NASA TECH BRIEF

NASA Tech Briefs are issued to summarize specific innovations derived from the U.S. space program, to encourage their commercial application. Copies are available to the public at 15 cents each from the Clearinghouse for Federal Scientific and Technical Information, Springfield, Virginia 22151.

Instrument Accurately Measures Weld Angle and Offset

The problem:
In welding, misalignment can result from one member being welded to the other at an angle, with an offset, or both at an angle and with an offset. To correlate the effect of this angle and offset on the tensile strength of welded structures, it is necessary to be able to accurately measure these variables. In the past they have been either estimated or only roughly measured.

The solution:
An instrument designed to measure offset from a reference plane at two locations on a test coupon. These measurements are then used to determine weld angles to the nearest arc minute and weld offset to the nearest one thousandth of an inch. Dial indicators R1 and R2 are set to zero with reference to the instrument’s clamping surface.

(continued overleaf)
**How it's done:**

A welded tensile coupon is positioned on the instrument as shown with the center of the weld at the center of the instrument and positioned so that the reading of R₁ is equal to or less than the reading of R₂. Readings of R₁ and R₂ are noted and recorded. The angle and offset of the weld is then computed trigonometrically.

**Notes:**

1. To simplify the computation of angle and offset data, a special table has been prepared for use with the instrument.
