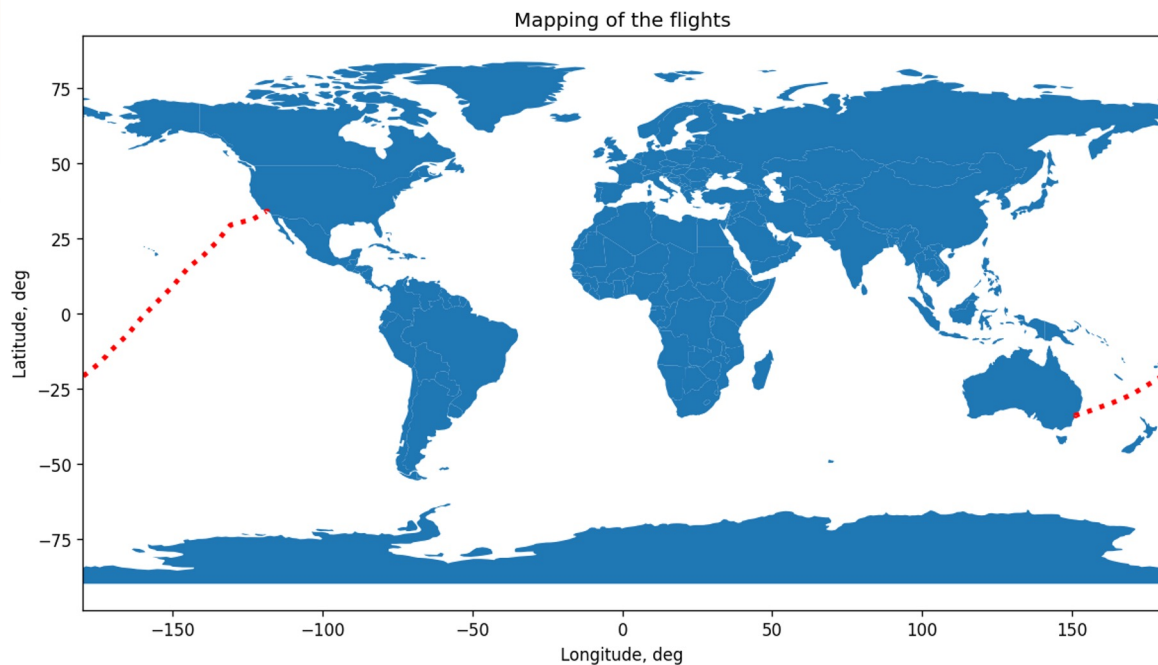

# Flights Completed

# Example measurement: Sydney to Los Angeles

- One of the most interesting flights in the data set: crosses the equator
- The muon counts are sensitive to the geomagnetic cutoff / Lshell

# Summary

- Radiation Data Portal enhances the discoverability of the radiation measurements at the airplane flights
- We are expanding the portal by providing more data sources and visualization capabilities, including GSU measurements of cosmic ray muons
- We are preparing a comprehensive ML-ready data set for the prediction of radiation during airplane flights
- We are collecting the muon measurements on the airplane flights. Measurements along 14 routes have been completed, more are coming!

Thank You for
