GENERALIZED DECOMPOSITION THEORY OF FINITE SEQUENTIAL MACHINES*

by H. Allen Curtis

Lewis Research Center

SUMMARY

As a direct outgrowth of a study of the decomposition structure of finite sequential machines, an extended decomposition theory of finite sequential machines is developed and presented in this report. From the theory it can be determined how any finite sequential machine can be realized from a set of smaller, concurrently operating machines. This ability assumes practical significance in problems vital to the further advancement of space science, such as the design of control systems and of data-gathering data-analyzing systems.

INTRODUCTION

The use of control systems and of data-gathering data-analyzing systems has been and will undoubtedly continue to be instrumental in advancing man's knowledge of space. Among the most exciting and interesting research aspects of this area are the design of control systems which must be devoid of human control for environmental reasons and the design of compact space-borne computers with much greater capabilities.

It has been suggested that solutions to such problems will increasingly depend on formal automata theory to the extent that it concerns itself with the finite and with considerations imposed by dynamic environments demanding the completion of computation within a fixed time (ref. 1). Of the recent studies in this direction, the ones dealing with the theory of decomposition of finite sequential machines are among those which offer the most promise of direct application (refs. 2 to 5).

In the present report, extensions of the theories and results of the aforementioned studies are developed. In particular, the basic result of the research described herein is the formulation of a generalized decomposition theory of finite sequential machines. Unlike previous investigations dealing with the theory of the decomposition of sequential machines, the admissible class of realizations treated is not limited to series, parallel, or combinations of series and parallel connections - nor is it limited to specialized realizations containing feedback loops. But, it does include additionally those realizations having a general class of feedback loop interconnections.

*Subsequent to the writing of this report in February 1966, the author learned Mr. Arthur T. Pu had submitted a doctoral thesis to the University of Illinois entitled "Generalized Decomposition of Incomplete Finite Automata," December 1965. Some of the results reported in Mr. Pu's thesis are comparable to some of those in this report, but the approaches used were significantly different.
Preliminaries

Before an explanation of the formulations of this report are given, fundamental concepts and terminology are presented as background material.

Definition 1

A finite sequential machine \( M \) is a quintuple \( \langle I, S, 0, \Delta, \Lambda \rangle \) where

- \( I = \{ I_1, I_2, \ldots, I_\ell \} \) is a set of inputs,
- \( S = \{ S_1, S_2, \ldots, S_m \} \) is a set of internal states,
- \( 0 = \{ 0_1, 0_2, \ldots, 0_n \} \) is a set of outputs,
- \( \Delta \) is the next state function that maps the set of pairs \( \langle I_j, S_k \rangle \) into \( S \),
- \( \Lambda \) is the output function that maps the set of pairs \( \langle I_j, S_k \rangle \) onto \( 0 \).

In figure 1 the behavior of \( M \) is described by a flow table. The flow table shows, for instance, that if the present state of \( M \) is \( S_2 \) and input \( I_3 \) is applied, then \( M \) goes into a new state \( S_{12} \) and supplies the output \( O_{21} \). In terms of the definition, this observation is expressed by saying that the next state function \( \Delta \) maps the pair \( \langle I_3, S_2 \rangle \) into \( S_{12} \) a member of \( S \) and that the output function \( \Lambda \) maps the pair \( \langle I_3, S_2 \rangle \) onto \( O_{21} \), a member of \( 0 \). If a next state or an output is unspecified, this is denoted in the flow table by means of a dash for the associated entry. If all thenext states and outputs of \( M \) are specified, then the flow table contains no dashed entries, and \( M \) is said to be complete; otherwise, \( M \) is incomplete.

Algebraic techniques have been introduced as convenient means of studying sequential machines (refs. 5 to 7). Elements of an algebraic theory of sequential machines and certain results obtained in previous studies using algebraic techniques will be introduced.

The states are also represented by positive integers in cases where it is the more convenient notation.
as they are needed. With the aid of the example machine $A$ of figure 2, some of the elements of the algebraic theory are now presented.

**Definition 2**

The Cartesian product $P \times Q$ of two sets $P$ and $Q$ is the set of all ordered pairs $\langle p, q \rangle$ with $p$ in $P$ and $q$ in $Q$ - that is, with $p \in P$ and $q \in Q$.

A concrete illustration of the Cartesian product is provided by considering the sets $I = \{1, 2\}$ and $S = \{1, 2, 3, 4, 5\}$ of machine $A$. The Cartesian product $I \times S$ is the set $\{\langle 1, 1 \rangle, \langle 1, 2 \rangle, \langle 1, 3 \rangle, \langle 1, 4 \rangle, \langle 1, 5 \rangle, \langle 2, 1 \rangle, \langle 2, 2 \rangle, \langle 2, 3 \rangle, \langle 2, 4 \rangle, \langle 2, 5 \rangle\}$. This set is precisely the one that $\Delta$ and $\Lambda$ of machine $A$ map into $S$ and onto $0$, respectively.

**Definition 3**

A binary relation between two sets $P$ and $Q$ is a set $\rho$ of ordered pairs $\langle p, q \rangle$ with $p \in P$ and $q \in Q$. Usually $\langle p, q \rangle \in \rho$ is expressed as $p \rho q$. A binary relation between the set $P$ and itself is called a binary relation on $P$.

Associated with the output function $\Lambda$ of machine $A$ are two binary relations between the sets $S = \{1, 2, 3, 4, 5\}$ and $0 = \{0_1, 0_2\}$. Corresponding to inputs 1 and 2 are the binary relations $\Lambda(1)$ and $\Lambda(2)$, respectively; $\Lambda(1)$ and $\Lambda(2)$ are given as follows:

\[
\Lambda(1) = \{\langle 1, 0_1 \rangle, \langle 2, 0_2 \rangle, \langle 3, 0_2 \rangle, \langle 4, 0_1 \rangle, \langle 5, 0_2 \rangle\}
\]

\[
\Lambda(2) = \{\langle 2, 0_1 \rangle, \langle 3, 0_1 \rangle, \langle 4, 0_2 \rangle, \langle 5, 0_1 \rangle\}
\]

It is worthwhile noting that there is no pair in $\Lambda(2)$ involving state 1. The reason for this is that the output is unspecified when the input 2 is applied to machine $A$ in state 1.
Each pair in these relations is essential to a complete description of the behavior of A. For instance, $\langle 3, 0_2 \rangle \in \Lambda(1)$ shows the relation between state 3 and output $0_2$ when input 1 is applied to A.

There are associated with the next state function $\Delta$ of machine A two binary relations between the set $S$ and itself:

$$\Delta(1) = \{ \langle 1, 4 \rangle, \langle 2, 1 \rangle, \langle 3, 5 \rangle, \langle 4, 3 \rangle \}$$

$$\Delta(2) = \{ \langle 1, 2 \rangle, \langle 2, 5 \rangle, \langle 3, 2 \rangle, \langle 4, 1 \rangle, \langle 5, 4 \rangle \}$$

The absence of a pair involving a present state 5 in $\Delta(1)$ indicates that the relation between present state 5 and any next state is unspecified for input 1. Each pair in these relations is also essential to a complete description of the behavior of A. In fact, the flow table representation of A can be readily derived from the four binary relations $\Delta(1)$, $\Delta(2)$, $\Lambda(1)$, $\Lambda(2)$, and vice versa. The aforementioned relations, besides providing a description of the behavior of A, are useful in algebraic manipulations. This discussion serves as an introduction to the first two of the next three definitions.

**Definition 4**

The next state function $\Delta$ of a sequential machine M is a mapping that associates with every input $i \in I$, a next state relation $\Delta(i)$ on $S$.

**Definition 5**

The output function $\Lambda$ of a sequential machine M is a mapping that associates with every input $i \in I$, an output relation $\Lambda(i)$ between $S$ and $0$.

**Definition 6**

For two sets $P$ and $Q$, $P$ is a subset of $Q$, written $P \subseteq Q$, if each element of $P$ is an element of $Q$. $P$ is a proper subset of $Q$ if $P$ is a subset of $Q$ and there is an element of $Q$ which is not in $P$.

In the case of machine A, $\Delta(1)$ and $\Delta(2)$ are proper subsets of $S \times S$. Similarly, $\Lambda(1)$ and $\Lambda(2)$ are proper subsets of $S \times 0$. Also, $\{1, 2, 5\}$ is a proper subset of $S$. The set $S$ as a subset of itself is an example of a subset that is not proper.

The next two definitions are conveniently illustrated together.
Definition 7

If \( P \) is a set, the set \( N \) of all those elements in \( P \) which have a property \( R \) is expressed as

\[
N = \{ p \in P \mid p \text{ has the property } R \}
\]

Definition 8

If \( \rho \) is a binary relation between \( P \) and \( Q \), the domain \( D(\rho) \) of \( \rho \) is given by

\[
D(\rho) = \{ p \in P \mid p\rho q \text{ for some } q \text{ in } Q \}
\]

With respect to machine \( A \),

\[
N = \{ s \in S \mid s\Lambda(2) o \text{ for all } o \text{ in } 0 \} = \{ 2, 3, 4, 5 \}
\]

since the elements of \( S \) which have the property \( s\Lambda(2) o \) for \( 0_1 \) and \( 0_2 \) are 2, 3, 4, and 5. Furthermore, \( N \) is the domain \( D(\Lambda(2)) \) of the output relation \( \Lambda(2) \). The fact that \( D(\Lambda(2)) \) is a proper subset of \( S \) shows that machine \( A \) is not complete. In general, for all \( i \in I \), both \( D(\Delta(i)) \) and \( D(\Lambda(i)) \) must be \( S \) for a sequential machine \( M \) to be complete.

Definition 9

If \( N \subseteq P \), then

\[
N\rho = \{ q \in Q \mid p\rho q \text{ for some } p \text{ in } N \}
\]

A specific illustration of this definition is provided by considering a set \( N = \{ 1, 2, 5 \} \), a proper subset of \( S \) of machine \( A \), and the next state relation \( \Delta(1) \):

\[
N \Delta(1) = \{ 1, 2, 5 \} \{ \langle 1, 4 \rangle, \langle 2, 1 \rangle, \langle 3, 5 \rangle, \langle 4, 3 \rangle \}
\]

\[
= \{ 4, 1 \}
\]
Definition 10

If \( p \subseteq P \times Q \) and \( \sigma \subseteq Q \times R \), then

\[
\rho \sigma = \{ (p, r) \in P \times R \mid \rho p q \text{ and } q \sigma r \text{ for some } q \in Q \}
\]

For machine \( A \), \( \Delta(1) \subseteq S \times S \) and \( \Lambda(2) \subseteq S \times 0 \); thus,

\[
\Delta(1) \Lambda(2) = \{ (1, 4), (2, 1), (3, 5), (4, 3) \} \{ (2, 0_1), (3, 0_1), (4, 0_2), (5, 0_1) \}
= \{ (1, 0_2), (3, 0_1), (4, 0_1) \}
\]

The binary relation \( \Delta(1) \Lambda(2) \) relates the present states of \( A \) to the outputs supplied after the successive application of inputs 1 and 2.

Definition 11

The set intersection of a family \( P_1, P_2, \ldots, P_n \) of sets, written \( P_1 \cap P_2 \cap \ldots \cap P_n \), is the set of elements which are in all of the sets of the family. Two sets \( P \) and \( Q \) are disjoint if \( P \cap Q = \emptyset \), where \( \emptyset \), called the empty set, is the set with no elements in it.

In the case of machine \( A \), \( P_1 = \{ 1, 2, 5 \} \), \( P_2 = \{ 1, 4 \} \), \( P_3 = \{ 1, 4, 5 \} \) is a family of the subsets of \( S \). The intersection of these subsets is

\[
P_1 \cap P_2 \cap P_3 = \{ 1, 2, 5 \} \cap \{ 1, 4 \} \cap \{ 1, 4, 5 \} = \{ 1 \}
\]

Two other subsets, \( P_4 = \{ 1, 3 \} \) and \( P_5 = \{ 2, 4 \} \), of \( S \) are disjoint since there is no element common to both \( P_4 \) and \( P_5 \) so that

\[
P_4 \cap P_5 = \emptyset
\]

Definition 12

The set union of a family \( P_1, P_2, \ldots, P_n \) of sets, written \( P_1 \cup P_2 \cup \ldots \cup P_n \), is the set of elements in at least one set of the family.
The union of the subsets \( P_1, P_2, \) and \( P_3 \) of the previous example is
\[
P_1 \cup P_2 \cup P_3 = \{1, 2, 5\} \cup \{1, 4\} \cap \{1, 4, 5\} = \{1, 2, 4, 5\}
\]

**Definition 13**

A partition \( \pi \) of a set \( S \) is a family \( P_1, P_2, \ldots, P_n \) of nonempty pairwise disjoint sets such that \( P_1 \cup P_2 \cup \ldots \cup P_n = S \). The sets \( P_1, P_2, \ldots, P_n \) are called the blocks of \( \pi \).

The subsets \( P_1 = \{1, 5\}, P_2 = \{2, 4\}, \) and \( P_3 = \{3\} \) of \( S \) of machine \( A \) are pairwise disjoint. Their union is \( P_1 \cup P_2 \cup P_3 = S \) and the partition \( \pi \) is given by
\[
\pi = \{P_1, P_2, P_3\}
\]

**Definition 14**

The canonical relation \( \pi^* \) between \( S \) and \( \pi \) is given by
\[
\pi^* = \{(s, P) | s \in P \in \pi\}
\]

In particular, the relation \( \pi^* \) between \( S \) of machine \( A \) and the partition \( \pi \) of the previous example is
\[
\pi^* = \{\langle 1, P_1 \rangle, \langle 5, P_1 \rangle, \langle 2, P_2 \rangle, \langle 4, P_2 \rangle, \langle 3, P_3 \rangle\}
\]

Then
\[
S\pi^* = \{1, 2, 3, 4, 5\} \{\langle 1, P_1 \rangle, \langle 5, P_1 \rangle, \langle 2, P_2 \rangle, \langle 4, P_2 \rangle, \langle 3, P_3 \rangle\}
\]
\[
= \{P_1, P_2, P_3\} = \pi
\]

**Definition 15**

The inverse of a binary relation \( \rho \) is
\( \rho^{-1} = \{ (q, p) \mid p \rho q, \ p \in P \text{ and } q \in Q \} \)

The inverse of the relation \( \pi^* \) of the previous example is given, for instance, by

\( (\pi^*)^{-1} = \{ (P_1, 1), (P_1, 5), (P_2, 2), (P_2, 4), (P_3, 3) \} \)

Thus,

\[ \pi(\pi^*)^{-1} = \{ P_1, P_2, P_3 \} \{ (P_1, 1), (P_1, 5), (P_2, 2), (P_2, 4), (P_3, 3) \} = \{ 1, 5, 2, 4, 3 \} = S \]

Furthermore, \( S\pi^*(\pi^*)^{-1} = S \) and \( \pi(\pi^*)^{-1} \pi^* = \pi \).

**Definition 16**

The greatest lower bound (g.l.b.) of two partitions \( \pi_\alpha \) and \( \pi_\beta \) is given by

\[ \pi_\alpha \cdot \pi_\beta = \{ P \cap Q \mid P \in \pi_\alpha \text{ and } Q \in \pi_\beta \}. \]

There are two trivial partitions of a set \( S \). The partition \( I \) contains one element \( S \). The partition \( 0 \) is the partition whose blocks are precisely the elements of the set \( S \). These partitions have the properties

\[ I \cdot \pi = \pi \]

\[ 0 \cdot \pi = 0 \]

The use of the symbols \( I \) and \( 0 \) for these partitions as well as for input and output sets is consistent with conventional usage. Whether these symbols refer to the trivial partitions or the aforementioned sets in subsequent discussions should be clear from the context.

For machine \( A \), the definition is illustrated by considering partitions

\( \pi_1 = \{ P_1 = \{ 1, 2, 3 \}, P_2 = \{ 4, 5 \} \}, \pi_2 = \{ Q_1 = \{ 1, 3, 4 \}, Q_2 = \{ 2, 5 \} \}, I = \{ S = \{ 1, 2, 3, 4, 5 \} \}, \text{ and } 0 = \{ 1, 2, 3, 4, 5 \} \):
\[ \pi_1 \cdot \pi_2 = \{ P_1 \cap Q_1 = \{1, 3\}, P_1 \cap Q_2 = \{2\}, P_2 \cap Q_1 = \{4\}, P_2 \cap Q_2 = \{5\} \] 

\[ I \cdot \pi_1 = \{ S \cap P_1 = P_1, S \cap P_2 = P_2 \} = \pi_1 \]

\[ 0 \cdot \pi_1 = \{ 1 \cap P_1 = 1, 2 \cap P_1 = 2, 3 \cap P_1 = 3, 4 \cap P_2 = 4, 5 \cap P_2 = 5 \} = 0 \]

**Definition 17**

That a partition \( \pi_\alpha \) of \( S \) is the refinement of a partition \( \pi_\beta \) of \( S \) is expressed by

\[ \pi_\alpha \subseteq \pi_\beta = \{ P \subseteq Q \mid \text{for every } P \in \pi_\alpha \text{ and some } Q \in \pi_\beta \} \]

Illustrative of this definition are the partitions \( \pi_1 \cdot \pi_2 \) and \( \pi_2 \) of the previous example:

\[ \pi_1 \cdot \pi_2 \subseteq \pi_1 \]

since

\[ \{1, 3\} \subseteq \{1, 2, 3\}, \{2\} \subseteq \{1, 2, 3\}, \{4\} \subseteq \{4, 5\}, \{5\} \subseteq \{4, 5\} \]

**Definition 18**

Partitions \( \pi \) and \( \pi' \) of \( S \) of a sequential machine \( M \) form a partition pair \((\pi, \pi')\) if and only if for every \( P \in \pi \) and every \( i \in I \) there exists a \( Q \in \pi' \) such that \( P \Delta(i) \subseteq Q \).

With respect to machine \( A \),

\( (\pi = \{ P_1 = \{1, 2\}, P_2 = \{3, 5\}, P_3 = \{4\} \}, \pi' = \{ Q_1 = \{1, 2, 4, 5\}, Q_2 = \{3\} \} ) \)

is a partition pair since

\[ P_1 \Delta(1) = \{1, 2\} \{1, 4\}, \{2, 1\}, \{3, 5\}, \{4, 3\} = \{4, 1\} \subseteq \{1, 2, 4, 5\} = Q_1 \]

\[ P_2 \Delta(1) = \{5\} \subseteq Q_1 \]

\[ P_3 \Delta(1) = \{3\} \subseteq Q_2 \]
DECOMPOSITION OF SEQUENTIAL MACHINES

In previous studies valuable insight into the structure of sequential machines has been gained by investigating the decompositional properties of these machines (refs. 2 to 5). The problem of sequential machine decomposition is that of determining how a sequential machine can be realized from interconnected sets of smaller machines. The aforementioned studies have been concentrated either on specialized classes of feedback loop realizations of machines or else on loop-free connections of machines, that is, machines connected in series, parallel, or series-parallel combinations. The present study is a presentation of a unified decomposition theory that encompasses both loop-free decompositions and a general class of feedback loop decompositions.

In the loop-free decomposition theory all smaller machines in any given realization are assumed to be Moore type machines (ref. 4). A Moore machine is a sequential machine for which the output mapping function $\Lambda$ is independent of the input set $I$ (refs. 4 and 7). When all component machines in a realization are of the Moore type, the output of each machine is used as an input to the other machines. Since the outputs are determined by the present state of the machines, all component machines can compute their next states simultaneously after an external input has been applied. Hence, the advantage of a realization composed of an interconnection of Moore machines is that it does not slow down the machine because all smaller machines operate concurrently and do not require waits for carry computations. This property of concurrency of operation will be exploited further in the development of the extended theory of decomposition of sequential machines.

Definition 19

The set $\{M_1, M_2, \ldots, M_j\}$ is a set of Moore machines. The set of inputs, states, and outputs of machine $M_k$, $1 \leq k \leq j$, are $I^{(k)}$, $S^{(k)}$, and $O^{(k)}$, respectively. Furthermore, the input set $I^{(k)}$ is given by

$$ I^{(k)} \subseteq I \times C^{(k)} $$
unless either $I$ or $C^{(k)}$ contains one and only one element, in which case

$$I^{(k)} \subseteq C^{(k)} \text{ or } I^{(k)} \subseteq I$$

respectively. The set $C^{(k)}$ is the set of internal inputs or carry inputs, which are derived from the outputs of other machines in a realization of a sequential machine $M$ as an interconnection of machines $M_1, M_2, \ldots, M_j$. The set $I$ is the set of external inputs applied to $M$.

**Definition 20 (ref. 4)**

The set \{ $M_1, M_2, \ldots, M_j$ \} of interconnected Moore machines, in which the outputs of any $M_k (1 \leq k \leq j)$ may be used as inputs to other machines, is concurrently operating if the next state of each machine $M_k$ depends on the present state of $M_k$, the present outputs of the machines to which it is connected, and the present external input. The ordered $j$-tuple of the present states of the machines $M_1, M_2, \ldots, M_j$ is referred to as the state of the interconnected machine.

**Definition 21 (ref. 4)**

The state behavior of the sequential machine $M$, the behavior of $M$ exclusive of its outputs, is realized by a concurrently operating interconnection of the machines $M_1, M_2, \ldots, M_j$ with the sets of states $S^{(1)}, S^{(2)}, \ldots, S^{(j)}$, respectively, if the following obtains:

1. The input $I$ of $M$ is a subset of the set of possible inputs of the machine realized from the machines $M_1, M_2, \ldots, M_j$.
2. There is a one-to-one mapping $\Phi$ between the set of states $S$ and $M$ and a subset $R$ of the Cartesian product of the sets of states of $M_1, M_2, \ldots, M_j$

$$S^{(1)} \times S^{(2)} \times \ldots \times S^{(j)}$$

which is preserved by the operations of $M$ and the machine realized from $M_1, M_2, \ldots, M_j$. In other words, if the two machines are initially in corresponding states, they will again be in corresponding states after any sequence of inputs from $I$.

Central to the decomposition theory developed in this report is the concept of an $S^{(k)}$-image of a finite sequential machine $M$. This concept is embodied in the next definition.
Definition 22

Given sequential machines \( M \) and \( M_k \), \( M_k \) is an \( S^{(k)} \)-image of \( M \) if and only if for every \( s^{(k)} \in S^{(k)} \), \( i \in I \), and \( i^{(k)} = \langle i, c^{(k)} \rangle \in I^{(k)} \)

1. Every \( s \in S \) belongs to some \( s^{(k)} \in S^{(k)} \) and to some \( c^{(k)} \in C^{(k)} \)
2. \( (c^{(k)} \cap s^{(k)}) \Delta(i) \subseteq s^{(k)} \Delta^{(k)}(i^{(k)}) \)

For the case in which \( I^{(k)} \subseteq I \), the quantity \( c^{(k)} \cap s^{(k)} \) of part (2) reduces to \( s^{(k)} \).

Also, when \( I^{(k)} \subseteq I \), the concept of an \( S^{(k)} \)-image reduces to a concept which has found some previous usage (ref. 7).

In the development of the theory of this section it is convenient to consider the subsets \( s^{(k)} \) of \( S \) to be disjoint and also the subsets \( c^{(k)} \) of \( S \) to be disjoint. In a later section the case for which these subsets may not necessarily be disjoint is considered.

An example of the concept of an \( S^{(k)} \)-image is furnished by the consideration of machine \( A \) of figure 2 and machine \( A_1 \) of figure 3. The elements of the sets,

\[
S^{(1)} = \{ S_1^{(1)} \} = \{ 1, 3, 5 \}, \quad S_2^{(1)} = \{ 2, 4 \} \quad \text{and} \quad C^{(1)} = \{ C_1^{(1)} = \{ 1, 2, 4, 5 \}, \quad C_2^{(1)} = \{ 3 \} \}, \quad \text{of}
\]

\[
\begin{array}{cccc|c}
\langle 1, c_1^{(1)} \rangle & \langle 1, c_2^{(1)} \rangle & \langle 2, c_1^{(1)} \rangle & \langle 2, c_2^{(1)} \rangle & o^{(1)} \\
S_1^{(1)} & S_1^{(1)} & S_1^{(1)} & S_1^{(1)} & o^{(1)} \\
S_2^{(1)} & S_2^{(1)} & S_2^{(1)} & S_2^{(1)} & o^{(1)} \\
\end{array}
\]

Figure 3. - Machine \( A_1 \).

machine \( A_1 \) satisfy condition (1):

\[
1, 3, 5 \in S_1^{(1)} \quad 2, 4 \in S_2^{(1)} \quad S_1^{(1)} \cup S_2^{(1)} = S
\]

\[
1, 2, 4, 5 \in C_1^{(1)} \quad 3 \in C_2^{(1)} \quad C_1^{(1)} \cup C_2^{(1)} = S
\]

Condition (2) is also satisfied:

\[
(C_2^{(1)} \cap S_2^{(1)}) \Delta(1) = \{ 3 \} \cap \{ 2, 4 \}) \Delta(1) = \varnothing \quad \Delta(1) = \varnothing = S_2^{(1)} \Delta^{(1)}(\langle 1, C_2^{(1)} \rangle)
\]

\[
(C_2^{(1)} \cap S_2^{(1)}) \Delta(2) = \varnothing \quad \Delta(2) = \varnothing = S_2^{(1)} \Delta^{(1)}(\langle 2, C_2^{(1)} \rangle)
\]
Therefore, machine $A_1$ is an $S^{(1)}$-image of machine $A$.

The following theorem relates the concept of an $S^{(k)}$-image of a machine $M$ to a partition pair on the states of $S$ of $M$. The partition pair as in previous investigations into the decomposition structure of sequential machines (refs. 3 and 4) is a valuable tool in the development of the theory. Adding to the importance of this relation between the concept of an $S^{(k)}$-image and a partition pair is the fact that one of the aforementioned partitions corresponds to the set of states $S^{(k)}$ of $M_k$ and the other to both $S^{(k)}$ and the set of carry inputs $C^{(k)}$ to $M_k$.

**Theorem 1:**

Given a sequential machine $M$, there exists a sequential machine $M_k$, which is an $S^{(k)}$-image of $M$, if and only if there exists a partition pair $(\pi_k, \pi'_k)$ on the states of $S$ of $M$ such that $\pi_k = C^{(k)} \cdot \pi'_k$, where $C^{(k)}$ and $\pi'_k$ are partitions whose blocks are the elements of the carry input set $C^{(k)}$ to $M_k$ and the set of states $S^{(k)}$ of $M_k$, respectively.

**Proof:**

According to the hypothesis of the "only if" half of the theorem, $M_k$ is an $S^{(k)}$-image of $M$, and $C^{(k)}$ and $\pi'_k$ are partitions whose blocks are the elements of the carry input set $C^{(k)}$ and of the state set $S^{(k)}$ of $M_k$, respectively. All pairs of inter-
sections \( P = c^{(k)} \cap s^{(k)} \) are disjoint because of the disjointness of the pairs of the \( c^{(k)} \) and of the \( s^{(k)} \). The union of all nonempty \( P \) defines a partition \( \pi^{(k)}_k \) of the states of \( S \) since every \( s \) is in some \( c^{(k)} \) and some \( s^{(k)} \) according to (1) of definition 22. The partition \( \pi^{(k)}_k \), in accordance with definition 16, is the g.l.b. \( C^{(k)} \cdot \pi^{(k)}_k \) of the partitions \( C^{(k)} \) and \( \pi^{(k)}_k \). According to definition 22, \( P \Delta(i) \subseteq s^{(k)} \Delta(k)(i^{(k)}) \subseteq Q \), where \( Q \in \pi^{(k)}_k \) and \( P \in \pi^{(k)}_k \). This is precisely the definition of the partition pair

\[(\pi^{(k)}_k, \pi^{(k)}_k') = (C^{(k)} \cdot \pi^{(k)}_k, \pi^{(k)}_k').\]

Now for the "if" half of the theorem, it can be assumed that there exists a partition pair \((\pi^{(k)}_k, \pi^{(k)}_k')\) on the states of \( S \) of \( M \) such that \( \pi^{(k)}_k = C^{(k)} \cdot \pi^{(k)}_k' \), where \( C^{(k)} \) is a partition of the states of \( S \). With the use of this information a sequential machine

\( M_k = \langle I^{(k)}, S^{(k)}, O^{(k)}, \Lambda^{(k)}, \Delta^{(k)} \rangle \)

can be defined as follows: According to the definition of a partition pair \((C^{(k)} \cdot \pi^{(k)}_k, \pi^{(k)}_k')\), there exists, for every \( P = c^{(k)} \cap s^{(k)} \subseteq \pi^{(k)}_k \) and every \( i \in I \), a \( Q \in \pi^{(k)}_k' \) such that \( P \Delta(i) \subseteq Q \). Let the blocks of \( \pi^{(k)}_k \) and \( C^{(k)} \) be the elements of the sets \( S^{(k)} \) and \( C^{(k)} \) of \( M_k \). Because \( \pi^{(k)}_k \) and \( C^{(k)} \) are partitions corresponding to the sets \( S^{(k)} \) and \( C^{(k)} \), respectively, every \( s \in S \) necessarily belongs to some \( s^{(k)} \subseteq S^{(k)} \) and to some \( c^{(k)} \subseteq C^{(k)} \); that is, condition (1) of definition 22 is satisfied. Let \( I^{(k)} \) be defined by \( i^{(k)} = \langle i, c^{(k)} \rangle \subseteq I^{(k)} \). Moreover, the definition of \( \Delta^{(k)} \) is established by letting \( P \Delta(i) \subseteq S^{(k)} \Delta^{(k)}(i^{(k)}) \subseteq Q \). Thus, condition (2) of definition 22 is satisfied. Furthermore, \( o^{(k)} \) and \( \Lambda^{(k)} \) can be defined by letting \( S^{(k)} \Lambda^{(k)}(i^{(k)}) = o^{(k)} \subseteq o^{(k)} \) for all \( i \in I \). In the process of defining \( M_k \) it was shown that definition 22 was satisfied. Therefore, machine \( M_k \) is indeed an \( S^{(k)} \)-image of \( M \).

In the previous example it was shown that machine \( A_1 \) is an \( S^{(1)} \)-image of machine \( A \). The partition pair \((\pi^1, \pi^1')\) which is implied as a consequence of the theorem is

\[(\pi^1 = \{ P_1 = \{ 1, 5 \}, P_2 = \{ 2, 4 \}, P_3 = \{ 3 \} \}, \quad \pi^1' = S^{(1)} = \{ S_1^{(1)} = \{ 1, 3, 5 \}, S_2^{(1)} = \{ 2, 4 \} \})\]

where \( \pi^1 = C^{(1)} \cdot \pi^1' \) and \( C^{(1)} = \{ C_1^{(1)} = \{ 1, 2, 4, 5 \}, C_2^{(1)} = \{ 3 \} \} \). Furthermore, given machine \( A \) and the partition pair \((\pi^1, \pi^1')\), one can construct machine \( A_1 \) as an \( S^{(1)} \)-image of machine \( A \). Illustrative of this construction is the following: Let

\[
I^{(1)} = \{ \langle 1, C_1^{(1)} \rangle, \langle 1, C_2^{(1)} \rangle, \langle 2, C_1^{(1)} \rangle, \langle 2, C_2^{(1)} \rangle \}
\]

As a consequence of

\[(C_1^{(1)} \cap S_1^{(1)}) \Delta(1) = \{ 4 \} \subseteq S_2^{(1)}\]
Lemma 1:

If the state behavior of a sequential machine \( M \) is realized by a concurrently operating interconnection of two machines \( M_1 \) and \( M_2 \), then there exist partition pairs \((n_1', \pi_1')\) and \((n_2', \pi_2')\) on the states of \( S \) of machine \( M \) such that

\[
(C_1^{(1)} \cap S_2^{(1)}) \Delta(1) = \{1, 3\} \subseteq S_1^{(1)}
\]

let

\[
S_2^{(1)} = S_1^{(1)} \Delta(1)(\langle 1, C_1^{(1)} \rangle)
\]

\[
S_1^{(1)} = S_2^{(1)} \Delta(1)(\langle 1, C_1^{(1)} \rangle)
\]

so that

\[
\Delta^{(1)}(\langle 1, C_1^{(1)} \rangle) = \{ \langle S_1^{(1)}, S_2^{(1)} \rangle, \langle S_2^{(1)}, S_1^{(1)} \rangle \}
\]

Similar constructions yield

\[
\Delta^{(1)}(\langle 1, C_2^{(1)} \rangle) = \{ \langle S_1^{(1)}, S_1^{(1)} \rangle \}
\]

\[
\Delta^{(1)}(\langle 2, C_1^{(1)} \rangle) = \{ \langle S_1^{(1)}, S_2^{(1)} \rangle, \langle S_2^{(1)}, S_1^{(1)} \rangle \}
\]

\[
\Delta^{(1)}(\langle 2, C_2^{(1)} \rangle) = \{ \langle S_1^{(1)}, S_2^{(1)} \rangle \}
\]

\[
\Lambda^{(1)}(\langle 1, C_1^{(1)} \rangle) = \Lambda^{(1)}(\langle 1, C_2^{(1)} \rangle) = \Lambda^{(1)}(\langle 2, C_1^{(1)} \rangle) = \Lambda^{(1)}(\langle 2, C_2^{(1)} \rangle) = \{ \langle S_1^{(1)}, 0_1^{(1)} \rangle, \langle S_2^{(1)}, 0_2^{(1)} \rangle \}
\]

Lemma 1:

If the state behavior of a sequential machine \( M \) is realized by a concurrently operating interconnection of two machines \( M_1 \) and \( M_2 \), then there exist partition pairs \((n_1', \pi_1')\) and \((n_2', \pi_2')\) on the states of \( S \) of machine \( M \) such that

\[
\pi_1' \cdot \pi_2' = 0
\]

\[
\pi_1 = C^{(1)} \cdot \pi_1'
\]

\[
\pi_2 = C^{(2)} \cdot \pi_2'
\]
where
\[
\pi_2 \leq \mathcal{C}^{(1)}
\]
\[
\pi_1 \leq \mathcal{C}^{(2)}
\]

Proof:

By the hypothesis the state behavior of a sequential machine \( M \) is realized by a concurrently operating interconnection of two machines \( M_1 \) and \( M_2 \). According to definition 20, the state of the interconnection is the ordered pair of present states of \( M_1 \) and \( M_2 \), that is, \( \langle s^{(1)}, s^{(2)} \rangle \) where \( s^{(1)} \in S^{(1)} \) and \( s^{(2)} \in S^{(2)} \). Also, by definition 21 there is a one-to-one mapping \( \Phi \) between the states of \( S \) of \( M \) and members of a subset \( R \) of \( S^{(1)} \times S^{(2)} \). Thus, \( R \) is the set of states of the interconnection of \( M_1 \) and \( M_2 \). In accordance with the mapping \( \Phi \), each element \( S_j^{(1)} \subseteq S^{(1)} \) is given by

\[
S_j^{(1)} = \{ u | u \in S \text{ such that } u \text{ corresponds to an ordered pair } \langle s^{(1)}, s^{(2)} \rangle \in R \text{ for which } s^{(1)} = S_j^{(1)} \}
\]

Similarly,

\[
S_k^{(2)} = \{ v | v \in S \text{ such that } v \text{ corresponds to an ordered pair } \langle s^{(1)}, s^{(2)} \rangle \in R \text{ for which } s^{(2)} = S_k^{(2)} \}
\]

No two elements of \( S^{(1)} \) can have any states \( s \in S \) in common if the mapping \( \Phi \) is to be preserved. A similar statement applies to the elements of \( S^{(2)} \). Also, the mapping \( \Phi \) requires that every \( s \in S \) belongs to some \( s^{(1)} \subseteq S^{(1)} \) and to some \( s^{(2)} \subseteq S^{(2)} \). Each element \( C_l^{(2)} \) of the carry input set \( C^{(2)} \) to \( M_2 \) is obtained from the output set \( O^{(1)} \) of \( M_1 \) according to

\[
C_l^{(2)} = \{ S_j^{(1)} | S_j^{(1)} \Lambda^{(1)} (i^{(1)}) = 0_l^{(1)} \}
\]

where

\[
S_j^{(1)} \subseteq S^{(1)} \text{ and } 0_l^{(1)} \subseteq 0^{(1)} \}
\]
If the output set $O(1)$ contains one and only one element $0_i^{(1)}$, then the only element of $C_i^{(2)}$ is $C_i^{(2)} = S(1)$ in which case $I(2) \subseteq I$; otherwise, $I(2) \subseteq I \times C(2)$. It should be noted that $\Lambda(1)(i^{(1)})$ is the same for all $i \in I$ because $M_1$ is a Moore machine. Each element $C_i^{(2)}$ of $C(2)$ is the union of the subsets $S_j^{(1)}$ of the set of states $S$ and hence can also be expressed as a subset of $S$. As such, no two elements of $C(2)$ can have any state $s \in S$ in common and also every $s \in S$ belongs to some $C(2) \in C(2)$. A similar consideration of $C(1)$ shows that a statement analogous to the previous one applies to $C(1)$ and its elements. Hence, thus far it has been shown that $M_1$ and $M_2$ satisfy condition (1) of definition 22. To prove that these two machines also satisfy condition (2) of definition 22 and consequently are $S^{(1)} -$ and $S^{(2)} -$images, respectively, of $M$, the following analysis is made: According to the mapping $\Phi$,

$$S_j^{(1)} \cap S_k^{(2)} = \{ u \cap v | u \in S \text{ and } v \in S \text{ such that } u \text{ corresponds to an ordered pair} \langle s^{(1)}, s^{(2)} \rangle \in R \text{ for which } s^{(1)} \text{ is } S_j^{(1)}, \text{ and } v \text{ corresponds to an ordered pair} \langle s^{(1)}, s^{(2)} \rangle \in R \text{ for which } s^{(2)} \text{ is } S_k^{(2)} \}$$

Thus, either $S_j^{(1)} \cap S_k^{(2)} = \varnothing$ when there exists no ordered pair $\langle s^{(1)}, s^{(2)} \rangle \in R$ for which both $s^{(1)}$ is $S_j^{(1)}$ and $s^{(2)}$ is $S_k^{(2)}$, or else $S_j^{(1)} \cap S_k^{(2)}$ is the state $s \in S$ corresponding to $\langle S_j^{(1)}, S_k^{(2)} \rangle$. Since $C_i^{(2)}$ is the union of subsets $S_j^{(1)}$, the quantity $C_i^{(2)} \cap S_k^{(2)}$ is either $\varnothing$ or else a subset of $S$. In the latter case, the subset corresponds to a set of ordered pairs $\langle s^{(1)}, s^{(2)} \rangle \in R$ whose first elements are the subsets $S_j^{(1)}$ and whose second elements are all the same, the subset $S_k^{(2)}$. The aforementioned set of ordered pairs is mapped by $\Delta^{(1)}(i^{(1)})$ and $\Delta^{(2)}(i^{(2)})$ into another not necessarily distinct set of ordered pairs. In particular, $\Delta^{(1)}(i^{(1)})$ is used to map the first elements of the given set of ordered pairs into the first elements of the resulting set of ordered pairs. The second elements of the resulting ordered pairs are obtained from the mapping $\Delta^{(2)}(i^{(2)})$ in an analogous manner. If all the ordered pairs resulting from the mappings correspond to $s^{(1)} \cap s^{(2)} = \varnothing$, then the resulting states of the interconnection of $M_1$ and $M_2$ are unspecified. In such a case, to preserve the mapping $\Phi$.
\[(C_i^{(2)} \cap S_k^{(2)}) \Delta(i) = \varnothing \subseteq S_k^{(2)} \Delta(i^{(2)})\]

If one or more of the resulting ordered pairs do belong to \(R\), they must correspond to the set of states resulting from the mapping \(\Delta(i)\) of \(C_i^{(2)} \cap S_k^{(2)}\) to preserve the mapping \(\Phi\). Since each of the resulting ordered pairs contains the same second element \(s^{(2)} \in S^{(2)}\), the union of intersections \(s^{(1)} \cap s^{(2)}\) corresponding to this resulting set or ordered pairs must be a subset of the element \(s^{(2)} \subseteq S^{(2)}\) resulting from the mapping \(\Delta^{(2)}(i^{(2)})\) of \(S_k^{(2)}\). Consequently,

\[(C_i^{(2)} \cap S_k^{(2)}) \Delta(i) \subseteq S_k^{(2)} \Delta(i^{(2)})\]

Therefore, machine \(M_2\) satisfies condition (2) of definition 22 and is an \(S^{(2)}\)-image of \(M\). A similar analysis shows \(M_1\) to be an \(S^{(1)}\)-image of \(M\). By Theorem 1, then there exist partition pairs \((\pi_1, \pi_1) = (C^{(1)} \cdot \pi_1, \pi_1)\) and \((\pi_2, \pi_2) = (C^{(2)} \cdot \pi_2, \pi_2)\). Because \(\pi_1\) and \(\pi_2\) are partitions whose blocks are the elements of \(S^{(1)}\) and \(S^{(2)}\), respectively, and because each intersection \(s^{(1)} \cap s^{(2)}\) is either \(\varnothing\) or a single element \(s \in S\), it follows that \(\pi_1 \cdot \pi_2 = 0\). Furthermore, since the partition \(C^{(2)}\) is the partition whose blocks are the elements of the carry input set \(C^{(2)}\) and the elements of the lattice are composed of subsets of the elements \(s^{(1)} \subseteq S^{(1)}\), it follows that \(\pi_1 \leq C^{(2)}\), in the case where the carry input set \(C^{(2)}\) is composed of a single element, then the partition \(C^{(2)}\) is the trivial partition \(I\) and it is still true that \(\pi_1 \leq C^{(2)}\). Similarly, \(\pi_2 \leq C^{(1)}\).

The machines \(B, B_1,\) and \(B_2\) of figure 4 are used to exemplify Lemma 1. Machines \(B_1\) and \(B_2\) comprise the concurrently operating interconnection realizing the

![Figure 4](image_url)

Figure 4. - Representations of machines \(B, B_1,\) and \(B_2\).
state behavior of machine $B$. Under the mapping $\Phi$ the following correspondences obtain:

- $1 \sim \langle 7, 11 \rangle$
- $2 \sim \langle 8, 11 \rangle$
- $3 \sim \langle 8, 12 \rangle$
- $4 \sim \langle 9, 11 \rangle$
- $5 \sim \langle 9, 12 \rangle$
- $6 \sim \langle 10, 12 \rangle$

The state 7 of machine $B_1$ appears in only one ordered pair, and that pair corresponds to state 1 of machine B; therefore, $7 = \{1\}$. The state 8 appears in two ordered pairs corresponding to states 2 and 3; hence, $8 = \{2, 3\}$. Similarly, $9 = \{4, 5\}$ and $10 = \{6\}$. The states of machine $B_2$ are found to be $11 = \{1, 2, 4\}$ and $12 = \{3, 5, 6\}$. Thus, there exists the partition pair $(\pi_1, \pi_1')$ on $S$ of machine $B$, where

$$\pi_1' = \{7 = \{1\}, 8 = \{2, 3\}, 9 = \{4, 5\}, 10 = \{6\}\}, \quad C^{(1)} = \{11 = \{1, 2, 4\}, 12 = \{3, 5, 6\}\},$$
and $\pi_1 = C^{(1)} \cdot \pi_1' = 0$. Moreover, there exists $(\pi_2, \pi_2')$, where $\pi_2' = \{11 = \{1, 2, 4\}, 12 = \{3, 5, 6\}\}, \quad C^{(2)} = \{7, 9\} = \{1, 4, 5\}, \quad \{8, 10\} = \{2, 3, 6\}\},$ and $\pi_2 = C^{(2)} \cdot \pi_2' = \{\{1, 4\}, \{2\}, \{3, 6\}, \{5\}\}$. Finally, it is observed that $\pi_2 = C^{(1)} \cdot C^{(2)}$, $\pi_1' < C^{(2)}$, and $\pi_1' \cdot \pi_2' = 0$.

Theorem 2:

The state behavior of a sequential machine $M$ is realized by a concurrently operating interconnection of two machines $M_1$ and $M_2$ if and only if there exist partition pairs $(\pi_1, \pi_1')$ and $(\pi_2, \pi_2')$ on the states of $S$ of $M$ such that

$$\pi_1' \cdot \pi_2' = 0$$

$$\pi_1 = C^{(1)} \cdot \pi_1'$$

$$\pi_2 = C^{(2)} \cdot \pi_2'$$

Proof:

The "only if" half of the theorem follows directly from Lemma 1.

For the "if" half of the theorem it can be assumed that there exist partition pairs $(\pi_1, \pi_1')$ and $(\pi_2, \pi_2')$ on $S$ of $M$ such that $\pi_1' \cdot \pi_2' = 0$, $\pi_1 = C^{(1)} \cdot \pi_1'$, and...
Moreover, there exist partition pairs \((\pi_1, \pi'_1)\) and \((\pi_2, \pi'_2)\) on \(S\) of \(M\) with the additional properties that \(\pi'_2 \leq \pi_1 \leq \pi_2 \leq \pi'_1\). That this last assertion is true is verified by the following arguments: Suppose that \(\pi_1 = 0\); then \(\pi'_1 \leq \pi_1 = \pi_2 \leq \pi'_2\) is a contradiction. Now, suppose that the first of the partition pairs assumed to exist is represented by \((\pi_1 = \pi'_1, \pi'_1)\) such that neither \(\pi'_1\) nor \(\pi'_2\) is a refinement of the other. Hence, \(\pi_1 = \pi'_2 = \pi_1\), where \(\pi < \pi'_1\) and \(\pi < \pi'_2\). Then \(\pi = \pi'_1 \leq \pi'_2 = \pi'_1\). Because of the existence of \((\pi_1, \pi'_1)\) on \(S\) of \(M\), the partition pair \((\pi \cdot \pi'_1, \pi'_1)\) also exists on \(S\) of \(M\) (ref. 3). Therefore, let the partition pair \((\pi \cdot \pi'_1, \pi'_1)\) replace \((\pi_1, \pi'_1)\) in all further considerations; also let \(\pi = \pi_1\) and \(\pi_1 = \pi \cdot \pi'_1\) so that \(\pi'_1 \leq \pi'_2\). For this case, it has already been shown that \(\pi_1 = 0\), and hence \(\pi'_1 \leq \pi'_2\). Similar arguments show that there also exists a partition pair \((\pi_2, \pi'_2)\) on \(S\) of \(M\) such that \(\pi'_2 = \pi_2\). According to Theorem 1, there exist machines \(M_1\) and \(M_2\) which are \(S(1)\)- and \(S(2)\)-images, respectively, of machine \(M\). Because \(\pi'_1\) and \(\pi'_2\) are partitions whose blocks are elements of \(S(1)\) and \(S(2)\), respectively, and because \(\pi'_1 \cdot \pi'_2 = 0\), it follows that each intersection \(s(1) \cap s(2)\) is either \(\varnothing\) or a single \(s \in S\). The nonempty intersections \(s(1) \cap s(2)\) can be put into a one-to-one correspondence with a subset \(R\) of \(S(1) \times S(2)\). With the aid of definition 22 and a reversal of the arguments presented in Lemma 1, it follows that there exists a mapping \(\Phi\) which is a one-to-one correspondence between the states of \(S\) of \(M\) and the subset \(R\) such that \(M_1\) and \(M_2\) are the component machines of a concurrently operating interconnection realizing the state behavior of machine \(M\). This completes the proof of the theorem.

The reader should be warned that the partition pairs given in the "if" half of the theorem are not necessarily those directly associated with \(M_1\) and \(M_2\) as \(S(1)\)- and \(S(2)\)-images, respectively, of \(M\). As is brought out in the proof, if the given partition pairs do not have the property that \(\pi'_2 \leq \pi_1 \leq \pi_2 \leq \pi'_1\), then they imply the existence of partition pairs that do possess this property. The implied partitions pairs only differ from the given ones in that their first partitions are refinements of the corresponding partitions of the given partition pairs. Thus, the implied partition pairs are the ones that are directly associated with \(M_1\) and \(M_2\).

A consideration of machine \(B\) again along with the partition pairs derived in the previous example afford a concrete illustration of Theorem 2. Machines \(B_1\) and \(B_2\) can be derived as \(S(1)\)- and \(S(2)\)-images, respectively, of \(B\) in the manner illustrated in the example following Theorem 1. Typical of a specific demonstration that \(B_1\) and
B₂ are interconnected to operate concurrently and realize the state behavior of B is the following: Suppose that machine B is in state 2 when the input 1 is applied; then, the next state of B is 4 according to \( \{2\} \Delta(1) = \{4\} \). Since \( 8 \cap 11 = \{2\} \) where \( 8 \in S^1 \) and \( 11 \in S^2 \), let it be supposed that machines B₁ and B₂ are in states 8 and 11, respectively, when B is in state 2: that is, let \( 2 \sim \langle 8, 11 \rangle \). Because for B₁

\[ \{11 \cap 8\} \Delta(1) = \{2\} \Delta(1) = \{4\} \subseteq 8 \Delta(1) \langle 1, 11 \rangle = 9 \]

for B₂

\[ \{\{8, 10\} \cap 11\} \Delta(1) = \{2\} \Delta(1) = \{4\} \subseteq 11 \Delta(2) \langle 1, \{8, 10\} \rangle = 11 \]

and

\[ 9 \cap 11 = \{4\} \]

the combined next state of B₁ and B₂ after the application of the input 1 is 4; that is, \( 4 \sim \langle 9, 11 \rangle \).

The fundamental theorem of the decomposition theory developed here is a generalization of Theorem 2 and is as follows:

**Theorem 3:**

The state behavior of a sequential machine M is realized by a concurrently operating interconnection of j machines M₁, M₂, . . . , Mₓ if and only if there exist partition pairs \( (\pi_1', \pi_1) \), \( (\pi_2', \pi_2) \), . . . , \( (\pi_x', \pi_x) \) on the states of S of M such that

\[ \pi_1' \cdot \pi_2' \cdot \ldots \cdot \pi_x' = 0 \]

\[ \pi_1 = C^1 \cdot \pi_1' \]

\[ \pi_2 = C^2 \cdot \pi_2' \]

. . .

\[ \pi_x = C^x \cdot \pi_x' \]

**Proof:**

For the "only if" half of the theorem, it can be assumed that the state behavior of M is realized by a concurrently operating interconnection of j machines M₁, M₂, . . . , Mₓ. That part of the given interconnection consisting of all machines M₁, M₂, . . . , Mₓ₋₁, Mₓ₊₁, . . . , Mₓ but Mₓ is a Moore machine which will be called Mₓ₊₁. The carry inputs to Mₓ₊₁ come from the outputs of machine Mₓ. The outputs from Mₓ₊₁ serve as the carry inputs to Mₓ. Thus, the state behavior of M
is realized by a concurrently operating interconnection of machines $M_{\alpha+k-1}$ and $M_k$.

By Lemma 1 there exist partition pairs $(C^{(\alpha+k-1)} \cdot \pi'_{\alpha+k-1}, \pi'_{\alpha+k-1})$ and $(C^{(k)} \cdot \pi'_{k}, \pi'_{k})$ on the states of $S$ of $M$ such that $\pi'_{\alpha+k-1} \cdot \pi'_{k} = 0$ where $\pi'_{k} \leq C^{(\alpha+k-1)}$ and $\pi'_{\alpha+k-1} \leq C^{(k)}$. There are $j$ such pairs of machines $M_{\alpha+k-1}$ and $M_k$ corresponding to $k = 1, 2, \ldots, j$. Their existence implies the existence of $j$ partition pairs on the states of $S$ of $M$, $(\pi_k = C^{(k)} \cdot \pi_k', \pi_k')$, where $k = 1, 2, \ldots, j$. Also implied is that $\pi'_{\alpha+k-1} = \pi'_{i_1} \cdot \pi'_{i_2} \cdot \ldots \cdot \pi'_{i_{k-1}} \cdot \pi'_{i_k} \cdot \ldots \cdot \pi'_{i_j}$. Hence, $\pi'_{i_1} \cdot \pi'_{i_2} \cdot \ldots \cdot \pi'_{i_j} = 0$.

For the "if" half of the theorem, it can be assumed that there exist $j$ partition pairs $(\pi_k = C^{(k)} \cdot \pi_k', \pi_k')$, $k = 1, 2, \ldots, j$, on the states of $S$ of $M$ such that $\pi'_{i_1} \cdot \pi'_{i_2} \cdot \ldots \cdot \pi'_{i_j} = 0$. As a notational convenience the given partition pairs are represented by $(\pi_k = C^{(k)} \cdot \pi_k', \pi_k')$. There exists a partition pair $(\pi_{\beta}, \pi_{\beta}') = (\pi_{i_1} \cdot \pi_{i_2} \cdot \ldots \cdot \pi_{i_{j-1}}, \pi_{i_1} \cdot \pi_{i_2} \cdot \ldots \cdot \pi_{i_{j-1}}')$ on the states of $S$ of $M$ (ref. 3). Since $\pi_{\beta} = C^{(1)} \cdot C^{(2)} \cdot \ldots \cdot C^{(j-1)} \cdot \pi'_{\beta}$, there certainly exists a partition $C^{(\beta)}$ such that $\pi_{\beta} = C^{(\beta)} \cdot \pi_{\beta}'$. Therefore, according to Theorem 2, the state behavior of machine $M$ is realized by a concurrently operating interconnection of two machines $M_{\beta}$ and $M_j$.

The proof of Theorem 2 also indicates how the partition pairs $(\pi_{\beta}, \pi_{\beta}')$ and $(\pi_{i_1}, \pi_{i_1}')$, which are directly associated with machines $M_{\beta}$ and $M_j$ as $S^{(\beta)}$- and $S^{(j)}$-images of $M$, are derived from $(\pi_{\beta}, \pi_{\beta}')$ and $(\pi_{i_1}, \pi_{i_1}')$. A partition, which will be called $\pi'_{k}'$, on the states of $S^{(\beta)}$ of $M_{\beta}$ can be derived from $\pi'_{k}$ on the states of $S$ of $M$ as follows:

In accordance with definition 14, there exist canonical relations

$$\pi'^*_{\beta} = \{ \langle s, s^{(\beta)} \rangle | s \in S^{(\beta)} \in S^{(\beta)} \}$$

$$\pi'^*_{k} = \{ \langle s, s^{(k)} \rangle | s \in S^{(k)} \in S^{(k)} \}$$

By definition 15, the inverse of $\pi'^*_{\beta}$ is

$$(\pi'^*_{\beta})^{-1} = \{ \langle s^{(\beta)} , s \rangle | s^{(\beta)} \in S^{(\beta)} \in S^{(\beta)} \}$$

By definition 10,

$$\pi'_{k}' = (\pi'^*_{\beta})^{-1} \pi'^*_{k} = \{ \langle s^{(\beta)} , s^{(k)} \rangle | s^{(\beta)} \pi'^*_{\beta} s^{(\beta)} \in S \text{ and } s^{(\beta)} \in S^{(\beta)} \}$$

Thus,

$$S_{\pi'^*_{\beta}} = S^{(\beta)} , S_{\pi'^*_{k}} = S^{(k)} \text{ so that } S^{(\beta)} (\pi'^*_{\beta})^{-1} = S$$

22
and

\[ S^{-1} \beta k = S^{-1} (\beta (\pi_1')) = S^{-1} (\beta (\pi_2')) = S^{-1} (\beta (\pi_3')) = S^{-1} (\beta (\pi_4')) = S^{-1} (\beta (\pi_{k'})) \]

Then, \( \pi_{k'} \), is the partition whose blocks are the elements of \( S^{(k)} \). That the blocks of \( \pi_{k'} \) as defined by the previous mapping are indeed pairwise disjoint is guaranteed by the fact that \( \pi_{k'} \leq \pi_k \). A partition pair \((\pi_{k'}, \pi_{k''})\) on the states of \( S^{(\beta)} \) of \( M_{\beta} \) can be derived by an application of definition 18 (ref. 3). Since \((0, \pi_{k''})\) always exists, it follows that there exists a partition pair of the form \((\pi_{k'}, \pi_{k''})\) on the states of \( S^{(\beta)} \) of \( M_{\beta} \).

Hence, there exist \( j - 1 \) partition pairs \((\pi_{k'}, \pi_{k''})\), \( k = 1, 2, \ldots, j - 1 \), on the states of \( S^{(\beta)} \) of \( M_{\beta} \) such that \( \pi_1' \cdot \pi_2' \cdot \ldots \cdot \pi_{j-1}' = 0 \) where \( 0 \) on \( S^{(\beta)} \) of \( M_{\beta} \) corresponds to \( \pi_{\beta} \) on \( S \) of \( M \). The process given thus far in this half of the proof can now be iterated to show that the state behavior of machine \( M_{\beta+k-1} \) is realized by a concurrently operating interconnection of machines \( M_{\beta+k-1} \) for \( k = 1, 2, \ldots, j - 3 \). The process terminates when it is established that the state behavior of machine \( M_{\beta+j-3} \) is realized by a concurrently operating interconnection of machines \( M_1 \) and \( M_2 \). Hence, the state behavior of \( M \) is realized by a concurrently operating interconnection of machines \( M_1, M_2, \ldots, M_j \), which establishes the theorem.

Machine \( B \) of figure 4 provides a specific example of the "if'" half of Theorem 3. Associated with machine \( B \) are partition pairs \((\pi_2 = C^{(2)} \cdot \pi_2', \pi_2''), \( (\pi_3 = C^{(3)} \cdot \pi_3', \pi_3''), \) and \( (\pi_4 = C^{(4)} \cdot \pi_4', \pi_4'') \), where

\[
\begin{align*}
\pi_2' &= \{11 = \{1, 2, 4\}, 12 = \{3, 5, 6\}\} & C^{(2)} &= \{13 = \{1, 4, 5\}, 14 = \{2, 3, 6\}\} \\
\pi_3' &= \{13 = \{1, 4, 5\}, 14 = \{2, 3, 6\}\} & C^{(3)} &= \{17 = \{1, 2, 4\}, 18 = \{3, 5\}, 19 = \{6\}\} \\
\pi_4' &= \{15 = \{1, 2, 3\}, 16 = \{4, 5, 6\}\} & C^{(4)} &= \{20 = \{1, 2, 3, 5, 6\}, 21 = \{4\}\}
\end{align*}
\]

such that \( \pi_2' \cdot \pi_3' \cdot \pi_4' = 0 \). According to the theorem, this implies that the state behavior of machine \( B \) can be realized by a concurrently operating interconnection of three machines - \( B_2, B_3, \) and \( B_4 \). This interconnection can be derived by the process introduced in the proof: The partition pairs \((\pi_2, \pi_2')\) and \((\pi_3, \pi_2')\) are considered. The partition \( \pi_{\beta} \) is precisely the partition \( \pi_{1'} \) given in the previous example. From that example it is also seen that there exists a partition \( \pi_{\beta} = \pi_1 = \pi_{1'} \) such that \( \pi_2' \leq C^{(1)} \) and that there exists
a partition $r_2 = \pi_2$ such that $\pi_1 = \mathcal{C}(2) = \mathcal{C}(2)$. The construction of flow tables for machines $B_1$ and $B_2$ would ordinarily comprise the next step of the process, but these tables have already been presented in the previous example and are shown in figure 4. Next, partitions $\widetilde{\pi}_3'$ and $\widetilde{\pi}_4'$ on the states of $S(1)$ of $B_1$ are derived as

$$\widetilde{\pi}_3' = \{13 = \{7, 9\}, 14 = \{8, 10\}\}$$

$$\widetilde{\pi}_4' = \{15 = \{7, 8\}, 16 = \{9, 10\}\}$$

With the use of definition 18, the partition pairs

$$(\widetilde{\pi}_3, \widetilde{\pi}_3') = (\{15 = \{7, 8\}, 16 = \{9, 10\}\}, \{13 = \{7, 9\}, 14 = \{8, 10\}\})$$

and

$$(\widetilde{\pi}_4, \widetilde{\pi}_4') = (\{15 = \{7, 8\}, 16 = \{9, 10\}\}, \{15 = \{7, 8\}, 16 = \{9, 10\}\})$$

are generated. An inspection of partitions $\widetilde{\pi}_3'$ and $\widetilde{\pi}_4'$ reveals the existence of partitions $\gamma_3' = \mathcal{C}(3) \cdot \gamma_3 \leq \gamma_3$, $\gamma_4' = \mathcal{C}(4) \cdot \gamma_4 \leq \gamma_4$, where $\mathcal{C}(3) = \gamma_3'$ and $\mathcal{C}(4) = I$. Hence, $\gamma_3' \leq \mathcal{C}(3)$, $\gamma_3 \leq \mathcal{C}(4)$, and $\gamma_3' \cdot \gamma_4' = 0$ on $S(1)$ so that the state behavior of machine $B_1$ is realized by a concurrently operating interconnection of machines $B_3$ and $B_4$. These machines constructed as $S(3)$- and $S(4)$-images of machine $B_1$ are shown as the flow tables of figure 5.

It should be noted in the flow table of machine $B_3$ that the unspecified next stages can be selected in such a way that, for every input $i(3) \in I(3)$, $13 \Delta(3) = 14 \Delta(3)$. With such a specification machine $B_3$ can be simplified to the extent that its next states are independent of its present states. Such a machine is said to be

$$\begin{array}{cccccccc}
\langle 1, 11, 15 \rangle & \langle 1, 11, 16 \rangle & \langle 1, 12, 15 \rangle & \langle 1, 12, 16 \rangle & \langle 2, 11, 15 \rangle & \langle 2, 11, 16 \rangle & \langle 2, 12, 15 \rangle & \langle 2, 12, 16 \rangle \\
13 & 13 & 13 & -- & 14 & 13 & 13 & -- & 14 & 14 & 14
\end{array}$$

$$\begin{array}{cccc}
\langle 1, 11 \rangle & \langle 1, 12 \rangle & \langle 2, 11 \rangle & \langle 2, 12 \rangle \\
15 & 16 & 16 & 16 & 15 & 15 & 15 & 15
\end{array}$$

Figure 5. - Machines $B_3$ and $B_4$. 24
feedback free. It is worthwhile noting that the existence of a feedback-free machine \( B_3 \) could have been anticipated. On the states \( S \) of machine \( B \) there exists a partition pair \((C^{(3)} \cdot I, \pi^{(3)}_B)\), which implies for every \( i \in I \), \( i^{(3)} \in I^{(3)}, \ c^{(3)} \in C^{(3)}, \) and \( s^{(3)} \in S^{(3)} \) that \( c^{(3)} \Delta(i) \subseteq s^{(3)} \) or equivalently \( \Delta^{(3)}(i^{(3)}) \subseteq s^{(3)} \). The latter relation implies the existence of a machine \( B_3 \) independent of its present states.

**ADDITIONAL BACKGROUND**

Additional basic background material (ref. 2) is introduced in this section to facilitate the concluding theoretical investigations of this report. The presentation of a logical design problem serves a dual purpose as a convenient vehicle for illustrating the concepts comprising the additional background material and as an example of how the newly developed decomposition theory might be used in practice.

The design problem is that of deriving a two-layer "and/or" diode gate realization of a machine \( C \) represented by the flow table of figure 6. The solution of this problem is facilitated by the introduction of four definitions.

![Figure 6. - Tabular representation of machine C.](image)

**Definition 23**

A partition \( \pi \) on the set of states \( S \) of a sequential machine \( M \) is said to be output consistent, if for every block \( P \) of \( \pi \), all the states contained in the block have the same output. That is, for every \( P \in \pi \) and every \( i \in I \), \( P \Delta(i) = 0 \), where \( o \in 0 \) is not necessarily the same for any two inputs \( i \).

One such partition on the set of states \( S \) of machine \( C \) is
π = {P_1 = \{1, 6\}, P_2 = \{2, 3\}, P_3 = \{7\}, P_4 = \{4, 5\} }

since

\[ P_1 \Lambda(i) = 0_2 \]
\[ P_2 \Lambda(i) = 0_1 \]
\[ P_3 \Lambda(i) = 0_1 \]
\[ P_4 \Lambda(i) = 0_2 \]

where

\[ \Lambda(i) = \Lambda(1) = \Lambda(2) = \{ \langle 1, 0_2 \rangle, \langle 2, 0_1 \rangle, \langle 3, 0_1 \rangle, \langle 4, 0_2 \rangle, \langle 5, 0_2 \rangle, \langle 6, 0_2 \rangle, \langle 7, 0_1 \rangle \} \]

Definition 24

Given sequential machines M and M_r, M_r is a reduction of M if and only if the following conditions are satisfied:

1. There exists a partition pair \( (\pi_r, \pi_r') \) on the states of S of M such that \( \pi_r = \pi_r' \).
2. \( \pi_r' \) is output consistent.
3. The output set \( o^{(r)} \) of \( M_r \) is a subset of the output set \( o \) of M and has elements

\[ o = s^{(r)} \Lambda(i) = s^{(r)} \Lambda^{(r)}(i^{(r)}) \]

where

\[ o \in 0, s^{(r)} \in S^{(r)}, i \in I, \text{ and } i^{(r)} \in I^{(r)}. \]

From figure 6 it is observed that there exists a partition pair \( (\pi_r, \pi_r') \) on the states \( S \) of machine \( C \) such that

\[ \pi_r = \pi_r' = \{ 8 = \{1\}, 9 = \{2\}, 10 = \{3, 7\}, 11 = \{4\}, 12 = \{5\}, 13 = \{6\} \} \]
The calculation

\[ 8 \Lambda(i) = 0_2 = 8 \Lambda^{(r)}(i^{(r)}) \]

\[ 9 \Lambda(i) = 0_1 = 9 \Lambda^{(r)}(i^{(r)}) \]

\[ 10 \Lambda(i) = 0_1 = 10 \Lambda^{(r)}(i^{(r)}) \]

\[ 11 \Lambda(i) = 0_2 = 11 \Lambda^{(r)}(i^{(r)}) \]

\[ 12 \Lambda(i) = 0_2 = 12 \Lambda^{(r)}(i^{(r)}) \]

\[ 13 \Lambda(i) = 0_2 = 13 \Lambda^{(r)}(i^{(r)}) \]

where \( i = i^{(r)} \), serves both to show that \( \pi_r \) is output consistent and to establish the output set of a reduction \( C_r \) of machine \( C \). That such a machine exists is guaranteed by Theorem 1 which implies that machine \( C_r \) is an \( S^{(r)} \)-image of \( C \). The flow table representation of machine \( C_r \) is given in figure 7.

**Definition 25**

Two sequential machines are said to be equivalent if they have the same input-output relations. A sequential machine \( M \) and any reduction \( M_r \) of \( M \) are equivalent.
Definition 26

The state behavior of a sequential machine \( M \) is said to be realized by a concurrently operating interconnection of the machines \( M_1, M_2, \ldots, M_j \) if the state behavior of a sequential machine \( M_e \) equivalent to \( M \) is realized by the aforementioned interconnection.

To obtain the desired realization of machine \( C \) the decomposition theory is now used to derive a concurrently operating interconnection of three machines \( C_1, C_2, \) and \( C_3 \) which realize the state behavior of machine \( C_r \). An examination of the flow table of machine \( C_r \) given in figure 7 shows that there exist on the states of \( S^{(r)} \) the partition pairs \((\pi_1 = C^{(1)}, \pi_1'), (\pi_2 = C^{(2)}, \pi_2'), \) and \((\pi_3 = C^{(3)}, \pi_3')\), where

\[
\begin{align*}
\pi_1 &= \{14 = \{8, 12\}, 15 = \{9, 10, 11, 13\}\} \\
C^{(1)} &= \{20 = \{8, 13\}, 21 = \{9, 10, 11, 12\}\} \\
\pi_2 &= \{16 = \{8, 10, 13\}, 17 = \{9, 11, 12\}\}, C^{(2)} = \{22 = \{8\}, 23 = \{12\}, 24 = \{11, 13\}, 25 = \{9, 10\}\} \\
\pi_3 &= \{18 = \{8, 11, 13\}, 19 = \{9, 10, 12\}\}, C^{(3)} = \{26 = \{8\}, 27 = \{12\}, 28 = \{10, 13\}, 29 = \{9, 11\}\}
\end{align*}
\]

and \( \pi_1' \cdot \pi_2' \cdot \pi_3' = 0 \). Therefore, Theorem 3 is satisfied. Furthermore, because

\[
\begin{align*}
\pi_2' \cdot \pi_3' &= \pi_4' < C^{(1)} \text{ and } \pi_1' = C^{(4)} \text{ for } (\pi_1, \pi_1') \text{ and } (\pi_4, \pi_4') \\
\pi_1' \cdot \pi_3' &= \pi_5' = C^{(2)} \text{ and } \pi_2' = C^{(5)} \text{ for } (\pi_2, \pi_2') \text{ and } (\pi_5, \pi_5') \\
\pi_1' \cdot \pi_2' &= \pi_6' = C^{(3)} \text{ and } \pi_3' = C^{(6)} \text{ for } (\pi_3, \pi_3') \text{ and } (\pi_6, \pi_6')
\end{align*}
\]

it follows as indicated in the proof of Theorem 3 that the three given partition pairs are those directly associated with the machines \( C_1, C_2, \) and \( C_3 \) as \( S^{(1)} - S^{(2)} - S^{(3)} \) images, respectively, of \( C_r \). The flow table representations of these machines are shown in figure 8.

A representation of this decomposition in terms of physical switching elements is afforded by making the following associations: Associate with the external inputs 1 and 2 of the three machines the binary variables \( \overline{x} \) and \( x \), respectively; \( \overline{x} \) denotes the complement of \( x \). Likewise, with the present states \( 14, 15, 16, 17, 18, 19 \) associate the binary variables \( y_1, \overline{y}_1, y_2, \overline{y}_2, y_3, \overline{y}_3 \), respectively. Also, let the next states \( 14, 15, 16, 17, 18, 19 \) be associated with the binary variables \( Y_1, \overline{Y}_1, Y_2, \overline{Y}_2, Y_3, \overline{Y}_3 \), respectively. Since \( 20 = \{8, 13\} = 16 \cap 18 \), associate with the element 20 of the carry input set \( C^{(1)} \) to \( C_1 \) the "and" function \( y_2 \overline{y}_3 \) of \( y_2 \) and \( \overline{y}_3 \). Similarly, associate
Figure 8. - Machines C₁, C₂, and C₃.

\[ Y_1 = \overline{x} \overline{y} \overline{z} + \overline{y} \overline{y} \overline{y} \overline{z} \]

\[ \begin{array}{cccc}
\overline{x} \overline{y} \overline{z} & \overline{x} \overline{y} \overline{y} + \overline{x} \overline{y} \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\end{array} \]

\[ Y_2 = \overline{x} \overline{y} + \overline{x} \overline{y} \overline{y} \]

\[ \begin{array}{cccc}
\overline{x} \overline{y} & \overline{x} \overline{y} & \overline{x} \overline{y} & \overline{x} \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\end{array} \]

\[ Y_3 = \overline{x} \overline{y} + \overline{x} \overline{y} \overline{y} \]

\[ \begin{array}{cccc}
\overline{x} \overline{y} & \overline{x} \overline{y} & \overline{x} \overline{y} & \overline{x} \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\overline{y} & \overline{y} & \overline{y} & \overline{y} \\
\end{array} \]

Figure 9. - Truth tables of the switching functions Y₁, Y₂, Y₃.
with \( y_1 \) the 'or' function \( y_2 + y_3 \). In an analogous manner, associate with the carry input elements 22, 23, 24, 25 or \( C(2) \) to \( C_2 \) \( y_1\bar{y}_3, y_1y_3, \bar{y}_1\bar{y}_3, \bar{y}_1y_3 \), respectively. Finally, associate with the carry input elements 26, 27, 28, 29 of \( C(3) \) to \( C_3 \) \( y_1y_2, y_1\bar{y}_2, \bar{y}_1y_2, \bar{y}_1\bar{y}_2 \), respectively. Under these associations the flow tables of machines \( C_1, C_2, \) and \( C_3 \) become truth tables for the logical switching functions \( Y_1, Y_2, \) and \( Y_3 \), respectively (see fig. 9). Moreover, the part of the flow table of machine \( C_1 \) specifying the input-output relations is transformed into a truth table for the output function of the decomposition. This output switching function, designated by \( Z \), is

\[
\begin{array}{c|cc}
Z \cdot \bar{y}_1y_3 & \bar{Z} \\
8 & y_1\bar{y}_2y_3 & \bar{Z} \\
9 & \bar{y}_1\bar{y}_2y_3 & Z \\
10 & \bar{y}_1y_2y_3 & Z \\
11 & \bar{y}_1\bar{y}_2\bar{y}_3 & \bar{Z} \\
12 & y_1\bar{y}_2y_3 & \bar{Z} \\
13 & \bar{y}_1y_2\bar{y}_3 & \bar{Z} \\
\end{array}
\]

Figure 10. - Truth table of the switching function \( Z \).

Figure 11. - Realization of machine C.
associated with 0; whereas its complement \( \overline{Z} \) is associated with 0. The truth table for \( Z \) is given in figure 10.

Corresponding to each of the switching functions \( Y_1, Y_2, Y_3, \) and \( Z \) are logical switching circuits made up of transistor inverters, diode "and/or" gates, and delay units. These circuits, shown in figure 11, comprise the sought-after realization of machine C.

STATE SPLITTING

An important concern of the previous section was the realization of the state behavior of a given machine \( M \) as that interconnection of concurrently operating machines realizing the state behavior of a reduction \( M_r \) of \( M \). A reciprocal concern of equal importance is the realization of the state behavior of a given machine \( M_r \) as that interconnection of concurrently operating machines realizing the state behavior of a machine \( M \) of which \( M_r \) is a reduction (refs. 5 and 9). It is clear that the latter realization can be obtained merely by applying the newly developed decomposition theory to machine \( M \). There is a problem, however, of deriving the machine \( M \) from \( M_r \). The derivation of such a machine \( M \) from a given machine \( M_r \) is achieved by means of a process called state splitting (refs. 5 and 10).

**Definition 27**

A state \( S_{j}^{(r)} \in S^{(r)} \) of a sequential machine \( M_r \) is said to be split if it is replaced by two or more states \( S_{j}^{(r)1}, S_{j}^{(r)2}, \ldots, S_{j}^{(r)n} \). A sequential machine \( M \) is said to be a state split version of \( M_r \) if it is derived from \( M_r \) as follows:

1. If a state \( S_{j}^{(r)} \) of \( M_r \) is split, then the states \( S_{j}^{(r)1}, S_{j}^{(r)2}, \ldots, S_{j}^{(r)n} \) are taken as states of \( S \) of \( M \).
2. If a state \( S_{k}^{(r)} \) of \( M_r \) is not split, then the state \( S_{k}^{(r)} \) is taken as a state of \( S \) of \( M \).
3. If \( S_{k}^{(r)} \Delta(i) = S_{j}^{(r)} \) for \( M_r \), then for \( M \) \( S_{k}^{(r)} \Delta(i) = S_{j}^{(r)} \), where \( i = i \in I \) and \( l \) is an integer such that \( 1 \leq l \leq n \).
4. If \( S_{j}^{(r)} \Delta(i) = S_{k}^{(r)} \) for \( M_r \), then for \( M \) \( S_{j}^{(r)} \Delta(i) = S_{k}^{(r)} \), where \( l \) assumes all integer values such that \( 1 \leq l \leq n \).
5. If \( S_{j}^{(r)} \Delta(i) = S_{j}^{(r)} \) for \( M_r \), then for \( M \) \( S_{j}^{(r)} \Delta(i) = S_{j}^{(r)m} \), where \( l \) assumes all integer values such that \( 1 \leq m \leq n \) and \( m \) takes on some integer values such that \( 1 \leq m \leq n \).
(6) If $S_k^{(r)}\Delta^{(r)}(i^{(r)}) = S_i^{(r)}$, where both $S_k^{(r)}$ and $S_i^{(r)}$ are not split, for $M_r$, then for $M$ $S_k^{(r)}\Delta(i) = S_i^{(r)}$.

A concrete illustration of the definition is provided by considering machine $D_r$ of figure 12. If only state 4 of machine $D_r$ is split into states $4^1$ and $4^2$, then according to parts (1) and (2) of the definition, the set $S$ of states of machine $D$, which is a state split version of $D_r$, is $\{1, 2, 3, 4^1, 4^2, 5, 6, 7\}$. By part (3) of the definition, because it is true that
\[
2\Delta^{(r)}(1) = 4
\]
\[
6\Delta^{(r)}(1) = 4
\]
\[
3\Delta^{(r)}(2) = 4
\]
for machine $D_r$, then for machine $D$
\[
2\Delta(1) = 4^1
\]
\[
6\Delta(1) = 4^1
\]
\[
3\Delta(2) = 4^1
\]
where the choice of $4^1$ in each case is arbitrary. By part (4) of the definition
\[
4\Delta^{(r)}(1) = 7
\]
for D, implies that

$$4^1 \Delta(1) = 7 \text{ and } 4^2 \Delta(1) = 7$$

for machine D. By part (5) of the definition

$$4 \Delta(2) = 4$$

for D, implies that

$$4^1 \Delta(2) = 4^2 \text{ and } 4^2 \Delta(2) = 4^1$$

for D, where the choice of next states $4^2$ and $4^1$, respectively, is arbitrary. Typical of part (6) of the definition is

$$3 \Delta(1) = 6$$

for D, implies that

$$3 \Delta(1) = 6$$

for machine D. The flow table representation of machine D is shown in figure 13.

It is clearly impractical to determine at random what states of a given machine should be split and to what degree they should be split. Bases for systematic determination procedures must be developed if state splitting is to be useful. Information about the decomposition structure of a given sequential machine should most properly be the basis for state splitting when the primary objective is to design the machine as a con-

$$
\begin{array}{c|cc|cc}
| & 1 & 2 & 1 & 2 \\
\hline
1 & 5 & 2 & 0_1 & 0_1 \\
2 & 4^1 & 1 & 0_1 & 0_2 \\
3 & 6 & 4^1 & 0_1 & 0_1 \\
4^1 & 7 & 4^2 & 0_2 & 0_1 \\
4^2 & 7 & 4^1 & 0_2 & 0_1 \\
5 & 6 & 3 & 0_2 & 0_2 \\
6 & 4^1 & 6 & 0_2 & 0_1 \\
7 & 5 & 3 & 0_1 & 0_2 \\
\end{array}
$$

Figure 13. - Machine D.
currently operating interconnection of smaller machines. A step toward the development of such a systematic state splitting determination procedure has been made by introducing concepts among which are generalizations of partitions and partition pairs (ref. 5). These generalizations carry information about the loop-free decomposition structure of sequential machines. These concepts must, however, be extended further to convey sufficient information about the general decomposition structure of sequential machines. Obvious extensions of the aforementioned concepts are now introduced.

Definition 28

A nondisjoint partition $\theta$ of a set $S^{(r)}$ is a family $P_1, P_2, \ldots, P_n$ of nonempty sets such that $P_1 \cup P_2 \cup \ldots \cup P_n = S^{(r)}$. The sets $P_1, P_2, \ldots, P_n$ are called the blocks of $\theta$. The blocks of $\theta$ are not necessarily pairwise disjoint.

With respect to machine $D_r$, a nondisjoint partition $\theta_1$ is given by

$$\theta_1 = \{P_1 = \{1, 2\}, P_2 = \{3, 4\}, P_3 = \{4, 5\}, P_4 = \{6, 7\}\}$$

where the union of the blocks $P_1, P_2, P_3, P_4$ is

$$\{1, 2\} \cup \{3, 4\} \cup \{4, 5\} \cup \{6, 7\} = \{1, 2, 3, 4, 5, 6, 7\} = S^{(r)}$$

and blocks $P_2$ and $P_3$ are nondisjoint.

Definition 29

A canonical relation $\theta^*$ between $S^{(r)}$ and $\theta$ is given by

$$\theta^* = \{\langle S^{(r)}, P\rangle | S^{(r)} \in P \subseteq \theta\}$$

In particular, the relation $\theta_1^*$ between $S^{(r)}$ of machine $D_r$ and $\theta_1$ of the previous example is

$$\theta_1^* = \{\langle 1, P_1\rangle, \langle 2, P_1\rangle, \langle 3, P_2\rangle, \langle 4, P_2\rangle, \langle 4, P_3\rangle, \langle 5, P_3\rangle, \langle 6, P_4\rangle, \langle 7, P_4\rangle\}$$
Definition 30

Nondisjoint partitions \( \theta \) and \( \theta' \) of \( S^{(r)} \) of a sequential machine \( M_r \) form a nondisjoint partition pair \((\theta, \theta')\), if and only if for every \( P \subseteq \theta \) and every \( i^{(r)(r)} \in I^{(r)} \) there exists a \( Q \in \theta' \) such that \( P \Delta^{(r)(r)}(i^{(r)}) \subseteq Q \).

Illustrative of this definition is the nondisjoint partition pair

\[
(\theta_1, \theta_1') = (\{P_1 = \{1, 2\}, P_2 = \{3, 4\}, P_3 = \{4, 5\}, P_4 = \{6, 7\}\})
\]

of the machine \( D_r \):

\[
\begin{align*}
\{1, 2\} & \Delta^{(r)(r)}(1) = \{5, 4\} \subseteq Q_1 \\
\{3, 4\} & \Delta^{(r)(r)}(1) = \{6, 7\} \subseteq Q_2 \\
\{4, 5\} & \Delta^{(r)(r)}(1) = \{7, 6\} \subseteq Q_2 \\
\{6, 7\} & \Delta^{(r)(r)}(1) = \{4, 5\} \subseteq Q_1 \\
\{1, 2\} & \Delta^{(r)(r)}(2) = \{2, 1\} \subseteq Q_1 \\
\{3, 4\} & \Delta^{(r)(r)}(2) = \{4\} \subseteq Q_1 \ \text{or} \ Q_2 \\
\{4, 5\} & \Delta^{(r)(r)}(2) = \{4, 3\} \subseteq Q_2 \\
\{6, 7\} & \Delta^{(r)(r)}(2) = \{6, 3\} \subseteq Q_2
\end{align*}
\]

Definition 31

A nondisjoint partition \( \theta_\alpha \) of \( S^{(r)} \) is said to be a refinement of a nondisjoint partition \( \theta_\beta \) of \( S^{(r)} \), written \( \theta_\alpha \leq \theta_\beta \), if and only if the following conditions are satisfied:

1. Every \( P \subseteq \theta_\alpha \) is contained in some \( Q \subseteq \theta_\beta \).
2. The union of all \( P \) contained in the same \( Q \) equals that \( Q \).
The nondisjoint partitions $\theta_1$ and $\theta'_1$ of machine $D_r$ afford a concrete example of the definition. Since $P_1 \subseteq Q_1$ and $P_3 \subseteq Q_1$ such that $P_1 \cup P_3 = Q_1$ and $P_2 \subseteq Q_2$ and $P_4 \subseteq Q_2$ such that $P_2 \cup P_4 = Q_2$, $\theta_1 = \theta'_1$.

**Definition 32**

The multiplicity of the element $S_j^{(r)}$ in $\theta_\alpha$ of $S^{(r)}$ is one less than the number of blocks of $\theta_\alpha$ that contain $S_j^{(r)}$. The multiplicity of $S_j^{(r)}$ in $\theta_\alpha$ is denoted by $m_\alpha;S_j^{(r)}$

In particular, the multiplicity $m_{1,4}$ of state 4 in $\theta_1$ of machine $D_r$ is 1; whereas, the multiplicity of all other states of $S^{(r)}$ in $\theta_1$ is 0.

**Definition 33**

The multiplicity-dependent intersection of two blocks $P \in \theta_\alpha$ and $Q \in \theta_\beta$, written as $P \subseteq Q$, is any subset of $P \cap Q$ such that the following are true:

1. Every $S_j^{(r)}$ contained in $P \cap Q$, for which either or both $m_\alpha;S_j^{(r)}$ and $m_\beta;S_j^{(r)}$ is 0, also belongs to $P \subseteq Q$.

2. Any $S_j^{(r)}$ contained in $P \cap Q$, for which $m_\alpha;S_j^{(r)} > 0$ and $m_\beta;S_j^{(r)} > 0$, may be chosen to be a member of $P \subseteq Q$, but is not necessarily so.

A specific illustration of the multiplicity-dependent intersection of two blocks is provided by considering the nondisjoint partitions

$\theta'_1 = \{8 = \{1, 2, 4, 5\}, 9 = \{3, 4, 6, 7\}\}$ and $\theta'_2 = \{10 = \{1, 2, 3, 4\}, 11 = \{4, 5, 6, 7\}\}$

of machine $D_r$. By part (1) of definition 33

$\{1, 2\} \subseteq 8 \subseteq 10$

and by part (2) either

$\{1, 2\} = 8 \subseteq 10$

or

$\{1, 2, 4\} = 8 \subseteq 10$
Definition 34

The multiplicity-dependent greatest lower bound of two nondisjoint partitions \( \theta_\alpha \) and \( \theta_\beta \), written as \( \theta_\alpha \sqcup \theta_\beta \), is a nondisjoint partition

\[
\theta_{\gamma} = \{ P \sqcap Q \mid P \in \theta_\alpha, Q \in \theta_\beta \text{ and } m_{\gamma}; S_k^{(r)} = m_\alpha; S_j^{(r)} \text{ if } m_\alpha; S_j^{(r)} \preceq m_\beta; S_j^{(r)}; \\
\text{otherwise, } m_{\gamma}; S_j^{(r)} = m_\beta; S_j^{(r)} \}
\]

such that

\[
\theta_{\gamma} \preceq \theta_\alpha
\]

\[
\theta_{\gamma} \preceq \theta_\beta
\]

Specifically, the multiplicity-dependent greatest lower bound of \( \theta_1^* \) and \( \theta_2^* \) of the previous example is

\[
\theta_3 = \{ 8 \sqcap 10, 8 \sqcap 11, 9 \sqcap 10, 9 \sqcap 11 \}
\]

where

\[
8 \sqcap 10 = \{1, 2\} \text{ or } \{1, 2, 4\}
\]

\[
8 \sqcap 11 = \{5\} \text{ or } \{4, 5\}
\]

\[
9 \sqcap 10 = \{3\} \text{ or } \{3, 4\}
\]

\[
9 \sqcap 11 = \{6, 7\} \text{ or } \{4, 6, 7\}
\]

such that precisely two blocks of \( \theta_3 \) contain the state 4 and

\[
(8 \sqcap 10) \cup (8 \sqcap 11) = 8
\]

\[
(9 \sqcap 10) \cup (9 \sqcap 11) = 9
\]
Thus, $\theta_3$ can be chosen to be either

$$\{8 \text{ m } 10 = \{1, 2\}, \ 8 \text{ m } 11 = \{4, 5\}, \ 9 \text{ m } 10 = \{3, 4\}, \ 9 \text{ m } 11 = \{6, 7\}\}$$

or

$$\{8 \text{ m } 10 = \{1, 2, 4\}, \ 8 \text{ m } 11 = \{5\}, \ 9 \text{ m } 10 = \{3\}, \ 9 \text{ m } 11 = \{4, 6, 7\}\}$$

**Definition 35**

Given sequential machines $M_r$ and $M_k$, $M_k$ is a generalized $S^{(k)}$-image of $M_r$ if and only if for every $s^{(k)} \subseteq S^{(k)}$, $i^{(r)} \subseteq I^{(r)}$, and $i^{(k)} \subseteq I^{(k)}$ the following conditions are satisfied:

1. Every $s^{(r)} \subseteq S^{(r)}$ belongs to some $s^{(k)} \subseteq S^{(k)}$ and to some $c^{(k)} \subseteq C^{(k)}$.
2. $(c^{(k)} \circ m s^{(k)}) \Delta^{(r)} l^{(r)} \subseteq s^{(k)} \Delta^{(k)} (l^{(k)})$.

The machine $D_1$, shown in figure 14, is a generalized $S^{(1)}$-image of $D_r$, and affords a specific example of the previous definition. The carry input set to $D_1$ is

$$C^{(1)} = \{10 = \{1, 2, 3, 4\}, \ 11 = \{4, 5, 6, 7\}\}$$

and the state set is

$$S^{(1)} = \{8 = \{1, 2, 4, 5\}, \ 9 = \{3, 4, 6, 7\}\}$$

From calculations carried out in examples 30, 31, 33, and 34, it is clear that machine $D_1$ satisfies the conditions of definition 35 to be a generalized $S^{(1)}$-image of $D_r$.

$D_1$

Figure 14. - Representation of machine $D_1$ as a generalized $S^{(1)}$-image of machine $D_r$. 38
Theorem 4:

Implied by a generalized $S^{(k)}$-image $M_k$ of a given sequential machine $M_r$ is a family of state split versions each of which is an $S^{(k)}$-image of some state split version $M$ of $M_r$. Reciprocally, implied by the $S^{(k)}$-image of any state split version $M$ of $M_r$ is a generalized $S^{(k)}$-image $M_k$ of $M_r$.

Proof:

For the first half of the theorem, it can be assumed that there is given the sequential machine $M_k$ which is a generalized $S^{(k)}$-image of a given machine $M_r$. Also, according to part (1) of definition 35, corresponding to the sets $S^{(k)}$ and $C^{(k)}$ of machine $M_k$ are nondisjoint partitions $\theta_k'$ and $C^{(k)}$. Each state $S_j^{(r)}$ whose multiplicity $m_k; S_j^{(r)}$ is greater than zero for either $\theta_k'$ or $C^{(k)}$ can be split as follows:

1. If the multiplicity of $S_j^{(r)}$ in $\theta_k'$ is greater than that of $S_j^{(r)}$ in $C^{(k)}$ and is $m_k; S_j^{(r)} = n - 1 > 0$, replace $S_j^{(r)}$ in each block of $\theta_k'$ that it appears by one of the states $S_j^{(r)}1, S_j^{(r)}2, \ldots, S_j^{(r)}n$. The replacement can be made such that $S_j^{(r)}1$ is assigned to the first block of the arbitrarily ordered blocks of $\theta_k'$ containing $S_j^{(r)}$, $S_j^{(r)}2$ to the second such block, etc. Corresponding to every multiplicity-dependent block intersection $C^{(k)} \cap s^{(k)}$ originally containing $S_j^{(r)}$, the state $S_j^{(r)}$ for the sake of compatibility must be replaced in $C^{(k)}$ by the state $S_j^{(r)}l$ just assigned to the associated block of $\theta_k'$.

2. If the multiplicity of $S_j^{(r)}$ in $C^{(k)}$ is greater than that of $S_j^{(r)}$ in $\theta_k'$ and is $m_k; S_j^{(r)} = n - 1 > 0$, replace $S_j^{(r)}$ in each block of $C^{(k)}$ that it appears by one of the states $S_j^{(r)}1, S_j^{(r)}2, \ldots, S_j^{(r)}n$. The replacement can be made such that $S_j^{(r)}1$ is assigned to the first block of the arbitrarily ordered blocks of $C^{(k)}$ containing $S_j^{(r)}$, $S_j^{(r)}2$ to the second such block, etc. If the state $S_j^{(r)}$ is contained in the multiplicity-dependent block intersection $C^{(k)} \cap s^{(k)}$, for the sake of compatibility replace $S_j^{(r)}$ in the block $S_j^{(k)}$ of $\theta_k'$ by the state $S_j^{(r)}l$ just assigned to the block $C^{(k)}$ of $C^{(k)}$. Some blocks of $\theta_k'$ will now contain two or more replacements for the original state $S_j^{(r)}$ under this procedure.

3. Once the present states of $M_r$ have been split as described, the next states of $M_r$ must be split. Each next state of $M_k'$, before state splitting, corresponded to a block of $\theta_k'$. Let the next states of $M_r$ be split in such a way that each next state of $M_k$ corresponds to the associated block resulting from the procedure of (1) and (2). Each next state which is left unsplit after this process can be arbitrarily replaced by any member of its replacement set of states.
In the state splitting process (1) to (3) just given, the parts (1) and (2) of definition 27 are obviously satisfied. In accordance with step (3) of the state splitting process, to every state \( S_j^{(r)} \subset S^{(r)} \) in some \( s^{(k)} \subset S^{(k)} \) implied by a state \( s^{(r)} \subset c^{(k)} \) \( \Delta \) \( s^{(k)} \) for an input \( i^{(r)} \) there corresponds a state \( S_j^{(r)} \), where \( I \) is an integer such that \( 1 \leq I \leq n \). Thus, part (3) of definition 27 is also satisfied. Moreover, similar reasoning shows that parts (4), (5), and (6) of definition 27 are satisfied. Therefore, the state splitting process presented herein serves to derive a state split version \( M_1, \) of the derived machine \( M \) is a member of a family of state split versions of \( M_1 \). The number of members in this family is \( 2^a \), where \( a \) is the number of replacements which can be made arbitrarily in step (3) of the above state splitting process. The state splitting has been accomplished in such a way that the relation

\[
(c^{(k)} \Delta s^{(k)})^{(r)}(i^{(r)}) \subseteq s^{(k)} \Delta (i^{(k)})
\]

where \( c^{(k)} \) and \( s^{(k)} \) are elements of the given sets, corresponds to

\[
(c^{(k)} \cap s^{(k)}) \Delta (i) \subseteq s^{(k)} \Delta (i^{(k)})
\]

where \( c^{(k)} \) and \( s^{(k)} \) are blocks of the newly derived partitions \( C^{(k)} \) and \( \pi^{(k)}_1, \) respectively. Hence, the partition pair \( (C^{(k)} \cdot \pi^{(k)}_1, \pi^{(k)}_1) \) on \( S \) of \( M \) implies by Theorem 1 the existence of an \( S^{(k)} \)-image of \( M \).

For the second half of the theorem, it can be assumed that machine \( M \) and an \( S^{(k)} \)-image of \( M \) are given. By Theorem 1 there exists the partition pair \( (C^{(k)} \cdot \pi^{(k)}_1, \pi^{(k)}_1) \) on the states of \( S \) of \( M \). Machine \( M_1 \) can be derived directly from \( M \) as a reduction of \( M \). The states of \( S^{(r)}_1 \) of \( M_1 \) are the blocks of an output-consistent partition pair \( (\pi^{*r}_1, \pi^{*r}_1) \) on the states of \( S \) of \( M \). Canonical relations \( \pi^{*r}_1, C^{(k)} \) * , \( (\pi^{*r}_1)^{-1} \) exist such that \((\pi^{*r}_1)^{-1} \pi^{*r}_1 \) maps the partition \( \pi^{*r}_1 \) into a nondisjoint partition \( \delta^{*r}_1 \); likewise, \((\pi^{*r}_1)^{-1} C^{(k)} \) * maps the partition \( C^{(k)} \) into a nondisjoint partition \( C^{(k)} \) on the states of \( S^{(r)}_1 \) of \( M_1 \). Because \( i^{(r)} = 1 \), the relation

\[
(c^{(k)} \cap s^{(k)}) \Delta (i) \subseteq s^{(k)} \Delta (i^{(k)})
\]

under the aforementioned mappings goes into

\[
(c^{(k)} \Delta s^{(k)})^{(r)}(i^{(r)}) \subseteq s^{(k)} \Delta (i^{(k)})
\]

where the latter elements \( c^{(k)} \) and \( s^{(k)} \) are those belonging to new sets \( C^{(k)} \) and \( S^{(k)} \) corresponding to the derived nondisjoint partitions \( C^{(k)} \) and \( \delta^{*r}_1 \), respectively. There-
fore, in accordance with definition 35 there does exist a machine \( M_k \) which is a generalized \( S^{(k)} \)-image of \( M_{\Gamma} \). This completes the proof of the theorem.

A consideration of machines \( D_{\Gamma} \) and \( D_1 \) provides a concrete illustration of the first half of the theorem. Corresponding to the sets \( S^{(1)} \) and \( C^{(1)} \) of \( D_1 \), a generalized \( S^{(1)} \)-image of machine \( D_{\Gamma} \), are the nondisjoint partitions

\[
\theta'_{1} = \{8 = \{1, 2, 4, 5\}, 9 = \{3, 4, 6, 7\}\} \quad \text{and} \quad C^{(1)} = \{10 = \{1, 2, 3, 4\}, 11 = \{4, 5, 6, 7\}\}.
\]

The only state whose multiplicity is greater than 0 in either \( \theta'_{1} \) or \( C^{(1)} \) is state 4. In accordance with step (1) of the proof, state 4 is split such that \( \theta'_{1} \) becomes

\[
\pi_{1}' = \{8 = \{1, 2, 4^1, 5\}, 9 = \{3, 4^2, 6, 7\}\}
\]

Since \( 9 \cap 10 = \{3, 4\} \), state 4 in 10 of \( C^{(1)} \) is replaced by \( 4^2 \). Likewise, since \( 8 \cap 11 = \{4, 5\} \), state 4 in 11 of \( C^{(1)} \) is replaced by \( 4^1 \). Thus, \( C^{(1)} \) becomes

\[
C^{(1)} = \{10 = \{1, 2, 3, 4^2\}, 11 = \{4^1, 5, 6, 7\}\}
\]

By step (3) of the proof, the next state implied by state 2 when the input \( \langle 1, 10 \rangle \) is applied is \( 4^1 \) since

\[
(10 \cap 8)\Delta^{(r)}(1) = \{1, 2\} \Delta^{(r)}(1) = \{5, 4^1\} \subseteq 8
\]

Similarly, the next states implied by present states 6 and \( 4^1 \) for inputs \( \langle 1, 11 \rangle \) and \( \langle 2, 11 \rangle \), respectively, are \( 4^1 \) and \( 4^2 \), respectively, since

\[
(11 \cap 9)\Delta^{(r)}(1) = \{6, 7\} \Delta^{(r)}(1) = \{4^1, 5\} \subseteq 8
\]

\[
(11 \cap 8)\Delta^{(r)}(2) = \{4^1, 5\} \Delta^{(r)}(2) = \{4^2, 3\} \subseteq 9
\]

The next states implied by present states 3 and \( 4^2 \) must be the same because

\[
(10 \cap 9)\Delta^{(r)}(2) = \{3, 4^2\} \Delta^{(r)}(2) = \{4^1\} \quad \text{or} \quad \{4^2\}
\]

Let these next states be arbitrarily chosen to be \( 4^1 \). With this choice, state 4 of machine \( D_{\Gamma} \) will have been split precisely as it was in the illustration of definition 27. Hence, machine \( D \) of figure 13 is an implied state split version of \( D_{\Gamma} \). Furthermore, from the nondisjoint partitions \( \theta'_{1} \) and \( C^{(1)} \) comes the partition pair
which implies the existence of an $S^{(1)}$-image of machine $D$ whose flow table representation is like that of machine $D_1$ of figure 14. The two representations differ only in that the next state implied by state 9 for input $\langle 2, 10 \rangle$ is unspecified for machine $D_1$ but is state 8 for the $S^{(1)}$-image of machine $D$.

For an illustration of the second half of the theorem, machine $D$ and its $S^{(1)}$-image are considered. An examination of the flow table of machine $D$ shown in figure 13 reveals in addition to $(p_1^*, p_1)$ the existence of the output-consistent partition pair $(p_1', p_1')$, where $p_1' = \{ 1, 2, 3, 4 = \{ 4^1, 4^2 \}, 5, 6, 7 \}$. From $(p_1^*, p_1')$ the reduction $D_r$ of machine $D$ is directly derivable and is seen to have the representation given in figure 12. Additionally,

$$(p_1^*)^{-1} p_1^* = \{ \langle 1, 1 \rangle, \langle 2, 2 \rangle, \langle 3, 3 \rangle, \langle 4, 4^1 \rangle, \langle 4, 4^2 \rangle, \langle 5, 5 \rangle, \langle 6, 6 \rangle, \langle 7, 7 \rangle \}

\{ \langle 1, 8 \rangle, \langle 2, 8 \rangle, \langle 4^1, 8 \rangle, \langle 5, 8 \rangle, \langle 3, 9 \rangle, \langle 4^2, 9 \rangle, \langle 6, 9 \rangle, \langle 7, 9 \rangle \}

= \{ \langle 1, 8 \rangle, \langle 2, 8 \rangle, \langle 4, 8 \rangle, \langle 5, 8 \rangle, \langle 3, 9 \rangle, \langle 4, 9 \rangle, \langle 6, 9 \rangle, \langle 7, 9 \rangle \}

= 0_1^*$$

from which

$$\theta_1^* = \{ 8 = \{ 1, 2, 4, 5 \}, 9 = \{ 3, 4, 6, 7 \} \}$$

on the states of $S^{(r)}$ of $D_r$. Similarly,

$$(p_1^*)^{-1} C^{(1)*} = (p_1^*)^{-1} \{ \langle 1, 10 \rangle, \langle 2, 10 \rangle, \langle 3, 10 \rangle, \langle 4^2, 10 \rangle, \langle 4^1, 11 \rangle, \langle 5, 11 \rangle, \langle 6, 11 \rangle, \langle 7, 11 \rangle \}

= \{ \langle 1, 10 \rangle, \langle 2, 10 \rangle, \langle 3, 10 \rangle, \langle 4, 10 \rangle, \langle 4, 11 \rangle, \langle 5, 11 \rangle, \langle 6, 11 \rangle, \langle 7, 11 \rangle \}

from which

$$C^{(1)} = \{ 10 = \{ 1, 2, 3, 4 \}, 11 = \{ 4, 5, 6, 7 \} \}$$

on the states of $S^{(r)}$ of $D_r$. The two thusly derived partitions define the nondisjoint
partition pair \((\theta_1 = C^{(1)} m \theta_1, \theta_1')\) considered previously and shown to imply the existence of machine \(D_1\), a generalized \(S^{(1)}\)-image of \(D\).

Theorem 5:

Given a sequential machine \(M_r\), then there exists an \(S^{(k)}\)-image \(M_k\) of a state split version \(M\) of \(M_r\) if and only if there exists a nondisjoint partition pair \((\theta_k, \theta_k')\) on the states of \(S^{(k)}\) of \(M_r\) such that \(\theta_k = C^{(k)} m \theta_k\) and such that when the states are split, the blocks of \(C^{(k)}\) and \(\theta_k\) become the elements of the carry input set \(C^{(k)}\) to \(M_k\) and of the set of states \(S^{(k)}\) of \(M_k\), respectively.

Proof:

The proof follows immediately from Theorems 1 and 4.

Theorem 5 shows that the nondisjoint partition pairs of a sequential machine convey vital information about its decomposition structure. Such information is of the type sought for as a basis for the development of a systematic state splitting determination procedure. Included in the proof of Theorem 4 is a model of such a procedure.

The fact that Theorem 5 is the state split generalization of Theorem 1 furnishes some promise that the fundamental theorem, Theorem 3, also has a state split generalization. The following embodies the fulfillment of this promise:

Theorem 6:

The state behavior of a sequential machine \(M_r\) can be realized by a concurrently operating interconnection of \(j\) machines \(M_1, M_2, \ldots, M_j\) if and only if there exist nondisjoint partition pairs \(\theta_1, \theta_1', (\theta_2, \theta_2'), \ldots, (\theta_j, \theta_j')\) on the states of \(S^{(k)}\) of \(M_r\) such that \(\theta_1 m \theta_2 m \ldots m \theta_j = 0, \theta_1 = C^{(1)} m \theta_1, \theta_2 = C^{(1)} m \theta_2, \ldots, \theta_j = C^{(J)} m \theta_j\), and furthermore the machines \(M_1, M_2, \ldots, M_j\) are \(S^{(1)}\)-, \(S^{(2)}\)-, \ldots, \(S^{(J)}\)-images, respectively, of the same split version \(M\) of \(M_r\).

Proof:

With the use of definitions 31 and 34, the proof follows directly from Theorems 3, 4, and 5.

The next example shows the significance of the requirement in the theorem that the machines \(M_1, M_2, \ldots, M_j\) are \(S^{(1)}\)-, \(S^{(2)}\)-, \ldots, \(S^{(J)}\)-images, respectively, of the same state split version \(M\) of \(M_r\). Previously, it was shown that an \(S^{(1)}\)-image of a
state split version of machine $D_r$ existed corresponding to the nondisjoint partition pair $(C^{(1)}m\theta^*_1, \theta^*_1)$. With the aid of Theorem 5, it is found that additionally there exist $S^{(2)}$- and $S^{(3)}$-images of state split versions of $D_r$ corresponding to $(C^{(2)}m\theta^*_2, \theta^*_2)$ and $(C^{(3)}m\theta^*_3, \theta^*_3)$, respectively, where

$$\theta^*_2 = C^{(1)}, \ C^{(2)} = \{12 = \{1, 3, 4, 6\}, 13 = \{2, 4, 5, 7\}\}$$

$$\theta^*_3 = C^{(2)}, \ C^{(3)} = \theta^*_1$$

$$\theta^*_3 = \{8 \ m\ 12 = \{1, 4\}, 8 \ m\ 13 = \{2, 5\}, 9 \ m\ 12 = \{3, 6\}, 9 \ m\ 13 = \{4, 7\}\}$$

The nondisjoint partitions $\theta^*_1, \theta^*_2, \text{and } \theta^*_3$ are such that

$$\theta^*_1 \ m\theta^*_2 \ m\theta^*_3 = 0$$

Nevertheless, there exists no state split version $D$ of machine $D_r$ whose state behavior is realized by a concurrently operating interconnection of the aforementioned $S^{(1)}$, $S^{(2)}$, and $S^{(3)}$-images. The reason for this is made evident by deriving from $(C^{(2)}m\theta^*_2, \theta^*_2)$ a state split version of machine $D_r$. The only such state split version, which can be derived so that the transformation of the nondisjoint partition $\theta^*_2 = C^{(1)}$ to the partition $\pi^*_R$ is compatible with transforming $C^{(1)}$ on $S^{(r)}$ of $D_r$ to $C^{(1)}$ on $S$ of $D$, is the machine represented in figure 15. This machine is not the same state split

Figure 15. - State split version of $D_r$

derived from $(\theta^*_2, \theta^*_2)$.
version of $D_r$ derived previously and shown in figure 13. Moreover, it is not the same as any member of the family of state split versions derivable from $(C^{(1)}_1, \theta_1)$. Therefore, Theorem 6 must indeed include a compatibility condition requiring in essence that all nondisjoint partition pairs concerned imply a common state split version of the given machine.

It is suggested that the interested reader illustrate to himself the further workings of Theorem 6 by deriving a concurrently operating interconnection of three machines realizing the state behavior of $D_r$ as follows: Replace the nondisjoint partition $C^{(2)}_2$ already given in the example by $C^{(2)}_2 = \theta_3$ such that $C^{(2)}_2 \theta_2 = 0$. Then by using Theorem 4 proceed to verify that now the three nondisjoint partition pairs do imply for machine $D_r$ a common state split version $D$, shown in figure 13. During the verification process, partition pairs $(\pi_1', \pi_1'), (\pi_2', \pi_2'),$ and $(\pi_3', \pi_3')$ on the states of $S$ of $D$ such that $\pi_1' \cdot \pi_2' \cdot \pi_3' = 0$ will have been derived. As a final step, with the derived partition pairs apply Theorem 3, as illustrated in previous examples, to construct the machines $D_1$, $D_2$, and $D_3$ of the required interconnection.

Theorem 6 is of twofold importance. First, it is a fundamental statement of the generalized decomposition theory; as such Theorem 6 also represents the attainment of the primary objective of this report. Second, it provides a basis for an adequate state splitting determination procedure insofar as the design of machines from their decompositional properties is concerned.

CONCLUDING REMARKS

The basic result of the research reported herein is the development of a generalized decomposition theory of finite sequential machines.

It is hoped that the newly developed theory will lay the foundation for the successful completion of many other research projects. Such projects might, for instance, involve the following:

1. The formulation of algorithms for the derivation of the "best" decompositions of sequential machines under varying criteria
2. The founding of similar algorithms for determining the best decomposition of a combination of two machines given one machine already realized (the realized machine might be a computer and the other, an addition to it)
3. The establishment of criteria under which the specification of sequential machines can be changed to improve their decomposition structure
4. The gaining of a more practical understanding of iterative arrays of logical circuits (ref. 11)
5. The development of methods for the synthesis of sequential machines with given classes of modular building blocks (refs. 12 and 13)

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Scientific and technical information generated under a NASA contract or grant and considered an important contribution to existing knowledge.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

TECHNOLOGY UTILIZATION PUBLICATIONS: Information on technology used by NASA that may be of particular interest in commercial and other non-aerospace applications. Publications include Tech Briefs, Technology Utilization Reports and Notes, and Technology Surveys.

Details on the availability of these publications may be obtained from:
