High Noise Immunity One Shot

The problem:
In their usual configurations, multivibrators which deliver pulses of duration longer than a second contain R-C timing components which allow power supply fluctuations to pass through and act as triggers. For certain applications, it is desirable to have a multivibrator that produces output pulses of long duration but is not triggered by transients in the supply lines.

The solution:
A one-shot multivibrator circuit which includes a constant current source to isolate line noise from the timing circuitry, and a field-effect transistor to control the circuit's operational modes.

How it's done:
The constant current source, transistor Q1 in the schematic diagram, supplies current to transistor Q2 and resistor R1. The voltage across R1 is fixed by diode D1 and the V_{BE} drop of Q2. Transistor Q3 is a low pinch-off FET, and is normally conducting (V_{GS} = +0.4 volt) to keep the current source on. When a positive trigger pulse arrives at the input of Q4, V_{GS} is driven negative approximately to —1.0 volt and the FET is nonconducting. Q1 is thus turned off.
off, and this turns off Q2. Resistor R1 holds the
timing line at low potential while Q1 is nonconduct-
ing. When $V_{OS}$ of the FET reaches about $-0.3$ volt
due to the discharge of $C_T$, Q3 conducts and turns
on the current source. The circuit is now back in its
steady-state condition, ready for another trigger pulse.

Capacitor $C_1$ is needed to prevent misfiring from
high-frequency noise spikes on the supply line. A
value of 0.01 $\mu$F is sufficient for most purposes; $R_T$
should be much larger than $R1$ for proper operation.
A minimum value for $R_T$ is around 10K. Because of
this limitation, the one shot is not capable of short-
duration pulses (less than 50 $\mu$sec).

Reference:

Notes:
1. The circuit has a high immunity to supply line
noise; for example, with a supply voltage of 15
volts, supply voltage spikes of $\pm 12$ volts will
not cause misfire.
2. For the circuit shown, the supply voltage may
vary from 4 to 40 volts. This wide variation in
supply voltage causes only a 10% change in the
timing period.
3. If $R_T = 10M$, and $C_T = 330 \mu F$, a timing period
of about 1 hour is obtained.
