### Motivation

Flow regimes during

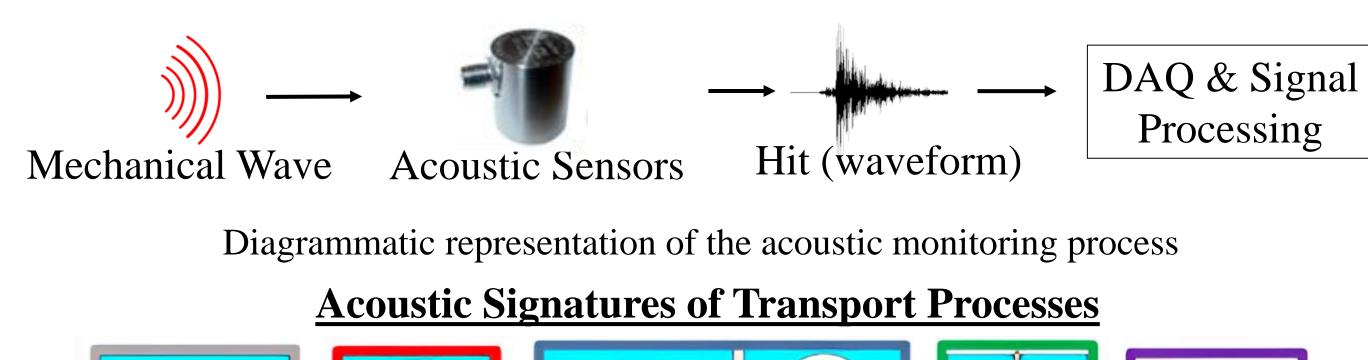

flow condensation

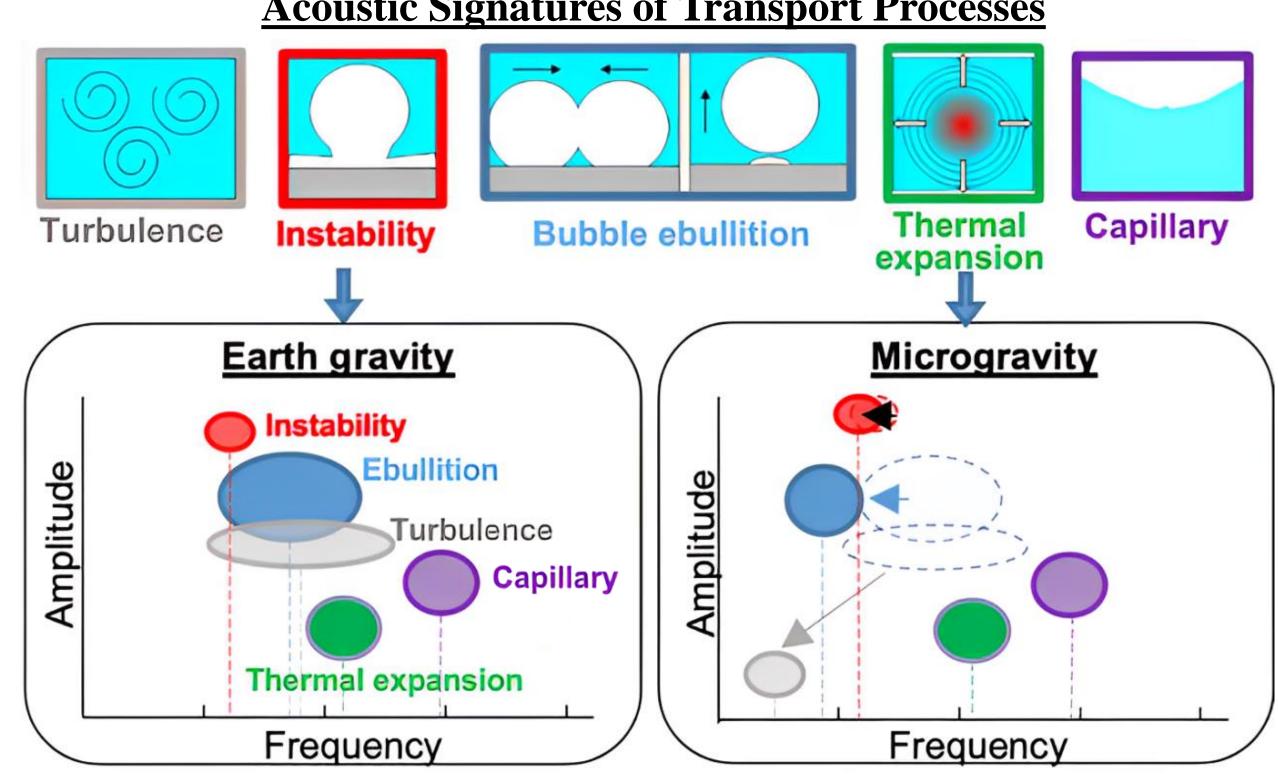

- Flow condensation occurs in a variety of thermal-fluid applications, with distinct heat transfer characteristics observed across different flow regimes.
- Interfacial instabilities in flow condensation have potential to degrade thermal performance.
- Traditional analysis of flow condensation, such as thermofluidic measurements or high-speed visualization, are not always available and lack the sampling rate required to capture rapid dynamics.

### **Innovative Solution**

#### **Acoustic Sensing Techniques**

- Does not require direct visualization access, providing greater flexibility in flow condensation studies
- Offers a better time resolution compared to optical imaging, enabling the capture of high-frequency characteristics
- Enables non-destructive measurement of acoustic waves, minimizing impact on the flow condensation dynamics

Acoustic signatures may fully decouple under microgravity

### Objective

Using non-destructive acoustic sensors to characterize flow condensation and identify dominant transport mechanisms during flow regime transitions under gravity and microgravity

### **Experimental Setup** Vapor (npfh) NASA Condensation Module – Heat Transfer (CM-HT) Water channel **Quick Disconnects** npfh channel Thermocouple Non-transparent enclosure Pressure transducer Cross-section of Acoustic sensors attaching on CM-HT npfh channel vapor Accelerometer, Counterflow Acoustic Emission (AE) 50 kHz sampling **Cooling Water** Sensor, 1 MHz sampling rate

#### **System Overview**

### Test fluid: normal perfluorohexane (npfh)

- nPFH flow rate: 2 g/s 25 g/s
- Water flow rate: up to 27 g/s
- Vapor inlet conditions: subcooled, saturated, or superheated

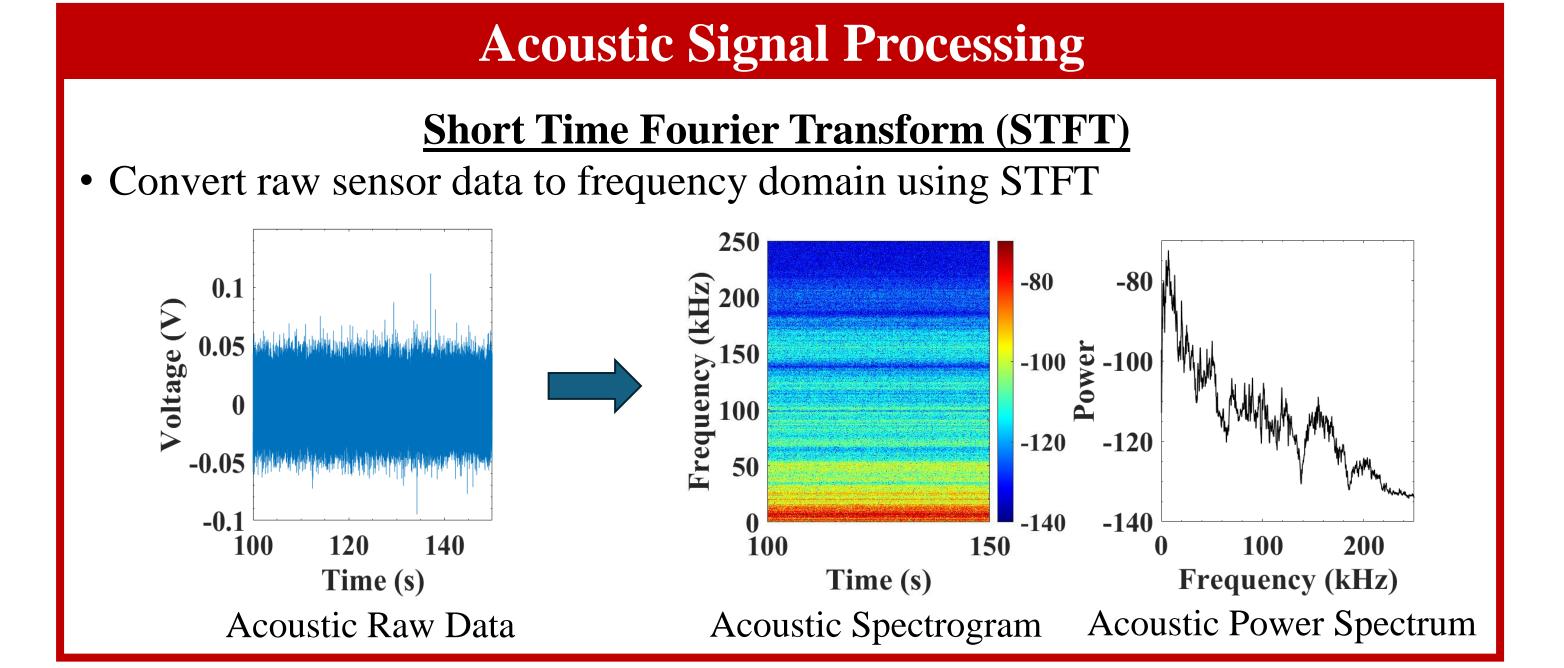

### **Testing Conditions**

resume Conditions		
Flow	Vertical	
Orientation	downflow	
Target Inlet	1.15/ 1.0 /0.8	
Quality	/0.6	
Gnpfh kg/m <sup>2</sup> s	115-419	

Gwater kg/m<sup>2</sup> s

324

#### Vapor Quality Calculation Inlet quality of saturated vapor: $Pwr_{HT} - \dot{m}_v C_{p,l,v} (T_{v,sat} - T_{HT,in})$ $npfh(v) \Longrightarrow$ Inlet quality of superheated vapor: $x_{e,in} = 1 + \frac{C_{p,g,v}(T_{v,in} - T_{v,sat})}{C_{p,g,v}(T_{v,in} - T_{v,sat})}$ O'Neill 2019 Subsequent local quality: (Axial location) $\mathbf{x}_{\mathrm{e},n+1} = \mathbf{x}_{\mathrm{e},n} -$ Schematics of vapor quality calculation Vapor quality profiles at various Gnpfh and set inlet vapor qualities $-251.2 \text{ kg/m}^2\text{s}$ $\sim$ 213.5 kg/m<sup>2</sup>s $374.2 \text{ kg/m}^2\text{s}$ $\sim$ 316.5 kg/m<sup>2</sup>s $-183.3 \text{ kg/m}^2\text{s}_{-1}$ $-183.3 \text{ kg/m}^2\text{s}$ $296.4 \text{ kg/m}^2 \text{s}$ **251.2** kg/m<sup>2</sup>s $\sim$ 115.5 kg/m<sup>2</sup>s $_{\perp}$ **—125.6** kg/m<sup>2</sup>s $\sim$ 251.2 kg/m<sup>2</sup>s -213.5 kg/m<sup>2</sup>s $-170.8 \text{ kg/m}^2 \text{s}$ $-125.6 \text{ kg/m}^2\text{s}$ $\sim$ 125.6 kg/m<sup>2</sup>s z axis (mm) z axis (mm) z axis (mm) z axis (mm)

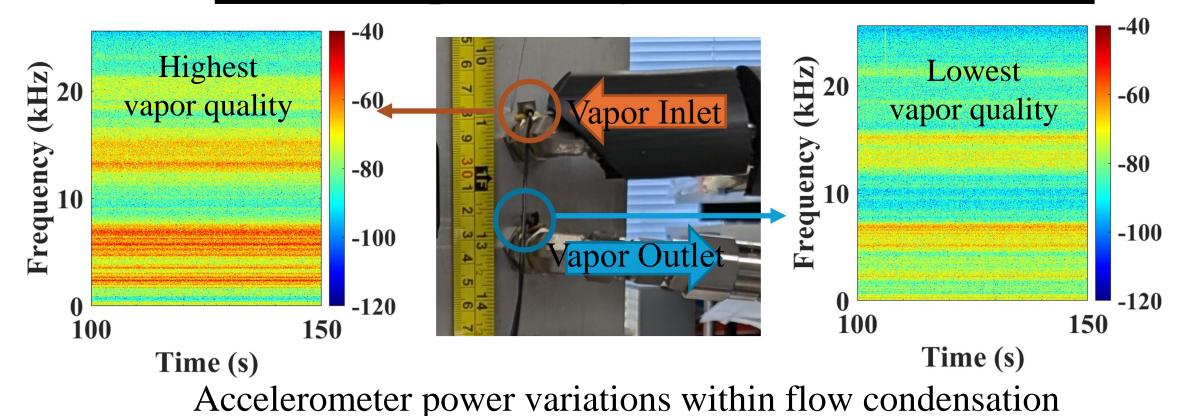

#### Results Acoustic Signatures Comparison between flows w/ and w/o condensation -w/ condensation $(b)_{-80}$ Without w/o condensation Condensation Condensation ₹ 5150 **2** 100 Frequency (kHz) Time (s) Time (s)

Flow condensation generates significant acoustic power

Acoustic (a) spectrogram and (b) power of flow w/ vs. w/o condensation

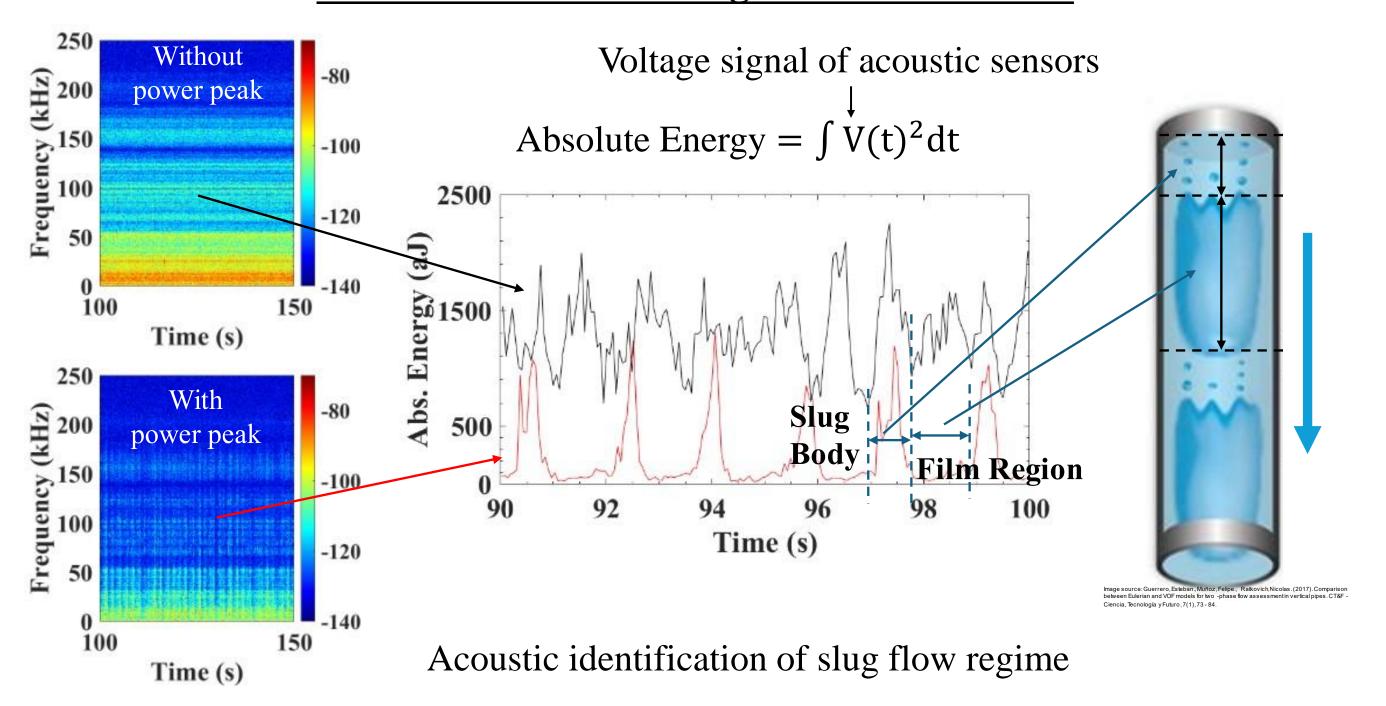

- Broad frequency interaction (250 kHz) during condensation
- Minimum acoustic power in non-condensation flow

## Effect of Vapor Quality on Accelerometer Power

Stronger accelerometer power associated with higher vapor quality

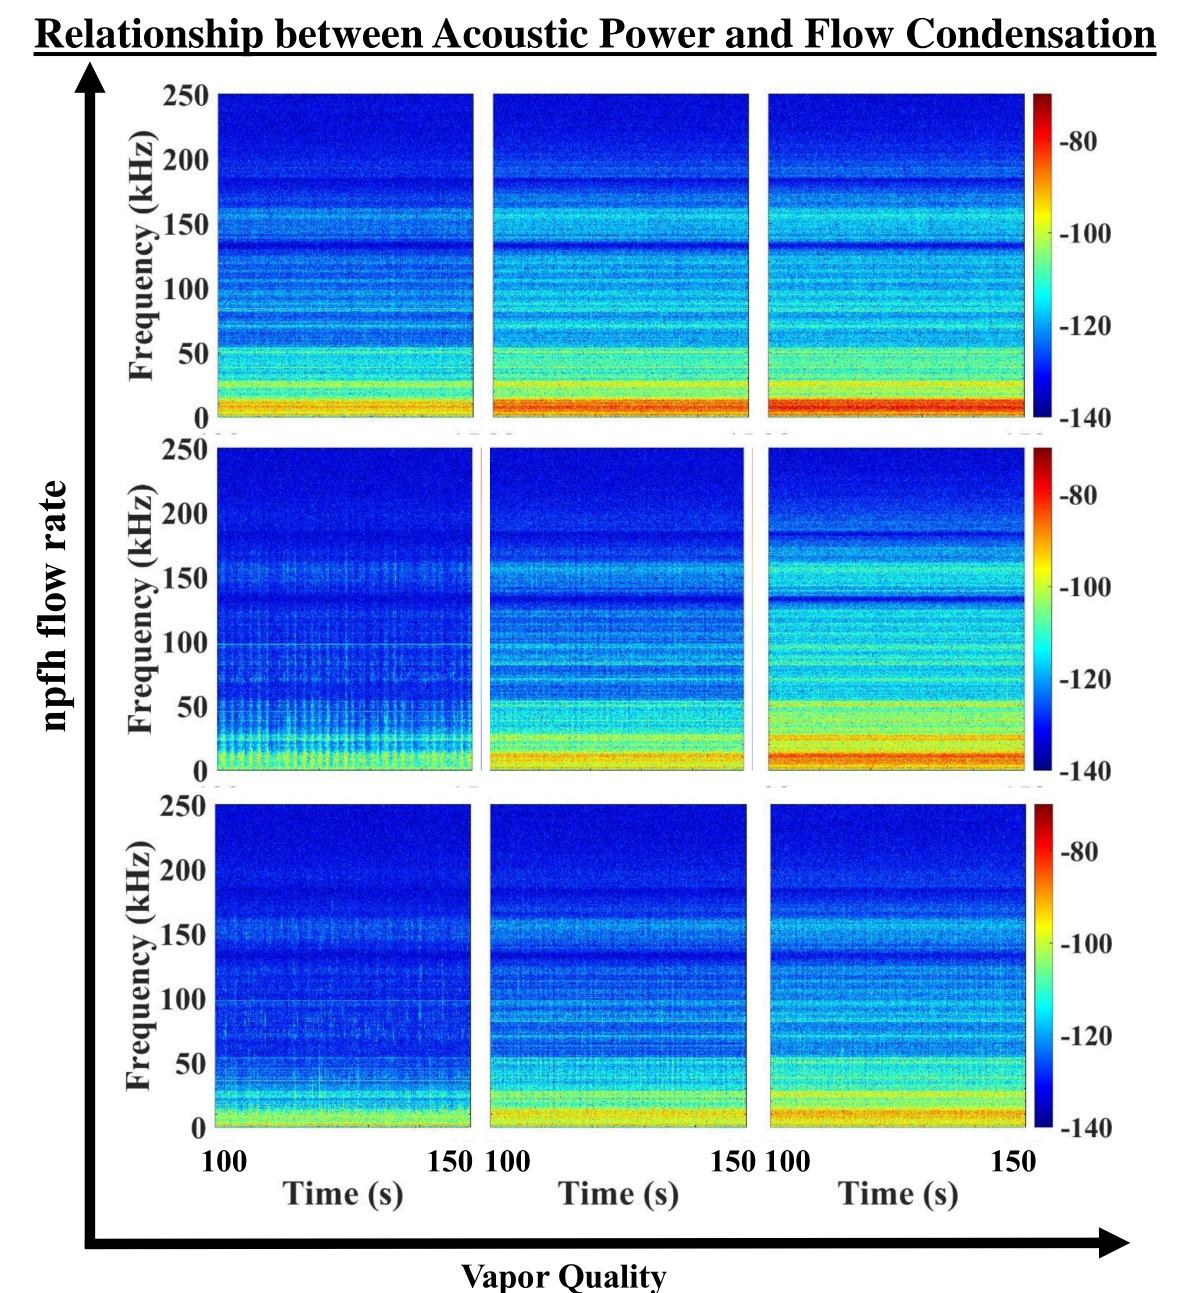

#### Flow Condensation Regime Identification

Periodic vertical power bands observed at certain acoustic spectrograms

Periodic peaks in absolute energy aligned with slug flow regime characteristics

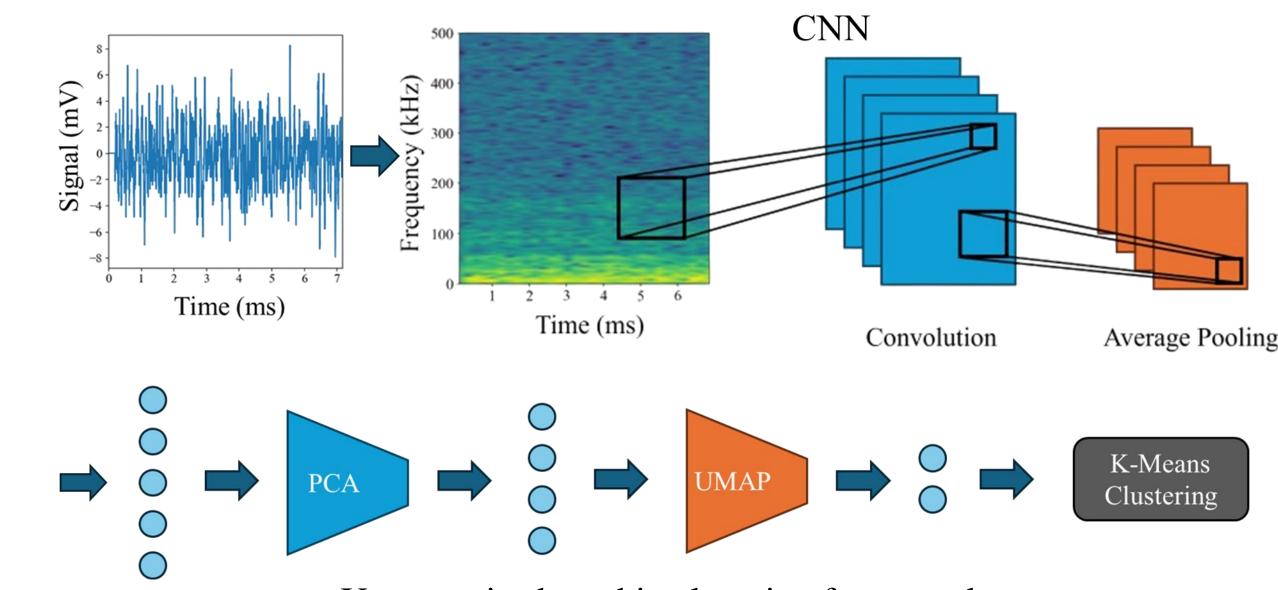

## Results (cont.)

Acoustic spectrogram matrix across varying flow conditions.

Acoustic power intensifies with increasing vapor flow rate and quality

#### Acoustic Signatures Classification via Unsupervised Machine Learning (UML)

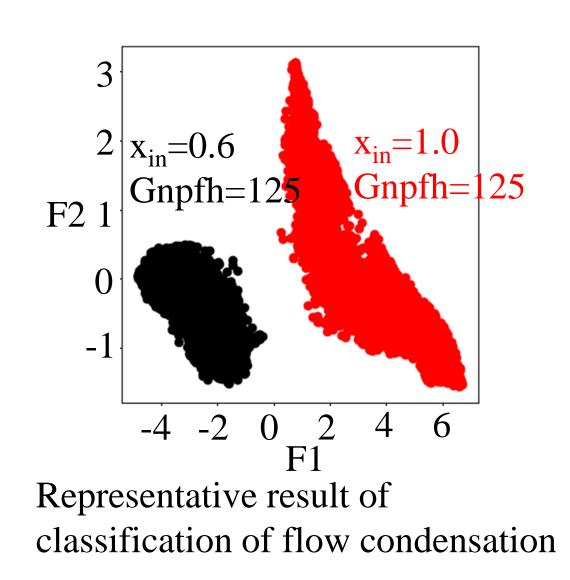

Unsupervised machine learning framework

Purpose for each step

CNN (Convolutional Neural Network):

- Extracts features using convolutional layers and filters PCA (Principal Component Analysis):
- Linearly reduces CNN features, focusing on PCs to denoise data UMAP (Uniform Manifold Approximation and Projection):
- Nonlinearly reduces data, preserving local and global structures K-Means Clustering
- Organizes data into clusters, evaluated by the Adjusted Rand Index (ARI)

Performance of unsupervised machine learning			
Test Set	Set Inlet Vapor Quality	Gnpfh	Accuracy
1	0.6, 1	125	0.9035
2	0.6, 1, 1.15	178	0.9480
3	0.8, 1	213	0.9996
4	0.6, 0.8, 1.15	250	0.9723
5	0.6, 1, 1.15	285	1.0000
6	0.6, 0.8	305	0.9980
7	0.6, 0.8	364	0.9894

UML effectively classifies acoustic signatures by vapor qualities.

#### Summary

- Flow condensation exhibited significantly stronger acoustic signals than single phase liquid flow.
- Acoustic signatures proved effective in capturing flow condensation dynamics.
- Slug flow regime was effectively identified through distinct acoustic patterns. Unsupervised machine learning with feature extraction enhance raw data
- retention and facilitate the classification of flow condensation. Future testing will be conducted under microgravity.
