ABSTRACT

We consider an electron of a given energy moving in a mono-
energetic, isotropic radiation field. The energy spectrum of the pho-
tons that are scattered by the electron has been calculated both exactly
and in a greatly simplified approximate form suitable for astrophysical
calculations. The approximation may be derived either by expanding
the exact solution in a small parameter and keeping only the leading
terms or by employing a simplifying physical approximation at the be-
ginning of the calculation. The approximate spectrum is similar to one
previously derived by Ginzburg and Syrovatskii, the principal difference
being that the present one does not break down if $\hbar \omega_1 E > (m_e c^2)^2$ where
$\hbar \omega_1$ is the initial photon energy and $E$ the electron energy. We indicate
the astrophysical applications of our approximate spectrum by calcu-
lating the spectrum of photons scattered by electrons with an inverse-
power-law energy distribution.
I. INTRODUCTION

In recent years the process referred to as inverse Compton scattering has had a revival of interest among astrophysicists. It was introduced in 1947 by Follin\(^1\) as a mechanism for the loss of energy of cosmic ray electrons and was investigated by Feenberg and Primakoff\(^2\) and by Donahue\(^3\) in this context. Since that time it has been employed in many treatments\(^4-8\) of cosmic ray electrons and the process was investigated in some detail by the present author in an earlier paper.\(^9\)

It was first suggested as a source of energetic photons by Savedoff\(^10\) and by Felten and Morrison\(^11\) and has since received considerable attention\(^12-19\) from this point of view. Most of the calculations of photon spectra to date have been based on a rather simple approximation. It has been noted that the average energy transferred to a photon in a Compton collision is proportional to the initial energy of the photon and the square of the electron energy. This dependence on the square of the electron energy is reminiscent of the synchrotron process and for this reason the radiated photon spectra for a single electron energy is approximated by a delta function spike at the average radiated energy. This spectrum is then folded into the distribution of electron energies.
to produce the resultant photon spectrum. Although this method is known to give satisfactory results for synchrotron spectra it is now known\textsuperscript{20} that the inverse Compton spectra are sufficiently different to raise some doubts as to its applicability in this area. However, it can be shown\textsuperscript{21} that in the case of inverse power law distributions of electron energies the method is applicable to both cases in spite of their differences.

In the present paper we derive exact formulas for the scattered photon energy distribution for the case of an electron of energy $\gamma = E/mc^2$ moving through a region of space filled with a unit density of photons distributed isotropically with initial energy $\alpha_1 = \hbar \omega_1/mc^2$. We shall also derive several approximate formulas and discuss their validity in the light of the exact formulas. Similar calculations have been recently published by Baylis et al.\textsuperscript{22} however, we find that our results disagree with theirs in several respects. In particular we disagree with their conclusion that a particular approximate spectrum is of as wide a validity as they claim. On the contrary we derive correction terms that become significant when certain conditions of validity first stated by Ginsburg and Syrovatskii\textsuperscript{20} are violated.

In Section II we derive an approximate spectrum based on a simplifying physical assumption. The breakdown of this approximation will also be discussed from a physical point of view. In Section III the
scattered spectrum will be calculated exactly and compared (as well possible) with the approximate spectrum. We will see that the exact form is often not too useful for computation and the reason for this will be discussed. In Section IV we shall exhibit a method of expanding the exact formula in the small parameter that causes the trouble. This provides not only a method for computing the exact spectrum but provides a systematic way of rederiving our approximate formula along with some correction terms. In Section V we will discuss some astrophysical implications of these results.
II. AN APPROXIMATE SPECTRUM

In this section we shall derive an approximate spectrum by making a simplifying physical assumption concerning angles. Figure 1 illustrates the angles involved in a scattering problem as seen in the rest frame of the electron (E. R. frame). All quantities as measured in this frame will be primed and energies of the photon before and after collision \( (\alpha_1 \text{ and } \alpha \text{ respectively}) \) as well as the electron energy \( \gamma \) are understood to be in units of the electron rest energy \( mc^2 \). The polar angles \( \theta_1' \) and \( \theta' \) are measured with respect to the electron velocity \( \beta = v/c \) (strictly with respect to minus \( \beta \); \( \alpha_1 \cdot \beta = -\alpha_1 \beta \cos \theta \)). The scattering takes place through a polar angle \( \chi' \) and an azimuthal angle \( \phi' \) where the \( \alpha_1' \beta \) plane is chosen as the \( \phi' = 0 \) plane.

The presence of so many angles along with the constraining relations between them complicates the problem as we shall see later. It would greatly simplify things if we could eliminate some of them. To this end let us examine the angular distribution of the incoming photons in the E. R. frame.

For photons, isotropic and monoenergetic with energy \( \alpha_1 \) in the lab frame, the angular distribution in the E. R. frame is given by

\[
n' (\theta_1') d(\cos \theta_1') = \frac{d(\cos \theta_1')}{2\gamma^2 (1 - \beta \cos \theta_1')^2} \quad \text{(1)}
\]
If $\beta \sim 1$ half of the photons have polar angles within the range $0 \leq \theta_1^' \leq \theta_{1/2}^'$ where $\theta_{1/2}^' \approx 1/\gamma$. In other words as the electron becomes more and more energetic the incoming photons appear to be more and more like a monodirectional beam with $\theta_1^' = 0$.

The approximation to be made is now obvious; we shall consider the electron to be energetic enough so that we may take $\theta_1^' = 0$. A glance at Fig. 1 shows that in this case $\chi^' = \theta^'$ and since the scattering cross section is independent of the azimuth $\phi^'$ we really have only one angle left to worry about.

The energy distribution of the photons in the E. R. frame before collision is given by

$$n^' (a_1^') \, da_1^' = \frac{a_1^'}{2\gamma a_1^2} \, S(a_1^'; a_1^/, \gamma, a_1, 2\gamma) \, da_1^' \quad (2)$$

for $\gamma >> 1$ and where $S(x; a, b)$ is the characteristic function of the interval $a, b$ i.e.

$$S(x; a, b) = \begin{cases} 1 & \text{for } a \leq x \leq b \\ 0 & \text{for } x < a, b < x. \end{cases}$$

The Klein-Nishina cross section for Compton scattering is given by

$$\sigma(a^', a_1^', y^') = \frac{r_0^2}{2} \frac{(1 + y^2)}{\left[1 + a_1^'(1 - y^')\right]^2} \left\{1 + \frac{a_1^{'2} (1 - y^{'2})}{\left[1 + y^{'2}\right] \left[1 + a_1^'(1 - y^{'})\right]}\right\} \times \delta\left(a^' - f(a_1^', y^')\right) \quad (3)$$
where \( y' = \cos \chi', \ r_0 = e^2/mc^2 \) and \( f(a_1', y') = a_1' [1 + a_1' (1 - y')] \).

The number of collisions per unit time \( t' \) is just \( N' c \sigma \) and since 
\[
dN/dt = \gamma^{-1} dN/dt' \text{ we have after integrating over } \phi'
\]
\[
\frac{d^4 N}{d t d a_1' d a' d y'} = \frac{\pi r_0^2 c}{2a_1^2 \gamma^2} \left[ \frac{1 + y'^2}{\left[ 1 + a_1' (1 - y') \right]^2} \right] \left( 1 + \frac{a_1'^2 (1 - y')^2}{(1 + y'^2) [1 + a_1' (1 - y')]} \right)
\]
\[
\times a_1' \delta \left( a' - f(a_1', y') \right) S(a_1'; a_1/2\gamma, a_1 2\gamma) \] (4)

Since \( d a' da_1' d y' = \left[ 1 + a_1' (1 - y') \right]^2 d a' d y' d f \) we may integrate over \( f \) immediately to obtain
\[
\frac{d^3 N}{d t d a' d y'} = \frac{\pi r_0^2 c}{2a_1^2 \gamma^2} \left\{ (1 + y'^2) + \frac{a'^2 (1 - y')^2}{1 - a' (1 - y')} \right\}
\]
\[
\times \frac{a'}{1 - a' (1 - y')} S \left( \frac{a'}{1 - a' (1 - y')}; a_1/2\gamma, a_1 2\gamma \right) \] (5)

We may relate \( a' \) to the final lab frame energy \( a \) by the Doppler shift formula \( a' = a/\gamma (1 - \beta y') \). If we introduce the variable \( \eta = (1 - \beta y') \) we have
\[
\frac{d^3 N}{d t d a d \eta} = \frac{\pi r_0^2 c a}{2\gamma^4 a_1^2 (1 - a/\gamma)} \left\{ \eta^2 - 2\eta + 2 + \frac{(a/\gamma)^2}{(1 - a/\gamma)} \right\} \times \frac{S(\eta; \eta_1, \eta_2)}{\eta^2} \] (6)
where we have assumed \(1 - \gamma' \approx \eta\) and where \(\eta_1 = a/2a_1 \gamma^2 (1 - a/\gamma)\) and \(\eta_2 = 2a/a_1 (1 - a/\gamma)\). The integral may be readily performed to give

\[
\left[ \eta - 2 \ln \eta \frac{2}{\eta} - \frac{(a/\gamma)^2}{(1 - a/\gamma) \eta} \right]_L^U
\]  

(7)

where the upper and lower limits, \(U\) and \(L\) depend on what part (if any) of the interval \(\eta_1, \eta_2\) lies within the limits \(1/2\gamma^2\) and 2.

For \(a_1/4\gamma^2 \leq a \leq a_1\) we have \(\eta_1 \leq 1/2\gamma^2\) and \(1/2\gamma^2 \leq \eta_2 \leq 2\). We then have, neglecting terms of order \(1/\gamma^2\) or less when compared to unity.

\[
\frac{d^2 N}{dt da} \approx \frac{\pi r_0^2 c}{2\gamma^4 a_1} \left( \frac{4\gamma^2 a}{a_1} - 1 \right)
\]  

(8)

For \(a_1 \leq a \leq 4a_1 \gamma^2/(1 + 4a_1 \gamma)\) we have \(\eta_2 \geq 2\) and \(1/2\gamma^2 \leq \eta_1 \leq 2\) and

\[
\frac{d^2 N}{dt da} \approx \frac{2\pi r_0^2 c}{a_1 \gamma^2} \left[ 2q'' \ln q'' + (1 + 2q'') (1 - q'') \right. \\
\left. + \frac{1}{2} \frac{(4a_1 \gamma q'')^2}{(1 + 4a_1 \gamma q'')} (1 - q'') \right]
\]  

(9)

where

\[q'' = \frac{\alpha}{4a_1 \gamma^2 (1 - a/\gamma)}\]

and \(\frac{1}{4\gamma^2} < q'' \leq 1\)

7
In the above equations we see that the maximum value that \( a/\gamma \) can have is \((a/\gamma)_{\text{max}} = 4a_1 \gamma/(1 + 4a_1 \gamma) < 1\). If \( 4a_1 \gamma << 1 \) then \( a/\gamma << 1 \) and we have \( q'' \approx a/4a_1 \gamma^2 \). The last term in the square brackets may be dropped and we are left with the approximate spectrum of Ginzburg and Syrovatskii\(^{20} \).

Expression (9) is valid, however, no matter how large \( 4a_1 \gamma \) may become.

However, we must not assume that this approximation is uniformly valid. In fact it turns out that it is not a good approximation for \( a/a_1 \approx 1/4\gamma^2 \).

To see the reason for this let us consider what would happen if we took our assumption that \( \theta_1' = 0 \) seriously and transformed our photon energy distribution, Expression (2), back to the lab frame with no scattering at all. We would obtain a spectrum given by

\[
n(a) \, da = \left( a/a_1^2 \right) S(a; a_1/4\gamma^2, a_1) \, da \tag{10}\]

We can see from this that the approximation alone tends to populate the region of the spectrum from \( a_1/4\gamma^2 \) to \( a_1 \) with no scattering at all and that this region will be exaggerated for small angle scattering as well. In other words, due to the large sensitivity of the Doppler shift formula to slight changes in \( \theta' \) for small \( \theta' \) neglect of these small deviations of \( \theta' \) from zero introduces considerable error for small angle scattering.
Small angle scattering would be, of course, angles of the order of $1/\gamma$ or smaller or for $y' \gtrsim 1 - 1/2\gamma^2$. Since for most values of $a/a_1$ there is a contribution from a considerable range of $y'$ other than the region $1 \gtrsim y' \gtrsim 1 - 1/2\gamma^2$ this error will be negligible. However, for the very bottom of the spectrum $a/a_1 \approx 1/4\gamma^2$ the contribution is entirely from the region $\eta = 1 - \beta y' \approx 1/2\gamma^2$ and here we would expect a significant error. This will be borne out by the results of Section IV.
III. EXACT CALCULATION

In this section we shall calculate in closed form the scattered photon spectrum for the case of an electron of energy $\gamma$ moving through a region of space filled with a unit density of isotropically distributed, monoenergetic photons of energy $a_1$. As in the last section we will first transform the incident photon distribution to the E. R. frame and formulate the problem in this frame. The final energy will then be expressed in its lab frame value $a$ and we will integrate over all available angles holding $a_1, \gamma$, and $a$ fixed.

In the E.R. frame the incident photon distribution has the form

$$n' (a_1', x') \, da_1' \, d\Omega' = \frac{a_1'}{a_1} \frac{\delta \left[ a_1' \gamma (1 - \beta x') - a_1 \right]}{4\pi \gamma (1 - \beta x')} \, da_1' \, d\Omega'$$

where $x' = \cos \theta'$ and $d\Omega'$ is the element of solid angle $2\pi \, dx'$. Expression (11) may be obtained by noting that $n(a_1, x) \, da_1 \, d\Omega$ is a density and hence transforms like an energy. If we divide by the energy $a_1$ we obtain an invariant and hence

$$\frac{1}{a_1} \, n(a_1, x) \, da_1 \, d\Omega = \frac{1}{a_1'} \, n'(a_1', x') \, da_1' \, d\Omega'$$

and

$$n'(a_1', x') \, da_1' \, d\Omega' = \frac{a_1'}{a_1} \, n(a_1, x) \, da_1 \, d\Omega$$
Expressing \( a_1 \) and \( x \) in terms of \( a_1' \) and \( x' \) completes the derivation.

The cross section is given by expression (3)

\[
\sigma(a_1', a', y') \, \text{d}N' (y') \, \text{d}a' = \frac{r_0^2 (1 + y'^2)}{2 \left[ 1 + a_1' (1 - y') \right]^2} \left\{ 1 + \frac{a_1'^2 (1 - y')^2}{(1 + y'^2) \left[ 1 + a_1' (1 - y') \right]} \right\} \times \delta \left( a' - f(a_1', y') \right) \, \text{d}\phi' \, \text{d}y' \, \text{d}a' .
\]  

(3)

Since \( \frac{\text{d}N}{\text{d}t} = n' \cos \gamma / \gamma \) we have

\[
\frac{\text{d}^6 N}{\text{d}t \, \text{d}x' \, \text{d}y' \, \text{d}\phi' \, \text{d}a_1' \, \text{d}a'} = \frac{r_0^2 c \, \delta \left( a_1' \gamma (1 - \beta x) - a_1 \right)}{4 \gamma^3 \left( 1 - \beta x' \right)^2} \delta \left( a' - f(a_1', y) \right) \times \left[ \frac{1 + y'^2}{[1 + a_1' (1 - y')]^2} + \frac{a_1'^2 (1 - y')^2}{[1 + a_1' (1 - y')]^3} \right].
\]  

(12)

where we have used the relation \( a_1/a_1' = \gamma (1 - \beta x') \). Once again employing the relation \( \text{d}a_1' = \left[ 1 + a_1' (1 - y') \right]^2 \, \text{d}f \) we may integrate over \( f \) immediately. We also note that since \( z = \cos \theta' = \cos \theta_1' \cos \chi' + \sin \theta_1' \sin \chi' \cos \phi' \) we have

\[
\text{d}\phi' = \frac{2 \text{d}z'}{\left( 1 - x'^2 - y'^2 - z'^2 + 2x' y' z' \right)^{1/2}}.
\]
With this substitution we now have

\[
\frac{d^5 N}{d t \, dx' \, dy' \, dz' \, d\alpha'} = \frac{c r_0^2}{2} \frac{\delta}{\gamma^3 (1 - \beta x')^2} \frac{\alpha' \gamma (1 - \beta x')}{1 - \alpha' (1 - y')} - \frac{\alpha}{1 - \beta z'}
\]

\[
\times \left(1 + y'^2 + \frac{\alpha'^2 (1 - y')^2}{1 - \alpha' (1 - y')}\right) \left(1 - x'^2 - y'^2 - z'^2 + 2x' y' z'\right)^{-1/2}
\]  

(13)

Transforming \( \alpha' \) to \( \alpha \) using the relation

\[
\alpha' = \frac{\alpha}{\gamma (1 - \beta z')}
\]

we have

\[
\frac{d^5 N}{d t \, d\alpha \, dx' \, dy' \, dz'} = \frac{c r_0^2}{2} \frac{\delta}{\gamma^4 (1 - \beta x')^2 (1 - \beta z')} \frac{\alpha (1 - \beta x') - \alpha_1 (1 - \beta z')}{1 - \beta z'}
\]

\[
+ \frac{\alpha_1}{\gamma} \frac{\alpha}{(1 - y')} \left(1 + y'^2 + \frac{\alpha^2 (1 - y')^2}{\gamma^2 (1 - \beta z') \left[1 - \beta z' - \frac{\alpha}{\gamma} (1 - y')\right]}\right) J^{-1/2}
\]  

(14)

where \( J = 1 - (x'^2 - (y')^2 - (z')^2 + 2x' y' z' \) and where we have made use of

\[
\delta(Ax - B) = \frac{1}{A} \delta \left(x - \frac{B}{A}\right).
\]
From this point on the object is to integrate over all possible values of $x'$, $y'$, and $z'$ holding $a$, $\gamma$ and $\alpha_1$ fixed. For a given set of values for the parameters $a$, $\gamma$ and $\alpha_1$ only a certain volume of $x'$, $y'$, $z'$ space (possibly zero) will be compatible kinematically with this particular choice. This requirement is expressed by the condition that the Jacobian of the transformation from $\phi'$ to $z'$ be real or that $J \geq 0$. Inspection of the form of $J$ shows that the requirements that $|x'|$, $|y'|$ and $|z'|$ be $\leq 1$ is automatically fulfilled by keeping $J \geq 0$ unless all three variables are simultaneously out of bounds in such a way that $(x' y' z') > 0$. Therefore this requirement need be consciously enforced on only one of the three variables.

It is immaterial which order we choose in integrating the three variables and we arbitrarily choose the order $x'$, $y'$, $z'$. The first integration is trivial because of the delta function and we obtain

\[
\frac{d^4 N}{dt \, da \, dy' \, dz'} = \frac{c r_0^2}{2} \frac{\alpha}{\gamma^4 \alpha_1^2 \left[ 1 - \beta z' - \frac{\alpha}{\gamma} (1 - y') \right] (1 - \beta z')}
\]

\[
\times \left( 1 + y'^2 + \frac{(a/\gamma)^2 (1 - y')^2}{(1 - \beta z') \left[ 1 - \beta z' - \frac{a}{\gamma} (1 - y') \right]} \right) (\beta^2 J)^{-1/2} \tag{15}
\]

where

\[
\beta^2 J = \left( \beta^2 + \epsilon^2 + 2 \beta \epsilon z' \right) (y_2 - y') (y' - y_1) \tag{16}
\]
\[ y_2 = y_0 + \delta \]
\[ y_1 = y_0 - \delta \]  
(17)

\[ y_0 = \frac{(\epsilon + \beta z') (\rho + \epsilon - 1 + \beta z')}{\rho (\beta^2 + \epsilon^2 + 2\beta \epsilon z')} \]  
(18)

\[ \delta = \frac{\beta (1 - z'^2)^{1/2} [\rho^2 \beta^2 + 2\epsilon \epsilon (1 - \rho) (1 - \beta z') - (\rho - 1 + \beta z')^2]}{\rho (\beta^2 + \epsilon^2 + 2\beta \epsilon z')} \]  
(19)

and \( \rho = \alpha/a_1, \epsilon = \alpha_1/\gamma. \)

The integration over \( y' \) may be facilitated by the transformation

\[ y' = y_0 + \delta \eta \quad \text{where} \quad -1 \leq \eta \leq 1. \]

We then have

\[ \frac{d^4 N}{dt \, da \, dz' \, d\eta} = \frac{\pi r_0^2 a}{2\gamma a_1^2 (\beta^2 + \epsilon^2 + 2\beta \epsilon z')^{1/2}} \left( \frac{1}{(1 - \beta z')^{1/2}} + \frac{y_0^2 + 2y_0 \delta \eta + \delta^2 \eta^2}{(a + b\eta)^2} \right) \]

\[ \left( \frac{1}{1 - \eta^2} \right)^{1/2} \left( 1 - \beta z' \right) \]  
(20)

where \( a = 1 - \beta z' - (\alpha/\gamma)(1 - y_0); \ b = a \delta/\gamma. \)

Integration of \( \eta \) from -1 to 1 gives

\[ \frac{d^3 N}{dt \, da \, dz'} = \frac{\pi r_0^2 a}{2\gamma a_1^2 (\beta^2 + \epsilon^2 + 2\beta \epsilon z')^{1/2}} \left( \frac{1}{(1 - \beta z')^{1/2}} + \frac{y_0^2}{(1 - \beta z')(a^2 - b^2)^{1/2}} \right) \]

\[ + \frac{2y_0 \gamma}{a(1 - \beta z')} + \frac{2y_0 a}{\alpha(1 - \beta z')(a^2 - b^2)^{1/2}} - \frac{a \gamma^2}{a^2 (1 - \beta z')^{1/2}} + \frac{a^2 \delta^2}{a^2 (1 - \beta z')(a^2 - b^2)^{1/2}} \]

\[ + \frac{\alpha (1 - y_0)}{\gamma (1 - \beta z')(a^2 - b^2)^{3/2}} + \frac{\alpha^2 \delta^2}{\gamma^2 (1 - \beta z')(a^2 - b^2)^{3/2}} \]  
(21)
After some manipulation we have

\[ a^2 - b^2 = \frac{(1 - \frac{a}{\gamma})^2 - 1}{\gamma^2 (1 - \beta z')^2 + 2\epsilon \rho (1 - \beta z')} \]

\[ = \frac{\gamma^2 (1 - \epsilon \rho)^2 - 1}{\gamma^2 (1 - \beta z')^2 + 2\epsilon \rho (1 - \beta z')} \]

(22)

If we introduce the variable \( \zeta = 1 - \beta z' \) and the following quantities

\[ E_1 = (\beta^2 + \epsilon^2 + 2\epsilon) - 2\epsilon \zeta = (1 + \epsilon)^2 - 1/\gamma^2 - 2\epsilon \zeta \]

\[ E_2 = \gamma^2 [(1 - \epsilon \rho)^2 - 1/\gamma^2] \zeta^2 + 2\epsilon \rho \zeta \]

the final integration over \( z' \) may be performed in a straightforward manner, and after some rearrangement of terms we obtain

\[ \frac{d^2 N}{dt da} = \frac{\pi r_0^2 \rho}{2\gamma^2 \beta \alpha_1^2} \left[ F(\zeta_+) - F(\zeta_-) \right] \]

(23)

where \( \zeta_\pm \) are the upper and lower limits of the integration in \( \zeta \) and the function \( F \) is given by

\[ F(\zeta) = f_1(\zeta) + f_2(\zeta) + f_3(\zeta) + f_4(\zeta) \]

\[ f_1(\zeta) = E_1^{-1/2} \left[ \frac{\gamma}{a} \left( 1 + \frac{2(1 + a \alpha)}{(\gamma + a \alpha)^2 - 1} \right) + \frac{\gamma^2}{a^2} \left( \frac{\gamma^2 - 1}{\gamma \alpha_1} + \frac{a_1}{\gamma} + 3 - \frac{a}{a_1} \right) - \frac{3\gamma^2}{a^2} \zeta - \frac{1}{\zeta} \right] \]

(24)
We now turn to the question of determining the limits of integration $\zeta$. These are determined by the requirements that the quantity $\delta$ be real and in addition that $|z'| \leq 1$ for we see upon inspection of Expression (19) that $\delta$ may be real for certain values of $z'$ that violate this condition. These two requirements are fulfilled if the quantity $\zeta$ lies between the values $1 \pm \beta$ called the boundary lines and simultaneously lies between the values

$$\zeta_\pm(\rho) = \rho \left[ (1 + \epsilon - \epsilon \rho) \pm \sqrt{(1 + \epsilon - \epsilon \rho)^2 - 1/\gamma^2} \right]$$

(28)

called the boundary curve. It is easy to see that at $\rho = 1$ the boundary curve intersects the boundary lines. At $\rho_s = 1 + (\gamma - 1)/\gamma\epsilon = 1 + (\gamma - 1)/a_1$
the radical in (28) vanishes and the boundary curve becomes imaginary. This clearly represents an absolute upper limit on \( \rho \) (the other real branch of the boundary curve for even larger \( \rho \) can be shown to lie entirely in a region of \( z' > 1 \)). The physical significance of this limit is quite simply seen if we write it as \( \alpha = \alpha_1 + (\gamma - 1) \). At this limit the scattered photon has picked up all of the electrons kinetic energy in the collision.

This limit is not usually reached in any situation that will interest us since it only occurs when the initial photon momentum is of the order of or greater than that of the electron. Figures 2a, 2b and 2c illustrate the three different situations that can exist. It is quite obvious that the usual situation in astrophysics will be that depicted in Fig. 2a where for \( \alpha_1 \leq \gamma \beta / [1 + \gamma (1 + \beta)] \) the maximum value of \( \rho \) is given by the point where the lower boundary curve intersects the upper boundary line; \( \zeta_\rho (\rho) = 1 + \beta \) or

\[
\rho_c = \frac{1 + \beta}{1 - \beta + 2\alpha_1 / \gamma}.
\]

In the relativistic limit \( 1 - \beta \approx 1/2\gamma^2 \) and we have

\[
\rho_c = \frac{4\gamma^2}{1 + 4\alpha_1 \gamma} \quad \text{or} \quad \alpha_{\text{max}} \approx \frac{4\alpha_1 \gamma^2}{1 + 4\alpha_1 \gamma}
\]
which is just the result derived in Section II. The minimum value of $\rho$
is always given by

$$\rho_m = \frac{1 - \beta}{1 + \beta + 2a_1/\gamma}$$

which in the relativistic limit is

$$\rho_m \approx 1/4\gamma^2 \quad \text{or} \quad a_{\min} \approx a_1/4\gamma^2$$

also a result of Section II.

The formula given in expressions (23-27) are not very useful in
most astrophysical applications either for insight, since they are quite
complex, or for direct computation since they require that terms of the
order of $(\gamma/a)^2$ be balanced out to yield a true leading term of order
of $\gamma^2 a_1/a$. This requires computation to be carried out to an accuracy
of $(aa_1 p)/%$ to obtain an answer that is correct to an accuracy of p%.
Since the quantity $aa_1$ can often be quite small direct application of
Expressions (23-27) is in general not very satisfactory.

In the next section we shall discuss various expansions of the func-
tion $F(\zeta)$ which will be useful not only for computing the spectrum to
any desired order but also for recovering a simple approximation with
a wide range of validity.
IV. EXPANSIONS OF EXACT FORMULA

The chief difficulty in computing directly with our exact formula is the fact that the quantity \( \epsilon \rho = a/\gamma \) is often quite small and appears as \((\epsilon \rho)^{-1}, (\epsilon \rho)^{-2}\) in some of the terms. This in itself suggests the way out, namely an expansion in this or some other small quantity. The quantity that turns out to be most useful as an expansion quantity is \( \epsilon = a_1/\gamma \). This quantity is small in almost all physical applications and becomes smaller the more energetic the electron.

The first step in this procedure is to expand the functions \( E_1^{-1/2}, E_2^{-1/2}, \cosh^{-1}, \) and \( \sinh^{-1} \) as power series in the quantities \( 2\epsilon \gamma /[(1 + \epsilon)^2 - 1/\gamma^2] \) and \( 2\epsilon \gamma /[(2^2 (1 - \epsilon)^2 - 1)] \). The expansion in the first quantity can be easily shown to be convergent for all allowed values of the parameters and the second expansion is convergent so long as we have the condition

\[
\alpha_1 < \frac{2 \sqrt{1 + \beta}}{7 + 9\beta} - 2 + \frac{3\beta}{\gamma(1 + \beta)(7 + 9\beta)}
\]

\[
\sim \sqrt{2/8} - 5/32\gamma \quad \text{for} \quad \gamma >> 1
\]

This will be true in most cases of interest and in those situations where it is not true the expansion will still converge as long as

\[
\epsilon \rho < 2 + \beta - 2 \sqrt{1 + \beta} \sim 0.172 - 0.146/\gamma^2, \quad \gamma >> 1
\]
If this condition is violated we see that $\epsilon \rho$ is not a small number and there is no real need for the expansion. In the following we shall always assume that $\alpha_1$ is small enough that this first expansion is fairly rapidly convergent.

At this point we have an expression for the function $F(\zeta)$ of the form

$$F(\zeta) = \sum_{n=-\infty}^{\infty} K_n(\epsilon) \left( \frac{\zeta^n}{n!} \right)$$

(29)

where the term $\zeta^0/0 = \ln \zeta$ arises as the leading term in the expansions of $\cosh^{-1}$ and $\sinh^{-1}$. There are no terms independent of $\zeta$ since all we are interested in is the quantity $F(\zeta) - F(\zeta)$ and such terms would make no contribution. The coefficient $K_n(\epsilon)$ is a rather complicated function of $\epsilon$ whose dominant term is of the order of $\epsilon^{n-1}$. $K_n(\epsilon)$ contains the two denominators which are functions of $\epsilon$

$$D_1 = (1 + \epsilon)^2 - 1/\gamma^2$$

$$D_2 = (1 - \epsilon \rho)^2 - 1/\gamma^2$$

(30)

These denominators appear in half powers of various orders (typically $|n|/2$) and are the next items on the list to be expanded in $\epsilon$. Before proceeding, however, we must first decide how we are to order the
quantity $\rho = a/a_1$. Recalling the limits on $\rho$, $1/4\gamma^2 \leq \rho \leq 4\gamma^2/(1+4a_1\gamma)$ we see that the question hinges on the magnitude of $a_1\gamma$. If $a_1\gamma \ll 1$ we have $1/4\gamma^2 \leq \rho \leq 4\gamma^2$ and $\epsilon \ll 1/\gamma^2$. We may then consider $\rho$ to be of $O(1)$ and expand in $\epsilon$ and $\epsilon\rho$ as well. On the other hand if $a_1\gamma \gg 1$ then $\epsilon \gg 1/\gamma^2$ and $O(\epsilon) \leq \rho \leq O(1/\epsilon)$ and the quantity $\epsilon\rho$ ranges from $O(\epsilon^2)$ to $O(1)$. In this case we must expand in quite a different manner.

We shall now consider the case where $a_1\gamma \ll 1$ and treat $\epsilon\rho$ as $O(\epsilon)$. First noting that

$$D_1 = (1 + \epsilon)^2 - 1/\gamma^2 = (1 + 1/\gamma + \epsilon)(1 - 1/\gamma + \epsilon)$$

we may expand the denominator as

$$D_1^{-m} = \sum_{n=0}^{\infty} \frac{(-\epsilon)^n}{(1 - 1/\gamma^2)^{n+m}} P_{n,m} \left(1/\gamma^2\right)$$

where

$$P_{n,m} \left(1/\gamma^2\right) = \sum_{p+q=n} \alpha_m(p) \alpha_m(q) (1 - 1/\gamma)^p (1 + 1/\gamma)^q$$

and the $\alpha_m(p)$ are the expansion coefficients of

$$(1 - x)^{-m} = \sum_p \alpha_m(p)x^p$$
given by

\[ \alpha_m(p) = \frac{m(m+1)(m+2) \cdots (m+p-1)/p!}{(1)} \]  

(33)

where \( \alpha_m(0) = 1 \) and \( \alpha_m(-n) = 0 \). We may also write \( P_{n,m}(1/\gamma^2) \) as

\[ P_{n,m}(1/\gamma^2) = \sum_{p=0}^{p'} \alpha_m(p) \alpha_{2m+2p}(n-2p) (1/\gamma^2)^p \]  

(32')

where \( p' \) is the largest integer not greater than \( n/2 \).

A completely equivalent expansion exists for \( D_2 \) so our coefficient \( K_n(\epsilon) \) may be in turn written as a power series in \( \epsilon \) of the form

\[ K_n(\epsilon) = \sum_p K_{n,p} \epsilon^{n+p} . \]

If we now regroup the terms in powers of \( \epsilon \) we may write

\[ F(\zeta) = \sum_{M=-2}^{\infty} \epsilon^M F_M(\zeta) \]  

(34)

\( F_M(\zeta) \) is a rather complex function of \( \zeta \) but for completeness we shall give its general form for arbitrary \( M \). First, however, we note that the expansion of \( F(\zeta_+) - F(\zeta_-) \) is obtained by simply replacing \( \zeta^n \) by \( \zeta_+^n - \zeta_-^n \) wherever it appears in \( F_M(\zeta) \). In what follows we shall use
We may now write the general expression for $F_M (\zeta_+ - \zeta_-) = F_M$.

$F_M = (-1/\beta^2)^M \sum_{N=2}^{\infty} (-2)^{N+2} \alpha_{1/2} (N + 2) \left\{ \frac{P_{M-N,N+5/2} (1/\gamma^2)}{\beta^3} \left[ \frac{(N + 1)}{\rho^2} Z(N + 3) \right] + \frac{(N + 2)}{\rho} Z(N + 1) - \frac{(N + 2)}{\rho^2} Z(N + 2) + (-\rho)^M \left[ \frac{1}{\gamma^2} \right] \right\} + \frac{P_{M-N,N+3/2} (1/\gamma^2)}{\beta^3} \left[ \frac{2(N + 1)}{2N + 3} \rho Z(N) - \frac{(N + 1 + N\rho)}{2N + 3} \rho^2 Z(N + 1) + (-\rho)^M \frac{(N + 3 + (N + 1) \gamma^2)}{(2N + 3)} \frac{Z(-N - 1)}{(\gamma^2)^{N+1}} \right] + \frac{P_{M-N,N+1/2} (1/\gamma^2)}{\beta} \left[ \frac{(N + 1)}{(2N + 1)} \frac{Z(1 - N)}{(2N + 3)} Z(N - 1) + (-\rho)^{M-1} \frac{N(N + 1)}{(2N + 3)} \left( \frac{Z(1 - N)}{(\gamma^2)^{N-1}} + \gamma^2 (1 - \rho) \frac{Z(N)}{(\gamma^2)^M} \right) \right] + \frac{P_{M-N,N-1/2} (1/\gamma^2)}{\beta} \left[ (-\rho)^M \frac{N(N + 1)}{(2N + 3)} \gamma^2 \frac{Z(-N - 1)}{(\gamma^2)^{N+1}} \right] + \beta \frac{P_{M-N,N-1/2} (1/\gamma^2)}{\beta} \left[ (-\rho)^{M-1} \frac{(N - 1)}{(2N - 1)} \frac{(N + 1)}{(2N + 3)} \frac{Z(1 - N)}{(\gamma^2)^{N-1}} \right] \right\}$

(35)
In deriving the above expression much use has been made of the recursion relations for the various \( \alpha_n(p) \) coefficients, i.e.,

\[
\alpha_{1/2}(N) = \frac{2N + 2}{(2N + 1)(2N + 3)} \alpha_{3/2}(N + 1), \text{ etc.}
\]

Explicit calculation of the \( M = -2, -1 \) terms shows that they are identically zero so the leading term in our expansion is of zero order in \( \epsilon \). Our series may then be written

\[
F(\xi_+) - F(\xi_-) = \sum_{M=0}^{\infty} F_M \epsilon^M.
\]

It should be noted that there are terms with \((-\rho)^M\) appearing in \( F_M \) and in the case \( \rho \approx O(1/\epsilon) \) each term in the series will be \( O(1) \) and our expansion breaks down completely.

Although the expression for \( F_M \) looks rather formidable, it is a straightforward matter to program a computer to evaluate our function to any order in \( \epsilon \) that is desired.

It is interesting to examine the zero order term \( F_0 \).

\[
F_0 = \beta^{-5} \left( 2 + 2/(\gamma \beta)^2 + 3/2(\gamma \beta)^4 \right) Z(-1) - \beta^{-7} \left( 2 + 3/(\gamma \beta)^2 \right) \left( 1 + 1/\rho \right) Z(0) \\
+ \beta^{-9} \left( 1 + 6/\rho + 1/\rho^2 + \frac{\rho^2 + 1}{2\gamma^2 \rho^2} \right) Z(1) - \beta^{-9} \left( 3(1 + \rho)/\rho^2 \right) Z(2) \\
+ \beta^{-9} \left( 3/2\rho^2 \right) Z(3)
\]

(36)
If we also assume $\beta \gg \epsilon$ we have $\zeta_+ = 1 + \beta$ and to zero order in $\epsilon$,

$\zeta_\rho = \rho(1 - \beta)$ for $\rho \geq 1$ so that

$$Z(-1) = \frac{\gamma^2}{\rho} (1 + \beta - \rho(1 - \beta))$$

$$Z(0) = -\ln \left( \frac{\rho}{\gamma^2 (1 + \beta)^2} \right)$$

$$Z(1) = 1 + \beta - \rho(1 - \beta)$$

$$Z(2) = \frac{1}{2} (1 + \beta)^2 - \frac{1}{2} \rho^2 (1 - \beta)^2$$

$$Z(3) = \frac{1}{3} (1 + \beta)^3 - \frac{1}{3} \rho^3 (1 - \beta)^3.$$  \hspace{1cm} (37)

Expressions (36), (37) and (23) may be combined to obtain an approximate spectrum that is valid for $\beta \gg \epsilon$ and $a_1 \gamma \ll 1$.

We may further simplify this approximation by assuming that the electron is relativistic, $\beta \approx 1$, $1 - \beta \approx 1/2\gamma^2$. We then have, neglecting terms of order $1/\gamma^2$ as compared to 1,

$$\frac{d^2 N}{dt \, d\alpha} = \frac{2\pi r_0^2 c}{a_1 \gamma^2} \left\{ 2q \ln q + (1 + 2q)(1 - q) + O(1/\gamma^2) \right\}$$ \hspace{1cm} (38)

where $q = \alpha / (4a_1 \gamma^2)$. This is just the approximate spectrum of Ginzburg and Syrovatskii.$^{20}$
For \( \rho \leq 1, \zeta_+ = \rho (1 + \beta) \) and \( \zeta_- = 1 - \beta \). This gives

\[
Z(-1) = \frac{\gamma^2}{\rho} \left[ \rho (1 + \beta) - (1 - \beta) \right]
\]

\[
Z(0) = \ln \left[ \rho \gamma^2 (1 + \beta)^2 \right]
\]

\[
Z(1) = \rho (1 + \beta) - (1 - \beta)
\]

\[
Z(2) = \frac{1}{2} \left[ \rho^2 (1 + \beta)^2 - (1 - \beta)^2 \right]
\]

\[
Z(3) = \frac{1}{3} \left[ \rho^3 (1 + \beta)^3 - (1 - \beta)^3 \right] \quad (39)
\]

Once again neglecting terms of order \( 1/\gamma^2 \) we have

\[
\frac{d^2 N}{dt \, dc} = \frac{\pi r_0^2 c}{2 \gamma^4 a_1} \left\{ (q' - 1) \left( 1 + \frac{2}{q'} \right) - 2 \ln q' + O \left( \frac{1}{\gamma^2} \right) \right\} \quad (40)
\]

where \( q' = 4 \gamma^2 \rho = 4 \gamma^2 a/a_1 \). We note that this is just our approximate spectrum, Expression (8) with additional correction terms that become important at the bottom of the spectrum where \( a/a_1 \approx 1/4 \gamma^2 \). These correction terms are expected on the basis of the discussion at the end of Section II.

We now consider the case where \( a_1 \gamma \) is of order unity or greater and \( \epsilon \rho \) may become of order unity. We first note that if \( a_1 \gamma > 1 \) then
$1/\gamma^2 \lesssim \epsilon$ and it would be inconsistent not to expand in $1/\gamma^2$ as well as in $\epsilon$.

The expansion procedure is very much the same as before. The denominators $D_1$ and $D_2$ (Expression (30)) may be first expanded in $1/\gamma^2$ and then the term $(1 + \epsilon)^2$ that comes from $D_1$ is expanded in $\epsilon$. The term $(1 - \epsilon \rho)^2$ arising from $D_2$, however, is not expanded and all factors of $\rho$ are combined with an $\epsilon$ to make terms of $O(1)$. The resulting expressions are then grouped according to the power of $\epsilon$ and the power of $1/\gamma^2$ to give a double power series expansion of $F(\zeta)$ as

$$F(\zeta_+) - F(\zeta_-) = \sum_{N,P=0}^{\infty} F_{N,P} \left(1/\gamma^2\right)^N \epsilon^P$$

where $F_{N,P}$ is given by

$$F_{N,P} = \sum_{p=0}^{P} \frac{\alpha_{1/2}(P-p)\alpha_{P-p+1/2}(N)\alpha_{2(N+p-p)+1}}{2^P(N+p-p+1/2)(P+N-p/2)(\epsilon \rho)^2} \left(1 - \frac{(P-p)(P-p-1)(P-p+N)}{2(P+N-p/2+1/2)(P+N-p/2)(\epsilon \rho)^2}\right) Z(P-p)$$

$$\times \left\{ \frac{(P-p+2N+2)}{\epsilon \rho} - \frac{P-p}{(\epsilon \rho)^2} \right\} Z(P-p)$$

$$+ \left\{ \frac{P-p-1}{(\epsilon \rho)^2} - \frac{2N+2P-p+1}{2(N+P-p+1)\epsilon \rho} \right\} Z(P-p+1) \right\}$$

(41)
\[ + \frac{1}{(1 - \epsilon\rho)^{2N}} \sum_{m=0}^{N} \alpha_{3/2}^{m} (N - m) \alpha_{N-m+1/2}^{m} \frac{(-2\epsilon\rho)^{N-m}}{(1 + 2N - 2m)} \]

\[ \times \left\{ \frac{\delta_{p0}}{(\epsilon\rho)^{2}(1 - \epsilon\rho)} Z(m - N + 1) \right\} \]

\[ + \frac{\delta_{p0} \left( 2(N - m)^2 + N - m - 2 \right)}{(\epsilon\rho)(1 - \epsilon\rho)} - \frac{\delta_{p1} (1 + 2N)}{(1 - \epsilon\rho)^2} \right\} Z(m - N) \]

\[ + \left( \frac{\delta_{p0} \left[ \frac{1 + 2N}{(1 - \epsilon\rho)^2} - \frac{(1 + 2N - 2m)(N - m)}{(1 - \epsilon\rho)} \right]}{\frac{\delta_{p1} (1 + 2N)(1 + \epsilon\rho)}{(1 + 2N - 2m)(1 - \epsilon\rho)^3}} \right) Z(m - N - 1) \]

(41) con't

where

\[ \delta_{m,n} = 1 \quad \text{if} \quad m = n \]

\[ = 0 \quad \text{if} \quad m \neq n \]

Once again we examine the lowest order term \( F_{0,0} \).

\[ F_{0,0} = Z(-1) + \frac{2}{\epsilon\rho} Z(0) - \frac{(1 + \epsilon\rho)(1 - \epsilon\rho)}{(\epsilon\rho)^2} Z(1) \]

\[ + \frac{Z(1)}{(\epsilon\rho)^2(1 - \epsilon\rho)} - \frac{2}{\epsilon\rho(1 - \epsilon\rho)} Z(0) + \frac{Z(-1)}{(1 - \epsilon\rho)^2} \]

\[ = \frac{Z(1)}{1 - \epsilon\rho} - \frac{2Z(0)}{1 - \epsilon\rho} + \left( \frac{2}{1 - \epsilon\rho} + \frac{(\epsilon\rho)^2}{(1 - \epsilon\rho)^2} \right) Z(-1) \] (42)
To lowest order in $\epsilon$ and $1/\gamma^2$ the boundaries of $\xi$ are given by $\xi_+$

$= 1 + \beta \approx 2; \xi_- = \rho/2\gamma^2 (1 - \epsilon \rho)$ so we have

$$F_{0,0} = \frac{2}{(1 - \epsilon \rho)} \ln \left( \frac{\rho}{4\gamma^2 (1 - \epsilon \rho)} \right) + \left( \frac{4\gamma^2 (1 - \epsilon \rho)}{\rho} + 2 \right) \left( 1 - \frac{\rho}{4\gamma^2 (1 - \epsilon \rho)} \right) (1 - \epsilon \rho)^{-1}$$

$$+ \frac{1}{2} \frac{(\epsilon \rho)^2}{(1 - \epsilon \rho)^2} \left( \frac{4\gamma^2 (1 - \epsilon \rho)}{\rho} - 1 \right)$$

Combining this with Expression (23) we have

$$\frac{d^2 N}{dt \, d\alpha} \approx \frac{2\pi r_0^2 c}{a_1 \gamma^2} \left\{ 2q'' \ln q'' + (1 + 2q'') (1 - q'') \right. + \frac{1}{2} \left( \frac{4a_1 \gamma q''}{1 + 4a_1 \gamma q''} \right)^2 (1 - q'') \left\} \right.$$  \hspace{1cm} (44)

where now

$$q'' = \frac{\rho}{4\gamma^2 (1 - \epsilon \rho)} = \frac{a}{4a_1 \gamma^2 (1 - a/\gamma)}$$

We see that we have recovered our approximate spectrum of Section II Expression (9). Now, however, it appears in a complete mathematical setting as the lowest order term in a double expansion in $\epsilon$ and $1/\gamma^2$

where $a/a_1 = O(1/\epsilon)$.
We have seen that the assumption that \( a/a_1 \gg 1 \) is necessary in deriving this formula. We now may ask what happens to this approximation when we no longer have \( a/a_1 = O(1/\epsilon) \) but return to the region where \( \epsilon \rho = O(\epsilon) \). We can see at once from Expression (41) that due to terms containing various powers of \( \epsilon \rho \) and denominators \( (1 - \epsilon \rho) \) to various powers that a term that was originally of a given order will now contain contributions of all higher orders in \( \epsilon \). For any approximation to a given order this does not cause any loss of accuracy. What does hurt is the presence of terms containing \( (\epsilon \rho)^{-1} \) and \( (\epsilon \rho)^{-2} \). This means that any given order now has contributions from terms that were previously as much as two orders higher. To maintain our zero order approximation we must now include those parts of \( \epsilon F_{01} \) and \( \epsilon^2 F_{02} \) that contribute to zero order in \( \epsilon \). These terms may be found in a straightforward manner and we find that \( \epsilon F_{01} \) to zero order in \( \epsilon \) gives \( (1/\rho)(6Z(1) - 3Z(2) - 2Z(0)) \) and \( \epsilon^2 F_{02} \) gives

\[
\frac{1}{\rho^2} \left( Z(1) - 3Z(2) + \frac{3}{2} Z(3) \right).
\]

These terms are the same terms in \( 1/\rho \) and \( 1/\rho^2 \) that appeared in Expression (36) (neglecting \( 1/\gamma^2 \)). They did not appear in Expression (38), however, since they are always at least \( (1/\gamma^2) \) smaller than the leading term in \( Z(-1) \) which is \( 2\gamma^2/\rho \). For that reason they should not be included in our present formula.
We, therefore, offer Expression (44) as an approximation to the spectrum of inverse Compton scattered photons that is accurate to zero order in $\epsilon$ and $1/\gamma^2$ for values of $\alpha$ such that $\alpha_1 \leq \alpha \leq 4\alpha_1 \gamma^2/(1 + 4\alpha_1 \gamma)$ and for $\alpha_1 \gamma$ as large as desired. Expression (44) is not an entirely consistent formula in that it always contains contributions from higher (and hence negligible) orders but it is complete in that it always includes all zero order contributions.

In the situation where $\rho = O(1/\epsilon)$ the exact formula should be expanded once again, this time considering $\epsilon/\rho = O(1)$. However, if we are interested only in the lowest order approximation a simple inspection of Expression (35) will suffice. Keeping in mind that for $\rho \leq 1$,

$$Z(N) = \frac{\left[(4\gamma^2 \rho)^N - 1\right]}{N(2\gamma^2)^N}$$

we see that for every value of $M$ there are terms of order $\rho^{-1}$ and higher but of no lower order. Therefore, Expression (35) to zero order in $\epsilon$ and lowest order in $1/\gamma^2$ will give us our dominant term. This is exactly what we obtained in Expression (40) so we see that this formula gives the correct approximation to lowest orders in $\epsilon$ and $1/\gamma^2$ no matter what the magnitude of $\alpha_1 \gamma$. This could have been expected from our discussion in Section II.
In Figure 3 we compare the approximate spectrum of Expressions (40) and (44) with a computer calculation of Expression (35) correct to order $\epsilon^5$. We see that the electron does not have to be extremely relativistic for the approximate spectrum to give a good representation.
V. ASTROPHYSICAL APPLICATIONS

In astrophysics, inverse Compton scattering provides a mechanism for energy loss of high energy cosmic ray electrons and a source of x and γ radiation whenever energetic electrons and soft photons exist together in a region of space. The energy loss effect has been calculated exactly by the author in a previous publication.\(^9\) However, it would be of interest to see how well our spectrum, Expression (44), serves in giving the correct energy-loss formula. In keeping with the spirit of our approximation, we shall assume that Expression (44) is valid for \(0 \leq q'' \leq 1\) even though we know it is quite invalid for \(q'' < 1/4\gamma^2\).

When we consider effects that depend on the entire spectrum the region \(0 < q'' < 1/4\gamma^2\) contributes a part that is \(O(1/\gamma^2)\) and hence, negligible.

The energy loss is given by

\[
\left\langle \frac{d\epsilon}{dt} \right\rangle_{\text{Avg.}} = \int_{a_1}^{a_{\text{max}}} \alpha \left( \frac{d^2 N}{dt \, da} \right) \, da \approx \int_0^1 \alpha(q'') \left( \frac{d^2 N}{dt \, dq''} \right) \, dq''
\]

\[
= 3\tau_T \, c \beta \gamma \int_0^1 \left\{ \frac{2q''^2 \ln q''}{(1 + bq'')^3} + \frac{q''(1 + 2q'')(1 - q'')}{(1 + bq'')^3} + \frac{b^2 q''^3 (1 - q'')}{2(1 + bq'')^4} \right\} \, dq'' \quad (45)
\]

where \(\tau_T = (8/3)E_0^2\) and \(b = 4\alpha_1 \gamma\). The indicated integrals are performed in a straightforward manner to give, after some rearranging of terms.
\[ \langle \frac{dE}{dt} \rangle = \frac{3c^3 \gamma}{b^2} \left\{ \frac{(b/2 + 6 + 6/b) \ln (1+b)}{b^2} \right\} \]

\[ - \left( \frac{11}{12} b^3 + 6b^2 + 9b + 4 \right) (1+b)^{-2} \]

\[ - 2 + 2 Li_2 (-b) \] \tag{46}

where \( Li_2 \) is the dilogarithm. If we make the substitution \( b = 2a \) we have

\[ \langle \frac{dE}{dt} \rangle = \frac{1}{2} \pi r_0^2 c \left( \frac{F(a)}{a_1^2 \gamma^2} \right) \]

\[ F(a) = \gamma \left[ (a + 6 + 3/a) \ln (1 + 2a) \right. \]

\[ - \left( \frac{22}{3} a^3 + 24a^2 + 18a + 4 \right) (1 + 2a)^{-2} \]

\[ - 2 - 2 Li_2 (-2a) \] \tag{47}

This expression may be directly compared to Expressions (13) and (14) of Reference (9). It can be seen that the present result is equal to that previously calculated (for the mono-energetic background case) if one sets \( \epsilon = 1/\gamma^2 = 0 \) in the exact formula.

In considering inverse Compton scattering as a source of x and \( \gamma \) rays we are interested in the radiation from electrons with a wide
distribution of energies. In astrophysics the inverse power law is one of the most commonly occurring distributions so we shall consider the spectrum

\[ (2\pi r_0^2 c) R(\alpha) = \int_1^\infty \left( \gamma - \Gamma \frac{d^2 N}{dt \, d\alpha} \right) d\gamma \]  

(48)

If we note that

\[ \gamma = \frac{\alpha}{2} \left( 1 + \sqrt{1 + \frac{p q''}{pq''}} \right) \]

\[ d\gamma = \frac{\alpha^2 a_1}{4} \frac{dq''}{(pq'')^{3/2} (1 + pq'')^{1/2}} \]

where \( p = a a_1 \) we may write Expression (48) as

\[ R(\alpha) = \frac{2^{\Gamma} a_1 \alpha_1^{(\Gamma - 1)/2}}{a^{(\Gamma + 1)/2}} F(p, \Gamma) \]  

(49)

where

\[ F(p, \Gamma) = \int_0^1 q''^{(\Gamma - 1)/2} \frac{[2q'' \ln q'' + (1 + 2q'') (1 - q'') + 4pq''(1 - q'')]^{\Gamma + 2}}{(1 + \sqrt{\frac{pq''}{1 + pq''}}) (1 + pq'')^{(\Gamma + 3)/2}} dq'' \]  

(50)
It is easy to see that for \( p = a \alpha_1 \ll 1 \), \( F(p, \Gamma) \) is essentially independent of \( p \) and we obtain

\[
R(\alpha) = 2^{\Gamma+1} \left( \frac{1}{\Gamma+3} + \frac{1}{\Gamma+1} - \frac{2}{\Gamma+5} - \frac{4}{(\Gamma+3)^2} \right) \alpha_1^{(\Gamma-1)/2} \alpha^{-2(\Gamma+1)/2}
\]

\[
= c' \alpha^{-(\Gamma+1)/2} \tag{51}
\]

This is just the well known approximate spectrum of Felten and Morrison which they obtained by approximating \( \frac{d^2N}{dt \, da} \) by a delta function \( \delta(\alpha - 4/3 \alpha_1 \gamma^2) \). It can be shown that this spectrum is a good approximation for a much more general assumption about the form of \( \frac{d^2N}{dt \, da} \) than that made by Felten and Morrison.

For \( p \gg 1 \), on the other hand there is no expansion in powers of \( p \) or inverse powers of \( p \) that will be valid for the entire range of the integration in \( q \). However, the integral may be broken up into two pieces as

\[
\int_0^{1/p} + \int_{1/p}^1
\]

and appropriate expansions made in each range. The leading terms in \( p \) may be extracted and after a certain amount of re-summing of
coefficients we obtain the asymptotic form of $F(p, \Gamma)$ for $p \gg 1$ as,

$$F(p, \Gamma) \sim \frac{\ln p - c(\Gamma)}{2^{\Gamma} p^{(\Gamma+1)/2}}$$

(52)

where unfortunately

$$c(\Gamma) = \frac{\Gamma}{\Gamma + 1} + 2 \int_0^1 \frac{x - \left(\frac{2x}{1 + x}\right)^{\Gamma+2}}{1 - x^2} \, dx$$

(53)

Inserting (52) in (49) we have for the case $a \gg (a_1)^{-1}$

$$R(a) \sim \frac{c}{a_1} \left(\ln a a_1 + c(\Gamma)\right) a^{-\Gamma-1}$$

(54)

c(\Gamma) may be computed by numerical integration and is plotted in Fig. 4.

In the intermediate region $p \approx 1 F(p, \Gamma)$ must be computed numerically. In Fig. 5 we have plotted $F(p, \Gamma)$ as a function of $p$ for various values of $\Gamma$ and in Fig. 6 we have the complete spectra $R(a)$ for the same values of $\Gamma$.

ACKNOWLEDGMENTS

The author wishes to express his gratitude to many of his colleagues at the Laboratory for Theoretical Studies, Goddard Space Flight Center, for many many discussions and much helpful advise. In particular, thanks are due to Drs. Thomas Birmingham and Richard Drachman for help with some of the knottier problems.
