1. REPORT NO. NASA TN D-5686	2. GOVERNMENT ACCESSION NO.	3. RECIPIENT'S CAT	
4. TITLE AND SUBTITLE WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC PRESSURES ON THE APOLLO LAUNCH ESCAPE VEHICLE CONFIGURATION		5. REPORT DATE April 1970	6. PERFORMING ORGANIZATION CODE
7. AUTHOR(S) William C. Moseley, Jr., MSC, and B. J. Wells, Federal Electric Corp.		8. PERFORMING ORGANIZATION REPORT NO. MSC S-230	
9. PERFORMING ORGANIZATION NAME AND ADDRESS Manned Spacecraft Center Houston, Texas 77058		10. WORK UNIT NO. 914-50-10-03-72	11. CONTRACT OR GRANT NO.
12. SPONSORING AGENCY NAME AND ADDRESS National Aeronautics and Space Administration Washington, D. C. 20546		13. REPORT TYPE AND PERIOD COVERED Technical Note	
15. SUPPLEMENTARY NOTES			
16. ABSTRACT A program of wind-tunnel tests was conducted at Mach numbers from 0.4 to 9.08 to determine the pressure distribution on the Apollo launch escape vehicle. Data are presented for the angle-of-attack range from 0° to 136°. The data are plotted as the pressure coefficient versus the physical position of the pressure orifice to show some effects of the flow separator, of the escape-tower length, and of the angle of attack on the pressure distribution over the command module in the presence of the escape tower.

# WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC PRESSURES ON THE APOLLO LAUNCH ESCAPE VEHICLE CONFIGURATION

By William C. Moseley, Jr., and B. J. Wells \*  
Manned Spacecraft Center

## SUMMARY

Wind-tunnel tests were conducted to determine the effects of the tower length and the flow separator on the pressure distribution over the Apollo launch escape vehicle configuration at Mach numbers from 0.4 to 9.08 and at an angle-of-attack range from 0° to 136°. The data are presented as the pressure coefficient versus the physical position of the pressure orifice.

From the data, aerodynamic loads on the Apollo launch escape vehicle can be determined by the analysis of the pressure distribution over the surface of the command module.

## INTRODUCTION

In late 1959, personnel from several NASA Centers recommended a circumlunar flight and an earth-orbiting laboratory program to be called the Apollo Program. The program was initiated and assigned to the NASA Space Task Group. On May 25, 1961, the Apollo Program was reoriented to achieve a manned lunar landing, as part of the continuing program of space exploration following Project Mercury and the Gemini Program.

In the formulation of the design criteria, the guidelines established by NASA personnel were developed around certain stipulations. With these stipulations and with the aerodynamic limitations, many possible types of configurations were considered. The basic configuration chosen for development was the one that was determined to be most practical for the development of the state of the art at that time.

The launch escape vehicle (LEV) provides an escape capability in the event of a malfunction of the booster or spacecraft (refs. 1 and 2). The LEV is used only during the atmospheric portion of the ascent trajectory and is composed of an escape rocket, the escape tower, and the command module (CM). After the atmospheric portion of the ascent trajectory is completed, the escape tower and rocket are jettisoned.

---

\*ITT Federal Electric Corp.

The basic design of the Apollo spacecraft had to be evaluated thoroughly. One method used to evaluate the basic design was the Apollo wind-tunnel testing program (AWTTP), which is discussed more thoroughly in reference 3. Some of the early wind-tunnel studies that were used to support and verify the design are reported in references 4 to 7.

The AWTTP incorporated tests that were designed to gather data necessary for the study of atmospheric abort situations involving the LEV from the launch pad through atmospheric flight. Also, investigations were made to determine the aerodynamic pressures on the LEV configuration. From these tests, the load distribution was determined and was used to define the criteria for the structural design of the vehicle.

The purposes of this paper are to present the pressure distributions on the LEV and to indicate the effects of the tower length and the flow separator on the pressure distribution. Pressure distribution data will be presented with minimal analysis and discussion because the static and dynamic stability characteristics of the LEV configurations have been discussed in references 1 and 2.

Pressure coefficients have been determined at Mach numbers from 0.4 to 9.08 and at an angle-of-attack range from 0° to 136°. The data are presented in plotted form as the pressure coefficient versus the physical position of the pressure orifice.

## SYMBOLS

Some of the symbols defined in this section are illustrated in figure 1, where the positive directions of the body axes system are also shown.

$C_p$  pressure coefficient,  $\frac{P_x - P_\infty}{q_\infty}$

$D$  maximum diameter of CM (154 in., full scale)

$M$  Mach number

$P_x$  orifice pressure

$P_\infty$  free-stream static pressure

$q_\infty$  free-stream dynamic pressure,  $\left(\frac{1}{2}\right)\rho V^2$

$R$  radius of CM corners, in.

$R_A$  radius of CM apex, in.

$R_C$	radius of CM corner, in.
$R_O$	radius of CM aft heat shield, in.
Re	Reynolds number, $\frac{\rho}{\mu}VD$ (based on maximum diameter of CM)
r	radius of CM at maximum diameter, in.
s	distance to orifice from center of launch face (CM apex) of the model measured along the surface of the model, in.
V	velocity
X, Y, Z	body reference axes
$\alpha$	angle of attack in the X-Z plane, deg
$\lambda$	angle of instrumentation plane relative to pitch plane, deg
$\mu$	coefficient of viscosity of the fluid
$\rho$	air density

## MODELS AND TEST TECHNIQUES

The model nomenclature and full-scale dimensions are presented in table I. The 0.045- and the 0.02-scale static pressure models were tested. The test conditions are presented in table II.

The body axes system is presented in figure 1, and sketches of the test models are presented in figure 2. The basic rocket configurations are shown in figures 2(a), 2(b), and 2(c); the shorter rocket shown in figure 2(a) was tested early in the AWTTP. The longer rocket (figs. 2(b) and 2(c)) represents a later configuration as the design developed. The escape-rocket towers shown in figures 2(d) and 2(e) represent early configurations before the nominal 120-inch length was selected (fig 2(f)). The tower bracing was modified later to the hour-glass configuration to preclude escape-rocket impingement on the upper portion of the tower. The apex radius of the basic CM design, configuration C, was decreased for the final CM design, configuration  $C_2$  (fig. 2(g)).

Sketches of the models which define the pressure-orifice location that were used in the different wind tunnels are shown in figure 3. These static pressure orifices are located over the surface of the Apollo CM. The physical position of the individual orifice is indicated by the ratio of  $s/r$  and  $\lambda$  (fig. 3) for the various models tested.

Each orifice is connected to a calibrated transducer and a known reference pressure is used. The data are presented as pressure coefficients and are defined by

$$C_p = \frac{P_x - P_\infty}{q_\infty}.$$

## FACILITIES

The broad range of expected flight conditions ( $M$ ,  $Re$ , and  $\alpha$ ) and the limitations of any single wind tunnel to simulate all these conditions required the use of a number of test facilities. The wind-tunnel test facilities used to obtain pressure distributions of the LEV configuration, along with the tunnel size and capability, are listed in table III.

## TEST CONDITIONS AND ACCURACY

The test conditions for each facility are given in table II.

In the North American Aviation 7- by 7-Foot Trisonic Wind Tunnel (NAA-TWT), the  $C_p$  was repeated to within  $\pm 0.012$ , based on transducer sensitivities and the repeatability of the data system. The pressure measuring accuracy of the Jet Propulsion Laboratory 20-Inch Supersonic Wind Tunnel (JPL-20SWT) and the Jet Propulsion Laboratory 21-Inch Hypersonic Wind Tunnel (JPL-21HWT) is  $\pm 0.25$  percent of the full-scale transducer capability or approximately  $\pm 0.008 C_p$ .

## SUMMARY OF RESULTS

The stability and dynamic characteristics of the Apollo LEV configuration (with the power on and off) were investigated; the results are presented in reference 1. The results of a configuration investigation during the development of the LEV configuration are presented in reference 2.

The pressure-coefficient data presented as plotted data in this paper represent measurements over the CM in the presence of the escape tower and rocket. Limited data were determined for orifice locations on the escape rocket. These data are presented in table IV for Mach numbers of 0.4, 1.05, and 1.34. The orifice locations for the escape-rocket measurements are defined in figure 3(c). Limited measurements were made both with and without the flow separator.

Effects of the flow separator on the CM pressure distribution are shown in figure 4. Data are given for  $\lambda = 0^\circ$  only. Data for the same data plane are given in figure 5 to show some of the effects that varying the escape-tower length has on the pressure distribution. Data for nominal tower lengths of 85 and 119 inches are presented.

The data presented in figures 6 to 19 are for the nominal tower length of 120 inches. Although the tower bracing was modified later to the hour-glass spacing to preclude escape-rocket impingement at the upper braces of the tower, the data presented are considered indicative of the final flight configuration. These figures present data for the three data planes ( $\lambda = 0^\circ$ ,  $\lambda = 45^\circ$ , and  $\lambda = 90^\circ$ ) at angles of attack from  $0^\circ$  to  $136^\circ$  and at Mach numbers from 0.4 to 9.08.
